Background Previous studies have reported depressive symptoms in patients with persistent delusional disorder (PDD). Patients with PDD and depression may need antidepressants for treatment.

Aim The aim of the study was to compare the sociodemographic profile, clinical presentation and treatment response in patients with PDD with and without comorbid depressive symptoms.

Methods We conducted a retrospective chart review of patients diagnosed with PDD (ICD-10) from 2000 to 2014 ($n=455$). We divided the patients into PDD + depression ($n=187$) and PDD only ($n=268$) for analysis.

Results Of the 187 patients with PDD + D, only eighteen (3.9%) were diagnosed with syndromal depression. There were no significant differences in sociodemographic profile including sex, marital and socioeconomic status (all $P>0.05$). PDD + D group had a significantly younger age at onset ([PDD + D: 30.6 9.2 years vs. PDD: 33.5 11.1 years]; $t=2.9, P<0.05$). There was no significant difference between the clinical presentation including mode of onset, the main theme of their delusion and secondary delusions (all $P>0.3$). However, comorbid substance dependence was significantly higher in patients with PDD only. ($\chi^2=5.3, P=0.02$). In terms of treatment, response to antipsychotics was also comparable ([$>75\%$ response: PDD + D = 77/142 vs. PDD = 106/179]; $\chi^2=1.9, P=0.3$). There was a significant difference between the two groups in terms of antidepressant treatment ([PDD + D = 32/187; 17% vs PDD: 17/268; 6%], $\chi^2=12.9, P=0.001$).

Discussion Patients with PDD + D had significantly earlier onset of illness. These patients may require antidepressants for treatment.

Association between Internet addiction and depression in medical students, faculty of medicine in Thailand

S. Kuladee*, T. Boonvisudhi

Faculty of medicine Ramathibodi hospital, psychiatry, Bangkok, Thailand

* Corresponding author.

Introduction Internet addiction has become a harmful behavioral problem found to be highly prevalent in high school and college students. Many studies demonstrated significantly association between Internet addiction and depression.

Aims To study the prevalence of Internet addiction and the association between internet addiction and depression in medical students, faculty of medicine, Ramathibodi hospital.

Methods A cross-sectional study was conducted. Participants were the first to fifth-year medical students who agreed to participate in this study. Demographic characteristics were derived from self-rated questionnaire and were analyzed by descriptive statistics. Thai version of Young's Internet Addiction Diagnostic Questionnaire and Thai version of Patient Health Questionnaire (PHQ-9) were used to assess internet addiction and depression, then χ^2 test and logistic regression were used to analyze the associations between internet addiction, depression and associated factors.

Results From 705 participants, 24.5% had internet addiction and 29.0% had depression. There was statistically significant association between Internet addiction and depression (odds ratio: 1.92; 95% confidence interval [CI]: 1.34–2.77, P -value <0.000). Logistic regression analysis illustrated that the Internet addiction group had risk of depression 1.58 times higher than the group without Internet addiction (95% CI: 1.04–2.38; P -value <0.031). Academic problem was found to be a significant predictor of both Internet addiction and depression. Furthermore, Internet addiction, relationship problems with friend and lover, and health problem were also significant predictors of depression.

Conclusions Internet addiction was common psychiatric problem which associated with depression among medical students. We suggest that surveillance of Internet addiction should be considered in medical schools.

* Corresponding author.

Introduction The first phase following the diagnosis of a first psychotic episode (FEP), is crucial to determine clinical and functional long-term outcome. Cannabis exerts a mediating action on the debut of the disease and determines a poor prognosis.

Objectives The description of a specific population profile of increased vulnerability to maintain cannabis use after a FEP could help to identify this high risk subtype of patients and speed up the implementation of specific interventions.

Materials and methods One hundred and seventy-eight patients were recruited from PAFIP (early intervention program on FEP), obtaining detailed socio-demographic assessment. They were followed-up for a year during which cannabis consumption was assessed by Drake scale every three months. We divided the sample into two groups:

- those patients who neither smoked cannabis before the FEP nor during follow-up period (nn);
- consumers group: cannabis users before the FEP who kept on smoking during the follow-up period (ss) and those who smoked before the FEP and gave up consumption during follow-up (sn).

Results Statistically significant differences between groups were observed. The consumers group (ss + sn) had an earlier age of onset, most were male, unemployed, single, prone to loneliness and they were concomitant users of alcohol and tobacco.

Conclusions The use of cannabis has a detrimental effect on the outcome of schizophrenia. A specific and early intervention could contribute to prognostic improvements. Identifying cannabis consumption subtypes could be useful for this purpose.

Association between ADHD and psychopathy among inmates in a high-security prison in Portugal

D. Loureiro^{1,*}, A. Machado¹, T. Silva¹, T. Veigas², J. Cerejeira¹

¹ Centro hospitalar e universitário de Coimbra, psychiatry, Coimbra, Portugal

² Universidade de Coimbra, medicine faculty, Coimbra, Portugal

* Corresponding author.

Introduction ADHD is associated with psychopathic traits, both in the general population and in perpetrators, due to the impulsivity, but not the affective component of psychopathy.

Objectives To analyze this relationship among a sample of inmates from a high-security male prison, using an instrument that further divides the callous-unemotional factor of psychopathy into boldness and cruelty, and see if they relate to ADHD independently from the impulsivity/disinhibition.

Methods One hundred and one subjects aged 18–65, with at least 4 years of formal education, were interviewed for socio-demographic data and completed the ASRS-v1.1 (Adult ADHD Self-Report Scale) and the TriPM (Triarchic Psychopathy Measure). Subjects were divided into ADHD positive or negative according to their score in the ASRS-v1.1, and then compared regarding TriPM score (total, disinhibition, boldness and cruelty) using Student's *t*-test. Linear regression was used to assess independency between the subscales of TriPM.

Results Seventeen subjects scored positive for ADHD. They significantly differed from the non-ADHD group regarding all psychopathy scores (total, $t = -5.03$, $P < 0.0001$; disinhibition, $t = -3.53$, $P = 0.0006$; and cruelty, $t = -4.96$, $P < 0.0001$), except for boldness ($t = 1.97$, $P = 0.005$). The cruelty score is independent from boldness ($R^2 = 0.03$) but not from the disinhibition score ($R^2 = 0.24$). Disinhibition and boldness are also unrelated ($R^2 = 0.01$).

Conclusions In line with previous work, our study shows a strong association between ADHD and psychopathy, with both conditions sharing the disinhibition/impulsivity factor. Although ADHD subjects score higher for cruelty, this isn't independent from disinhibition, and may be a result of them being more prone to admit to cruel behaviours, due to deficient response inhibition.

Novel psychoactive substances in a psychiatric young adults sample: A multicenter, observational study

M. Lupi*, T. Acciavatti, S. Marini, E. Cinosi, R. Santacroce, M. Corbo, V. Mancini, T. Galanti, M. Carlucci, G. Martinotti, M. Di Giannantonio

University "G. D'Annunzio", department of neuroscience and imaging, Chieti, Italy

* Corresponding author.

Introduction Comorbidities between psychiatric diseases and consumption of traditional substances of abuse are common. Nevertheless, there is no data regarding the use of novel psychoactive substances (NPS) in the psychiatric population.

Objectives The purpose of this multicentre survey is to investigate the consumption of a wide variety of psychoactive substances in a young psychiatric sample.

Methods Between September 2013 and November 2015, a questionnaire has been administered, in ten Italian psychiatric care facilities, to a sample of 671 psychiatric patients (48.5% men; 51.5% women), aged between 18 and 26 years (mean age: 22.24).

Results 8.2% of the sample declared use of NPS at least once in a lifetime and 2.2% have assumed NPS in the last three months. The NPS more used were synthetic cannabinoids (4.5%), followed by methamphetamine (3.6%). The three psychiatric diagnosis with more frequent NPS consumption were bipolar disorder (23.1%), personality disorders (11.8%) and schizophrenia and related disorders (11.6%). Bipolar disorder was associated with NPS consumption ($P < .001$). Among the illicit drugs investigated, 31.4% of the sample was cannabis smoker and 10.7% cocaine user. Moreover, 70.6% of the sample declared alcohol use and 47.7% had binge drinking conducts. In univariate regression analysis, bipolar disorder was positive associated with binge drinking while obsessive compulsive disorder resulted negative associated.

Conclusions The use of novel psychoactive substances in a young psychiatric population appears to be a frequent phenomenon, probably still underestimated. Bipolar disorder shows an association with NPS use. Therefore, careful and constant monitoring and accurate evaluations of possible clinical effects related to their use are necessary.

Personality traits and tobacco smoking among male alcoholics with secondary depression

G. Mandić-Gajic*, M. Dolic, A. Eror, Z. Spiric

Military medical academy, psychiatry clinic of psychiatry, Belgrade, Serbia

* Corresponding author.

Introduction After alcohol withdrawal, secondary depression may persist and might be a risk factor for relapse among primary alcoholics.

Objectives The differences between male alcoholics with secondary depression (D) and without depression (wD) regarding the personality dimensions and tobacco smoking were explored.

Aims The aim was to investigate risk factors for secondary depression.

Methods One hundred male primary alcoholics were recruited during inpatient treatment, and 86 completed the study. The assessment of depression by Hamilton Depression Rating Scale - HAMD (Hamilton, 1960), the pattern of cigarette use and personality dimensions assessment by Eysenck personality questionnaire - EPQ (Eysenck & Eysenck, 1975) were performed for all participants on admission. After four weeks according HDRS cut off score, they were divided into D group ($n = 43$) and wD ($n = 43$) group. The differences between groups were tested by Student *t*-test and Pearson's correlation test was applied.

Results The personality traits showed difference between D and wD alcoholics' subgroups for neuroticism 15.07 ± 4.89 vs. 10.37 ± 4.40 ($P < 0.01$) and for extraversion 11.74 ± 5.05 vs. 14.30 ± 4.24 ($P < 0.05$) respectively. The positive correlation between the mean HDRS score and neuroticism ($r = 0.487$, $P < 0.001$), without significant correlation between other EPQ dimensions and

depression was recorded. The D group started smoking earlier, but without differences of cigarettes daily.

Conclusions The group of alcoholics with depression started smoking earlier. They were characterized by higher neuroticism and lower extraversion on admission, which could predict persistent secondary depression. Screening on personality traits among alcoholics on admission could improve prevention of secondary depression after alcohol withdrawal.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Addictive status in neurotic disorders

N. Maruta*, S. Kolyadko, G. Kalenska, M. Denysenko
 Institute of neurology, psychiatry and narcology, National academy of medical science of Ukraine SI, borderline pathology, urgent psychiatry and narcology, Kharkiv, Ukraine

* Corresponding author.

Introduction At the present stage of psychiatry development, the problem of co-morbidity, which is an important factor determining the effectiveness of treatment. One of such tendencies is the combination of neurotic pathology and addictive behavior (AB).

Objectives To research AB features in neurotic disorders.

Methodology One hundred and forty-eight patients with neurotic disorders: neurasthenia (F48.0), dissociative disorder (F44.7), anxiety-phobic disorder (F40.8), according to ICD-10 criteria. Clinical-psychopathological, psychodiagnostic (AUDIT-like tests), statistical methods were used.

Results It was found out that the patients with neurotic disorders had a high risk of AB formation (59.73%). The most prominent among AB were: the use of psychoactive substances (tea/coffee [11,682], tobacco [8,091], sedatives [6,964], food addiction [14,036]), as well as socio-acceptable AB, such as Internet (13,527), watching television (9,982), computer games (2,909), shopping (7,264), workaholism (15,018). Socio-demographic characteristics of the generation of neurotic disorders with AB were determined: young age (50.46%), AB presence among the surrounding people (91.64%), a short interval of time between the psychogenic factor exposure and the first signs of neurotic disorder (50.46%). The clinical pattern of neurotic disorders with AB was characterized by a predominance of anxiety-obsessive (35.78%), as well as anxiety-phobic (45.95%) syndromes associated with AB: "Shopping" (−0.32; −0.51, respectively), "Sleeping pills, sedatives" (−0.37; −0.42), "Sex" (−0.41; −0.37) and "Tea/coffee" (−0.34; −0.39).

Conclusions The data obtained determine AB specificity and should be taken into account in pharmaco- and psychotherapy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Addiction co-morbidity in bipolar disorder

A. Baatout¹, U. Ouali^{1,*}, R. Jomli¹, H. Elkefi², A. Oumaya², F. Nacef¹

¹ Razi hospital, psychiatry A, Mannouba, Tunisia

² Hôpital militaire, service de psychiatrie, Tunis, Tunisia

* Corresponding author.

Introduction Addiction is often underdiagnosed in bipolar disorder (BD), although it is frequent and known to complicate its clinical course.

Objectives The aim of our study was to study socio-demographic and clinical factors associated with addiction in BD patients.

Methods This is a retrospective, cross-sectional, descriptive and comparative study on 100 patients followed in our department and diagnosed with BD type I according to DSM 5. Demographic and clinical data was compared across the groups: Addiction+ (A+) and Addiction− (A−).

Results Nineteen patients had an addiction co-morbidity (A+), whereas 81 had not (A−). The mean age of the (A+) group was 39.47 years whereas it was 42.52 years in the (A−) group. Males represented 68.4% of the (A+) group and 48.1% of the (A−) group. Age of illness onset was lower in the (A+) group (mean = 23.16, median = 21) compared to the (A−) group (mean = 26.04, median = 27). Addiction co-morbidity was significantly associated with predominant manic polarity ($P=0.03$). All (A+) patients presented mood episodes with psychotic features, whereas psychotic features were only found in 86.6% of (A−) patients. Co-morbid addiction was significantly associated with a higher number of mood episodes ($P=0.04$), a higher number and duration of hospitalisations ($P=0.02$, $P=0.015$), and a poorer compliance ($P=0.07$). All A+ subjects received antipsychotics, and they were significantly more to receive long-acting antipsychotics ($P=0.06$).

Conclusions Addictions worsen the prognosis of bipolar disorder and require specific therapeutic strategies. They deserve therefore the particular attention of clinicians.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Trajectories of depression and anxiety symptoms in coronary heart disease strongly predict health care costs

J. Palacios^{1,*}, M. Khondoker², A. Mann³, A. Tylee³, M. Hotopf¹

¹ Institute of psychiatry, psychology, and neuroscience, psychological medicine, London, United Kingdom

² Institute of psychiatry, psychology, and neuroscience, biostatistics, London, United Kingdom

³ Institute of psychiatry, psychology, and neuroscience, health service and population research, London, United Kingdom

* Corresponding author.

Introduction There is little information describing the trajectories of depression and anxiety symptomatology in the context of coronary heart disease (CHD), and their comparison according to sociodemographic and disability measures, cardiac risk factors, and health care costs.

Methods Using a primary care cohort of 803 patients with a diagnosis of CHD, a latent class growth curve model was developed to study the distinct trajectories of depression and anxiety symptoms (using the hospital anxiety and depression scale) over a 3-year period comprised of 7 distinct follow-up points. Multinomial regression analysis was then conducted to study the association between latent classes, baseline risk factors, and total health care costs across time.

Results The 5-class model yielded the best combination of statistical best-fit analysis and clinical correlation. These classes were as follows: "stable asymptomatic" ($n=558$), "worsening" ($n=64$), "improving" ($n=15$), "chronic high" ($n=55$), and "fluctuating symptomatology" ($n=111$). The comparison group was the "stable asymptomatic" class. The symptomatic classes were younger and had higher proportion of women, and were also associated with non-white ethnicity, being a current smoker, and having chest pain. Other measures of disease severity, such as a history of myocardial infarction and co-morbidities, were not associated with class membership. The highest mean total health care costs across the 3 years were the "chronic high" and "worsening" class, with the lowest being the "improving" and "stable low" classes. The total societal

costs for patients in the “chronic high” and “worsening” class were significantly higher, as compared to the “stable low” class.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Incidences and risk factors of severe infections in young adults with schizophrenia: A nationwide register-based cohort study in Denmark

M. Pankiewicz-Dulacz*, E. Stenager, E. Stenager, M. Chen
University of Southern Denmark, institute of regional health services research, Odense C, Denmark

* Corresponding author.

Introduction Patients with schizophrenia deal with many risk factors that make them more susceptible to infections. However, knowledge about incidence and the nature of infections among people with schizophrenia is scarce.

Aims To investigate the occurrence and risk factors for severe infections in schizophrenia patients.

Objectives – to determine incidence rates of infections among young adults with schizophrenia;
– to define risk factors for infections.

Method Population-based nationwide cohort study with selection of all individuals born in Denmark between 1975–1990 and follow-up period from 1995–2013 was conducted. Data from the Danish Psychiatric Central Register and the Danish National Hospital Registry were used. A Poisson regression was chosen to estimate incidence rate ratios of infections and to explore the associations of different risk factors like sex, age, substance abuse and medical co-morbidity with the rates of infections.

Preliminary results 922,564 individuals born between 1975–1990 were included in the study. Overall, 3520 women and 5479 men were identified with schizophrenia. In percentages, 36% with schizophrenia had infectious diseases compared to 25% of background population. Some of severe infections like HIV (0.23% vs 0.05%), sepsis (0.72% vs 0.27%), hepatitis (1.4% vs 0.22%) skin infections (12% vs 6.2%) and tuberculosis (0.12% vs 0.06%) were highly increased in persons with schizophrenia, whereas smaller differences were found regarding CNS infections (0.5% vs 0.4%) and gastrointestinal infections (8.7% vs 6.2%).

Conclusions The preliminary data results suggest, that individuals with schizophrenia have higher prevalence of all types of severe infectious compared to the background population.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Prevalence of depression and anxiety in patients with chronic non-malignant pain—A Danish register-linkage cohort study

S. Søndergård^{1,*}, H.B. Vægter^{2,3}, A. Erlangsen^{1,4}, E. Stenager¹

¹ Institute for regional health services, university of Southern Denmark, research unit in mental health, Aabenraa, Denmark

² Pain Centre South-Odense university hospital, pain research group, Odense, Denmark

³ Faculty of health science, university of Southern Denmark, department of clinical research, Odense, Denmark

⁴ Danish research institute for suicide prevention, mental health centre Copenhagen, Copenhagen, Denmark

* Corresponding author.

Introduction Anxiety and depression disorders are common in patients with chronic pain. Studies using clinical interviews in patients with chronic pain report prevalence rates ranging between 30–54% for depression and 17–29% for anxiety. This is the first study using contacts with a hospital psychiatric ward to investigate prevalence of depression and anxiety in patients with chronic pain.

Objectives Estimate the prevalence of anxiety and depression in patients with chronic pain referred for interdisciplinary treatment.

Aims To increase the knowledge about mental disorders and chronic pain in secondary health care.

Methods All chronic pain patients referred to and treated at an interdisciplinary pain clinic at Odense university hospital, Denmark from 1 Jan 2005–13 Nov 2015 were included as participants. The Danish National Patient Register was used to collect information on contacts with a hospital psychiatric ward 10-year prior to the first contact at the pain clinic due to depression (ICD-10: F32-F33) and/or anxiety (ICD-10: F40-F41).

Results In total, 7204 patients (64% women; mean age: 48.2) were included. Altogether, 17.8% (95% CI: 16.9–18.7) of patients had contact to a psychiatric ward. The prevalence of unipolar depression were: 6.1% (95% CI: 5.5–6.6) and anxiety: 2.1% (95% CI: 1.8–2.5), while 0.7% (95% CI: 0.5–0.9) had both depression and anxiety.

Conclusions The prevalence rates of depression and anxiety noted in this study were lower than those reported in previous studies. A hospital-based diagnosis seems likely to be less frequent than interview-based measures, yet, might have a higher validity due to the clinician-based assessment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychosomatic and psychopathological paradigms of alcoholic anorexia

I. Sosin*, Y. Chuev, O. Goncharova, G. Misko, A. Volkov
Kharkov medical academy of postgraduate education, narcology, Kharkov, Ukraine

* Corresponding author.

Introduction Alcoholic anorexia (AA), being one of prevalent narcology diseases, up to now has not been studied in psychosomatics and psychopathology paradigm.

Aims and objectives To identify multifactorial pathopsychological, psychopathological, nervous, alimentary, toxicological constituents of AA pathogenesis.

Method Twenty-four patients with alcohol dependence (males aged 29–37) have been studied. Diagnosis was objectified by psychosomatic, pathopsychological complex international valid tests and rating, adequate for investigation design, laboratory, electrophysiology, biochemical, ultrasound and other methods.

Results AA was accompanied with mental and physical post-intoxication exhaustion, asthenizing, tremor, dissomnia, depression, pre-delirium signs. Psychosomatic concept was proposed for reasonable identification of intranosological AA clinical forms in narcological clinical course. Anorectic dipsomaniac conditions are explained pathogenetically with psychosomatic mechanisms of deviant addictive craving behaviour as pathopsychological target and patient's intentional complete or partial refuse food consumption in favour of real in time more quick and brutal attainment of alcoholic drunkenness (Ebrietas Alcoholic). This anorexia fabula draws AA closer to Anorexia Nervosa and mostly reflects compulsive obsession with alcohol use. Pathopsychological, psychosomatic, neurogenous mechanisms of alcoholic anorexia of drinking bout early stages are transformed gradually to post-intoxication alimentary, nervous, psychic exhaustion. Meanwhile,

AA is valid for alcohol withdrawal syndrome diagnosis and plays situation relapsing role in alcoholizing prolongation.

Conclusions Alcoholic anorexia is starting to declare even at early stages of alcoholic addiction formation. It is more illustrative in periodically recurrent and exaggerating drinking bouts when dynamic intestinal obstruction risk is high. Findings obtained ground alcoholic anorexia attribution to urgent conditions with necessary integrated relieving therapy and secondary prevention.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Evaluation of the cardiovascular disease risk of the psychiatric inpatients of a university hospital by using Framingham risk score

P. Tas Durmus*, R. Kose Cinar, M.B. Sonmez, Y. Gorgulu, N. Ozkan

Trakya university school of medicine, psychiatry, Edirne, Turkey

* Corresponding author.

Introduction According to literature, the patients with severe mental disorder have higher cardiovascular disease risk than the normal population.

Objectives The current study based on the assumption that elevated inflammatory markers may be related to cardiovascular disease risk in psychiatric patient population.

Aims This study is aimed to define the relation between the inflammatory reactant, C-reactive protein levels and 10-year risk of coronary heart disease according to Framingham risk score (FRS).

Methods A total of 204 patients (106 female–98 male) who admitted to the psychiatric service between March and November 2015 and diagnosed with major depression, bipolar disorder and psychotic disorder were included in the study. Participants were evaluated by their gender, age, body mass index, waist circumference, high density lipoprotein levels, total cholesterol levels, systolic and diastolic blood pressures, diabetes comorbidity and CRP levels.

Results Ten-year risk of cardiovascular disease was found significantly higher at males than females ($P < 0.001$). There was no correlation between the FRS and the CRP levels which is an acute phase reactant and a contributor of atherogenesis ($P = 0.763$). However, mean values of CRP levels were determined as 0.59 ± 0.07 mg/dL for females and 0.56 ± 0.07 mg/dL for males. These levels are both high compared to the normal value which is up to 0.34 mg/dL. There was also a remarkable correlation between FRS scores and waist circumference ($P = 0.012$).

Conclusions Framingham risk score can be used to detect cardiovascular disease risk and can be helpful in management of pharmacotherapy of the high-risk population.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Co-morbidity of psychiatric/physical disorders with alcohol abuse/dependence in a sample of clients of the emergency department of the psychiatric hospital of Attica–Greece

D. Tsaklakidou^{1,*}, I. Rizavas², V. Efstathiou¹, C. Christodoulou¹, A. Papadopoulou¹, A. Douzenis¹

¹ “Attikon” university general hospital, 2nd department of psychiatry, Athens, Greece

² “Dafni” psychiatric hospital of Attica, emergency department, Athens, Greece

* Corresponding author.

Introduction Increased coexistence of psychiatric symptoms in patients with alcohol abuse/addiction is highlighted in the literature. Equally high is the coexistence of physical illnesses due to the harmful effects of alcohol.

Aims To record the profile and the characteristics of individuals with psychiatric/somatic co-morbidity who attend the psychiatric emergency department/(PED) of the largest psychiatric hospital in Greece.

Methods/Results A total of 1058 individuals, with a mean age of 44.4 years, were identified having alcohol problems in a five-year time period (2010–2015) in the context of the PED, while the majority of them was found to have psychiatric co-morbidity. The most common diagnosis was psychotic syndromes (24.2%), followed by affective (23.8%), personality (12.5%), and somatoform and anxiety disorders (6.3%). About 3% of the sample presented acute alcohol poisoning or severe withdrawal symptoms, coexistence with severe somatic disease and organic mental disorders. More than a third (37%) of them had to be hospitalized, while the involuntary hospitalization rates (21%) were higher than the voluntary ones (16%). Finally, 13.65% suffered from co-morbid somatic diseases with need of immediate emergency and hospital care.

Conclusions The abuse and/or dependence of alcohol are largely associated with the coexistence of psychiatric and physical diseases. The psychiatric and physical co-morbidity, as regards attendance and hospitalization–involuntary and voluntary–, present a higher rate in men (86%) and mainly affects people of productive age. Additional data are needed to explore detailed factors that could contribute to a better design of more appropriate services for patients with alcohol use disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The eating disorders iceberg: Emotional deregulation and impulsivity lay below

S. Valente*, G. Di Girolamo, F. Cerrato, L. Vannucci, D. De Ronchi, A.R. Atti

Psychiatry, istituto di psichiatria, Bologna, Italy

* Corresponding author.

Introduction Eating disorders (ED) and personality disorders (PD) are often interplayed in every-day clinical practice. Less is known on patient's emotional deregulation and impulsivity.

Aims To investigate whether clinical features of ED and PD correspond to a specific impulsivity and emotional background pattern.

Objective ED, PD, impulsivity and emotional regulation.

Methods A group of outpatients with ED ($n = 39$) was compared to a group of healthy controls ($n = 40$) by means of semi-structured interviews and standardized questionnaires (BIS-11, DERS, Eat-26, SCID-II and STAI), in order to evaluate association between clinical features (ED and PD) and altered impulsivity or/and emotion regulation.

Results Seventy-five percent of ED cases matched also diagnostic criteria for PD. Cluster B diagnoses occurred more frequently in Bulimia Nervosa (BN) and Binge eating disorders (BED) whereas Cluster C PD was strongly associated with restrictive anorexia (AN-R) ($P < 0.001$). BIS-11 scores were significantly higher in cluster B as compared to cluster C PD ($P = 0.019$). People with PD have a significantly higher DERS score compared to people without ($P < 0.001$). Mean DERS scores were similar in BN, BED and AN Binge purging (AN-BP) but lower in AN-R ($P < 0.001$).

Conclusions ED is an iceberg top, of a three-step ladder. The intermediate step is built of personality traits and disorders forging the variety of ED clinical expressions. The hidden base of iceberg is represented by both the emotional (de)regulation and the level of impulsivity. Therapies focused on the base of this iceberg are needed for a clinical resolution of eating symptoms.

Benefits of antidepressant treatment after a stroke

O. Zerriaa*, O. Moula, S. Ben Saadi, I. Jelalia, R. Ghachem
Razi hospital, B, Mannouba, Tunisia

* Corresponding author.

Introduction Stroke is an important cause of morbidity and is responsible for 9% of all deaths worldwide. The most frequent neuropsychiatric consequence of stroke is post-stroke depression (PSD). It has been shown to be associated with both impaired recovery and increased mortality. The aim of our study is to determine the benefits of antidepressant prescription after a stroke.

Method The databases from *Medline* and *PubMed* were reviewed for articles related to post-stroke depression (PSD), antidepressant treatment and stroke, post-stroke depression and functional recovery, stroke related impairment.

Results Antidepressant drugs have been shown to be effective in treating PSD in six double blind randomized studies. Patients treated with antidepressants had better recovery from disability than patients who did not receive antidepressant therapy: it was proved that antidepressant drugs cause an improvement in cognitive skills and functional recovery in PSD patients. In patients with ischemic stroke and moderate to severe motor deficit, the early prescription of fluoxetine with physiotherapy enhanced motor recovery after 3 months. Some studies showed that PSD can be effectively prevented: nortriptyline, fluoxetine, milnacipran and sertraline appeared to be efficacious in preventing depression after stroke and are to use without significant adverse effects in stroke patients.

Conclusion Antidepressant treatment plays an increasing role in the management of patients with acute stroke. Therefore, early initiation of antidepressant therapy, in non-depressed stroke patients, may reduce the odds for development of PSD, and improve cognitive and functional recovery.

Polypharmacy among elderly populations

I. Leal^{1,*}, P. Ordás², R. Vicente¹, C. Avila²

¹ Hospital de la Princesa, psychiatry, Madrid, Spain

² Universidad Autonoma Madrid, psychiatry, Madrid, Spain

* Corresponding author.

Introduction Potentially inappropriate prescribing, is highly prevalent among older patients hospitalized with major psychiatric illness. Inappropriate use of psychotropic medications in elderly patients has become a focus of concern.

Objectives To determine the prevalence of potentially inappropriate prescribing including potentially inappropriate medications (PIMs) and potential prescription omissions (PPOs), according to STOPP-START, Beers and PRISCUS criteria applied by CheckTheMeds®.

Aims To identify potentially IP, PPO and the prevalence of contraindications, interactions and precautions in older patients hospitalized with major psychiatric illness.

Methods Retrospective cross-sectional study with patients over 65 discharged from the Psychiatric acute unit of the university hospital of La Princesa (Madrid) between January 2013 and October 2015 was conducted. The CheckTheMeds® program was used to identify IP.

Results A total of 104 elders—74 females and 30 males—were included, with a mean age of 76 years (range: 65–91). An average of 5.73 (range: 1–16) was prescribed drugs at discharge. The IP results STOPP 81.73% ($n=85$), START 43.26% ($n=45$), Beers 94.23% ($n=98$) y PRISCUS 40.38% ($n=42$). Contraindications were described in the 21.15% of the patients, precautions in 83.65% and interactions in 83.65%. Psychotropic drugs were the most often inappropriate prescribed medications.

Conclusion Prescribing omissions are twice as prevalent as IP in the elderly. Currently, inappropriate prescription of psychotropic agents is very common for the elderly. Application of such screening tools to prescribing decisions may reduce unnecessary medication, related adverse events, healthcare utilization and cost and non-pharmacological interventions, should be thoroughly explored.

To the question of the role of consultation liaison psychiatry in diagnostics of psychosomatic disorders

V. Lebedeva*, O. Pavlova, E. Yurovskaya

Mental health research institute, Tomsk national research medical center of RAS, Clinic, Tomsk, Russia

* Corresponding author.

Background Relevance of consultation liaison psychiatry is conditioned by trend of steady rise of psychosomatic disorders and insufficient development of supplied forms and methods of medical care to patients with this pathology.

Aim To study incidence rate of psychosomatic disorders in primary health care, to develop algorithm of medical care.

Material and methods A total of 2010 patients of the primary health care unit were examined. Methods used: clinical-psychopathological, clinical-dynamic, questionnaire screening, statistical (factor analysis).

Results Mental disorders, co-morbid with physical pathology, constituted 3.9% of the contingent with predominance of psychosomatic disorders—15.6 per 10,000 of the population. Respective from clinical-dynamic structure of psychosomatic disorders three groups of patients were distinguished: in need for consultation by a psychiatrist (22.9%); for course treatment by psychiatrist and subsequent observation by physicians (28%); and for systematic therapy and observation by psychiatrist (49.1%). Patients with psychosomatic disorders addressed general medicine network 1–2 years after onset of mental disorder and 6.4 ± 1.2 years after diagnostics of somatic pathology. Patients had predominantly cardiovascular (37.7%; $P < 0.05$), respiratory (20.5%), and gastrointestinal diseases (20.9%). Exacerbation of psychosomatic disorder was reliably interrelated with psychotraumatic situation and exacerbation of physical pathology. Introduced algorithm of psychiatric consultation consisted of:

- evaluation of mental and physical status;
- distinguishing the nosological groups;
- choice of therapy;
- formation of groups of observation (risk groups in need for course therapy, systematic therapy).

Conclusion Consultation liaison psychiatry in general medical institution allows widening accessibility of psychiatric care and makes its provision more cost-effective.

Psychopathological aspects of appearance dissatisfaction in aesthetic medicine

V. Medvedev^{1,*}, V. Frolova¹, V. Vissarionov²

¹ PFUR university, chair of psychiatry-psychotherapy and psychosomatic pathology, Moscow, Russia

² Beauty institute, Moscow, Russia

* Corresponding author.

Introduction The pathogenesis of dissatisfaction of the own appearance in patients without obvious abnormalities is still unexplored. The aim of the study was to investigate the structure of psychopathological disorders in patients without evident appearance abnormalities seeking for surgical or cosmetological correction.

Methods Study sample has included 227 women (average age: 35.8±4.9 years) and 54 men (average age: 30.9±5.7 years)–patients of plastic surgery and cosmetology clinic. The study used clinical psychopathological and follow-up methods of examination.

Results We have found the heterogeneous spectrum of mental disorders in this group of patients: overvalued dysmorphophobia was diagnosed in 26%, anxiety-phobic disorders–23.1%, obsessive-compulsive disorders–in 11%, depression–in 32%, delusional disorders–in 7.5% of patients.

Conclusions The results of our study show that the phenomenon of dissatisfaction with the appearance without obvious cosmetic defects manifests in the course of wide spectrum of mental disorders. The follow-up shows no improvement and even worsening of patients' mental state after cosmetological or surgical treatment. Decision about possibility and extent of the operation should be based on the analysis of patient's mental state and motive for reference to aesthetic medicine specialist.

The development of an abbreviated version of the Cornell scale for depression in dementia (CSDD) for the assessment of depression in palliative care inpatients

M. Mohamad^{1,*}, B. Davis¹, F. Twomey², M. Lucey², M. Conroy², D. Adamis³, D. Meagher¹

¹ University of Limerick, psychiatry, Limerick, Ireland

² Millford care centre, palliative medicine, Limerick, Ireland

³ Sligo mental health services, psychiatry, Sligo, Ireland

* Corresponding author.

Introduction In the palliative care setting, accurate identification of depression is important to allow delivery of appropriate treatments.

Aims: – 1. To assess rates of depression in palliative care inpatients using the CSDD, comparing with formal clinical diagnosis based on diagnostic and statistical manual of mental disorders (DSM-IV) criteria;

– 2. To identify items of the CSDD that most distinguish depressive illness in a palliative care setting.

Methods We measured rates of depression in patients admitted into a palliative care inpatient unit with the CSDD. DSM-IV clinical diagnosis of major depressive disorder (MDD) was achieved using all available clinical information by an experienced independent rater. We calculated Cohen's Kappa to measure concordance between the CSDD and DSM-IV diagnosis.

Results We assessed 142 patients (56.3% male; mean age: 69.6 years), the majority of which had a cancer diagnosis (93.7%). 18.3% (n=26) met DSM-IV criteria for MDD, while 12% scored ≥6 on the CSDD with 15 cases of depression common to these two methods (K=0.65). Discriminant analysis identified five CSDD items that were especially distinguishing of MDD; sadness, loss of interest, pessimism, lack of reactivity to pleasant events and appetite loss. An abbreviated version of the CSDD, based on these 5 items, proved highly accurate in identifying DSM-IV MDD (AUC=0.94), with sensitivity of 89% and specificity of 84% at a cut-off score ≥2.

Conclusions There was good level of concordance between the CSDD and DSM-IV diagnosis of MDD. We identified five depressive symptoms that are especially discriminating for depression in palliative care patients.

Second generation direct-acting antiviral (DAAs) Treatment on HCV+ patients: Patient reported outcomes (PROs) and psychiatric symptoms in a real world setting sample

M. Moneglia^{1,*}, A. Santangelo¹, I. Burian¹, L. Gragnani²,

F. Elisa², M. Quargnolo¹, S. Pallanti¹, A.L. Zignego²

¹ Azienda Ospedaliero-Universitaria Careggi, Neurofarba, Florence, Italy

² Azienda Ospedaliero-Universitaria Careggi, Masve, Florence, Italy

* Corresponding author.

Introduction Anti-HCV treatments are moving away from interferon-alpha towards DAAs, associated with fewer side effects, better tolerability, and better PROs.

Aims To describe neuropsychiatric symptoms and PROs during DAAs treatment in a group of HCV+ patients.

Methods Forty outpatients, scheduled for DAAs treatment, were assessed at enrolment (T0), 4 weeks (T1), at the end of treatment (EOT) and after 12 weeks of follow up (F-UP), by means of MDRS, HAM-D, HAM-A, MRS, Y-BOCS and SF-36. Afterwards the sample was divided into two groups as a function of a positive psychiatric history (19) and compared with each other.

Results Total sample mean scores between W0 and F-UP were compared and an improving trend was observed in all administered scales. An SF-36 items analysis showed a statistically significant difference in emotional role functioning between W0 vs EOT and EOT vs F-UP, in change in overall health status between W0 vs EOT and W0 vs F-UP. A multivariate logistic regression analysis showed that a positive psychiatric history was not associated with an improvement in vitality of 4.3 (minimal clinically important difference). Comparing the two groups, no significant fluctuations in SF-36 scores were founded and major deviations score increases were recorded in patients with a psychiatric history in all scales.

Conclusions Our real world data shows that new regimens do not seem to be associated with psychiatric side effects and conversely a clinical improvement compared to baseline was found, suggesting

an immediate gain in PROs over the treatment period, particularly the psychiatric subgroup.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A violation of emotion regulation as a central link in pathogenesis of stress-induced hypertension

E. Pervichko^{1,*}, Y. Zinchenko¹, O. Ostroumova²

¹ Lomonosov Moscow state university, faculty of psychology, Moscow, Russia

² Moscow State university of medicine and dentistry, faculty of general medicine, Moscow, Russia

* Corresponding author.

Introduction Essential hypertension (EH) is one of the most common diseases of the cardiovascular system. Today, scientists discover more and more patients whose BP values during work appear to be higher than those values during free time. This form of EH is called “hypertension at work”.

Objective To study the role emotion dysregulation in the pathogenesis of EH.

Materials and methods A projective study of emotion regulation was undertaken with our modified version of Rosenzweig Picture-Frustration Test (Zinchenko, Pervichko). At the second stage of the study, the simulation of emotional stress with the aspiration level modelling was carried out. The level of state anxiety, BP values and levels of catecholamines, renin and angiotensin I were taken before and after the experiment. Eighty-five patients with “hypertension at work” (mean age: 45.9 ± 2.8), 85 patients with “classical” EH (mean age: 47.4 ± 4.5 years) and 82 healthy subjects (mean age: 44.9 ± 3.1) took part in the study.

Results “Hypertension at work” patients significantly more frequently than patients from the second group and healthy subjects are more prone to rumination, disasterization and repression of their emotions. They will seldom employ the strategy of subjective-objective interactive transformations; their edibility to actualize new meanings in traumatic situations is diminished. We showed that emotion regulation strategies in “hypertension in the work” patients were ineffective in overcoming the emotional tension and created the conditions for chronization of high blood pressure, and could be considered as the central link in pathogenesis of stress-induced hypertension.

Conclusion The results contribute to enrich our understanding of etiology and pathogenesis of EH.

Parental styles and quality of life in the families with adolescents suffering from inflammatory bowel diseases

D. Zmeskalova, J. Prasko*, M. Ociskova, E. Karaskova, V. Mihal,

D. Kamaradova, K. Latalova

University hospital Olomouc, department of psychiatry, Olomouc, Czech Republic

* Corresponding author.

Background Inflammatory bowel diseases (IBD) in adolescents are chronic medical conditions with a substantial influence on the well-being of the family members.

Methods Total of 27 adolescents suffered from IBD, and 39 healthy adolescents completed questionnaires ADOR (parenting styles

assessed by teenagers), KidScreen-10 (quality of life), SAD (Scale of Anxiety in Children), and CDI (Children’s Depression Inventory). Their parents completed the Beck Anxiety Inventory (BAI), Beck Depression Inventory (BDI-II), and Pediatrics Quality of Life Family Impact Module (PedsQL).

Results The parental styles of mothers and fathers of IBD adolescents and the parents of healthy controls were without statistically significant differences except for the fathers’ positive parental style, which was significantly higher in the fathers of controls. There were no statistically significant differences between IBD children and the healthy controls in the quality of life assessed. However, the parents’ quality of life of ill children was statistically significantly lower than of the parents of the controls. The mothers of IBD adolescents were significantly more anxious and the fathers more depressed than the parents of the healthy controls, but there was no difference in the levels of anxiety or depression between IBD adolescents and the controls. Positive parental style of parents of IBD children positively correlated with the quality of life of adolescents. Positive parental style of the fathers correlated negatively with the state and trait children’s anxiety and negatively correlated with severity of childhood depression.

Conclusions The parents of the adolescents with IBD represent important group for psychosocial support.

Description of the prevalence of psychiatric disturbances in patients with refractory epilepsy

S. Ramos-Perdigues^{1,*}, E. Bailles², A. Mane³, L. Pintor⁴

¹ Psychiatry unit, Can Misses hospital, Ibiza, Spain

² Department of experimental and health sciences, psychiatry, university Pompeu Fabra, Barcelona, Spain

³ Institute of neuropsychiatry and addictions, Parc de Salut Mar and Foundation IMIM, psychiatry, Barcelona, Spain

⁴ Epilepsy unit, hospital clinic of Barcelona, Psychiatry, Barcelona, Spain

* Corresponding author.

Introduction Psychiatric morbidity in epilepsy is high, with prevalence rates of up to 50%, being higher in treatment-refractory cases. This co-morbidity worsen the quality of life. Psychiatric comorbidities are hampered by atypical presentations or disorders, which do not appear in the DSM-IV or ICD.

Objectives To describe the psychiatric morbidity in a group of patients with refractory-epilepsy.

Aims To provide evidence of the high morbidity and show the prevalence of the different psychiatric disorders.

Methods We cross-sectional assessed psychiatric disturbances in resistant-epileptic patients using SCID for DSM-IV and clinical interview for epileptic specific psychiatric conditions. We grouped psychiatric disturbances into six clusters:

- affective disorders;
- anxiety disorders;
- psychotic disorders;
- eating disorders;
- conduct disorder;
- substance use disorder.

We also considered epilepsy specific conditions as Interictal Psychotic Disorder (IPI) and Interictal Dysphoric Disorder (IDD) characterized by 3/8 symptoms: depressive mood, anergia, pain, insomnia, fear, anxiety, irritability, and euphoric mood.

Results The sample consist on 153 patients, with a mean age of 37. In total, 42.5% were males. One or more axis I diagnoses was seen in 38% of the patients. The most common condition was IDD (27.1%), followed by affective disorders (22%), anxiety disorders

(15.3%), psychotic disorders (4%) and drug use (2%). There were no patients with eating or conduct disorders or IPI.

Conclusions Psychiatric morbidity is frequent in resistant-epilepsy. Despite 38% of patients suffered from at least one axis I diagnoses, IDD was the most prevalent condition and not included in SCID interview.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cannabinoid hyperemesis syndrome, a treatment discussion

S. Ramos-perdigues*, M.J. Gordillo, C. Caballero, S. Latorre, S.V. Boned, M. Guisado, M. De Almuedo, P. Torres, M.T. Sanchez, E. Contreras, A. Fernandez, G. Esmeralda, E. Sanchez, M. Segura, C. Torres, G. Herrero, M. Tur, C. Merino
Psychiatry unit, Can Misses hospital, Ibiza, Spain

* Corresponding author.

Introduction Cannabinoid hyperemesis syndrome (CHS), is characterized by recurrent episodes of severe nausea and intractable vomiting, preceded by chronic use of cannabis. A pathognomonic characteristic is compulsive bathing in hot water. The resolution of the problem occurs when cannabis use is stopped. However, patients are often reluctant to discontinue cannabis. Treatment with anti-emetic medication is ineffective. Case series suggested haloperidol as a potential treatment. Other antipsychotics as olanzapine has been used as anti-emetic treatment in chemotherapy.

Objectives To describe three cases of patients with CHS whom showed a successful response to olanzapine, even when, haloperidol had failed.

Aims To present an alternative treatment for CHS which can offer benefits over haloperidol.

Methods We present three cases of patients who suffered from CHS and were admitted to emergency department. All patients were treated with olanzapine after conventional anti-hemetic treatment failure. One patient was also unsuccessfully treated with haloperidol.

Results All three patients showed a good response to olanzapine treatment. Different presentations were effective: velotab and intramuscular. Their nausea, vomits and agitation were ameliorated. They could be discharge after maintained remission of symptoms.

Conclusions Olanzapine should be considered as an adequate treatment for CHS. Its suitable receptorial profile, its availability in different routes of administration and its side effects profile could offer some benefits over haloperidol.

* Corresponding author.

Introduction Growing evidence has been collected over the complex, intertwined pathophysiological connection among subclinical cardiovascular (CV) disease, i.e. atherosclerosis, systemic low pro-inflammatory states and psychiatric disorders/symptomatology (anxiety, depression), with controversial results.

Aim Aim of this study was to investigate the possible link between subclinical CV risk factors (atherosclerosis), depressive symptoms, and inflammation.

Methods Cross-sectional study. Inclusion criteria: outpatients aged ≥ 40 years, attending colonoscopy after positive faecal occult blood test, negative medical history for cancer. Collected data: blood pressure, glycaemia, lipid profile, waist circumference, BMI, PCR (C reactive protein), LPS (bacterial lipopolysaccharide), ultrasound carotid intima-media thickness (c-IMT). Psychometric tests: HADS, TCI, IMSA, SF36. Statistical analysis performed with STATA13.

Results The 54 patients enrolled were equally distributed by gender. CV risk factors were common in the study population, with 33 patients (61.11%) with hypertension, 14 (25.93%) with hyperglycaemia, 20 (37.4%) with hypertriglyceridemia, 19 (35.19%) with low HDL and 64.81% with overweight. High levels of PCR were found in 24 subjects (44.44%). Right c-IMT was increased in 26.41% of the sample, and 11.32% had an atheromatous plaque. Left c-IMT was increased in 24.53% of patients, with a plaque in 7.55% of them. Clinically relevant depressive symptoms were found in the 18.87% of the sample and were statistically significantly associated with PCR (OR = 28.63; P = 0.01).

Conclusions Evidence contributing to the so-called “inflammation theory” of depression and supporting the association between mood and CV disorders was here collected, supporting the need for a multidisciplinary approach to the diagnosis and treatment of such conditions, assuming a clinically-translated PNEI (psycho-neuro-endocrino-immunological) perspective.

Introduction Metabolic syndrome (MetS) is defined by metabolic and cardio-vascular impairments and is frequently associated with anxiety and depressive disorders. Both MetS and anxiety-depressive syndromes feature similar systemic inflammatory alterations. Inflammation of the large bowel is also a key factor for the development of colorectal cancer (CRC).

Objective To measure the prevalence of MetS and symptoms of anxiety and depression among patients undergoing colonoscopy.

Methods Cross-sectional study. Patients undergoing colonoscopy aged 40 or more, with negative history for neoplasia or inflammatory bowel disease, were enrolled. Data collected: colonoscopy outcome, presence/absence of MetS (IDF and ATP III criteria), presence/absence of depressive and anxiety symptoms assessed with HADS.

Results The sample was made up of 53 patients (female 24, 45.3%). Mean age was 60.66 ± 9.08. At least one adenoma was found to 23 patients (43.3%). Prevalence of MetS ranged from 34% to 36% (ATP III and IDF criteria, respectively). Prevalence of depressive and anxiety symptoms was 20% and 33%, respectively.

Conclusion Prevalence of MetS, anxiety and depressive symptoms among patients undergoing colonoscopy was higher than in the general population.

Disclosure of interest The authors have not supplied their declaration of competing interest.

¹ *Università degli studi di modena e Reggio Emilia, Corso di Laurea in Medicina e Chirurgia, Modena, Italy*

² *Università degli Studi di Modena e Reggio Emilia, Scuola di Specializzazione in Psichiatria, Sassuolo, Italy*

³ *Università degli Studi di Modena e Reggio Emilia, Scuola di Specializzazione in Psichiatria, Modena, Italy*

⁴ *Università degli Studi di Modena e Reggio Emilia, Dipartimento di Medicina Diagnostica- Clinica e di Sanità Pubblica- sezione di Psichiatria, Modena, Italy*

* *Corresponding author.*

Introduction Several studies have shown an association between the Short-Form 36 (SF36) scores and anxiety-depressive symptoms, suggesting that depression in particular could reduce Quality of Life (QoL) to the same, and even greater, extent than chronic non-communicable diseases, such as diabetes and hypertension.

Aims To explore the relationship among QoL and anxiety, depressive and anxiety-depressive symptoms in an outpatient sample.

Methods Cross-sectional study. Inclusion criteria: outpatients aged ≥40 years, without history for cancer, attending colonoscopy after positive faecal occult blood test. Collected data: blood pressure, blood glucose, lipid profile. Psychometric test: Hospital Anxiety and Depression Scale (HADS). QoL was assessed with SF36. Statistics performed with STATA13.

Results 54 patients enrolled (27 females). Sixteen patients (30.2%) were positive for anxiety symptoms, ten (18.9%) for depressive symptoms and five (9.4%) for anxiety-depressive symptoms. The perceived QoL was precarious in twelve subjects (22.2%): eight (15.9%) had low score (≤ 42) at "Mental Component Summary" (MCS) subscale, three (5.7%) at the "Mental Health" item and one patient (1.9%) at the "Vitality" one. At the multiple regression analysis, depressive (OR=28.63; P=0.01) and anxiety-depressive symptoms (OR=11.16; P=0.02) were associated with MCS.

Conclusions The association emerging from the present study between depressive/anxiety symptoms and the MCS component of SF36 is consistent with available literature. Study design and small sample size do not allow to generalize results, that need further studies to be confirmed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Patients with severe mental illness (SMI) have been described at higher risk of cardiovascular disease (CVD). The aim of this systematic review and meta-analysis was to quantify prevalence, incidence, cross-sectional association and longitudinal increased risk of coronary heart disease (CHD), stroke, transient ischemic attack and cerebrovascular disease (CBVD), heart failure (HF), peripheral vascular disease (PVD), death due to CVD, and any CVD in patients with SMI. We included 92 studies, with a total population of 3,371,461 patients (BD=241,226, MDD=476,102, SCZ=1,721,586, SMI=932,547) and 113,925,577 controls. Pooled prevalence of any CVD in SMI was 9.9% (95% CI=7.4–13.3) (33 studies, 360,144 patients). Compared to controls, after adjusting for a median of 7 confounders, SMI was associated with higher risk of CVD in cross-sectional studies, OR:1.53 (95% CI=1.27–1.83) (11 studies), with CHD OR: 1.51 (95% CI=1.47–1.55) (5 studies), with CBVD OR: 1.42 (95% CI=1.21–1.66) (6 studies), and tended to be associated with HF OR: 1.28 (95% CI=0.99–1.65) (4 studies). Cumulative incidence was 3.6 CVD events in a median follow-up period of 8.4 years (range: 1.76–30). After considering a median of 6 confounders, SMI was associated with higher longitudinal risk of CVD in longitudinal studies HR: 1.78 (95% CI=1.6, 1.98) (31 studies), of CHD: HR: 1.54 (95% CI 1.30–1.82) (18 studies), of CBVD HR: 1.64 (95% CI 1.26–2.14) (11 studies), of HF HR:2.10 (95% CI 1.64–2.70) (2 studies), of PVD, unadjusted RR: 3.11 (95% CI 2.46–3.91) (3 studies), of death due to CVD, HR 1.85 (95% CI 1.53–2.24) (16 studies). In this meta-analysis, the

association between SMI and CVD has been quantified in a world representative sample; we suggest prevention of CVD should be warranted as standard care in SMI.

Psychological and clinical factors associated with emotional distress related to type 2 diabetes mellitus

Z. Stankovic^{1,*}, K. Lalic², M. Jasovic³

¹ Clinical centre of Serbia, clinic for psychiatry, Belgrade, Serbia

² Clinical centre of Serbia, school of medicine, university in Belgrade, institute for endocrinology, diabetes and diseases of metabolism, Belgrade, Serbia

³ Serbian medical society, academy of medical sciences, Belgrade, Serbia

* Corresponding author.

Introduction Stress and coping with diabetes can affect the severity of disease directly, through pathophysiological processes or indirectly, through the patient's own perception of disease by deteriorating adherence to therapy and daily functioning.

Objectives To investigate emotional distress related to T2DM according to demographic, clinical, psychological, metabolic and anthropometric characteristics.

Methods Eighty-two in- and outpatients of both sexes (<65 years) with endocrinologist-diagnosed T2DM, duration ≥ 5 years, treated with either oral therapy, insulin or both, were included in this cross-sectional study. The Beck Depression Inventory (BDI) was employed for assessment of severity of depressive symptoms. The Mini Mental State Examination (MMSE) was used for assessment of cognitive status. The Problem Areas in Diabetes (PAID) (subscale related to emotional problems associated with T2DM) was applied for assessment of emotional distress. Clinical characteristics of the illness were obtained from medical records. Laboratory and anthropometric measures (Body mass index, Waist circumference) were also performed. The level of significance in statistical analyses (Student's *t*-test, Pearson's correlation) was $P=0.05$.

Results The PAID (emotional distress) subscore was significantly higher in patients with psychiatric heredity ($P=0.028$) in relation to these without (Student's *t*-test). Considerable positive correlation between PAID subscore and BDI score ($r=0.588$) ($P=0.000$), and negative correlation between PAID subscore and MMSE score ($r=-0.201$) ($P=0.050$) were also found (Pearson's correlation).

Conclusions Psychological factors: psychiatric heredity, higher intensity of depression and poor cognitive functioning were significantly associated with emotional distress related to the illness in patients with type 2 diabetes mellitus.

Clinico-pathological profile evaluation in patients affected by chronic inflammatory bowel diseases

F. Travagliati^{*1}, E. Borrelli¹, S. Martinelli¹, L. Dattoli¹, D. Ferrarese², E. Gaetani², F. Scaldaferrri², A. Gasbarrini², L. Janiri¹, G. Camardese¹

¹ Università Cattolica del Sacro Cuore, psychiatry, Roma RM, Italy

² Università Cattolica del Sacro Cuore, gastroenterology, Roma RM, Italy

* Corresponding author.

Introduction Inflammatory bowel diseases (IBDs) have high social impact. Aetiology is still unknown, however multifactorial genesis is surely implicated. We tried to correlate IBDs and psychological distress through evaluated psychometrical instruments and subsequently to relate subjective influences with gastroenteric clinical manifestation, defining new critical elements on which IBD are based.

Methods In our study, we included 57 participants, selected according to their diagnosis, between those attending our gastrointestinal ambulatory: 26 had Chron's disease, while 31 had ulcerative colitis. 78 people without gastroenteric or psychiatric disorder were also included in the study as control group. Psychometric questionnaires were administered to evaluate anxiety and depressive symptoms, quality of live, self-efficacy and resilience (Fig. 1).

Results Levels of anxiety and depression were higher in patients with IBDs than in the control group. STAI-Y highlighted higher state anxiety and trait anxiety levels in first group. HADS showed higher scores in ill patients, as well as CD-RISC showed a more impaired resilience. EQ-VAS, PGWBI and GSE revealed significant differences in health status, psychological wellness and self-efficacy between the two groups.

Conclusions IBDs seem related to psychological diseases. Affected patients have higher anxiety and depression levels than general population as well as lower self-efficacy and resilience. Those elements being strictly linked to physical discomfort contributes to develop a loop in which patients get caught. Creating a model of integrated cooperation between gastroenterologist and psychiatrist during treatment of patients with IBDs seems fundamental to grant at once all the professional figures each patient needs for better care.

Differences in care intensity held by a consultation-liaison service in a general hospital among patients suffering from different somatic illnesses

J. Valdes-Stauber*, S. Bachthaler

Zentrum für Psychiatrie Südwürttemberg, department psychiatry and psychotherapy I, university of Ulm, Ravensburg, Germany

* Corresponding author.

Background There are differences in psychiatric comorbidity and perceived diagnosing and psychological supporting needs depending on professionals, units, programs, awareness, and diagnoses.

Objectives This investigation explores possible differences in psychiatric comorbidity, in care intensity and in care priorities by a psychiatric-psychosomatic consultation-liaison service among main physical disease groups.

Methods Three-year survey ($n = 1,862$ individuals) about all elective referrals from 16 different units in a middle-sized general hospital with 520 beds and 34,000 treated patients per annum. Five clinical and six care variables have been selected from the collected data by means of basic documentation of CLS. Chi-square-tests and ANOVA including Scheffé post-hoc test as well as multivariate regression analyses with robust regression coefficients were performed.

Results The sample consisting of 55% women is on average 61 years old, 79% showing current and 35% psychiatric comorbidity prior to hospitalisations. Average GAF amounted to 67.2 (SD = 20.5) and ECOG to 1.22 (SD = 1.38). Psychosomatic disorders (F4) amounted to 38%, mood disorders (F3) to 19% and mental organic disorders (F0) to 11% of psychiatric disorders. Each patient received on average 2.11 (SD = 2.63) contacts and 105 minutes (SD = 144) of treatment time, 59% psychopharmacological and 32% psychotherapeutic interventions. Men and older people receive less, but comorbid patients independently of age and gender more intensive psychological support. There are hardly differences according to physical diseases.

Discussion Cancer patients show less psychiatric comorbidity, but more psychotherapeutic interventions. Patients suffering from psychiatric comorbidity received more intensive care and more post-discharge recommendations. Patients treated because of chronic pain received much more interventions and treatment time.

A study of anxiety and depression in Vitiligo patients: New challenges to treat

D. Vernal

Government medical college, Kota, psychiatry, Bahraich, India

Introduction Vitiligo, a dermatological problem, affects a person's emotional and psychological well being, having major consequences on patient's life. Most of the patients of vitiligo report embarrassment, helpless and low self esteem.

Aims To study socio-demographic profile and psychiatric comorbidities and their correlation with site of lesion in vitiligo patients.

Methods and material 100 vitiligo patients and 100 subjects as control group who were well enough to complete the assessment were assessed with a semi-structured self designed Proforma, Hospital Anxiety Depression Scale (HADS) to obtain the relevant information. Data so obtained were tabulated, analyzed and conclusions were drawn using suitable statistics (i.e. Chi²).

Results 79% of vitiligo patients were between age 13 to 45 years, 67% were males, 33% were females patients in study group. In comparison to healthy controls, the psychiatric morbidity was found to be significantly higher in the vitiligo group (62% v/s 25%). 37%, 18%, and 7% vitiligo patients suffered from Mixed anxiety and depressive disorder, Depressive disorder and Generalized anxiety disorder respectively. Incidence of psychiatric morbidity was higher in patients who had lesions more on exposed body areas.

Conclusions Vitiligo affected marital, sex life and intimacy. This generates psychological distress and disrupts the social relationship and creates a vicious stress-vitiligo cycle. Among vitiligo cases, psychiatric morbidity was found more frequent in young participants and higher in patients having lesions on exposed body areas.

Keywords Vitiligo; Psychiatric morbidity; Anxiety; Depression; Stress

The effects of brain stimulation with direct electrical current in the treatment of resistant obsessive-compulsive disorders

K. Najafi^{1,*}, Y. Fakour², H. Zarrabi¹, S.M.R. Khalkhali¹, N. Ramezanghorbani², T. Najafi¹, S. Shabafrouz¹¹ School of medicine, Guilan university of medical sciences, department of psychiatry, Rasht, Iran² Ministry of health and medical education, department of development and coordination scientific information and publication, Tehran, Iran

* Corresponding author.

Introduction Direct brain stimulation with electrical currents is an effective treatment for depression and considering is an effective supplementary treatment of resistant obsessive-compulsive disorder.

Aim Assess the effects of brain stimulation with direct electrical current in the treatment of resistant obsessive-compulsive disorders.

Methods The present study is a paired clinical trial conducted in a group of 42 patients diagnosed with treatment resistant obsessive-compulsive disorder in the province of Rasht. Direct brain stimulation with electrical current was performed according to the protocol throughout the 15 treatment sessions. The effectiveness of the first, fifth, tenth and fifteenth session(s) of treatment were evaluated based on the Yale-Brown Obsessive Compulsive Scale (Y-BOCS) and results were analyzed using Repeated Measure ANOVA, Spearman Correlation and Pearson Correlation software SPSS version 22.

Results All 42 participants stayed throughout the study. Mean age of patients was 10.14 ± 29.10 . Mean test scores of Yale-Brown Obsessive Compulsive Scale in the first, fifth, tenth and fifteenth session of treatment was 6.78 ± 28.4 , 4.58 ± 22.8 , 6.3 ± 16.4 and 5.37 ± 10.8 , respectively which is significantly lower (P -value = 0.00, $F = 80.12$). No significant correlation was observed between the participant's age, sex, education level, marital status and employment status and in any of the test scores of Yale-Brown Obsessive Compulsive Scale in the first, fifth, tenth and fifteenth session of treatment (P -value > 0.05).

Conclusion In order to attain a sustainable long term effects of the proposed treatment, it is recommended that patients be reminded on their next schedule of treatment.

Who did it? Exploring gaze agency in obsessive-compulsive (OC) checkers

M. Giuliani^{1,*}, R. Gregori Grigc^{2,3,4}, R.M. Martoni¹, M.C. Cavallini¹, S.A. Crespi^{2,3,4,5}, C. de'Sperati^{2,3,4}

² Vita-Salute San Raffaele university, laboratory of action perception cognition, Milan, Italy

³ Vita-Salute San Raffaele university, faculty of psychology, Milan, Italy

⁴ IRCCS San Raffaele, division of neuroscience, Milan, Italy

⁵ IRCCS San Raffaele, CERMAC neuroradiology department, Milan, Italy

* Corresponding author.

Introduction Clinically, OC-checkers often report staring compulsions and “lack of action completion” sensations, which have been linked to self-agency alterations. Belayachi and Van der Linden (2009) theoretically proposed that “abnormal” checkers self-agency could be due to an over-reliability on environmental cues and to a tendency to specify actions in a procedural and inflexible way, conceiving them as “low-level” agents. Currently, no studies have experimentally address this issue.

Objectives To investigate self-agency in OC-checkers subtype, measuring gaze agency (the ability to understand that we can cause events through our eye movements) and taking into account both agency beliefs and agency feelings.

Methods 13 OC-checkers and 13 healthy controls underwent two tasks. “Discovery” task, a completely novel task used to examine causal learning abilities. Subjects watched bouncing balls on a computer screen with the aim of discovering the cause of concurrently presented acoustical beeps. “Detection” task, a two-alternative forced choice task that required subjects to tell whether or not the beeps were generated by their own eye movements.

Results Checkers exhibit:

- lower performance scores and confidence ratings when they have to self-attribute the beep cause, but not eye behavioral differences, during discovery task;

- lower confidence ratings, but a level of accuracy similar to that of controls, during detection task.

Conclusions Checkers do not show an altered self-agency per se, but what we have called a “doubtful” self-agency: indeed, we argue that agency beliefs alterations found during Discovery task can be due to pathological doubt, rather than to altered agency feelings.

Paroxetine concentrations in obsessive-compulsive disorder: Support for a therapeutic interval

M.B. Humble^{1,*}, M. Reis²

¹ Örebro university, school of medical sciences, Örebro, Sweden

² University health care in Region Skåne, department of clinical chemistry, division of laboratory medicine, Lund, Sweden

* Corresponding author.

Introduction Previous studies of concentrations of serotonin reuptake inhibitors (SRIs) versus therapeutic efficacy have yielded

inconsistent results. Even if the relationships between the individual's serotonergic system and the clinical symptoms of obsessive-compulsive disorder (OCD) are poorly understood, the SRIs are consistently effective in OCD. However, studies on SRI concentrations in OCD treatment are rare.

Objectives/aims To identify possible links between paroxetine concentrations and anti-obsessive response.

Methods In a randomised, double-blind trial, comparing clomipramine, paroxetine and placebo in OCD treatment, serum paroxetine levels were measured after 1 week and after 4 weeks of treatment in 18 patients. Anti-obsessive response was assessed with Yale-Brown obsessive compulsive scale (Y-BOCS) and patients' global evaluation (PGE), after 12 weeks of treatment.

Results Serum paroxetine concentrations after 4 weeks suggested a therapeutic interval between 50 and 240 nmol/L (13–63 ng/mL). The mean Y-BOCS decrease was 54% inside versus 7% outside this interval ($t=3.96$; $P=0.0011$).

Conclusions Paroxetine levels seemingly predicted clinical outcome. Studies with a greater number of patients are necessary in order to confirm this finding and to discern whether it is useful in clinical practice.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Augmentation in profound, SRI-refractory OCD: Is aripiprazole superior to other dopamine blockers?

I. Pampaloni*, H. Tyagi, L. Drummond

South West London and St Georges mental health NHS trust, national services for OCD and BDD, London, United Kingdom

* Corresponding author.

Introduction OCD is a common disorder, affecting 1% of the population and usually responds to treatment with serotonin reuptake inhibitors (SRIs) or exposure and response prevention (ERP) and to augmentation with antipsychotics. However, some patients fail to respond. The national inpatient unit for obsessive compulsive disorder (OCD) and body dysmorphic disorder (BDD) (i) is the only 24-hour staffed inpatient facility for OCD in the UK and treats patients with profound, treatment-refractory OCD. There is evidence of efficacy of aripiprazole in augmenting SRI in severe OCD (ii).

Objectives To compare the efficacy of aripiprazole versus other antipsychotics as SRI augmentation.

Methods One hundred and nine patients admitted to the unit between March 2006 and September 2011 and discharged on an antipsychotic and an SRI were included. The Yale-Brown obsessive compulsive scale (YBOCS) was administered at admission and at discharge. Data were analysed using SPSS version 23 using analysis of variance (ANOVA). Two groups were compared: those receiving SRI + aripiprazole versus those receiving SRI + another antipsychotic.

Results sixty-two patients received SRI with aripiprazole and 47 SRIs with another antipsychotic. Overall, patients showed improvement, with an average YBOCS reduction of 11.7 (33% reduction). Patients taking aripiprazole improved by an average of 13 (36% reduction, $P<0.05$).

Conclusions Patients of the national unit with severe, treatment refractory OCD treated with aripiprazole augmentation showed a greater improvement than those on other antipsychotics. Further research into aripiprazole in OCD is warranted.

Duration of untreated illness and outcome of obsessive-compulsive disorder: A naturalistic follow-up study

V. Prisco*, F. Perris, T. Iannaccone, M. Fabrazzo, F. Catapano
University of Naples SUN, department of psychiatry, Naples, Italy

* Corresponding author.

Duration of untreated illness (DUI) is a predictor of outcome in psychotic and affective disorders. Data available on DUI and its relationship with outcome in obsessive-compulsive disorder (OCD) suggest an association between longer DUI and poorer treatment response. The present study investigated socio-demographic and clinical predictors of DUI and its association with long-term outcome in OCD patients. Eighty-three OCD outpatients were treated with serotonin reuptake inhibitors (SRIs) and prospectively followed-up for 3 years. Baseline information was collected on demographic and clinical characteristics using standard assessments. Each patient was assessed through the structured clinical interview for DSM-IV axis I disorders (SCID-I), the structured clinical interview for DSM-IV axis II personality disorders (SCID-II), the Yale-Brown obsessive-compulsive scale (Y-BOCS) and the 17-item Hamilton rating scale for depression (HDRS). The DUI was explored by interviewing patients, family caregivers and clinicians. OCD subjects had a mean DUI of 7.3 (5.8) years. A younger age at onset and a greater severity of OCD symptoms at baseline were associated with a longer DUI. The DUI of patients with a “good outcome” was shorter than that of patients with a “poor outcome”. Logistic regression analysis revealed indeed a possible association between longer DUI and “poor outcome”. In the logistic multi-variable model, the association of DUI with treatment outcome held true whilst controlling for socio-demographic and clinical variables.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Prevalence and clinical correlates of sensory phenomena in obsessive compulsive disorder

S. Rayappa*, A. Hegde, J.C. Narayanaswamy, S.S. Arumugham, S. Bada Math, Y.C.J. Reddy

National institute of mental health and neurosciences NMHANS, psychiatry, Bengaluru, India

* Corresponding author.

Introduction A substantial number of patients suffering from obsessive compulsive disorder (OCD) report a subjective distressing experience prior to the repetitive behavior, known as sensory phenomena (SP).

Objectives Need to systematically evaluate SP and the clinical correlates in OCD.

Aims Assess prevalence of SP and clinical correlates in OCD.

Methods Subjects ($n=71$) fulfilling the criteria for DSM-IV-TR OCD were recruited consecutively from a specialty OCD clinic in Southern India and were assessed using the Yale Brown obsessive and compulsive scale (YBOCS), dimensional Yale-Brown obsessive compulsive scale (D-YBOCS) and the University of São Paulo Sensory Phenomena Scale (USP-SPS).

Results The prevalence of the SP was found to be 50.7%. Prevalence of SP is significantly greater in the patients with early age of onset ($P=0.47$). In subtypes of SP, Tactile was 12.7%, “just right” for look was 26.8%, “just right” for sound was 9.9%, “just right” for feeling was 16.9%, feeling of incompleteness leading to repetitive behavior was 22.5%, “energy release” sensation leading to repetitive behavior was 4.2% and “urge only” leading

to repetitive behavior was 11.3%. SP was found to have significant correlation with symmetry/ordering/arranging/counting dimension ($P=0.003$). Significant positive correlation existed between SP severity and the severity of the compulsions ($P=0.02$).

Conclusion Considering its high prevalence in OCD, it might be useful to incorporate SP assessment during the routine clinical assessment of OCD. It might warrant a place in the phenomenological and nosological description of OCD. Additionally, the neurobiological correlates of SP need to be explored.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Deep brain stimulation and anterior capsulotomy: The question of autonomy

S. Raymaekers^{1,*}, Z. Van Duppen², K. Demyttenaere¹, L. Luyten³, L. Gabriëls², B. Nuttin⁴, C. Bervoets²

¹ KU Leuven, psychiatry, Leuven, Belgium

² UPC KU Leuven, psychiatry, Leuven, Belgium

³ KU Leuven, centre for psychology of learning and experimental psychopathology, Leuven, Belgium

⁴ KU Leuven, neurosurgery, Leuven, Belgium

* Corresponding author.

Introduction In carefully selected treatment-refractory patients with obsessive compulsive disorder (OCD), deep brain stimulation (DBS) or anterior capsulotomy (AC) might be considered as a possible treatment. However, the direct intervention in the brain can raise questions about autonomy. Do patients still feel like they are in control of their actions when their behavior is changed by a surgical intervention?

Objective/aims To examine in both AC and DBS patients whether these intervention influenced perception of autonomy. We aimed to discover any differences in these perceptions when comparing AC and DBS patients.

Methods We conducted semi-structured interviews with AC and DBS patients. Interviews were recorded digitally and transcribed verbatim. We analyzed interviews in an iterative process based on grounded theory principles.

Results We interviewed 10 DBS patients and 6 AC patients. Sense of agency (the awareness that one is the author of his/her own actions) did not seem to be diminished by AC or DBS. However, especially DBS patients are aware of their dependency on a device for their well-being. Another important theme is authenticity (in how far patients perceive their actions and thoughts as matching their self-concept). Feelings of authenticity can be disturbed especially in cases of induced hypomania (for DBS) or apathy (for AC). OCD itself also has an impact on autonomy as patients describe a lack of freedom due to their disorder.

Conclusion Despite extensive changes in emotions, behavior and even personal identity after DBS or AC surgery, perceived autonomy was not greatly altered in these OCD patients.

Disclosure of interest Medtronic provided grants for research, education, and traveling to B. Nuttin and L. Gabriëls, who hold the Medtronic Chair for Stereotactic Neurosurgery in Psychiatric Disorders at KU Leuven. S. Raymaekers is supported by this Chair. B. Nuttin co-owns a patent on DBS in OCD.

Is there a relationship between morbid obesity and depression?

E. Ribera*, L. Martínez, L. Pujol, M. Angelats, I. Ezquiaga, M. Grifell, Á. Palma, E. Belmonte, L. Pérez, V. Pérez-Solá, P. Salgado

Institut de neuropsiquiatria i addiccions, Parc de Salut Mar, institut hospital del Mar d'Investigacions Mèdiques, CIBERSAM G21, psychiatry, Barcelona, Spain

* Corresponding author.

Introduction A considerable proportion of patients with morbid obesity require treatment with antidepressants.

Objectives The aim of this study is to determine the incidence of patients who are in antidepressant treatment and identify risk factors for the need of this treatment in patients with morbid obesity.

Materials and methods Retrospective cohort study of 292 patients with morbid obesity who underwent bariatric surgery at Hospital del Mar from January 2010 to November 2015. The incidence of antidepressant treatment was analyzed, and also its possible relationship with the following variables: age, sex, BMI, tobacco smoking, alcohol consumption and age of onset of obesity. Chi² test for categorical variables and Student *t*-test for quantitative variables were applied. Afterwards, a multivariate analysis was performed using logistic regression.

Results The mean age is 43.1 years. Most of the patients (76.4%) are women. Seventy-seven patients (26.4%) are receiving treatment with antidepressants. There is a statistically significant relationship between age and the need of treatment with antidepressants ($P < 0.001$). This relationship is still present when the variables are analyzed using logistic regression ($P < 0.005$, OR 1.049). We have not found any significant relationship with the rest of the variables.

Conclusions Despite the large number of patients in the study, there are limitations, such as being a retrospective study and not being adjusted for confounding factors. From all the variables that have been analyzed we have found that as the age of the patients increase, there is a higher number of patients that receive treatment with antidepressants.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Depressive disorder: Particularities of theory of mind

I.A. Ravis^{1,*}, I.E. Cristea¹, C. Giurgi-Onocu², M. Ienciu², C. Bredicean²

¹ "Pius Brinzeu" clinical emergency county hospital, "Eduard Pamfil" psychiatry clinic, Timisoara, Romania

² "Victor Babes" university of medicine and pharmacy, neuroscience departement, adult psychiatry discipline, Timisoara, Romania

* Corresponding author.

Introduction "Theory of mind" represents the cognitive ability to attribute mental states as belonging to others and it's essential in any social interaction.

Objectives Our objective was to evaluate the capacity of emotion recognition in patients with recurrent depressive disorder.

Aims This study aimed to determine if theory of mind is influenced by psychotic features and the type of emotions distinguished.

Methods We analyzed a sample of 45 patients with a diagnosis of recurrent depressive disorder (WHO ICD10) that was divided to include 23 patients with at least one episode with psychotic symptoms, while the rest had no history of psychotic symptoms. The "Reading the mind in the eyes" test was applied in an outpatient setting, in remission. The data has been processed in SPSS.

Results The study found that 72.72% of patients without psychotic symptoms have a low capacity of emotion attribution, while 27.72% demonstrated a normal capacity ($P = 0.00252$). The majority with a history of psychotic depression (82.60%) showed a low capacity of emotion recognition, while 17.39% had normal abilities ($P = 0$). None of the patients showed a high capacity of emotion recognition. There was a significant difference in the frequency of negative emotions recognition by all patients (77.77%), while only a few managed to detect positive emotions (22.22%), regardless of psychotic symptom history.

Conclusions In itself, a history of recurrent depressive disorder is directly related to a reduced ability to correctly attribute emotions. Moreover, these patients are more likely to detect negative emotions rather than positive ones.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Male depression – actual a male specific disorder or potentially a new subtype of depression?

V. Rößner-Ruff*, J. Krieger, I.T. Graef-Calliess
Klinikum Wahrendorff GmbH, Forschung und Entwicklung, Sehnde/OT Ilten, Germany

* Corresponding author.

Introduction Although depression is one of the most prevalent disorders around the world we know only little about the effect of factors like gender-related norms or personality-related aspects in the expression of depressive symptoms. Current findings of studies are heterogeneous and lead to the conclusion that depression is more prevalent in women as well as that they have a higher risk for depression. Women express more typical depressive symptoms while men offer more atypical symptoms like aggressiveness, irritability, alcohol misuse which is constituted as male depression (MD).

Objective Male and female patients with a diagnosis of depressive episode or recurrent depressive disorder (ICD-10) who are treated in in-patient or day clinic setting of two psychiatric institutions in Lower Saxony and one psychiatric university hospital in Austria. Study period: November 2016 to November 2017. No limitations to further diagnosis, age or other factors.

Methods To analyze the expression of (a) typical depressive symptoms as well as causes of and factors of influence in diverse types of depression different questionnaires and quantitative methods will be used.

Aims Investigate gender-specific differences in the expression of symptoms in male and female patients with a depressive disorder. Focus: whether symptoms of MD are more prevalent for depressive men than women. Furthermore, causes and factors of (a) typical depressive symptoms should be analyzed.

Results First results will be presented.

Conclusion The results of the study should lead to the conclusion whether there exist any gender-specific differences in the expression of depressive symptoms and what they might be caused by.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Burn out mainly occurs among healthcare employees. This professional category is exposed to a large load of emotional disturbance.

Objectives The aim of this work was to study the levels of burnout syndrome in caregivers who were victims to occupational accident.

Methods This cross-sectional study was conducted during 2014–2015 in the occupational medicine department. The target population consisted of the healthcare employees who reported their exposure to occupational accident. A semi-structured self-reported questionnaire including the Maslach questionnaire was used to collect information. Data were analyzed using SPSS-20.

Results One hundred and sixty health professionals returned the questionnaire (58% women, mean age 31.9 years old). Occupational accidents occurred mostly in the morning (62.5%). Among the healthcare providers, 112 health professionals (70%) had had sharp injuries. Burn out was found among 23.1% of the studied population. It was defined by its three domains: a high emotional exhaustion (46.9%), high depersonalization with low personal accomplishment (36.3%) and high depersonalization without low personal accomplishment (34.4%). Professionals with less years in the function ($P=0.031$) and technicians ($P=0.028$) were more affected by Burnout. A significant relationship was found between traumatic accidents ($P=0.012$), needle stick injuries ($P=0.009$) and burnout.

Conclusion The prevalence of burnout is high among health professionals which can increase the risk of occupational accidents and its subsequent risks. It seems that holding workshops and increasing healthcare givers' awareness and skills to face these risks can be effective in mitigating them.

³ Institut d'investigació biomèdica Sant Pau IIB-Sant Pau, psychiatry, Barcelona, Spain

⁴ Príncipe de Asturias university hospital, psychiatry, Madrid, Spain

* Corresponding author.

Introduction Major depression cognitive impairments lasts in remission periods, have an impact on treatment outcome and hamper psychosocial functioning. Thus, its accurate detection and specific treatment has become a crucial step.

Objectives In order to assess objective cognitive functioning (OCF), a neuropsychological battery was administered. For subjective cognitive functioning (SCF), cognitive perception was evaluated by clinicians and patients.

Aims To determine the concordance between OCF and SCF.

Methods One hundred and two patients were grouped according to Hamilton Depressive Rating Scale (HDRS–17): 18 remitters ($RE < 7$), 40 partly remitters (PR, 7–18) and 44 acutely depressed ($AD > 18$). OCF was computed combining T-scores of digit symbol substitution test (WAIS-IV) with two RAVLT subtests (learning and memory). SCF was assessed with a CGI adaptation for cognitive disturbances severity.

Results The OFC was 41.21(8.49) for all patients and 45.54(6.8), 41.93(6.8) and 38.7 (9.7) for RE, PR, and AD, respectively. Psychiatrist and patients' SCF had a poor agreement ($\alpha=0.518$), with Cronbach's alpha for RE, PR and AD of -0.607 , 0.518 and 0.404 . Concordance between OCF and SCF was calculated for all patients (psychiatrist, $r = -0.317$, $P=0.002$; patient, $r = -0.310$, $P=0.002$,

for RE ($r = -0.535$, $P=0.022$; $r = 0.395$, $P=0.105$) for PR ($r = -0.013$, $P=0.94$; $r = -0.328$, $P=0.045$) and for AD ($r = -0.252$, $P=0.122$; $r = -0.333$, $P=0.033$). Patients rated their SCF as more impaired than did clinicians.

Conclusions Concordance between clinicians and patients regarding SCF is very poor, worsening in AD group and being null in remission. This study also points out that CF is best detected by patients in acute episodes and by psychiatrists when patients are in clinical remission.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Life functioning difficulties are a relevant but undervalued consequence of major depression. Mood symptoms and cognitive deficits have a significant, and somehow independent, impact on them. Therefore, cognitive difficulties should be considered a potential target to improve patients' functioning.

Aims To examine the degree in which objective and subjective cognition explain functional outcome.

Objectives To assess objective cognitive function (CF) with a neuropsychological battery and to measure subjective CF using measures of cognitive perception.

Methods Ninety-nine patients with depression were assessed by age, sex and level of schooling. Depressive symptoms severity was measured by Hamilton Depression Rating Scale (HDRS-17). Objective CF consisted in the following cognitive domains: memory, attention, executive functioning and processing speed. Subjective CF was assessed with Perceived Deficit Questionnaire-Depression (PDQ-D). Functioning Assessment Short Test (FAST) was used to evaluate life functioning, excluding the cognitive domain. All the listed measures were included in a multiple regression analysis with FAST scores as dependent variable.

Results The regression model was significant ($F_{1,98}=67.484$, $P < 0.001$) with an R of 0.825. The variables showing statistical power included (from higher to lower β -coefficient) HDRS-17 ($\beta = 0.545$, $t = 8.453$, $P < 0.001$), PDQ-D ($\beta = 0.383$, $t = 6.047$, $P < 0.001$) and DSST ($\beta = -0.123$, $t = -1.998$, $P = 0.049$).

Conclusions The severity of depressive symptoms is the variable that best explains life functioning. Surprisingly, the second factor hindering it is the patients' perception of their cognition. Current findings highlight the importance of correcting cognitive bias in order to improve functionality. However, results have to be taken cautiously as mood symptoms could partly explain the bias.

* Corresponding author.

Introduction The occurrence of religious symptoms in obsessive compulsive disorder OCD patients ranges from 0% up to 93%. Although, frequent and influential nature of these symptoms, the explanations of its complexity and phenomenology are deficient in the literature.

Objectives Determine the most frequent OC religious symptoms among OCD patients. Assess relation between the frequent symptoms of religious OCD and depression.

Methods Cross-sectional study was conducted among 115 consented patients diagnosed as OCD according to DSM-IV. Patients were recruited in one year from Psychiatric clinics, Zagazig University, Egypt. Psychiatric interview and psychometric assessment using Beck Depression Inventory (BDI) and OC religious symptom scale [1] were done.

Results The majority of patients (57.4%) had various religious OC symptoms. About 44% had doubts in religion in general (e.g. existence of God) and 11.3% had Blasphemous ideas. More than one third reported doubts about performing prayers and ablution perfectly; 34.8% repeatedly claimed they forgot to declare intention to pray, 36.5% had doubts about violating their ablution and 29.6% were skeptical about doing all ablution duties. Moreover, 23.5% reported slow or repeated readings in prayers, 25.2% had suspicions of breaking their fasting. A strong correlation between religious OC symptoms and total score of OC symptoms scale was confirmed. Most of our patients showed positive correlation between degree of depression and total score OC symptoms scale.

Conclusions Muslim patient present with specific phenomenology of religious OC symptoms. These symptoms are very frequent and negatively influencing their mood.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Human neuropeptide gene – new target in depression?

P. Gałeczki*, J. Jasionowska, M. Talarowska

Medical university of Lodz, department of adult psychiatry, Lodz, Poland

* Corresponding author.

Introduction Neuropeptide (NP, kallikrein 8, KLK8)—a kallikrein gene-related (KLK) endoprotease—plays a key role in neuroplasticity processes. Neuropeptide expression takes places both extracellularly and inside neurons within the area of the hippocampus. Various forms of electrophysiological stimulation (kindling, LTP, stress) increase neuropeptide expression within the hippocampus and in many other regions of the brain (e.g. neocortex, amygdala). Neuropeptide is mainly engaged in the early stage of LTP and in the process of synaptogenesis. Social cognition deficits (difficulties with identification, naming and analysing experienced emotional states) in the group of people suffering from depression have been described in scientific papers published in recent years. They are considered the core features of major depressive disorders.

Aims The aim of this study is to link the human neuropeptide gene (hNP) expression with the ability of the examined subjects to use nonverbal communication in social interactions.

Methods 120 individuals meeting the diagnostic criteria for a recurrent depressive disorders (rDE) were qualified to participate in the study. The Emotional Intelligence Scale–Faces task and two subtests from The Right Hemisphere Language Battery (RHLB) were used in the study.

Results Significant interrelations between expression on the mRNA level for the hNP gene and the variables used to assess social competences were confirmed. Results of the statistical analysis make it possible to confirm an inversely proportional correlation between the analysed variables.

Conclusions Increased hNP expression is associated with a reduction of interpersonal abilities in the people affected by depression.

* Corresponding author.

Introduction Residual symptoms of depressive disorder are major predictors of relapse of depression and lower quality of life. This study aims to investigate the prevalence of residual symptoms, relapse rates and quality of life among Thai patients with depressive disorders.

Methods Hamilton Rating Scale for Depression (HAM-D) and EQ-5D were used to measure the symptoms of depression and quality of life, respectively. Prevalence of residual symptoms of depression was collected. Regression analysis was administered to predict relapse and patients' quality of life at the 6 months post-baseline.

Results Two hundred and twenty-four depressive disorder patients were recruited. Most of patients (93.3%) had at least one residual symptom, and the most common residual symptom was anxiety symptoms (76.3%; 95% CI, 0.71 to 0.82). After 3 months post-baseline, 114 patients (50.9%) were in remission and within 6 months, 44 of them (38.6%) relapsed. Regression analysis showed

that residual insomnia symptoms were significantly associated with these relapse cases (OR=5.290, 95% CI, 1.42 to 19.76). Regarding quality of life, residual core mood and insomnia significantly predicted the EQ5D scores at 6 months post-baseline ($B = -2.670$, 95% CI, -181 to -0.27 , and $B = -3.109$, 95% CI, -172 to -0.38 , respectively).

Discussion Residual symptoms are common in patients receiving treatment for depressive disorder and were found to be associated with relapses and quality of life. Clinicians need to be aware of these residual symptoms when carrying out follow-up treatment in patients with depressive disorders, so that prompt action can be taken to mitigate the risk of relapse.

* Corresponding author.

Objectives Discovery of biomarkers for evaluation of efficacy of psychopharmacotherapy is important task.

Aim To study parameters characteristic for albumin binding sited in melancholic depression (MD) using fluorescent laser spectroscopy in range of 30–50 picoseconds.

Methods 22 patients with MD (dep) (F33.1 and 2) were investigated in dynamics of antidepressant therapy (venlafaxine: 75–150 mg/daily) for 30 days. Control group (con) consists of 54 volunteers. Decay of fluorescence amplitude (A) of fluorescent probe K-35 from serum albumin was measured using laser. Earlier, we revealed 3 binding sites in albumin with amplitudes A_1 , A_2 and A_3 with decay time of 1, 3 and 9 nanoseconds, respectively.

Results There was revealed significant decrease of amplitude A_1 dep, normalized on mean value of A_1 for controls ($A_{1\text{ dep}}/A_{1\text{ con}}$), for patients with MD after treatment with venlafaxine. In this case, $A_{1\text{ dep}}$ values decreased and were equal to A_1 values of controls ($P < 0.01$): $A_{1\text{ dep}}/A_{1\text{ con}}$ before treatment–1.23 and after 30 days of therapy–0.97 relative units; for controls this value was–1.00 relative units. The same type of normalization was observed for amplitudes A_2 and A_3 of melancholic patients. There were revealed significant changes of A_3/A_1 ratio that points out on conformational changes of serum albumin molecule in dynamics of venlafaxine therapy.

Conclusion We have registered unidirectional changes in albumin molecule in patients with MD. Investigated parameters can serve as potential biomarkers for evaluation of efficacy of psychopharmacotherapy.

Usage of selective serotonin-noradrenalin reuptake inhibitors in treatment of depressive disorders

M. Uzbekov^{1,*}, N. Maximova²

¹ Moscow research institute of psychiatry, brain pathology, Moscow, Russia

² Moscow research institute of psychiatry, affective disorders, Moscow, Russia

* Corresponding author.

Objectives Relevance of current investigation is conditioned by the high prevalence of depression in population and tendency of increased rate of relapses.

Aim To study efficacy of selective serotonin-noradrenalin reuptake inhibitor–milnacipran in treatment of depressive disorders.

Methods There were investigated 22 patients. Patient's state was defined as depressive episode (F32.1) and recurrent depressive disorder (F33.1). Mean age–33 years, duration of disease–from 2 weeks to 18 years, duration of current depressive episode–5.3 months. Mean point according to HAM-D scale before treatment was 24.0. Patients were investigated in dynamics of antidepressant therapy (milnacipran–50–150 mg/daily) for 4–5 weeks.

Results Efficacy of treatment with milnacipran was 82% (18 responders, 4 nonresponders). In responder's group decrease of depressive symptoms was started after 1 week of treatment and practical reduction of all these symptoms was observed after 4–5 weeks of therapy (points of HAM-D scale–0.81). Patients of this group receive milnacipran as supportive therapy at least for 3 months after signing out of clinic. During 1 year after signing out of clinic, there were no signs of aggravation of patient's state. 2 patients independently discontinued to take the medicine; there were aggravation of state and they were hospitalized in psychiatric clinic.

Conclusion Milnacipran is effective in treatment of depressive disorders, ensured effective reduction of depressive symptoms. Its therapeutic effect is realized rather quickly. Milnacipran can be recommended as antidepressant of choice for prophylaxis of depressive disorders.

The choice of anesthetics and the effect on the Hamilton depression rating scale in therapy resistant depression

F. van Mensvoort^{1,*}, R. Teijeiro Permuy², C. Rijnders¹

¹ GGz Breburg, Tilburg, The Netherlands

² Elisabeth-TweeStedenziekenhuis, MPU, Tilburg, The Netherlands

* Corresponding author.

Introduction The Dutch guideline ECT does not favor any anesthetic drug during electroconvulsive therapy. Although there are differences in seizure duration which may influence the effect of ECT, ethomidate, methohexital and propofol are "equal". The influence of switching anesthetics during ECT is unknown. The reason for switching anesthetics is insufficient improvement in depressive symptomatology which is based on clinical picture. The Hamilton is a multiple item questionnaire which can give an indication of depression and which can evaluate recovery.

Objectives Does the choice of anesthetics or switching anesthetics influence the effect of ECT on the Hamilton depression rating scale?

Aims To determine whether the choice of anesthetic drugs in the case of switching influences the effect on the Hamilton depression rating scale.

Methods We collected data of patients who received ECT for therapy resistant depression over the past five years. Choice of anesthetics, eventually switch and the score on the HDRS before and after ECT were included. The data was statistical analyzed.

Results 50 patients received ECT during past 5 years. ECT gives an improvement on the HDRS in all cases, whether there was a switch or not. Switching from methohexital to etomidate when shock duration is less than 21 seconds gives a significant difference in improvement on the HDRS (BI 1.288 to 13.538) compared to patients who did not switch.

Conclusions There are no significant differences on HDRS effect between the different anesthetics. Switching from methohexital to etomidate gives a significant improvement on HDRS compared with no switch.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Intrinsic functional connectivity of cortico-basal ganglia-thalamo-cortical circuitry underlying psychomotor retardation in major depressive disorder

Y. Yin^{1,*}, Y. Yuan¹, L. Fan², C. Xie³, Z. Zhang³

¹ Affiliated ZhongDa hospital, institute of neuropsychiatry, Southeast university, department of psychosomatics and psychiatry, school of medicine, Nanjing, China

² Institute of automation, Chinese academy of sciences, Brainnetome center, Beijing, China

³ ZhongDa hospital, school of medicine, Southeast university, neurology, Nanjing, China

* Corresponding author.

Introduction Psychomotor retardation (PMR) in depression is analogous to the hypokinesia in Parkinson's disease, which is associated with the unbalanced direct and indirect pathways of cortico-basal ganglia-thalamo-cortical (CBTC) circuitry. This study hypothesized PMR in major depressive disorder (MDD) should be associated with the hyperactivity of CBTC indirect pathways.

Objectives To substantiate the hypothesis that the PMR symptom of MDD might attribute to the hyperactivity of the cortico-basal ganglia-thalamo-cortical indirect pathway which could inhibit psychomotor performance.

Methods We investigated the intrinsic striato-subthalamic nucleus (STN)-thalamic functional connectivity (FC), three pivotal hubs of the indirect pathway, in 30 MDD patients with PMR (PMR group) and well matched 30 patients without PMR (NPMR group) at baseline, and 11 patients of each group at follow-up who remitted after antidepressant treatment.

Results The results showed increased STN-striatum FC of PMR group at baseline and no more discrepancy at follow-up, and significant correlation between PMR severity and thalamo-STN FC.

Conclusions Our findings suggested the increased STN-striatum FC should be considered as a state biomarker to distinguish MDD patients with PMR from patients without PMR at acute period, and thalamo-STN FC could be identified as the predictor of the PMR severity for MDD patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Is an isolation room harmful to patients with schizophrenia?: A biochemical study of salivary amylase

A. Koreki*, M. Kiyohara, T. Koizumi, M. Onaya
National hospital organization simofusa psychiatric center, psychiatry, Chiba, Japan

* Corresponding author.

Introduction Some patients with acute phase schizophrenia are too agitated to receive treatment in a normal hospital room. They must be isolated for the treatment. Although the stay in an isolation room seems harmful to patients, no study detailing the stress response to isolation with objective measures has been conducted.

Method Nine patients with schizophrenia or schizoaffective disorder were recruited (mean age = 52 years, male = 3, schizophrenic = 7). At the time of evaluation, they were staying in an isolation room. To evaluate stress response to the environment, the level of salivary amylase was tested when the patients were either in the isolation room (T1) or out of the isolation room (T2). T2 was defined as one hour after the room's door was opened. The data were analyzed by the Wilcoxon rank-sum test.

Result There is a significant difference between the median (range) levels of salivary amylase at T1 and T2 (19 [2–146] vs 44 [9–178], respectively, $P = 0.021$).

Discussion The data demonstrate that the stress response at T2 was stronger than that at T1, which suggests that the isolation room environment is less stressful to the patient compared to being outside the room. An environment that has many potential stimuli, such as the presence of other patients and a television in the lobby, may be harmful to patients with acute phase schizophrenia. Therefore, although the isolation room is apparently harmful, it could, in fact, have a positive effect on patients.

Outcomes of involuntary hospital admission. Satisfaction with treatment and the effect of involuntary admissions on patients

T. Reshetukha*, N. Alavi, E. Prost, D. Groll, R. Cardy, N. Mofidi, P. Wang, C. Patel, S. Sajid

Queen's university, department of psychiatry, Kingston, Canada

* Corresponding author.

Introduction Involuntary hospitalization in those presumed to be mentally ill has been a common practice. Although some patients are hospitalized for aggression, two-thirds of the patients are hospitalized because of the threat they pose to themselves. Although these patients require risk assessment and evaluation for possible presence of mental illness, the question is how much these patients will benefit from involuntary admission and what the long-term outcome would be.

Method All patients admitted involuntarily to the psychiatric ward in Kingston, Canada, and psychiatrists involved in their care were interviewed to see whether they think the involuntary admission was helpful. All patients were asked to fill-out MacArthur AES to assess their satisfaction with hospitalization.

Results Although psychiatrists frequently reported that the admission was justified, only 29 out of 81 patients reported being

explained to why they had been admitted involuntarily. Also, there was a significant difference in AES scores between those who were and were not given an explanation for admission. In addition, psychiatrists more often reported that the involuntary admission worsened the therapeutic relationship which was significantly associated with involuntary admission that was not explained to patients.

Discussion The results of our study shows that patients admitted involuntarily often feel disappointed with staff and mental health system. It could lead to feeling of hopelessness, frustration and low self-esteem. If explained, some patients who present with risk to self might accept voluntary admissions, that will improve therapeutic alliance with psychiatrists and increase satisfaction from hospitalization. Result of this study could improve the decision making process for involuntary admissions.

Genetic counselling in patients with bipolar disorder—ethical challenges

D. Vasile*, O. Vasiliu

Central university and emergency military hospital “Dr. Carol Davila”, psychiatry, Bucharest, Romania

* Corresponding author.

Background Genetic counselling in psychiatric patients is almost always a challenge on multiple levels of communication, because the mental health specialist is situated between the need to validate the freedom of procreation, and the duty to inform patients about the risk of transmitting their disease to off-springs. Bipolar disorder (BPD) is reputed to be one of the most heritable psychiatric disorder, a factor that complicate even more the ethical situation.

Objectives To assess how psychiatrists and psychologists conducted genetic counseling for patients with BPD and the challenges that mental health professionals consider important when they need to make this type of counseling.

Methods Standardized interviewing of 15 psychiatrists and psychologists who experienced during their clinical practice aspects of genetic counseling in patients with BPD.

Results The most commonly reported problems related to the genetic counseling in bipolar patients were: lack of reliable data on family history (53.3%), amplification of patient stigmatization (46.6%), controversies in the literature on the assessment of the disease risk (40%), difficulties in maintaining a nondirective attitude (33.3%), lack of genetic counseling follow-up (33.3%), disproportionate interest from the partner without mental disorder, when compared to patients, in terms of aspects of genetic counseling (26.6%), alteration of the therapeutic relationship and patients interest in treatment (26.6%).

Conclusions Genetic counseling is a challenge for mental health professionals, who must cope with the lack of reliable data on the pathogenesis of BPD, negative reactions from the patients' partners, patient disinterest or hostility and possible negative effects on the therapeutic relationship.

Psychology feminine holiness

J. Garcia-albea^{1,*}, M. Navas²

¹ Instituto de psiquiatría San carlos, psiquiatría, Madrid, Spain

² Hospital universitario Infanta leonor, psiquiatría, Madrid, Spain

* Corresponding author.

Feminine holiness is a subject as complex as it is interesting—not least because of the very definition of the term—, in many occasions extraordinary and many others bitter, which has sparked interest throughout history, especially after the progress made on modernity.

Objective The main objective is less to show whether there is a psychiatric, infectious, neurological or any other form of pathological disorder linked to the behaviour of female saints, rather to evaluate all the psychological and social aspects that result in holiness as a mental state being largely a female attribute.

Material and methods For this, we have tested from birth to death, in what is possible, the lives of sixty religious women, through biographies and autobiographies since they were servants, pious or holy according to ecclesiastical terminology. This set was unavoidable to select twelve cases, which are set out exhaustively in this study.

Results and discussion Limiting ourselves to a purely psychiatric view, we can show the presence of psychopathology associated with exceptional states of consciousness, as would be ecstatic and mystical experience itself, present in most cases. We also found common psychological profiles, out of the sixty biographies and autobiographies of religious women analyzed: e.g. pain is used as a means of atonement and a way of removing the guilt of sin. We rule out major psychiatric disorders in the Santas we have analyzed. The behaviors they presented, even sometimes excessive, cannot be included in any of the current major psychiatric disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Nowadays, cosmopolitan populations increasingly applaud the broad physical, ethnic, racial, and cultural diversity of human beings. So long as we behave within sanctioned norms. This presentation will focus upon the above paradox: In contrast to delighting in physical, ethnic and cultural expressions of human diversity, present-day cosmopolitan societies increasingly call for conformity in behavioral and experiential realms. For example, at meetings such as this, we can freely express and celebrate racial, ethnic, and culturally differences, but we must communicate—within remarkably narrow ranges—cordiality, spontaneity, agreeableness, respectful disagreement and tact. And if we cannot?? We propose that the phenomenon of mental illness arises as a consequence of the phenomenon of human diversity coming up against constraints and limitations in mental and behavioral realms. This presentation will focus upon evolutionary, genetic, biological, anthropological, historical and cultural aspects of the primary role that human diversity plays in mental illness. We will discuss the adaptive origins and strengths associated with the extraordinary diversity of humans (and our pets/domestic animals) as well accompanying vulnerabilities. For example, diversity of skin pigmentation has enabled humans to extend across the globe. A consequence however, is enhanced vulnerability to skin cancer for some with fair skin and

vitamin D deficiency for others with dark skin. Psychological diversities can be viewed analogously. The thesis that mental illness is an inevitable consequence of the singular diversity of humanity will be exemplified by disorders such as ADHD, melancholia, schizophrenia and sociopathy.

Probability analysis of compassion: Enhancing compassionate care in psychiatry through mirror neurons

A. Shoka^{1,*}, C. Lazzari²

¹ University of Essex, school of health and social care, university of Essex, Colchester, United Kingdom

² North Essex NHS university foundation trust, general adult psychiatry, Colchester, United Kingdom

* Corresponding author.

Introduction The probability that psychiatric care becomes compassionate is higher when individual subjects, groups or organizations utilize mirror neurons to attune with the emotional world of their clients.

Objectives To create an algorithm for compassionate care in mental health by attunement of mirror neurons.

Aims To predict the probability of the occurrence of sympathetic care in mental health.

Methods Naturalistic observation of health care organizations identified the major nodes–agents of the organizational–neural network leading to a compassionate care (events A): individual, group, organization and society. Negative influences on compassionate care are (events B) subjective and collective acts.

Results The probability that compassionate care occurs as a result of a single mediator's action was only 0.167 (16%). The probability that compassion results from training mirror neurons were as follows: Multiple event probability formula:

– probability of event A that occurs $P(A) = 0.667$ (66%) [positive subject + group + organization + society];

– probability of event B that occurs $P(B) = 0.333$ [negative individual and group];

– probability that both the events occur $P(A \cap B) = P(A) \times P(B) = 0.222$ [inhibitory influence];

– probability that either of event occurs $P(A \cup B) = P(A) + P(B) - P(A \cap B) = 0.778$.

Conclusions The probability of organizational compassion (PA) is high when all the agents interact. As compassion is reinforced by mirror neurons, a reduction in the number of people involved in compassionate care also means the final outcome is less likely to appear.

Exact psychiatry: Six axioms

M.L. Vargas

Complejo Asistencial de Segovia, psychiatry, Segovia, Spain

Psychiatry is a clinical technological practice where the rational fundamentals, methods and knowledge “corpus” have a scientific nature. The science philosopher Mario Bunge proposes that philosophy, as well as science, may tend to be exact. Philosophy of science is the rational setting where any scientific discipline can ascribe sense to its theoretical models and factual sentences. Axiomatization is the method to exactify a discipline. By axiomatization, we can exactify psychiatry as “medicine of the soma”, therefore avoiding fallacies in the theoretical models we use.

Objective To describe six axioms for the definition of “exact psychiatry” as “medicine of the soma”. Six axioms will be defined and explained. They are ordered attending to hierarchical and historical priority:

–axiom of the cultural universal of social cohesion: since the antiquity all cultures have cultural universals which promote social cohesion;

–axiom of healing as a form of “isonomia”: health-related cultural constructs are related with help receiving due to body vulnerability. It appears with Hippocratic medicine;

–axiom of nosological realism: diseases really exist. They are biological regularities that accelerate death. It appears in the 17th century;

–axiom of illness subjectivity: the personal impact of disease is subjective. There exist diseases in patients. It appears in the 20th century;

–axiom of the unification of neuroscience: psychiatry and neurology have the same ontological reference, brain diseases. It consolidates in the 21st century;

–axiom of clinical phenomenology as the epistemological specificity of psychiatry: clinical phenomenology characterizes “soma” as the referring of psychiatry. The future.

Evaluation of a nonsmoking program in psychiatric clinic

J. Jaber*, A. Tomé, F. Castro, A. Hollanda, B. Reys

Clinica Jorge Jaber, Saúde Mental, Rio de Janeiro, Brazil

* Corresponding author.

Introduction The work evaluates the nonsmoking program successful experience, carried out between the years of 2008 and 2015 in a psychiatric clinic in the city of Rio de Janeiro, Rio de Janeiro, Brazil.

Objectives The program has as objectives to evaluate the treatment of tobacco dependence in patients with disorders for the use of substances and other psychiatric disorders and the experience of transforming the therapeutic space of the clinic in a tobacco-free environment, considering that the use of tobacco is responsible for a large number of avoidable deaths and other aggravations to health.

Methods The program achieved the objectives, assessing the promotion of the tobacco abstinence in a large number of patients, through the utilization of pharmacological treatment, cognitive behavioral psychotherapy, occupational therapy, art therapy and moderate physical activity.

Results In a 12-month period, after carrying out the program, 48% of the assessed patients kept in tobacco abstinence.

Conclusions The study showed the percentage of patients who were discharged on tobacco abstinence and the percentage of those who kept abstemious after 12 months, demonstrating that the nonsmoking program is an efficient tool in the tobacco dependence treatment and can be used over a psychiatric hospitalization with promising results.

Akathisia: Prevalence and risk factors in patients with psychosis and bipolar disorder

L. Jouini^{1,*}, U. Ouali¹, S. Ouanes², Z. Rania³, R. Jomli¹, Y. Zgueb¹, F. Nacef¹

¹ Razi hospital, “A” psychiatry department, Tunis, Tunisia

² Lausanne university hospital, old age psychiatry, Tunis, Tunisia

³ Razi hospital, psychiatry outpatient unit, Tunis, Tunisia

* Corresponding author.

Introduction Akathisia is probably the most common and one of the most distressing of the movement disorders associated with antipsychotic drugs. Little is known about its prevalence and its risk factors in real-world psychotic and bipolar patients to date.

Objectives The main objective of this study was to determine the prevalence of akathisia and to determine the risk factors and the treatments associated with it in a sample of Tunisian patients with schizophrenia, schizoaffective or bipolar disorder.

Methods Seventy-four patients with schizophrenia, schizoaffective or bipolar disorder were included and assessed with a validated scale: the Barnes Akathisia scale (BAS). Ongoing psychotropic treatments were recorded.

Results The global prevalence of akathisia (as defined by a score ≥ 2 on the global akathisia subscale of the BAS) was 20.5%. Akathisia was significantly more common in patients with schizophrenia or schizoaffective disorder than in patients with Bipolar disorder (27.5% vs 9.4%; $P=0.049$). However, the prevalence of akathisia did not differ according to sex, age, the illness duration, the presence of a comorbid anxiety disorder, the number of antipsychotics used, the type of the used antipsychotic (first vs second-generation), the antipsychotic chlorpromazine-equivalent total dosage, the use of benzodiazepines or anticholinergics, or the reported drug compliance.

Conclusions Akathisia seems to be more common in some psychiatric disorders than in others such as schizophrenia or schizoaffective disorder. Longitudinal studies would be required to draw any firm conclusions concerning the factors involved in the emergence of akathisia.

The relationship between parenting stress and parenting styles with coping strategies in adolescents: The moderating roles of emotional regulation and mindfulness

M. Kheradmand^{1,*}, S. Ghahari²

¹ Islamic Azad university, master of clinical psychology, Tonekabon, Iran

² Iran university of medical sciences, mental health, Tehran, Iran

* Corresponding author.

Object The aim of this study was to investigate the moderating role of emotional regulation and mindfulness in the relationship between parenting stress and styles with coping strategies.

Methods The method in this study is correlation. Statistical population consists of all adolescents in 2016, from among which 400 individuals were selected in a multi-stage cluster sampling method from different areas of Tehran and completed Adolescent Coping Scales, Parenting Stress Index, Baumrind parenting styles Inventory, emotional regulation checklist of kids and adolescents and of kids' and adolescents' mindfulness measurement. The data were analyzed using multivariate regression and Pearson correlation in SPSS-22.

Finding The results showed the mindfulness and emotional regulation play a moderating role in the relationship between parenting stress and coping strategies ($P>0.0001$) as well as the relationship between parenting styles and coping strategies ($P>0.0001$).

Conclusion Despite the poor parenting stress and parenting styles, if the adolescents have emotion regulation and mindfulness skills can reduce the negative effects of inappropriate parenting.

Keywords Parenting stress; Coping strategies; Parenting style; Emotional regulation; Mindfulness

From Hampstead to Norwich: Ritual violence or coaching?

R. Kurz

Cubiks, IPT, Guildford, United Kingdom

Introduction Video-recorded disclosures of two siblings emerged describing ritual violence activities in a Hampstead “cult” including human sacrifice murder. The UK court processes judged that the mother “coached” the children to make false allegations. In parallel, Marie Black, Jason Adams and Michael Roger were found guilty of child sexual abuse purely based on historical accounts of five children.

Objectives The presentation outlines two cases that illustrate the “unbelievable” nature of organized child abuse and what aspects make court rulings “unsafe”.

Aims The presentation aims to compare the Hampstead where the videos were watched by 4 million individuals world-wide with the little that is known about the “Norwich Three” case due to court reporting restrictions.

Methods Materials posted on websites, books and videos were reviewed alongside discussions with whistle-blowers, relatives and friends of people involved.

Results The disclosures in the Hampstead case were very extreme but similar accounts can be found in books by Sara Scott (UK) and De Camp (US). Those accused of sexual abuse claim that the children have been coached by their mother to make these allegations—the view that the judge adopted. In the Norfolk case, 7 of the 10 defendants were cleared of child sexual abuse allegations but three individuals were found guilty. It remains unclear what the basis was for the conviction as the disclosures could have been classed as the result of “coaching”.

Conclusions Anyone operating in forensic settings should familiarise themselves with the “hall of mirrors” that cases involving child sexual abuse routinely constitute.

Preliminary study for the Italian validation of the screen for cognitive impairment in psychiatry (SCIP)

D. Malanchin*, R. Caruso, M.G. Nanni, L. Grassi, G. Piazza, E. Croce, M. Leoni, E. Berretti, L. Negrelli, S. Battista, A. Faccini, R. Dall'Olio, S. Costa, E. Recla, G. Rossi, C. Colla
University of Ferrara, clinical psychiatry, department of biomedical and specialty surgical sciences, Ferrara, Italy

* Corresponding author.

Introduction The screen for cognitive impairment in psychiatry (SCIP) is a brief, accessible scale designed for detecting cognitive deficits in psychiatric disorders.

Objectives The objective of this study is to test the SCIP's validity as a cognitive test by comparison with standard neuropsychological scale using the Pearson's correlation.

Aims Test the convergent and discriminant validity of the SCIP within the Italian SCIP validation project.

Methods Patients between 18 and 65 years who are in a stable phase of the disease, diagnosed with schizophrenia, schizoaffective

disorder or bipolar I disorder were enrolled in this study, from the community mental health department of Ferrara.

Results The tests were administered to 110 patients (mean age: 45 ± 11.4) and to 86 controls (mean age: 35 ± 12.6) of both sex. SCIP presents high correlation with the R-BANS total score ($P < 0.01$) and the subscales (verbal learning test-immediate, working memory, verbal fluency test, verbal learning test-delayed, processing speed test, $P < 0.01$). There are significant differences ($P < 0.01$) in all SCIP dimensions between patient and control group (Table 1).

Conclusions Our analysis confirm the results of the English, French and Spanish version of the SCIP regarding convergent and discriminant validity. The SCIP represents a valid, simple and brief screening tool for the cognitive evaluation of patients with schizophrenia-spectrum disorders.

Table 1

SCIP subscales	Neuropsychological battery test(s)	Domains	r
VLT-I	RBANS	Immediate Memory	0,64*
WMT	RBANS	Attention	0,32*
	TMT A	Time for task	0,27*
	TMT B	Time for task	0,34*
	WCST	Perseverative errors	0,31*
VFT	RBANS	Language	0,50*
VLT-D	RBANS	Delayed Memory	0,52*
PST	RBANS	Visuospatial/Constructional	0,00
	RBANS	Attention	0,26*
	TMT A	Time for task	-0,47*
	TMT B	Time for task	-0,44*
	WCST	Perseverative errors	0,28*
Total score	RBANS		0,51*

VLT-I: verbal learning test-immediate; WMT: working memory test; VFT: verbal fluency test; VLT-D: verbal learning test-delayed; PST: processing speed test; R-BANS: repeatable battery for the assessment of neuropsychological status; TMT: trail making test; WCST: Wisconsin card sorting test. $P < 0.01$.

Effects of switching antipsychotics in 80 outpatients: A descriptive analysis from a mental health community

R. Medina Blanco*, R. Martín Gutiérrez, M.J. Cuesta Nuñez, D. Sierra Biddle, P. Suárez Pinilla
Hospital universitario marqués de Valdecilla, psychiatry, Santander, Spain

* Corresponding author.

Introduction In the general practice, psychiatrists widely prescribe antipsychotics for several conditions as schizophrenia, bipolar disorder and behavioral disorders among others.

Aim and objectives The aim of this study is to describe the clinical and sociodemographic features of typical patients receiving antipsychotics and their effects after switching to long-acting treatment.

Methods A descriptive analysis of 80 outpatients collected from a mental health clinic in Santander (Spain) was performed. All patients were taking antipsychotics at baseline, both oral and intramuscular, and were switched to a different long-acting antipsychotic drug.

Results At baseline, 24 patients were taking oral medication and 56 intramuscular. There were 37 females and 43 males. There were no gender differences in the final treatment, but Palmitate Paliperidone (71.3%) was the most prescribed drug, followed by intramuscular risperidone (16.3%) and long-acting aripiprazole (11.3%). We found gender differences regarding cannabis ($P = 0.002$), alcohol ($P = 0.004$) and tobacco ($P = 0.043$) consumption, being their use more common in males. In regard to diagnosis, schizophrenia was predominant in both gender groups, whereas

delusional and behavioral disorders were more frequent in females. There were no significant differences in the reason of switching, but the inefficacy was more common in males and the side effects in females. At the switching, females were significantly older than males ($P = 0.003$). We found significant differences before and after switching regarding the number of admissions, emergency visits and length of stay.

Conclusions Antipsychotic benefits are individual and unpredictable. When switching, some other different factors should be taking in account, not only regarding medication.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Association between smartphone addiction proneness and poor sleep quality in Korean university students

K.B. Min^{1,*}, M. Jin-young², K. Hyun-Jin², K. Hye-Jin³

¹ College of medicine, Seoul national university, department of preventive medicine, Seoul, Republic of Korea

² Seoul national university, institute of health and environment, Seoul, Republic of Korea

³ Seoul national university, school of public health, Seoul, Republic of Korea

* Corresponding author.

Background The number of Korean smartphone users exceeded 40 million in 2015, in which roughly 1 in 5 university students were expected to be addicted to their smartphone. Of importance is that smartphone addiction negatively affects physical and mental well-being and health. Sleep problems associated with smartphone is also a serious public concern; but the evidence is lacking. The aim of this study is to investigate the association between smartphone addiction proneness and sleep problems in Korean university students.

Methods We conducted an online-survey which received responses from 608 university students. All participants completed questionnaires on the Korean smartphone addiction scale (K-SAS), the Pittsburgh Sleep Quality Index (PSQI), and personal characteristics. Based on the scores of the K-SAS, university students were classified into two groups—the addiction proneness group and the normal-user group.

Results The addiction proneness groups had a higher PSQI score than the normal-user group (7.5 vs. 6.7, P -value < 0.0001). After adjustment for potential covariates (i.e., age, income, and smoking), PSQI scores was significantly increased in the addiction proneness groups (Beta coefficient = 0.69; 95% CI: 0.29 ~ 1.09). The risk of sleep problems was more increased in the addiction proneness groups (odds ratio = 1.99; 95% CI: 1.33 ~ 2.98) than the normal-user groups.

Conclusion We found that the smartphone addiction proneness was associated with sleep problems in university students. Although our findings are further confirmed by elucidating causal relationships between smartphone uses and sleep habits, smartphone addiction proneness may be a risk factor for poor sleep quality.

Methylphenidate challenge followed by therapeutic drug monitoring in adults with attention deficit/hyperactivity disorder: Clinical effects and its predictors

D. Piacentino^{1,2,*}, G. Giupponi², I. Maniscalco², S. Holzer³, M. Pompili¹, P. Girardi¹, A. Conca^{2,4}

¹ Nesmos department (neurosciences, mental health, and sensory organs), Sapienza university of Rome, school of medicine and psychology, Sant'Andrea hospital, Rome, Italy

² Psychiatric department, San Maurizio hospital, sanitary agency of South Tyrol, Bolzano, Italy

³ Specialistic outpatient service for ADHD in adults, sanitary agency of South Tyrol, Bolzano, Italy

⁴ Provincial service of developmental psychiatry and psychotherapy, sanitary agency of South Tyrol, Bolzano, Italy

* Corresponding author at: Corresponding author.

Introduction Attention deficit/hyperactivity disorder (ADHD) affects 5–6% of adults. Methylphenidate challenge is used to test functions such as concentration. Therapeutic drug monitoring (TDM) identifies optimal drug ranges in plasma.

Objectives/Aims We aimed to: assess the clinical impact of the drug challenge in adults with ADHD; analyze the relationship with the drug plasma levels after the challenge; identify predictors of the challenge's clinical impact.

Methods In 2015–2016, we recruited 45 consecutive adult DSM-5 ADHD outpatients (mean age \pm SD = 35.3 \pm 2.1 years; females = 64.4%) at the Bolzano hospital department of psychiatry. Before and after administration of methylphenidate 10 mg, we measured concentration, impulsivity, tension, and general well-being with a VAS and an interview. After two hours, TDM was performed. Deltas were calculated for pre-/post-challenge measures. Correlations were measured with Pearson's *r*/point-biserial coefficient. A generalized linear mixed model estimated the size of association between tension/general well-being improvement and patient characteristics.

Results After the challenge, the mean improvement \pm SD was 24 \pm 22 for concentration, 17 \pm 23 for impulsivity, 21 \pm 28 for tension, 16 \pm 24 for general well-being. The mean TDM \pm SD was 4.6 \pm 0.5 ng/mL. A negative correlation between TDM, tension ($P=0.009$), and general well-being ($P=0.028$) after the challenge emerged: higher drug plasma levels relate to less tension and greater general well-being. At the GLMM the main predictor for tension/general well-being improvement was psychopharmacological treatment ($P=0.011/P=0.05$, respectively). Older age and difficult tasks prevented improvement.

Conclusions Methylphenidate challenge had a positive effect on all patients' performance. TDM values were lower than literature ones, although the latter are usually obtained after the administration of methylphenidate 20 mg.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁷ Mood disorder program and psychopharmacology consultation clinic, Tufts medical center, Tufts university school of medicine, Boston, MA, USA

* Corresponding author.

Introduction To date, the proposition of recurrence as a subclinical bipolar disorder feature has not received adequate testing.

Objectives/Aims We used the Italian version of the bipolar spectrum diagnostic scale (BSDS), a self-rated questionnaire of bipolar risk, in a sample of patients with mood disorders to test its specificity and sensitivity in identifying cases and discriminating between high risk for bipolar disorder major depressive patients (HRU) and low risk (LRU) adopting as a high recurrence cut-off five or more lifetime major depressive episodes.

Methods We included 115 patients with DSM-5 bipolar disorder (69 type I, 41 type II, and 5 NOS) and 58 with major depressive disorder (29 HRU and 29 LRU, based on the recurrence criterion). Patients filled-out the Italian version of the BSDS, which is currently undergoing a validation process.

Results The BSDS, adopting a threshold of 14, had 84% sensitivity and 76% specificity. HRU, as predicted, scored on the BSDS intermediate between LRU and bipolar disorder. Clinical characteristics of HRU were more similar to bipolar disorder than to LRU; HRU, like bipolar disorder patients, had more lifetime hospitalizations, higher suicidal ideation and attempt numbers, and higher rates of family history of suicide.

Conclusions The BSDS showed satisfactory sensitivity and sensitivity. Splitting the unipolar sample into HRU and LRU, on the basis of the at least 5 lifetime major depressive episodes criterion, yielded distinct unipolar subpopulations that differ on outcome measures and BSDS scores.

Aggression and violence towards healthcare workers in a psychiatric service in Italy. A retrospective questionnaire-based survey

D. Piacentino^{*,a,b}, S. Moser^a, S. Tosato^c, C. Bonetto^c, A. Conca^{a,d}, J.V. Bizzarri^a

^a Psychiatric department, San Maurizio hospital, sanitary agency of South Tyrol, Bolzano, Italy

^b NESMOS department (neurosciences, mental health, and sensory organs), Sapienza university of Rome, school of medicine and psychology, Sant'Andrea hospital, Rome, Italy

^c Department of public health and community medicine, section of psychiatry, university of Verona, Verona, Italy

^d Provincial service of developmental psychiatry and psychotherapy, sanitary agency of South Tyrol, Bolzano, Italy

* Corresponding author.

Introduction Violence at work is a major concern in healthcare services. Prevention programs have been implemented, albeit being scarce in Italy.

Objectives or Aims The Bolzano psychiatric department adopted a de-escalation model developed by the Institut-für-Professionelles-Deeskalations-Management (ProDeMa®). It includes evaluation, prevention, and practical training aimed at preventing/reducing patients' aggressive behavior toward healthcare workers.

Methods In 2015, health professionals were interviewed by using a ProDeMa[®] 11-item questionnaire that assessed the type and frequency of endured patients' aggressive behavior, as well as the conditions capable of producing or preventing it. One-way ANOVA with Tukey post-hoc test was used for comparisons.

Results A total of 165/211 (78%) surveyed workers (mean age \pm DE = 44.9 \pm 7.7; females = 64.6%) completed the questionnaire, of whom 21% employed at the inpatients unit (INP), 37% at the outpatients unit (OUTP), 42% at the rehabilitation facility (REHAB). The one-year number of verbal aggressions (VA) was 9766, with INP (mean \pm SD = 15.2 \pm 29.6) vs. OUTP (mean \pm SD = 6.2 \pm 30.6) vs. REHAB (mean \pm SD = 8.4 \pm 26.1). The one-year number of physical aggressions (PA) was 1502, with INP (mean \pm SD = 3.3 \pm 12.2) vs. OUTP (mean \pm SD = 0.1 \pm 0.5) vs. REHAB (mean \pm SD = 0.1 \pm 0.7). The one-year number of injuries (IN) was 200, with INP (mean \pm SD = 0.5 \pm 1.9) vs. OUTP (mean \pm SD = 0.1 \pm 0.5) vs. REHAB (mean \pm SD = 0.1 \pm 0.2). ANOVA showed significant differences in terms of mean verbal/physical aggression and injuries among the three workplaces (P -values = 0.000), with post-hoc Tukey test showing a significant difference of INP vs. REHAB and OUTP. The most frequent risk factors identified by the staff for precipitating aggression included rigid rules (15.1%) and inadequate communication (9.1%).

Conclusions The three types of violence are common in all facilities of our Department.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A crossroad in ADHD – adult-onset ADHD

A. Ponte*, H. Prata Ribeiro, L. Carvalhão Gil, D. Pereira
Centro hospitalar psiquiátrico de Lisboa, psychiatry, Lisboa, Portugal
* Corresponding author.

Introduction Attention-deficit/hyperactivity disorder (ADHD) is a common disorder characterized by inattention or hyperactivity–impulsivity, or both. For a long time, ADHD was thought of as a disorder of children which would sometimes persist into adulthood. DSM 5 uses as a criterion that several symptoms have to be present prior to age 12 years.

Objectives To discuss the findings of 3 recent cohorts that show the onset of ADHD in adulthood.

Methods A review of selected articles of interest using PubMed database.

Results 3 large, longitudinal, population studies from Brazil, New Zealand (NZ) and the United Kingdom (UK) show that we are at a crossroads in our understanding of ADHD. In each study, the prevalence of adult-onset ADHD (Brazil, 10.3%; UK, 5.5%; and NZ, 2.7%) was much larger than the prevalence of childhood-onset adult ADHD (UK, 2.6%; Brazil, 1.5%; and NZ, 0.3%). They all propose different conclusions that would result in a paradigmatic shift in ADHD: in Brazil, that child and adult ADHD are “distinct syndromes”; in the UK, “that adult ADHD is more complex than a straightforward continuation of the childhood disorder” and in NZ, that adult ADHD is “not a neurodevelopmental disorder”. Faraone et al., in an editorial in *JAMA Psychiatry*, propose that these findings might correlate to subthreshold child ADHD before it emerges as adolescent- or adult-onset ADHD.

Conclusions It's an exciting time in ADHD research. These new data work as an incentive to study adult-onset ADHD and how it emerges. Future research will shape our understanding of adult ADHD.

The Chinese version of the brief assessment of cognition in schizophrenia: Data of a large-scale Mandarin-speaking population

L.J. Wang^{1,*}, S.T. Hsu²

¹ Kaohsiung Chang Gung memorial hospital, department of child and adolescent psychiatry, Kaohsiung City, Taiwan R.O.C.

² Kaohsiung municipal Kai-Syuan psychiatric hospital, department of community psychiatry, Kaohsiung City, Taiwan R.O.C.

* Corresponding author.

Objective The brief assessment of cognition in schizophrenia (BACS) is a cognitive assessment tool used to measure the broad aspects of cognition that are most frequently impaired in patients with schizophrenia. This study aims to develop the normative data of the Chinese version of the BACS among the Mandarin-speaking population.

Methods This cross-sectional study included 382 healthy participants (age range: 19–79 years; mean age: 48.0 \pm 16.7 years, 47.6% male) in Taiwan, who were evaluated with the BACS. Means and standard deviations of subtests and composite scores were arranged by age group and gender. The Z-scores calculated based on the U.S. norms were compared to our scores based on the norms established in the present study.

Results The raw scores of all the BACS tests (verbal memory, digit sequencing, token motor test, verbal fluency, symbol coding, and Tower of London) were negatively correlated with participants' age. Females were superior to males in verbal memory, but inferior to them in executive function. Furthermore, applying the U.S. norms of the BACS to determine the performance of the Chinese BACS results in bias with regard to verbal memory, token motor test, verbal fluency, symbol coding, Tower of London, and composite score.

Conclusions These findings demonstrate that directly applying Western cognitive norms to a Mandarin-speaking population can cause biased interpretations. The results of the current study can be an important reference for clinical settings and research related to cognitive assessments in Mandarin-speaking Chinese populations.

Disclosure of interest The authors have not supplied their declaration of competing interest.

¹ Alexandria faculty of medicine, neuropsychiatry, Alexandria, Egypt

² Columbia university, school of social work, New York, USA

* Corresponding author.

Background DBT proved to be effective in reducing suicidal behavior, non-suicidal self-injury, psychiatric hospitalization, treatment dropout, substance use, anger, and depression and improving social and global functioning in Borderline personality disorder. As a step towards increasing utilization of evidence based treatments in the Egyptian healthcare system, the team at Alexandria university started a comprehensive DBT program.

Aim To describe the implementation and dissemination experience of DBT in Egypt.

Methods The implementation of DBT is examined quantitatively. Numbers were calculated retrospectively from the records at the implementation start in December 2013 and after 3 years in September 2016.

Results Number of therapists increased from one team of 2 therapists and one observer to 16 therapists organized in 3 teams plus 4 observers. The initial team, 7 psychiatrists and 2 clinical psychologists, could host and attend the first DBT Intensive Training in the middle east in 2014. DBT intensive training is the official training model developed by Dr. Linehan. We started with 8 clients one group for adults in Alexandria at 2013, increasing to 150 clients in 12 groups for adults, adolescent and SUD patients in 2016 with an average increase of 18.75 folds. The team participated and presented about DBT in 23 local and regional scientific meetings and hosted two workshops in collaboration with BehavioralTech, the official training institute.

Conclusions Although the DBT implementation in Egypt represented a great challenge, results are showing a promising increase in the number of trained therapists and participating clients.

Physical examination of psychiatric patients who presented at emergency department in a tertiary care hospital in Sultanate of Oman

S. Alhuseini

Oman medical speciality board, Psychiatry, Muscat, Oman

Objective To examine the completeness of physical assessment of patients presenting with psychiatric problems to the emergency department (ED).

Methods This was observational study based on a retrospective review of the medical records of patients who attended the ED of Sultan Qaboos university hospital and referred to the on-duty psychiatrist for assessment over a 12-month period. All patients aged 16 years and above, who presented to the ED with a psychiatric complaint were included in the study. A data collection sheet was designed to gather each patient's demographic data such as age and gender, past psychiatric history, nature of the presenting complaints, thoroughness of physical assessment, medications prescribed by the ED doctor prior to psychiatric assessment, and whether the patient was discharged, admitted to a psychiatry.

Results A total of 202 patients met the inclusion criteria. The mean age of the patients was 34.2 years. Females represented 56% of the sample. The majority of the study group (60.4%) were patients with a documented past psychiatric history. Physical examination was conducted in the ED for 61.4% of the patients, while vital signs were recorded for 68.8% of them. Approximately, 31% of the patients required injectable psychotropic medications as tranquilizers in the ED. Patients with an isolated psychiatric complaint coupled with a documented past psychiatric history were more likely to be referred to the on-call psychiatrist without a physical examination by the ED doctors.

Conclusion In our institution, not all patients with psychiatric presentations had a complete physical examination by the ED doctors.

National child developmental and mental health disorders screening policy in Thailand

A. Benjaponpitak

Rajanukul institute, department of mental health, Bangkok, Thailand

Background Developmental disorders and mental health problems result in less optimal outcomes in children. Although awareness among the public had been improving, there was paucity of early identification frameworks, care pathways as well as the process of monitoring and evaluation in Thailand.

Objective To develop appropriate National child mental health policy in Thailand.

Aim To promote developmental and mental health outcomes of children.

Method Current child development and mental health research as well as policy development were reviewed. The framework of development together with major mental health disorders screening and intervention among children has been studied and established as a major policy in Thailand since 2014. The National developmental screening has been implemented in children aged 9, 18, 30 and 42 months. District level hospitals have been coached to facilitate Health promotion schools to screen and provide early intervention for grade 1 students with mental health problems. Annual data has been collected and analyzed to reflect the milestones of child development and mental health prevention-promotion policy in Thailand.

Result The coverage of National developmental screening ranges from 70–80% of children. About 20% of preschoolers are at risk of language delay while nearly 20% of grade 1 children are at risk of emotional, behavioral and learning problems. Parental awareness is the major challenge for those with limited financial resources.

Conclusion Investments in early childhood development are needed. The pathways to develop the appropriate intervention requires further collaboration among stakeholders.

A RCT of a staff training intervention to promote quality of care in long-term residential facilities—the PromQual study

G. Cardoso*, A. Papoila, J. Caldas-de-Almeida

Faculdade de Ciências Médicas Universidade Nova de Lisboa, chronic diseases research centre CEDOC, Lisbon, Portugal

* Corresponding author.

Introduction The shift of hospital-based to community-based mental health care, introduced the need to assess and promote quality of residential services.

Objectives This RCT aimed at assessing the effectiveness of a staff training intervention to improve quality of care in residential facilities.

Methods Twenty-three units with at least 12-hour on-site staff support per day in Portugal were assessed with the quality instrument for rehabilitative care (QuIRC) filled online by the manager. A random sample of service users were interviewed using standardised measures of autonomy, experiences of care, quality of life, and the time user diary (TUD) for level of activity. The intervention group units ($n = 12$) received workshops and a four-week hands-on training of the staff versus TAU in the control group ($n = 11$). All units and users were reassessed at 8-months. The staff knowledge gained during the workshops was assessed using pre- post-test. Generalized linear mixed effects models were used.

Results The residential units were mainly in the community ($n = 17$, 73.9%), and had QuIRC mean scores above 50% in the following dimensions: living environment, self-management and autonomy, social inclusion, and human rights. Service users' level of activity (TUD) at 8-months did not differ between intervention and control groups. At 8 months, all QuIRC dimensions scored higher in the Intervention group, without reaching statistical significance. Pre- post-tests comparison showed a significant increase in the knowledge acquired by the staff.

Conclusions The intervention had impact on the staff's knowledge without reaching significant change of users' activity and quality of care of the units.

Differences in symptom expression between Vietnamese and German patients utilizing a psychiatric outpatient service using the PHQ

A. Dreher¹, E. Hahn², T.M.T. Ta², M.H. Nguyen², A. Diefenbacher^{1,*}, R. Burian¹, M. Dettling²

¹ *Krankenhaus Königin Elisabeth Herzberge Berlin, psychiatry psychotherapie psychosomatics, Berlin, Germany*

² *Charité university hospital Berlin Campus Benjamin Franklin, psychiatry, Berlin, Germany*

* *Corresponding author.*

Objective Despite a large body of work on somatic symptom presentation among people of Asian descent, research has shown heterogeneous results. Examining symptom presentation in clinically and ethnically well-characterized populations constitutes a first step towards better understanding differing patterns symptom of presentation. This is the first larger study aiming to compare Vietnamese and German psychiatric outpatients regarding symptom presentation.

Methods 110 Vietnamese and 109 German patients seeking psychiatric treatment at two outpatient clinic services in Berlin were asked to complete the patient health questionnaire (PHQ). Comparisons of Vietnamese and German patients were conducted using independent t -tests. The somatic symptom module (PHQ-15), the depression module (PHQ-9) and the original PHQ-modules examining anxiety and psychosocial stress levels were compared for both groups using multivariate analysis. Categorical variables were evaluated using χ^2 analysis. Cronbach's alpha was calculated separately for both groups and all PHQ modules.

Results Vietnamese patients endorsed significantly higher levels of somatic symptoms overall and on individual somatic items, such as pain-related disturbances. Yet, German and Vietnamese patients did not differ in terms of depression severity. Vietnamese patients with fewer German language skills showed a significantly higher tendency for somatization. While German patients showed higher total scores on the anxiety- and stress-modules of the PHQ, this difference was not statistically significant. Vietnamese and German patients showed comparable Cronbach's alpha for all subscales.

Conclusion As data was collected from both groups upon the first visit to an outpatient clinic, the symptoms reported could be reflective of culture related symptom awareness when feeling discomfort in the context of mental illness.

Development and investigating the effectiveness of an integrated school-based program for changing attitude toward substance abuse based on philosophy for children components and emotional intelligence

H. Rezaee¹, A. Shafiabady¹, Y. Ghaedi², A. Delavar¹, M. Esmaeili¹, L. Fattah Moghaddam^{*,3}

¹ *Allameh Tabatabaeei university, department of psychology, Tehran, Iran*

² *Tehran Kharazmi university, educational philosophy department, Tehran, Iran*

³ *Islamic Azad university - Tehran, department of psychiatric nursing, Tehran, Iran*

* *Corresponding author.*

Background Substance abuse in the youth is one of the major problems of any society. The research purpose was the development of a program for changing female adolescents' attitude toward substance abuse and evaluating its effectiveness.

Methods To develop the treatment, important variables influencing in shaping attitudes toward substance abuse were selected. Afterwards, structural equation modeling approach was conducted for examining the relationship among variables (emotional intelligence, critical thinking, caring thinking and reasoning) and identifying significant paths and variables. Based on these variables, a program developed for changing students' attitudes. To evaluate effectiveness of programs a pretest-post test design with the control group was used. Random sampling was carried out for selecting 26 students attending senior high schools in district 2 of Tehran. Then, sample randomly assigned in experimental and control groups. Experimental group exposed to philosophy for children intervention in the form of community of inquiry. Control group didn't receive the intervention. The data were collected from Nazari's questionnaire for attitude toward substance abuse.

Results ANCOVA revealed that based on a composite score of attitude toward substance abuse (adjusting pretest effect), there is a significant difference between two groups at 0.99 significance level (partial = 0.329, $P < 0.001$, = 11.28).

Conclusions It is recommended that the school based program should be used for developing and strengthen the students' attitude based on exploring itself, rather than simply giving awareness about substance abuse. In this treatment, rather than highlighting accumulating knowledge, put emphasis on, thinking, decision-making, and management of emotions.

Medical assistance in dying: The Canadian experience

K. Gains

Humber River hospital, psychiatry, Toronto, Canada

Canada is in the midst of implementing new and rapidly evolving policies on medical assistance in dying (MAID). Following the landmark Canadian Supreme Court *Carter v. Canada* ruling in February 2015, the former prohibition against physician-assisted death was deemed to violate the Canadian Charter of Rights and Freedoms. The Court provided until 2016 for development of national legislation and policies that allowed for physician-assisted dying in cases of "grievous and irremediable" illness and "intolerable suffering". This session will review shifting public, societal and medical concepts regarding assisted dying and the Canadian experience

to date, including evolving local and national policies that have been developed to allow medical assistance in dying in certain circumstances. We will also review work of the Canadian psychiatric association task force on medical assistance in dying (presented by the Task Force Chair), with a focus on challenges and issues relevant to mental health and mental illness.

⁵ New York state psychiatric institute/Columbia college of physicians & surgeons, division of child and adolescent psychiatry, New York, USA

⁶ UT health McGovern medical school, department of psychiatry and behavioral sciences, Houston, USA

⁷ Hunter university, CUNY, New York, USA

* Corresponding author.

Introduction The importance of timely identification and treatment of psychosis are increasingly the focus of early interventions, with research targeting the initial high-risk period in the months following first-episode hospitalization. However, ongoing psychiatric treatment and service utilization after the symptoms have been stabilized over the initial years following first-episode has received less research attention.

Objectives To model the variables predicting continued service utilization with psychiatrists for adolescents following their first-episode psychosis; examine associated temporal patterns in continued psychiatric service utilization.

Methods This study utilized a cohort design to assess adolescents (age 14.4 ± 2.5 years) discharged following their index hospitalization for first-episode psychosis. Bivariate analyses were conducted on predictor variables associated with psychiatric service utilization. All significant predictor variables were included in a logistic regression model.

Results Variables that were significantly associated with psychiatric service utilization included: diagnosis with a schizophrenia spectrum disorder rather than major mood disorder with psychotic features (OR = 24.0; $P = 0.02$), a first degree relative with depression (OR = 0.12; $P = 0.05$), and months since last psychiatric inpatient discharge (OR = 0.92; $P = 0.02$). Further examination of time since last hospitalization found that all adolescents continued service utilization up to 18 months post-discharge.

Conclusions Key findings highlight the importance of early diagnosis, that a first degree relative with depression may negatively influence the adolescent's ongoing service utilization, and that 18 months post-discharge may a critical time to review current treatment strategies and collaborate with youth and families to ensure that services continue to meet their needs.

Opinions of professionals and family members about the National mental health law regulating involuntary commitment of psychiatric patients: An international comparative study in 10 countries

I. Georgieva^{*1}, C. Lauvrud¹, R. Almvik¹, R. Whittington²

¹ St. Olav's university hospital, Forensic department, Trondheim, Norway

² St. Olav's university hospital, Forensic department Brøset, centre for research and education in forensic psychiatry, Trondheim, Norway

* Corresponding author.

Introduction Previous research illustrated that the laws regulating involuntary placement and treatment of persons with mental health problems are very diverse across countries; procedures for involuntary commitment and stakeholders involved in the initiation and decision making vary across countries; most laws include criteria of danger/risk, which take various forms in EU Member States' legal frameworks, while the need for treatment in the best interests of the patient is sufficient to detain individuals in other countries, etc.

Objectives This study will compare the opinions of professionals and family members about the operation of the National mental health law regulating forcibly admission and treatment of psychiatric patients in ten countries: Ireland, Iceland, UK, Romania, Slovenia, Denmark, Sweden, Germany, Norway and India.

Aims To gain insights into stakeholders' satisfaction with the operation of their national legislation and to compare the effectiveness and acceptability of different legislative processes across countries. Such scientific findings are needed in order to improve and harmonize legal practices, and to enhance fundamental rights protection of persons with mental health problems, which eventually could result in a lower rate of compulsory admissions.

Methods A short anonymous questionnaire consisting of 9 items was developed, using the online software Survey Monkey. It was distributed to representative samples via e-mail to psychiatrists, general practitioners, acute and community mental health nurses, tribunal members, guards and family members in each collaborating country. The levels of agreement/disagreement were measured on a Likert- scale.

Results/Conclusions The study's results and conclusions will be presented at the conference.

Disclosure of interest The authors have not supplied their declaration of competing interest.

PALOMA project – developing National mental health policies for refugees

S. Jokela^{*}, J. Mäki-Opas

National institute for health and welfare THL, department of welfare, Helsinki, Finland

* Corresponding author.

Introduction Earlier researches have established that migrants with refugee background have increased risk for variety of mental health problems due to often traumatic reasons for leaving their home country, hazardous journey and post-migration adversity. The challenge is that mental health work with refugees is not systematically organized in Finland. PALOMA (developing National mental health policies for refugees 2016-2018) project was launched to answer these challenges. The project is carried out through the combined effort of National institute for health and welfare, The Finnish association for mental health, Helsinki and Kuopio university hospitals, and the municipality of Hämeenlinna. PALOMA

Project is founded by the Asylum, migration and integration fund (AMIF).

Objectives PALOMA project focuses on exploring existing good practices and weaknesses in mental health services in use for refugees. The objectives of the project are to develop a national model for effective mental health services for refugees and implement it nationwide in Finland.

Aims The aim of PALOMA Project is to develop a national model for effective mental health services for refugees in Finland.

Methods PALOMA Project includes three phases: data collection (interviews, literature review, seminars), building the model in expert groups and implementing the model.

Results As a result of PALOMA Project, there will be guidelines for professionals working in different levels of administration with refugees in Finland.

Conclusion Refugees' mental health and wellbeing will be improved as a result of better prevention, recognition and appropriate care of mental health problems.

* Corresponding author.

Introduction Internet use and depression is a significant problem regardless of social status and in almost all age groups. Internet addiction in adolescents is considered to be the most important risk groups.

Objectives This study was conducted to determine correlation of Internet addiction and depressive symptoms among secondary school students.

Method This research was conducted at two secondary public schools in İstanbul during 2015–2016 academic year. Ethics committee approval and permission was obtained from the Directorate of National Education Institutions. The population of the study was 2121 students. The sample group was 1312 students who completely filled in measuring instruments. The measuring instruments consisted of a personal information form, Internet Dependency Scale (IDS) and Children's Depression Inventory (CDI). The data were analyzed with the descriptive statistical analysis and Pearson correlation test.

Results The average of students' age was 12.44 ± 1.20 . 50.2% of the sample were women. 53.8% of the sample spent 1–2 hours per day in Internet. Mean IDS point was 38.942 ± 12.90 and mean CDI point was 12.52 ± 7.13 . According to the IDS cutpoint; 80.9% of students were normal users, 18.4% of them were high-risk users and 0.6% of them were Internet dependents. According to the CDI cutpoint, 16.8% of the students had depressive symptoms. A statistically significant moderate correlation was found between mean scores of CDI and IDS ($r=0.414$; $P<0.01$).

Conclusions There is a relation between Internet dependent and depressive symptoms. This finding supports the outcomes of previously performed studies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Satisfaction with psychiatric in-patient care across 11 countries: Final report of the IDEA-study (inpatient discharge: experiences and analysis)

D. Krupchanka^{1,*}, H. Khalifeh², G. Thornicroft², N. Sartorius³, IDEA research group²

¹ National institute of mental health, department of social psychiatry, Klecany, Czech Republic

² Institute of psychiatry, psychology and neuroscience, King's College London, health service and population research department, London, United Kingdom

³ Association for the improvement of mental health programmes, Geneva, Switzerland

* Corresponding author.

Introduction Satisfaction of patients with in-patient care is a relatively rare focus of research in mental health.

Objectives The IDEA-study (inpatient discharge: experiences and analysis) was initiated to shed the light on the issue internationally.

Aim The IDEA project aimed to:

- develop a collaborative network of young psychiatrists;
- use this network to explore satisfaction of people treated in psychiatric in-patient facilities in a range of high-, middle- and low-income countries.

Methods Study was conducted in 25 hospitals across 11 countries. We measured satisfaction with in-patient care using the 5-item study-specific questionnaire. Individual and institution level correlates of "low satisfaction" were examined by comparisons of binary and multivariate associations in multilevel regression models.

Results A final study sample consisted of 673 participants. Total satisfaction scores were highly skewed towards positive responses. After taking clustering into account, the only independent correlates of low satisfaction were schizophrenia diagnosis and low psychiatrist to patient ratio.

Conclusion We could successfully establish a collaborative network of early career psychiatrists from different parts of the world and collect data in regards to the study aims. The positive skew of satisfaction scores need to be carefully considered in the context of literature and study limitations. In particular, we suggest further studies on patients' satisfaction to pay more attention to treatment expectations formed by the previous experience of treatment, service-related knowledge, stigma and patients' disempowerment, power imbalance.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW0681

Burnout as a form of mental health problem among nurses in the Philippines

J.L. Lu

National institutes of health, university of the Philippines Manila, institute of health policy and development studies, Manila, Philippines

Introduction Nurses are among the health professionals that are confronted with burnout due to workload demands. The dominance of females in the profession reinforce the prevailing notion that the caring professions such as nursing are relegated to women. This gives the study its gender perspective.

Objectives To determine the interaction between situational, factors, role stressors, hazard exposure and personal factors in the largest tertiary hospital in the Philippines.

Methods This was a cross-sectional study, which aimed to determine the interaction between situational, factors, role stressors, hazard exposure and personal factors among 246 nurses consisting most of females (78.5%) from the different wards and units in the Philippines General Hospital (PGH).

Results Almost half (49.6%) of the respondents reported being ill due to work in the past year, and 56.1% missed work because of an illness. Correlation statistics using the Spearman's rho showed organizational role stressors was most significant in burnout among nurses in the Philippine's largest tertiary hospital. Organizational role stressors consisted of ten dimensions, namely:

- inter-role distance (IRD);
- role stagnation (RS);
- role expectation conflict (REC);
- role erosion (RE);
- role overload (RO);
- role isolation (RI);
- personal inadequacy (PI);
- self-role distance (SRD);
- role ambiguity;
- resource inadequacy (RIIn).

Conclusion The contribution of the study is in advancing new concepts in the already existing framework of burnout, and thus, can assist nurses and hospital administration on how to control this problem.

Keywords Burnout; Organizational role stressors; Hazard exposures; Situational factors; Nurses

Collaborative care for treating common mental disorders in the community. Developing a clinical pathway for early intervention in Southeast Tuscany

M. Lussetti^{1,*}, R. De Lilla²

¹ Azienda USL Sud Est Toscana, department of mental health, Grosseto, Italy

² Azienda USL Sud Est Toscana, Società della Salute, Area Grossetana, Grosseto, Italy

* Corresponding author.

Introduction Common mental disorders (CMD) have a 12-month prevalence over 7% in the Italian population. Only 16.9% of people are treated by the health services, despite the high cost in disability and loss of productivity.

Objectives To improve access to low-intensity CBT (LI-CBT) treatments in primary care.

Aims To organize a clinical pathway in which general practitioners (GPs) identify the early signs of CMD and promote a collaborative care with a team of mental health practitioners (MHPs).

Methods A small team of MHPs outlined and implemented, in collaboration with a group of 9 GPs, a clinical pathway to treat CMD in stepped care. Guided self-help was the first and main intervention. Group and individual CBT were offered—when needed—as a second and third step. If the user opted for drug treatment, a psychiatrist conducted one or two sections of consultation to the GP. The MHP team was fully integrated within the community mental health center (CMHC). PHQ-9 and GAD-7 were rated at each appointment.

Results With a mean of 5,3 appointments, 90 persons were treated in 1 year. 68% reached recovery (both PHQ-9 and GAD-7 < 10), a result in line with the best performing English Clinical commissioning groups in the IAPT project.

Conclusions A small multi-professional team of MHP can build with GPs a simple clinical pathway able to reach high standards of care with relatively small resources offering LI-CBT integrated with drug treatment and high intensity care.

Barriers for unaccompanied refugee minors in accessing mental health care: Is it the therapy or the therapist?

P. Majumder^{1,*}, P. Vostanis², M. O'Reilly²

¹ University of Nottingham, medicine and health sciences, Nottingham, United Kingdom

² University of Leicester, psychology, Leicester, United Kingdom

* Corresponding author.

Introduction Refugee children, particularly unaccompanied refugee minors, present with disproportionately high prevalence of mental health and emotional difficulties. However, the mental health service access and treatment engagement of this vulnerable group has been consistently shown to be poorer than the general population. Despite of this, so far there hasn't been much research to explore the possible underlying reasons or barriers for these young people to access mental health service in their host countries.

Aims and objectives This research aims to understand unaccompanied refugee children's barriers to access and utilize mental health services. To explore any potential characteristics in the service provision that can be linked with the observed poor treatment engagement and service access is also an objective of this study.

Methods The study was conducted by using semi-structured interviews with 15 unaccompanied asylum seeking minors and their carers to elicit their views, perceptions and beliefs based on their experience of receiving treatment from a specialist mental health service in the UK.

Results The interview transcripts were analysed using thematic analysis. The main findings were categorised into two broad themes, the participants' perceptions of the intervention received, and perception of the professionals involved. The different elements and pertinent issues within these two broad areas were discussed.

Conclusions Findings will help stimulate further exploratory research gaining better understanding of the barriers for these young people to access treatment, and contribute in developing innovative services that are more efficient in engaging this vulnerable group and suitable to meet their specific needs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Miguel Torga institute, research centre for the study of population, economics and society, Coimbra, Portugal

⁴ Miguel Torga institute, faculty of medicine, university of Coimbra, Coimbra, Portugal

* Corresponding author.

Introduction From a life-span developmental perspective, retirement can be considered a life event that entails a complex

psychological challenge, including leaving one's professional life and organizing/enjoying the newly available free time. The literature about retirement identifies different stages and patterns of transition/adaptation associated with time spent in retirement.

Objectives To analyze the association between time spent in retirement and subjective measures of mental health, depressive symptomatology, loneliness and satisfaction with life.

Methods Quantitative cross-sectional study with 641 participants ($M=74,86$). The instruments included: sociodemographic questionnaire; mental health inventory (MHI-5); geriatric depression scale (GDS); UCLA loneliness scale; satisfaction with life scale (SWLS).

Results Statistically significant differences in all the health and well-being variables addressed were found between subgroups of time spent in retirement (MHI-5: $P=0.001$; GDS: $P<0.001$; UCLA: $P=0.038$; SWLS: $P=0.022$). Mental health and satisfaction with life increases in the first year after retirement, but during the second year, they decrease to the levels found in pre-retirement. Loneliness and depressive symptomatology follow an inverted pattern. With the passing of years, loneliness and depression tend to increase; mental health and satisfaction with life tend to decrease.

Conclusions The results provide support to the hypotheses of honeymoon and disenchantment phases in the recently retired and to the existence of different patterns of transition/adaptation associated with time spent in retirement. They also highlight the relevance of devising intervention strategies that enable individuals to maintain the satisfaction levels with life and mental health achieved during the first phase of retirement.

MINDing the gap: Service users' perspectives of the differences in mental health care between statutory and non-statutory organisations

S. McAndrew*, T. Warne, E. Beaumont, A. Hickey

University of Salford, school of nursing midwifery social work and social science, Salford, United Kingdom

* Corresponding author.

Introduction In the UK, almost 50% of illness diagnosed among working age adults is mental distress, depression and chronic anxiety being the two most prevalent illnesses. However, only 24% of those diagnosed receive appropriate interventions within the National Health Service (NHS). In light of this, third sector organisations, such as MIND, are left to fill the gap in providing therapeutic care. This paper reports on an evaluative study of what Mind offers as opposed to statutory services from a service user perspective.

Aim An exploration of the differences in mental health care between statutory and non-statutory organisations.

Objectives To identify how service users experienced MIND's counselling service. To establish the benefits and disadvantages of mental health care within statutory and non-statutory services. To identify the impact of mental health care from non-statutory services.

Method This qualitative research project, adopted a case study approach. Using one to one narrative interviews, data from 12 participants, five males and seven females were collected. Following transcription, each narrative was analysed individually, with thematic analysis being used across all 12 interviews.

Results Six themes were identified; mindful of the gap; easing like Sunday morning; magic moments; love is in the air; lighting up a future and changing the status quo.

Conclusion Mind plays a significant role in enabling those with psychological problems to move towards building a better future.

Findings suggest statutory services can learn important lessons from non-statutory organisations not least how best to provide cohesive, collaborative and compassionate mental health care for those in distress.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Aims Migration with its long-term changes and the resulting task to adjust to the new environment has been associated with an increased risk for mental health problems. This study aims to gain further insight on the relationship between the four acculturation strategies (integration, assimilation, separation, marginalization) and severity of depression.

Methods A total of $n=79$ first generation Vietnamese outpatients from a psychiatric outpatient clinic for Vietnamese migrants in Germany were investigated regarding self-reported depressive symptoms (patient health questionnaire-9) and acculturation (Stephenson multigroup acculturation scale; SMAS).

Results Patients with an integration acculturation strategy reported lower severity of depression compared to marginalized patients, who reported the highest severity of depression.

Conclusion The results implicate that the integration of both the mainstream society and the ethnic society might serve as a resource, whereas the rejection of both societies might increase the risk of depression.

Relationship between migration-stressors and self-reported symptoms of depression in an outpatient sample of Vietnamese migrants in Germany

T.M.T. Ta, S. Wolf, M.H. Nguyen*, M. Dettling, E. Hahn

Charité universitätsmedizin, psychiatry, Berlin, Germany

* Corresponding author.

Introduction Vietnamese migrants under the influence of migration-related stressors (MRS) represent a vulnerable group within the mental health care system in Germany.

Aims First study examining the relationship between the quantity of experienced MRS and the severity of self-reported symptoms of depression in a Vietnamese outpatient-sample.

Methods 137 first-generation Vietnamese migrants diagnosed with depression were asked to complete the BDI-II and 24 questions about stressful experiences related to the migration process. Linear regression models were performed to examine the influence of the MRS-quantity on BDI-II total score and on BDI-II subscales (Buckley et al., 2001).

Results A higher number of experienced MRS was found to be related to a higher BDI-II total score, as well as to a higher score on the cognitive subscale in particular. Regarding the cognitive

depression-dimension the BDI-II items pessimism, past failure, guilt feelings, punishment feelings and suicidal thoughts were positively related to the MRS-quantity.

Discussion and conclusion A dose-response-relationship was found, with a higher number of MRS being related to a higher severity level of self-reported depressiveness as well as to a higher level of cognitive depression-symptoms in particular. The increase in suicidal ideations in the light of MRS-exposure is in line with findings from other migrant populations. Therapeutic interventions may focus (more) on depressive cognitions as a result of recurring MRS-experiences. Special attention should be placed on suicidal thoughts being boosted by MRS.

Keywords Migration related stressors; Depression; BDI-II; Vietnamese migrants; Suicidality

Impact of socioeconomic position and distance on mental health care utilization by incident users of antidepressants. A Danish nationwide follow-up study

A. Packness^{1,*}, F. Waldorff¹, L. Hastrup², E. Simonsen², M. Vestergaard³, A. Halling⁴

¹ Research unit of general practice, department of public health, Odense, Denmark

² Psychiatric research unit, region of Zealand, Slagelse, Denmark

³ Institute of general medical practice, department of public health, Aarhus, Denmark

⁴ Center for primary care research, health, Lund, Sweden

* Corresponding author.

Introduction Equal access to health care treatment is a highly prioritized goal in most OECD countries. Timely access has become a priority too; in Denmark now with a 4-week deadline from referral to diagnosis. When mental health services become more centralized and allocation of patients to treatment further away from home become more common, it could have a negative impact on the goal of equal access.

Objective To determine the impact of socioeconomic position (SEP) and distance to provider on outpatient mental health care utilization among incident users of antidepressants.

Method A nationwide, Danish, register based, follow-up study on frequencies of contacts to out-patient psychiatric services, psychologist consultations supported by public funding and therapeutic talks by general practice.

Preliminary results Outpatient-psychiatric services were reached more often by patients in low SEP measured by income, but their frequencies of visits were less. Contacts to psychologists were less than half for patients in low SEP and less frequent too. Mental health service by GP showed low SEP associated with low contact. No difference in use of emergency or inpatient psychiatric services was found. Distance to provider showed interaction with SEP and contact to psychologist and frequencies of contact to outpatient psychiatrists. When distance increased by 5 km, contact to psychologist fell by 11% among lowest income group and frequencies of visits to outpatient psychiatrist fell by 5%.

Preliminary conclusion Lower SEP is associated with lower mental health care utilization. Increased distance to provider increases inequity in mental health service utilization.

* Corresponding author.

Introduction Homeless people are more likely to have higher prevalence of psychotic disorders than general population. However, we know less about the prevalence of psychotic symptoms in this group.

Objectives To estimate the lifetime and current prevalence of psychotic symptoms and their correlates among homeless people living in the Paris metropolitan area.

Methods We analysed data from 839 homeless randomly selected for the "Samenta" survey that studied mental health and addiction problems in this population. The mini-international neuropsychiatric interview was used to assess psychotic symptoms. Separate multivariate logistic regression analyses were conducted to estimate the associations of sociodemographic characteristics (age, gender, education level and migrant status), early life experiences (sexual abuse, physical and psychological violence, substance use) and psychiatric disorders.

Results The lifetime prevalence of psychotic symptoms was 35.4% (95% CI=28.1–43.5) and the prevalence of current symptoms was 14.0% (95% CI=9.8–19.6) with no significant difference between migrant and native groups, after exclusion of subjects with a diagnosis of psychotic disorder (n = 145). In multi-adjusted models, childhood sexual abuse was associated with an increased risk of lifetime or current psychotic symptoms (OR > 4, P < 0.05). Early life psychological violence was strongly associated with the risk of lifetime psychotic symptoms in natives (OR = 6.33; 95% CI = 2.10–19.0), whereas alcohol misuse in adolescence was related to lifetime or current psychotic symptoms in migrants (OR = 3.34; 95% CI = 1.20–9.37).

Conclusion Homeless people are at higher risk of psychotic symptoms compared to the general population in France. Our findings are consistent with the hypothesis that childhood abuse is an important risk factor of the psychosis continuum.

* Corresponding author.

Introduction The admission experience survey (AES) is a reliable tool for measuring perceived coercion in mental hospital

admission. We developed the Italian AES through translation back-translation and administered it to acutely hospitalized psychiatric patients.

Objectives/Aims To verify psychometric characteristics of the Italian AES. To Examine the AES factor structure.

Methods $n = 156$ acutely hospitalized patients (48% women, 69% voluntary) were recruited in two university hospitals in Rome (Umberto I Policlinic, Sant'Andrea Hospital) and were administered the Italian AES. We conducted a principal component analysis (PCA) with equamax rotation.

Results Socio-demographic and clinical characteristics of the sample are reported in Table 1. The Italian AES had good internal consistency (Cronbach's $\alpha = 0.90$); Guttman split-half reliability coefficient was 0.90. AES total score significantly differed between voluntary and involuntary patients (5.08 ± 4.1 vs. 8.1 ± 4.9 , $P < 0.05$). PCA disclosed a three-factor solution explaining 59.3 of the variance. Significant correlations emerged between AES total score and clinical variables (Table 2). Pearson's correlation coefficient disclosed a significant correlation between perceived coercion and psychiatric symptoms severity (BPRS total score).

Conclusions The Italian version of AES and proposed new factor structure proved reliable.

Table 1

Age, years, M (SD)	40.5 (12.7)
Women	48%
Education, years, M (SD)	12.1 (4.0)
Disease duration, years, M (SD)	12.1 (9.4)
Diagnosis	
Schizophrenia spectrum disorders	35.9%
Bipolar disorders	35.3%
Depressive disorders	19.2%
Others	9.6%
Number of previous psychiatric hospitalizations, M (SD)	1.4 (2.9)
Number of previous involuntarily psychiatric hospitalization, M (SD)	0.7 (2.6)
MMSE total score, M (SD)	25.6 (2.7)
BPRS total score, M (SD)	54.2 (13.0)

Table 2

Admission Experience Survey items	Perceived Coercion (Cronbach's alpha = 0.84)	External pressure (Cronbach's alpha = 0.79)	Choice expression (Cronbach's alpha = 0.71)
7. It was my idea to come into the hospital	0.78		
15. I had more influence than anyone else on whether I came into the hospital	0.73		
4. I chose to come into the hospital	0.69		
1. I felt free to do what I wanted about coming into the hospital	0.63		
13. My opinion about coming into the hospital didn't matter	0.60

⁶ Istanbul university Istanbul, faculty of medicine, psychiatry, Istanbul, Turkey

* Corresponding author.

Introduction Sexual dysfunctions are more common in individuals with psychotic disorders and has a major impact on both quality of life and compliance.

Objectives The purpose of this study is to investigate whether a relationship between sexual dysfunction and level of treatment compliance in individuals with psychotic disorders.

Methods The sample group of the study consisted of 173 in-patients who agreed to participate were selected by random sampling method. The permission was obtained from the hospital's ethics committee. In this study, to assess the sexual functionality Golombok-Rust inventory of sexual satisfaction male and female form and to assess the treatment compliance; medical treatment compliance rate scale is used.

Results When sexual problems and treatment compliance compared to gender, subscales of satisfaction ($t = 4.423$, $P = 0.000$), avoidance ($t = 3.348$, $P = 0.001$), touch ($t = 2.165$, $P = 0.032$) and overall total ($t = 4.015$, $P = 0.000$), although a statistically significant difference was found, there were no differences in treatment compliance. Additionally, there is no relation between sexual problems and treatment compliance in men. It is also found that there is a weak negative statistical relation amongst treatment compliance and communication ($r = -0.244$, $P = 0.027$), avoidance ($r = -0.270$, $P = 0.014$), anorgasmia ($r = -0.253$, $P = 0.022$) and overall total ($r = -0.249$, $P = 0.024$) in women. According to these findings while sexual problems increase, treatment compliance decreases.

Conclusions The level of compliance to the treatment and subscales of sexual problems; satisfaction, avoidance, and touch mean scores differ from each other. There was a weak negative correlation in between Women's compliance and sexual problems.

Post-traumatic stress disorder screening among Syrian war victims

A. Kutluoğlu¹, B.Ö. Ünsalver^{2,*}, A. Evrensel¹

¹ Uskudar university, psychology, İstanbul, Turkey

² Uskudar university, medical documentation and secretariat, İstanbul, Turkey

* Corresponding author.

Introduction War in Syria and related refugee crisis has caught worldwide attention for the past few years. The war is still continuing by the time of the writing of this abstract. War is one of the reasons of posttraumatic stress disorder (PTSD). Syrian people experience many traumatic events like witnessing death, torture and rape.

Aims The aim of this research is to screen for PTSD among Syrian war victims.

Methods A total of 150 (women = 52, men = 98) war victims between 18–65 years, inhabiting a Syrian camp near the Turkish border were screened with trauma response checklist for PTSD between March 11 and April 11 2015.

Results Significant amount of the interviewed participants were found to show symptoms of PTSD. Seventy-six percent ($n = 114$) of the participants had experienced a traumatic event. In total, 80.6% ($n = 121$) were experiencing distress. Seventy-eight percent ($n = 117$) had avoidance. Eighty-four percent ($n = 126$) had negative

interfering thoughts. Eighty-eight percent ($n = 132$) were experiencing trauma associated disturbance. Answers from 78.6% ($n = 118$) of the participants indicated that they should be further referred to a specialist. The findings were not affected by gender or age.

Conclusion We have found that most of the participants showed signs of PTSD. Our findings highlight the psychological impact of war on Syrian people. A definite diagnosis of PTSD can be made with detailed psychiatric examination, however given the amount of victims and available staff a brief screening instrument may help identify potential cases to be further evaluated. PTSD has life-long consequences and trauma can be passed through generations. International support for war victims should include psychological support and interventions.

Introduction Children are at greater risk than adults for weight gain and metabolic disorders including hyperlipidemia and diabetes with newer antipsychotics. A web-based safety-monitoring program using a prior documentation model required submission of patient safety data (prior documentation) for insurance coverage at the pharmacy point of sale. This program launched in April of 2011, covering all NC Medicaid and Health Choice recipients under age 18. Clinical monitoring parameters and interactive educational features were developed with pediatric psychiatric experts and key mental health stakeholder groups.

Objectives Using a four-year run in period and a full 9 months of post implementation claims data, evaluate the rates of antipsychotic prescribing and safety monitoring before and after the implementation of the A + KIDS program.

Results Implementation of this program was associated with a consistent monthly decrease in overall antipsychotic use and increases in patient monitoring of glucose and lipid (Figure. 1, Table 1).

Conclusions The prior documentation registry was effective in decreasing antipsychotic use and increasing safety monitoring. The impact of changing to more traditional prior authorization on the same clinical endpoints is currently under evaluation.

Fig. 1 A+KIDS Population Antipsychotic Prescription Fills per 1000 Medicaid Enrollees Per Day

Table 1 Percent of A+KIDS Patients on an Antipsychotic with Metabolic Monitoring Recorded in Claims.

Year Ending	Glucose Screening Percent	Cholesterol Screening Percent

³ Parc de Salut Mar, psychiatry, INAD, Barcelona, Spain

* Corresponding author.

Negative symptoms in schizophrenia, and specifically amotivation/apathy, have been correlated with impaired general functioning. Its neurobiological basis are thought to rely on an aberrant reward system. To study the association of reward deficits and negative symptoms, 25 schizophrenia patients and 35 controls underwent a new reward behavioral task. Briefly, patients had to choose a level of effort (1 to 3), each one corresponding to a progressively increasing number of required button presses and 3 different probabilities to win an economic reward. We compared the chosen effort between groups and correlated this output with the score of the Brief negative symptoms scale in the group of patients. Patients chose less effort than controls but without reaching significance level (mean patients effort: 2.49 vs controls: 2.76, $P = 0.064$). A negative correlation was found between BNSS score and effort chosen for the maximum reward corrected by sex ($t: -0.021, P = 0.045$). When the group of patients was split according to negative symptoms score, patients with more negative symptoms (BNSS score > 23) chose significantly less effort than patients

with less negative symptoms and controls (Fig. 1). Our reward task correlates well with negative symptoms. Thus, it could offer a behavioral measure of negative symptoms. It could be a good instrument to study the neurobiological basis of negative symptoms using functional techniques.

Brain connectivity in patients with schizophrenia related to psychological stress

M. Castro*, L. Drucaroff, E. Costanzo, A. Wainsztein, S. Guinjoan, M. Villarreal

Conicet, Fleni, UBA, psychiatry, Caba, Argentina

* Corresponding author.

Introduction It is commonly accepted that in most patients with schizophrenia external factors act on genetic predisposition to produce active psychotic symptoms. In fact, we showed that patients with schizophrenia have an abnormal brain activation and peripheral autonomic response to psychological stress. We sought to characterize the brain connectivity networks of such response in schizophrenia.

Methods We studied the pattern of brain connectivity in relation to mental arithmetic stress paradigm in 21 patients and 21 healthy subjects aged 18 to 50 years, using 3T-fMRI. A period of 6 minutes of resting state acquisition (PRE) were followed by a block design with three 1-minute CONTROL task (one digit sum), 1-minute STRESS task (two digit subtraction) and 1-minute rest after task (POST). Pairwise Pearson correlations were calculated between 90 regions of interest. Data were analyzed with MATLAB and SPSS software.

Results Patients with schizophrenia showed a lower connectivity network between fronto-temporal limbic areas compared with control subjects during control and stress task. Moreover, we observed a great variability of link density during resting state in patients but not in controls, and it diminishes in response to task.

Conclusions Patients present abnormalities in networks related to stress response showing an alteration in fronto-temporal connectivity, and a poor and random modulation of these networks at rest. Current and previous findings suggest abnormal fronto-temporal connectivity that ultimately would lead to psychotic symptoms emergency in response to an environmental stressor and, even, could be related to hypervigilance and misattribution feeding into the paranoid cognition characteristic of patients with schizophrenia.

Non-verbal learning disorder: Neuropsychological profile and neural correlates. A structural magnetic resonance imaging study

M. Cervino*, P. Castrillo, R. Guijarro

Complejo hospitalario universitario de Granada, servicio Andaluz de Salud, unidad de rehabilitación de Salud Mental, Granada, Spain

* Corresponding author.

Non-verbal learning disorder (NVLD) is a neurological condition which is considered to be a learning disability. It is characterised by a specific dysfunction in motor, visuospatial and social skills in patients with a normal intellect and development of language. Warning signs in school are poor psychomotor coordination, arithmetic skills and drawing activities. Social judgment and social problem solving are also typically impaired. Furthermore, these patients seem to have increasing risk of emotional disorders. Most of imaging studies and current theories suggest that a dysfunction of white matter in the right hemisphere could be the cause. However, there is a lack of consensus among experts regarding whether NVLD exists and what could be the underlying causes for NVLD symptoms. The aim of this paper is to clarify the neural correlates underlying the cognitive functioning of these patients. With this objective, we analyzed a sample of brains of children with and without NVLD. We used the structural MRI technique and the voxel-based morphometry analysis. The diagnosis of the children were based on neuropsychological data. The present study suggests that not only white matter of the right hemisphere is dysfunctional in these patients. Some other gray matter areas such as precuneus (superior parietal lobule) may also be affected in NVLD.

Apathy in depression: An arterial spin labeling study

C. Conan^{1,*}, J.M. Batail¹, I. Corouge², J. Palaric¹, G. Robert¹, D. Drapier¹

¹ Centre hospitalier Guillaume-Regnier, PHUPA, Rennes, France

² INRIA, VisAGeS project-team, Rennes, France

* Corresponding author.

Introduction Apathy is usually defined as a lack of goal-directed behavior. Although it is observed in about 30% of depressed patients, neurovascular mechanisms underpinning apathy remain little-known.

Objectives The main objective of this study was to compare the cerebral perfusion of apathetic depressed patients with non-apathetic depressed patients by arterial spin labeling (ASL), a quantitative and non-invasive perfusion magnetic resonance imaging (MRI) technique. The secondary objectives were to study their clinical profile and their correlation with cerebral perfusion data.

Methods This study was conducted from a cohort of depressed patients in Rennes, France. Eighty-three depressed patients were included, of whom 22 were apathetic (AES \geq 42), 61 non-apathetic (AES < 42). Everyone got a clinical evaluation with scale screenings, especially for apathy (AES), anxiety (STAI) and anhedonia (SHAPS) as well as a cerebral MRI, including a pseudo-continuous ASL sequence.

Results Apathetic depressed patients were significantly less anxious and less anhedonic. Apathetic perfused better than non-apathetic in the inferior frontal gyrus ($P=0.022$). We found a significant positive relationship between apathy and perfusion of the left frontal inferior gyrus ($P=0.05$, $r=0.21$). State-anxiety was positively correlated with perfusion of the cingulate cortex, the insula and the left amygdala. Anhedonia was positively correlated with the perfusion of the ventromedial prefrontal cortex, the cingulate cortex and the insula.

Conclusions We have shown that the clinical and perfusional profiles of apathetic depressed and non-apathetic differ. This study suggests the existence of two distinct neurobiological networks for depressed patients; one involving motivational networks for apathetic patients, and another one involving emotional networks for more anhedonic patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Although some magnetic resonance imaging (MRI) studies have investigated the existence of a relationship between clinical severity and neuroanatomical alterations in patients with schizophrenia (SCZ), the biological signature associated with illness severity in schizophrenia is still uncertain.

Objectives This study aims to investigate structural brain abnormalities in SCZ with particular regards to the identification of potential deficits associated to the severity of illness.

Methods 1.5 T MRI data were acquired for 61 subjects with SCZ and 59 matched healthy controls (HC). The patient group was divided in two subgroups based on clinical severity, one composed by 34 mild-to-moderately ill patients and the other one by 27 severely ill patients, and compared with matched HC.

Results The whole group of patients with SCZ had significantly reduced gray matter (GM) volumes in left inferior and middle temporal gyrus compared to HC ($P<0.05$, pFWE corrected). Furthermore, compared to HC, patients with mild-to-moderate illness showed decreased GM volumes in inferior temporal gyrus ($P<0.05$, pFWE corrected) whereas those with severe illness had reduced right cerebellum ($P<0.05$, cFWE corrected). No differences were observed between the two subgroups of patients.

Conclusions Our results showed significant GM volume reductions in left inferior and middle temporal gyrus in patients with SCZ compared to matched HC, confirming the role of this region in the pathophysiology of SCZ. Furthermore, we identified specific cerebellar gray matter volume reductions in patients with severe illness, which may contribute to stratify patients with SCZ according to their clinical phenotype expression, ultimately

helping in guiding targeted therapeutic/rehabilitation interventions.

Introduction Empathy is evolutionary preserved in social organisms and emotional face processing is one of its measures. Systems possibly active during empathic processing include perspective-taking, basic emotional contagion “mirroring” and “theory of mind” systems.

Objectives fMRI studies help clarifying neural correlates of empathic face processing; ALE meta-analysing fMRI studies allows identification of brain area activation/deactivation during empathy.

Aims To identify brain areas most consistently involved in empathy.

Methods We carried ALE meta-analysis of original studies focusing on cerebral activations during empathic face processing tasks and reporting data on Talairach or MNI space coordinates, converting the former in the latter. An 11-April-2016 PubMed search, using as keywords terms like empathy combined with functional magnetic resonance imaging (fMRI), produced 124 records of which 23 were finally included (568 participants, 247 males and 321 females; mean age 32.2 years). We followed the PRISMA statement. Whole-brain data were meta-analysed; significance was set at $P=0.0001$, uncorrected.

Results ALE meta-analysis of data from 21 experiments (totalling 527 foci) on empathic face processing during experimental task conditions showed that emotional vs. neutral/control conditions significantly correlated with activations of left anterior cingulate cortex (BA 32), right precentral gyrus (BA 6), left amygdala, right superior frontal gyrus (BA 9), left middle occipital gyrus (BA 37), right insula (BA 13), left putamen, and left posterior cingulate cortex (BA 31).

Conclusions Empathy is a complex process correlating with activation of different brain areas, which have been involved in emotional cue processing, self-other/same-different discrimination, perspective-taking, mirror neuron activation, emotional arousal and decision-making.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Objective Internet gaming disorder (IGD) is a type of behavioral addiction characterized by abnormal executive control, leading to loss of control over excessive gaming. Attention deficit and hyperactivity disorder (ADHD) is one of the most common comorbid disorders in IGD, involving delayed development of the executive control system, which could predispose individuals to gaming addiction. We investigated the influence of childhood ADHD on neural network features of IGD.

Methods Resting-state functional magnetic resonance imaging analysis was performed on 44 young, male IGD subjects with and without childhood ADHD and 19 age-matched, healthy male controls. Posterior cingulate cortex (PCC)-seeded connectivity was evaluated to assess abnormalities in default mode network (DMN) connectivity, which is associated with deficits in executive control.

Results IGD subjects without childhood ADHD showed expanded functional connectivity (FC) between DMN-related regions (PCC, medial prefrontal cortex, thalamus) compared with controls. These subjects also exhibited expanded FC between the PCC and brain regions implicated in salience processing (anterior insula, orbitofrontal cortex) compared with IGD subjects with childhood ADHD. IGD subjects with childhood ADHD showed expanded FC between the PCC and cerebellum (crus II), a region involved in executive control. The strength of connectivity between the PCC and cerebellum (crus II) was positively correlated with self-reporting scales reflecting impulsiveness.

Conclusion Individuals with IGD showed altered PCC-based FC, the characteristics of which might be dependent upon history of childhood ADHD. Our findings suggest that altered neural networks for executive control in ADHD would be a predisposition for developing IGD.

* Corresponding author.

Introduction Early life stressful events cause long-term neural changes that are associated with psychiatric disorders.

Objective Early life manipulations focus on commonly the impact of remaining separate from the mother in a specific period of time. The maternal odor is required for pups to approach the mother for nursing. What happens when there is a mother that smell like a real mother but does not take care her own pups?

Aim To investigate the fake mother effects on adult rat's behavioral changes, NMDAR2B protein level changes in prefrontal cortex and hippocampus.

Methods Wistar rats were used. Fake mother (n:13), early handling (n:12), maternal separation (n:14) and control (n:12) were the study groups. A fake mother is an object that smells like a real dam. When the real mother is separated from own pups fake mother stays with the pups for an hour. Manipulations were made during the postnatal first 14 days. Behavioral tests (social interaction test, elevated plus maze, novel object recognition test) were made between postnatal 62 and 78 days. NMDAR2B protein levels in prefrontal cortex and hippocampus were evaluated by using ELISA at postnatal 78 days.

Results In social interaction test, fake mother group exhibited less social behavior and more aggressive behavior than the other groups. Their long-term memory functions were the lowest. NMDAR2B protein levels in the hippocampus increased in rats that exposed to early stressful life events.

Conclusion These results support that being raised by fake mother increases aggressive behavior and decrease social behavior in adulthood.

* Corresponding author.

Introduction Deficits in behavioral inhibition leading to impulsivity occur frequently in many otherwise different psychiatric diseases, mainly ADHD and borderline personality disorder (BPD). However, the research is complicated by using of different tests and their parameters. Further, the role of frontoparietal network in behavioral inhibition has been questioned recently.

Objectives The aims of our studies were:

- to present the influence of differences in inhibition tasks parameters;
- to describe neural correlates of behavioral inhibition in healthy people;
- to compare them with BPD and ADHD patients.

Methods We implemented two different variants of Go/NoGo Task, one designed for behavioral research and the second for neuroimaging. Thirty healthy participants (37% of women, age range 15 to 33 years) underwent behavioral and fMRI measurement. Further, groups of patients with BPD, ADHD and their healthy controls underwent the Go/NoGo Task under both fMRI and EEG.

Results The results show differences in behavioral performance based on different task parameters. The fMRI results in healthy people show specific activation patterns within the frontoparietal network associated with inhibition trials (mainly inferior frontal gyrus, insula, cingulate gyrus, SMA, inferior parietal lobule). Further, we present differences between patients with BPD, ADHD and controls in BOLD signal and ERPs.

Conclusions Go/NoGo Task design substantially influences the subjects' behavioral performance. Our results with methodologically upgraded Go/NoGo Task design provide support for the inhibition frontoparietal brain network and its different activations in BPD and ADHD patients. The research was supported by Ministry of Health of the Czech Republic, grant nr. 15-30062A.

The squeezing snake, a psychiatric presentation of epilepsy: A case report

M. Mangas*, L. Bravo, Y. Martins, A. Matos Pires
Hospital José-Joaquim Fernandes, mental health and psychiatric service, Beja, Portugal

* Corresponding author.

Introduction Epilepsy is considered a complex neurological disorder with a great variety of clinical presentations that can resemble psychiatric disorders.

Objectives Disclose an unusual clinical case with psychiatric symptoms as the presentation of epilepsy.

Methods Psychiatric assessments and retrospective review of the clinical file and literature research.

Results A 40-years-old Romanian woman presented to the psychiatry outpatient service with a history of persistent depressive mood and disturbed sleep for the past 3 years, complaining of a feeling that she described as “a snake squeezing around her body, starting in her left leg and spreading to the rest of her body up to the neck” associated with a sense of pins and needles, occurring during night time. She attended general practice, neurosurgery and psychiatry appointments. Her medical history included “gastritis” and lower left leg fracture and a pituitary microadenoma revealed in brain CT-scan. Blood work, including endocrine tests and brain-MRI were normal. Her symptoms initially led to diagnosis of: anxiety, somatization, Ekblom syndrome and depression. She was treated with antidepressives, antipsychotics and anxiolytics, without response. After careful reconstruction of the clinical history and further analyses of her complaints, the diagnosis of focal sensory jacksonian seizure was made. Levetiracetam introduction led to symptomatic remission.

Conclusion Epilepsy includes a variety of neuropsychiatric symptoms. This case illustrates that epileptic patients may experience non-convulsive seizures that might be mistaken as primary psychiatric disorders. Neurologists and psychiatrists must be aware of this varied presentation while obtaining the medical history in order to investigate and manage this patient effectively.

A case of neurosyphilis in a patient presenting with bipolar mixed episode suggestive symptoms

M. Martins, R. Fernandes*
Centro hospitalar Psiquiátrico de Lisboa, psiquiatria geral e transcultural, Lisbon, Portugal

* Corresponding author.

Introduction Syphilis is a sexually transmitted disease caused by *Treponema pallidum*. Early invasion of the central nervous system might occur early in the course of the disease. Clinical manifestations may include acute meningeal syphilis, meningovascular syphilis, parietic neurosyphilis and tabetic neurosyphilis. Psychiatric symptoms are often the presenting symptoms of this illness and the correct diagnosis involves both a high degree of suspicion and adequate diagnostic tests.

Objectives The authors report a case of a patient, with no previous history of mental illness, initially admitted in a psychiatric unit with a clinical picture suggestive of a mixed bipolar disorder episode who has been diagnosed with neurosyphilis a year after.

Methods Review of clinical records and complementary exams.
Results By the first admission, the patient presented with depressed and irritable mood, emotional lability, aggressiveness, grandiose and racing thoughts. Upon discharge, he was diagnosed with bipolar disorder and referred to ambulatory unit. The following year he starts presenting cognitive deficits and a progressive loss of autonomy in daily living activities, being referred to neurology evaluation. A year after the first admission, he is admitted in a neurology unit and diagnosed with neurosyphilis.

Conclusions Current prevalence of symptomatic neurosyphilis in Western Europe is unknown. Atypical cases presenting with heterogeneous psychiatric and neurologic symptoms, with no previous history of mental illness, should raise a high index of clinical suspicion, since consequences for the patient's health might be severe if not properly diagnosed and treated.

Reduced left frontal GABA in ultra-high risk of psychosis patients. 1H MRS study

P. Menshchikov*, T. Akhadov, N. Semenova
Scientific research institute of urgent children's surgery and trauma, radiology, Moscow, Russia

* Corresponding author.

Introduction Some previous findings indicate participation disturbance of balance between excitatory (GABA) and inhibitory (Glu) neurotransmitters in pathogenesis of schizophrenia. The aim of this study was to evaluate GABA and GLX levels in the brain of medicated UHR subjects.

Objectives Twenty-one (18–25 years, mean = 19.4, SD = 3.5) right-handed medicated UHR men and 26 (18–25 years, mean = 19.8, SD = 2.2) mentally healthy volunteers participated in this study. The patients were included in the UHR group in accordance with criteria of prodromal states.

Methods 1H MRS (MEGA-PRESS pulse sequence [Mescher, NMR Biomed 1998;11:266]) was used for GABA and GLX detection. Volumes of interest in size of 30 × 30 × 30 mm were placed in the left and right frontal lobes in the areas of the anterior cingulate cortex (ACC) (Fig. 1).

Results The main effects on the GABA/Cr ($t[45] = 4.17, P < 0.01$) (Fig. 2A) and GABA/GLX ($t[45] = 2.84, P < 0.01$) (Fig. 2B), were found in the left ACC ($t[45] = 4.17, P < 0.01$), with the patients having lower GABA/Cr and GABA/GLX ratios as compared to the control group. Also significant negative correlation ($r = -0.49, P = 0.04$) between GABA/Cr in the right ACC and the current daily dosage of antipsychotic medication in CPZ-Eq was found (Fig. 3).

Conclusion This study reveals for the first time a significant reduction of (GABA) (25%) and GABA/GLX ratio (20%) in left AC of UHR subjects. According to (de la Fuente-Sandoval, Int J Neuropsychopharmacol 2015;19[3]) and association of (GABA) with daily dosage of medication found, this reduction may be caused by the antipsychotic treatment.

* Corresponding author.

Introduction Diffusion tensor imaging (DTI) is used frequently to explore white matter tract morphology and connectivity in psychiatric disorders. Connectivity alterations were previously reported for bipolar disorder, unipolar depression and schizophrenia. However, there is limited data on how these disorders differ from one another in terms of connectivity.

Aims In this study, we aimed to explore connectivity differences between these disorders.

Methods We analyzed DTI data of 37 patients with schizophrenia, 41 patients with bipolar disorder and 46 patients with unipolar depression. Group analyses were performed for schizophrenia versus bipolar and bipolar versus unipolar contrasts with using age as a covariate.

Results Threshold corrected results showed that connectivity at internal capsule and corpus callosum were most distinctive between groups. For corpus callosum (splenium), unipolar group showed the highest connectivity and schizophrenia group showed the lowest connectivity (Fig. 1). For internal capsule, schizophrenia group had the highest connectivity and unipolar group had the

lowest connectivity (Fig. 2). Bipolar group had intermediate values for both tracts.

Conclusions These results indicate that connectivity analysis may be helpful for differentiating psychiatric disorders.

Introduction The knowledge on brain mechanisms of psychopathology can be very useful for the diagnosis and treatment of patients.

Objectives Patients with major depressive disorder (MDD) show attention bias to the negative emotional stimuli. Automatic (unconscious) emotional processing in such patients may become a prospective biomarker for depression.

Aims We aimed at studying the EEG-correlates of unconscious expectation of angry human faces in MDD patients compared to healthy controls.

Methods 128-channel EEG was recorded in MDD (23 females and 7 males) and in healthy volunteers (22 females and 8 males) while they categorized pictures as humans or animals. Half of the pictures were neutral and half were showing the faces of angry humans or animals. The pictures were preceded by cues (one for each category), which meaning was not explained to the participants. We

performed the wavelet analysis on EEG recorded during the face expectation period: 1000–2000 ms from the cue onset.

Results We found the emotional modulation (EM) in EEG rhythms during the expectation of angry vs. neutral faces in both groups. Statistical comparison of the spectral power using 2×2 factorial design showed that the EM differences ($P < 0.05$) between the groups were in the left parietal locations in 9 Hz and in 16–18 Hz, in the right parietal locations in 27–28 Hz, and in the right frontal area in 30–31 Hz.

Conclusions The unconscious expectation of angry vs. neutral faces resulted in EM differences between the MDD and healthy controls in the right frontal and bilateral parietal areas mostly in beta and gamma ranges.

* Corresponding author.

Introduction Depression occurs frequently in patients suffering from Parkinson's disease (PD). However, the neural basis of depression in PD remains unclear. Diffusion magnetic resonance imaging (DMRI) connectometry is based on the spin distribution function (SDF), which quantifies the density of diffusing water.

Aim The aim of this study was to assess the microstructural changes in the brain connectivity of PD patients with and without depressive symptoms.

Methods DMRI was used to assess microstructural abnormalities in the brains of 16 PD patients with depressive symptoms compared to 11 PD patients without depressive symptoms. Data used in the preparation of this paper were obtained from the Parkinson's progression markers initiative (PPMI) database (<http://www.ppmi-info.org/data/>). This dataset was acquired on a 3-Tesla scanner (Siemens), producing 64 DWI at $b = 1000 \text{ s/mm}^2$ and one b_0 image. Diffusion MRI data were corrected for subject motion, eddy current distortions, and susceptibility artefacts due to magnetic field inhomogeneity. DMRI connectometry was conducted in a total of 27 patients using percentage measurement.

Results PD Patients with depressive symptoms showed decreased anisotropy ($FDR < 0.05$) in the fornix bilaterally, left inferior longitudinal fasciculus (ILF) and corticospinal tract bilaterally compared to PD patients without depressive symptoms.

Conclusions Lesser WM integrity of the left ILF fibers, which connect visual face recognition areas to the amygdala and hippocampus, seems to be associated with depressive symptoms in PD patients. Our study supports the hypothesis that neurodegenerative processes in projections from the somatosensory, cingulate, and insular cortices may be related to depression in PD.

⁵ Heinrich Heine university, department of clinical neuroscience and medical psychology, Duesseldorf, Germany

* Corresponding author.

Introduction Psychopathy is characterized by superficial charm, untruthfulness, lack of remorse, antisocial behavior, egocentricity as well as poverty in major affective reactions. This clinical profile has been empirically conceptualized and validated. Recent brain imaging studies suggest abnormal brain activity underlying psychopathic behavior. However, no reliable pattern of altered neural activity has been disclosed so far.

Objective To identify consistent changes of brain activity in psychopaths and to investigate whether these could explain known psychopathology.

Methods First, we used activation likelihood estimation to meta-analyze brain activation changes in psychopaths across 28 functional magnetic resonance imaging studies reporting 753 foci from 155 analyses ($P < 0.05$, corrected). Second, we functionally characterized the ensuing regions employing meta-data of a large-scale neuroimaging database ($P < 0.05$, corrected).

Results Psychopathy was consistently associated with decreased brain activity in the right amygdala, the dorsomedial prefrontal cortex (DMPFC), and bilaterally in the lateral prefrontal cortex (LPFC). Consistently increased activity was observed bilaterally in the fronto-insular cortex (FIC) (Fig. 1). Moreover, we found that the physiological functional role of the candidate regions related to social cognition (DMFPC), cognitive speech and semantic processing (left FIC/LPFC), emotional and cognitive reward processing (right amygdala/FIC) as well as somesthesia and executive functions (RLPFC).

Conclusion Psychopathy is characterized by abnormal brain activity of bilateral prefrontal cortices and the right amygdala, which mediate psychological functions known to be impaired in psychopaths. Hence, aberrant neural activity can account for pertinent psychopathology in psychopathy.

⁵ École polytechnique fédérale de Lausanne, laboratory of functional and metabolic imaging, Lausanne, Switzerland

* Corresponding author.

Recent evidences have consistently reported lower glutamate (Glu) levels in various brain regions, including the medial prefrontal cortex (mPFC), in chronic schizophrenia but findings in the early (EP) or in the prodromal phase of the disorder are equivocal. Although regular cannabis use has been associated with an increased risk of subsequent psychosis and with a perturbed Glu signalling, to date, the critical question of whether or not Glu abnormalities exist in EP and are related to cannabis use remains unanswered. Magnetic resonance spectroscopy was used to measure [Glu_{mPFC}] of 35 EP subjects (18 of whom were regular cannabis users) and 33 healthy controls (HC). For correlative analysis, neuropsychological performances were scored by a comprehensive cognitive battery. [Glu_{mPFC}] was lower in EP users comparing to both HC and EP non-users ($P=0.001$ and $P=0.01$, respectively), while no differences were observed between HC and EP non-users. In EP users Glu declined with age ($r=-0.46$; $P=0.04$) but this relationship was not observed in non-users. Among neuropsychological profiles, working memory was the only domain that differentiates patients depending on their cannabis use, with users having poorer performances. In summary, our research revealed that cannabis use in EP is associated with Glu decreased levels, which are normally not seen in the early phase of the disorder. This finding is in line with previous ¹H-MRS studies in cannabis users without a psychotic disorder and sheds light for the role of cannabis use in the progression of the disease.

* Corresponding author.

Objective Chronic exposure to alcohol causes neuroadaptive changes in the brain, which leads to the recurrence of the disease. Promising in this area is to find new safe and effective pharmacological agents acting on molecular targets of influence of alcohol in the CNS.

Methods Experiments were performed on male rats Wistar and male mice (CBAx57Bl/6)F1.U. Experimental animals were formed alcohol dependence, based on long-term use of alcohol solution. Animals in a state of alcohol dependence were injected original anticonvulsant meta-chloro-benzhydryl-urea. We evaluated parameters orienting-exploratory behavior and emotional reactivity of the animals in the test “open field”, the cellular and humoral immune response. Properties of benzodiazepine receptors of

the brain examined radioreceptor method using selective ligands [³H]flunitrazepam and [³H]Ro5-4864.

Results Chronic exposure to ethanol resulted in a significant change in the parameters of the experimental animal behavior and emotional reactivity in the test “open field”, observed suppression of immune response (~40%), and increase in the number of receptors on 54.8–59.4% associated with reduced receptor affinity. Administration of meta-chloro-benzhydryl-urea led to the abandonment of the use of ethanol, recorded a correction of the above immunological and behavioral disorders due to alcohol intoxication. Properties of benzodiazepine receptors in the brain of experimental animals receiving the drug at a dose of 100 mg/kg for 14 days, indicators affinity and receptor density were close to the values in the control group.

Conclusions Anticonvulsant has a modulating effect on the functional activity of the nervous and immune systems, reduces compulsive craving for alcohol.

Abstract Serotonin is well known to affect the multifaceted construct of impulsivity. Lowering brain serotonin levels is shown to increase impulsive choice in delay-discounting tasks (1) but improves response inhibition in stop-signal paradigms. (2) Administration of the antidepressant citalopram in healthy people increases tendency to perform go choices in a Go/No-Go task independent of outcome valence (3). It is rather unclear thought how serotonergic neurotransmission affects several aspects of cognition. We administered a single dose of 20mg escitalopram, a selective serotonin reuptake inhibitor, to 66 healthy participants, aged 18–45 years old, in a double-blind, randomized, placebo-controlled, parallel-groups study. Acute escitalopram administration had a beneficial effect on inhibitory control with reduced stop-signal reaction time observed in the treatment group. Participants made significantly more errors in a probabilistic learning task and had lower accuracy during the discrimination stage in an instrumental learning task thus indicating a learning impairment. More errors in the CANTAB intra-extra dimensional set shift task were also observed in the escitalopram-treated group. Our findings following acute administration of a clinically relevant dose of escitalopram show a dissociate role for serotonin in modulating cognition mediated by a potentially differential modulation of fronto-striatal loops.

Microstructural and metabolic disorders in CC of juvenile schizophrenia patients

M. Ublinskiy^{1,*}, N. Semenova¹, T. Akhadov¹, I. Melnikov¹, D. Kupriyanov¹, I. Lebedeva², V. Kaleda²

¹ Children's clinical and research institute emergency surgery and trauma, radiology, Moscow, Russia

² Psychiatry, National mental health research centre of the Russian academy of medical sciences, Moscow, Russia

* Corresponding author.

Introduction The aim of the study was to analyze the microstructural and metabolic features of the corpus callosum in recently onset schizophrenia.

Objectives 13 young (17–28 years old) male patients with recently onset schizophrenia (F20, ICD-10) and 15 sex and age matched mentally healthy subjects were examined.

Methods 3 T Philips Achieva scanner with 8-channel SENSE coil was used. DTI was conducted with EPI SENSE (TR=9431 ms; TE=70 ms). The values of diffusion coefficient (ADC), fractional anisotropy (FA), radial (RD) and parallel (PD) diffusivity were calculated using workstation Philips EBWS 2.6.3.4. Spectroscopic voxel (2 × 1 × 1 cm) was placed consequently in the corpus callosum genu and splenium. PRESS (TR/TE = 1500/40) was used.

Results In patients, increased ADC ($P=0.02$) and RD ($P=0.008$), decreased FA ($P=0.008$) and NAA ($P=0.03$) were found in the corpus callosum genu. No intergroup differences by PD, Cho, Cr, Glx were found in this area. Also, no statistically significant intergroup differences were observed for the DTI and MRS characteristics of the corpus callosum splenium.

Conclusions It has been shown that RD increase is associated with demyelination process. So, an increase of RD in the present study could reflect demyelination in CC genu. Cells membranes abnormalities should lead to an increase of Cho which was not found. NAA reduction could be caused by reduction of axonal integrity. The latter process is considered to precede demyelination and not to be accompanied by PD rise. Thus, the present study revealed axonal integrity reduction and low demyelination in the genu of the corpus callosum in the early stages of schizophrenia.

* Corresponding author.

Aim This study used proton magnetic resonance spectroscopy (¹H MRS) to evaluate neurochemistry of the frontal cortex in adolescents with symptoms of sleep and depression.

Methods 19 non-medicated adolescent boys (mean age 16.0 y; $n=9$ clinical cases with depression/sleep symptoms and $n=10$ healthy controls) underwent ¹H MRS at 3T. MR spectra were acquired from the anterior cingulate cortex (ACC), the dorsolateral prefrontal cortex, and frontal white matter. Concentrations of N-acetyl aspartate, total creatine, choline-containing compounds, total glutamine plus glutamate, and myo-inositol (mI) were compared between the two subgroups and correlated with sleep and clinical measures in the total sample. Sleep was assessed with self-report questionnaires and ambulatory polysomnography recordings.

Results Concentrations of mI were lower in both frontal cortical regions among the depressed adolescents as compared to healthy controls. No statistically significant differences in other metabolite concentrations were observed between the subgroups. Frontal cortex mI concentrations correlated negatively with depression severity, subjective daytime sleepiness, insomnia symptoms, and the level of anxiety, and positively with total sleep time and overall psychosocial functioning. The correlations between mI in the ACC and total sleep time as well as daytime sleepiness remained statistically significant when depression severity was controlled in the analyses.

Conclusion Lower frontal cortex mI may indicate a disturbed second messenger system. Frontal cortical mI may thus be linked to the pathophysiology of depression and concomitant sleep symptoms among maturing adolescents. Short sleep and daytime sleepiness may be associated with frontal cortex mI independently from depression.

What make suicide depressions different from non-suicide ones: A diffusion tensor imaging study

H. Zhang^{*}, Z. Jia

West China hospital, Sichuan university, radiology Huaxi MR research center, Chengdu, China

* Corresponding author.

Introduction Depression is a common psychiatric disorder affecting many people globally, and the worst outcome is suicide. But its neurobiology is hardly understood.

Objectives To use DTI to characterize abnormalities of white matter (WM) integrity in major depressive disorder patients with suicide attempts or suicidal ideation.

Aims Present study aimed to give a more complete profile for the association of cerebral WM abnormalities with suicidal behavior in major depressive disorder patients by quantifying the suicidal ideation and behavior severity.

Methods Thirteen depressive patients with suicide attempts (SA), 14 depressive patients with suicidal ideation but no suicide attempts (SI), 13 depressive patients without suicidal ideation or suicide attempts (NSD) and 40 healthy controls (HC) received MRI scans on a 3 T magnet. Whole brain voxel-based analysis of FA based on DTI was performed among the four groups using a threshold of $P < 0.05$ with FWE correction. FA values were extracted by Marsbar software to quantify the changes.

Results The four groups had significant differences of FA in the left splenium of corpus callosum (peak $Z=5.36$ at $-14, -36, 22$). Quantify comparison revealed that SA had significant decreased FA value than SI, NSD, and HC. There was no significant difference among the other three groups, although there was a trend that SI and NSD had lower FA values than HC in this region.

Conclusions Depression and suicide are associated with microstructure abnormalities of the white matter and patients with suicide attempts may have severe cerebral alteration.

Audit of patients with intellectual disabilities accessing a specialist neuropsychiatry service for epilepsy management

A. Adetoki^{a,b}

^a Coventry and Warwickshire NHS Partnership Trust, Coventry, UK

^b Birmingham and Solihull NHS Foundation Trust, Birmingham, UK

Introduction Epilepsy is a frequent co-morbidity in patients with intellectual disabilities, some of whom require specialist services. The National Institute for Health and Care Excellence (NICE) has recommended that there should be equity of access to high quality of care regardless of the existence of a diagnosis of intellectual disability.

Objectives To observe current practice with regards to NICE guidelines for epilepsy care in patients with intellectual disability.

Aims To identify the level of compliance with NICE guidelines and provide evidence which may inform care planning processes.

Methods A retrospective review of the electronic and paper-based records of a total sample of intellectually disabled patients who accessed a specialist neuropsychiatry service for the management of epilepsy during a six-month period was carried out.

Results The records of 21 patients whose ages ranged from 20 to 58 years were audited. The waiting period ranged from 4 weeks to 46 weeks. There was evidence of Carer involvement in the management of 100% of the patients and seizure improvement since referral was documented in 66%. Non-medication treatment was offered in 67% of cases. Evidence of special considerations in view of patient's intellectual disability was recorded in 24%, best interest considerations in 24% and capacity assessment in 19%.

Conclusions There is a significant improvement in the symptoms of 66% of patients in this audit. However there is room for improvement and a more specific plan for patients with intellectual disabilities should facilitate this.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Prevalence of ADHD symptoms among adults in the general population in Finland

L. Alaheino*, S. Leppämäki

Helsinki university central hospital, psychiatry, Helsinki, Finland

* Corresponding author.

Introduction Earlier considered a disorder affecting only children, today worldwide adult ADHD prevalence is estimated at 2.5%. The core symptoms; inattention, hyperactivity and impulsivity, often persevere impacting many fields of life.

Objectives To estimate the prevalence of ADHD symptoms in the general Finnish adult population.

Methods We started with a population based and randomly drawn sample of 3000 adults, aged 18–44 years. When contacted, participants were provided three alternative ways to participate (online, letter, telephone interview). Using the adult ADHD rating scale (ASRS) screener all participants ($n=748$) were categorized into groups: possibly symptomatic (≥ 4 points), controls (≤ 2 points) and undefined (3 points). Fifty-seven possibly symptomatic consented to further evaluation by a telephone interview, together with two age- and gender matched controls each.

Results Using the results from the ASRS screener, we calculated a 10.96% prevalence. Analysis of the complete ASRS resulted in a 5.08% and the recommended two-step evaluation in a 3.34% prevalence, out of whom two thirds considered being moderately or severely impaired by the symptoms.

Conclusions This study suggests that a large number of adults in the general population are negatively affected by ADHD symptoms, almost all unrecognized by health care professionals. As ADHD is a burden for the patient, his family and the society, adult ADHD deserves greater attention in the future.

Health-related quality of life and work productivity of adults with ADHD: A UK web-based survey

P. Asherson^{a,*}, C. Kosmas^b, C. Patel^b, H. Doll^b, A. Joseph^c

^a Institute of psychiatry, psychology and neuroscience, London, United Kingdom

^b ICON clinical research UK Ltd, Abingdon, United Kingdom

^c Shire, Zug, Switzerland

* Corresponding author.

Introduction European data on health-related quality of life (HRQoL) in adults with attention deficit/hyperactivity disorder (ADHD) in the general population is sparse.

Aims and objectives To report HRQoL in UK adults with ADHD.

Methods UK residents aged 18–55 years with a diagnosis of adult ADHD completed an online, cross-sectional survey including questions on disease history, the EuroQoL Five Dimensions questionnaire with five-levels (EQ-5D-5L) and the Work productivity and activity impairment questionnaire: general health (WPAI:GH). ADHD symptom severity was assessed by telephone using ADHD rating scale version IV with adult prompts (ADHD-RS-IV).

Results The survey was completed by 233 participants (65.2% women; 77.3% white British), mean age 32.6 years (standard deviation [SD] 9.5), mean ADHD-RS-IV total score 43.46 (SD 7.88). Their mean EQ-5D-5L utility score of 0.74 (SD 0.21) was lower than the UK population norm of 0.86 (SD 0.23). [1] WPAI:GH scores indicated that health problems resulted in impairments of 32.04% in work productivity and 45.79% in regular daily activities. Regression analyses adjusting for gender, age and co-morbidities demonstrated associations between EQ-5D-5L utility scores and gender (men had lower scores, $P < 0.001$), work impairment due to health problems (increasing impairment was associated with lower scores, $P = 0.005$) and age (for each additional year of age, scores decreased by 0.007, $P = 0.010$).

Conclusions These results highlight the impact on health utility, work productivity and regular daily activities, and add to the description of the disease burden of adult ADHD in the UK.

This study was funded by Shire Development LLC.

³ Norfolk and Suffolk NHS foundation trust, city 2 community mental health team, Norwich, United Kingdom

⁴ Norfolk and Suffolk NHS foundation trust, North community mental health team, Norwich, United Kingdom

* Corresponding author.

Introduction A significant number of people are not detained in hospital following assessment under the Mental Health Act 1983 (MHA) for possible detention. However, since amendments in 2007, some studies show an increase in total patient detentions. There is currently a lack of published research describing both outcomes and their affecting variables.

Objectives To determine rates, outcomes and affecting variables of MHA assessments in Norfolk, 2001–2011.

Methods This observational study involved data collection from all 11,509 referrals for detention assessment under the MHA. Data was collected by Norfolk Social Services from 2001–2011 including age, gender and marital status.

Results Following assessment, 6903 (60.0%) were admitted; of those, 1157 (16.8%) were voluntary and 5746 (83.2%) were detained; 4606 (40%) were not admitted. Admission rates for males (50.4%) and females (49.5%) were similar. Detention rates increased with age: 37.6% of <18s; 47.1% of 18–64s and 61.4% of 65+. A greater proportion of married (57.5%) and widowed patients (58.2%) were detained, compared with patients who were single (48%). Accommodation status showed 52% of those living with other were detained versus 43.9% of those with no fixed abode.

Conclusions The finding that a higher proportion of married than single people, and of those living with others versus living alone, were detained following assessment is unexpected but significant and needs further investigation.

Dissociative symptoms are associated with neurocognitive dysfunction in patients with MDD

E. Berdzenishvili^{1,2,*}, G. Tcheishvili¹, M. Sinitsa²

¹ Acad. O. Gudushauri national medical centre

² Georgian centre for psychosocial and medical rehabilitation of torture victims

* Corresponding author.

Introduction It is widely reported that persons with major depressive disorder (MDD) show impaired performance on cognitive functioning, including frontotemporally mediated cognitive functions. The presence of cognitive dysfunction among patients with dissociative symptoms in trauma-related disorders may contribute to poorer treatment outcomes. Patients with major depressive disorder (MDD) frequently report dissociative symptoms. Here we investigate association of dissociative symptoms and neurocognitive dysfunction in patients with depression. We predicted that higher levels of dissociative symptoms among persons with MDD would be associated with lower scores on objective measures of frontotemporally mediated neurocognitive functions.

Methods Patients who met DSM-V diagnostic criteria for a primary diagnosis of recurrent MDD were recruited. The Hamilton Rating Scale for Depression (HAM-D) was administered to assess the severity of depressive symptoms. To assess dissociative symptoms participants completed the Multiscale Dissociation Inventory (MDI). Two groups of patients were selected and matched. One group consisted of 13 patients having MDD and dissociative symptoms and second group consisted of 12 patients having MDD only. To measure frontotemporally mediated cognitive functioning following tests were administered: Color Trails Test; Wisconsin Card Sorting Test; Conners' Continuous Performance Test (CPT). To examine group differences on clinical and neuropsychological scores, two-tailed independent samples *t*-tests was performed.

Results Group comparisons of performance on neuropsychological tests showed that participants with depression and dissociative symptoms performed worse on Color Trails Test Part 2 completion time, a measure of mental flexibility and processing speed. MDI depersonalization scores were correlated with measures of processing speed, mental flexibility and sustained attention. Specifically, Color Trails Test Part 2 scores were negatively correlated with depersonalization symptoms, where lower scores indicate slower completion time. Depersonalization symptoms on the MDI were also related to the CPT Hit Reaction Time Interstimulus Interval Change (a measure of vigilance), such that higher levels of depersonalization were related to better performance in a less active environment.

Conclusions Our results suggest that dissociation is related to specific subtle impairments in neurocognitive functioning. Dissociative symptoms should ideally be assessed before treatment, as they may influence MDD treatment response. The findings point towards the need to further examine the impact of dissociation on functioning in patients with depression.

Factors influencing the rate of incidents in a United Kingdom high secure psychiatric hospital: Weekend, ward round and diagnostic effect?

F. Lewis, H. Blott*, S. Bhattacherjee

West London mental health trust, forensic psychiatry, London, United Kingdom

* Corresponding author.

Introduction Broadmoor is a high secure psychiatric hospital divided into personality disorder (PD) and mental illness (MI) pathways. Whenever an incident occurs, it should be recorded. To better understand which factors influence the rate of incidents, such as diagnosis or intervention by medical and psychological staff, we examined the difference in the number of incidents recorded on weekdays versus weekends, ward round (WR) versus non-WR days and the PD versus MI pathways.

Method All incidents recorded over a one-year period (3.11.2014–2.11.2015) were examined. Extraneous incidents were excluded, leaving subgroups of “aggressive” (physical and verbal) and “physical” (excluding verbal) incidents which were analysed. Data were adjusted for the difference in number of beds in each pathway.

Results Of the 2369 incident reports included, more were recorded per day on weekdays than weekends, with little difference on WR versus non-WR days. The rates of both types of incidents were similar on both PD and MI admission wards, although the rate of “physical” incidents was 2.6 times higher and “aggressive” incidents 3.3 times higher in PD compared to MI rehabilitation wards.

Conclusion The findings suggest the presence of medical and psychological staff during the week, and possibly the requirements

they place on patients, may increase the rate of incidents within the hospital. Despite comparable rates on admission, MI rehabilitation wards have far fewer incidents than PD rehab wards, which may reflect the more intractable nature of PD versus MI. More work is required to confirm these findings.

An analysis of emergency leaves of absence from a United Kingdom high secure psychiatric hospital with a view to identifying ways to reduce their number

H. Blott*, C. Gordon, J. Bickford, C. Ross

West London mental health trust, forensic psychiatry, London, United Kingdom

* Corresponding author.

Introduction Emergency leaves of absence (ELOAs) from high secure psychiatric care are both costly and increase the risk posed to staff, patients and the general public. ELOAs were analysed to identify whether greater on-site physical health provision could reduce their number, and quantify the potential financial saving to the trust to do so.

Method All ELOAs from Broadmoor hospital between 15.5.15–14.11.15 were assessed by a team of psychiatrists and a GP to identify whether they were “avoidable”, “unavoidable” or “potentially avoidable” if measures were taken. For the “potentially avoidable” group, we then calculated the staffing cost of these LoAs to help ascertain whether these measures would be cost effective.

Results There were 30 ELOAs during the period assessed, costing £79,240 (Table 1). The table also shows which additional on-site services or training may have prevented these ELOAs, and the cost saving to the trust if they had.

Conclusions The number of ELOAs from the hospital could be reduced by increased on-site physical health provision and training. This would improve the quality of care patients receive, as well as reducing both the cost to the trust and the risk posed to staff, patients and the general public. We must also consider the large potential cost and risks associated with a patient absconding from an ELOA.

Table 1

	Percentage of total ELOAs (30)	Cost in 6 months (£)
Avoidable	7% (2)	3,973
Unavoidable	40% (12)	49,044
Potentially avoidable	53% (16)	26,223
Of which	Preventing	Potential saving
Watchful waiting	10% (3)	14,307
Onsite x-ray	30% (9)	8,326
Wound care/suturing	7% (2)	2,603
Equipment	7% (2)	2,271

Table to show number of emergency leaves of absence (LoAs) felt to be preventable, and the measures and potential savings associated with doing so

The relationship between grief process and attachment styles in the cases with the treatment of complicated grief: A prospective study

H.P. Caglar Nazali^{1,*}, E.A. Yildirim²

¹ Baltalimani Metin Sabanci bone and joint diseases education and research hospita, psychiatry, Istanbul, Turkey

² Bakirkoy research and training for psychiatry neurology neurosurgery, psychiatry, Istanbul, Turkey

* Corresponding author.

The attachment style is one of the significant factors affecting the grief process and complicated grief. This study aims to research the relation between the factors determining the sociodemographic features, the reactions of grief, the suicidal behaviour and the grief process on the patients who are followed and treated with the complicated grief diagnosis and the features of attachment. The study includes 45 patients directed to a therapy unit and meet the criterions of complicated grief diagnosis. 33 of those patients have completed their treatment. Sociodemographic and clinical data form applied to the patients at the beginning, to evaluate for comorbid psychiatric disorders structured clinical interview for DSM-IV axis I disorders, adult attachment style questionnaire (AASQ), grief scale, hamilton rating scale for depression (HDRS), suicide behaviors questionnaire (SBQ), suicide probability scale (SPS), experiences in close relationships inventory (ECRI) are applied on the participants and compared the results of the scales prior to and following the treatment. In the dimensional evaluation of attachment, ECRI avoidance score is high over the patients diagnosed with comorbid psychiatric disorders with complicated grief. During the first application of the treatment, while evaluating the attachment categorically, in the complicated grief patients attached with avoidance grief scale, behavioural base scale and SPS negative self base scale are higher compared to the group whose HDRS scores attached with secure. The results show that in complicated grief cases the avoidance attachment is both dimensionally and categorically related with the strength of grief reaction and additional psychiatric problems.

Cognitive disturbances and mood disorders in ischemic stroke

E.I. Davidescu*, D.A. Sasu, I. Buraga

UMF Carol Davila, neurology Colentina clinical hospital, Bucharest, Romania

* Corresponding author.

Introduction Ischemic stroke is in increasing incidence, so that long term sequels are of great importance for management of quality of life and economics issues.

Objectives To determine risk factors associated with cognitive disturbances, after ischemic stroke.

Aims Assessment of social and medical risk factors in outcome of cognitive disturbances.

Methods During 6 months, 268 patients with antecedents of ischemic stroke and associated cognitive disturbances installed in first year after major stroke, were assessed in neurology department. We performed neuropsychological tests as mini mental state examination, sunderland clock test and beck depression inventory. Patients and caregivers were also assessed for quality of life. 53% were males, from urban areas (69%) and mean age was 72.2 years.

Results We found risk factors as hypertension (88%), dyslipidemia (63%), diabetes mellitus (22%), atrial fibrillation (11%), smoking (35%) and drinking (55%). According to DSM-5 criteria, 62.5% of our lot had major cognitive disorder and 37.5% had a minor one; most of the patients with major dysfunction had ischemia in left middle cerebral artery (31.71%) associated with language deficits and executive dysfunctions, and on the second place was the vertebro-basilar localization of stroke (29.86%). Ischemia in right middle cerebral artery was present only in 20.52% of the lot. 27%

of our patients developed depression, more in patients with major neurological deficits.

Conclusions Efforts must be done for primary prevention of stroke, early detection of risk factors and correct treatment, and for cessation of toxic habits. Treating associated depression may improve patients' quality of life and increase comfort for caregivers.

Inflammatory bowel disease symptoms and cognitive fusion's impact on psychological health: An 18-month prospective study

I.A. Trindade, C. Ferreira*, J. Pinto-Gouveia

Faculty of psychology and education sciences, university of Coimbra, CINEICC, cognitive behavioural centre for research and intervention, Coimbra, Portugal

* Corresponding author.

Although inflammatory bowel disease (IBD) is known to be associated with lower psychological health, research regarding which specific symptoms may lead to psychological dysfunction in IBD patients is inexistent. Further, the role played by emotion regulation, including the maladaptive process of cognitive fusion, in IBD patients' psychological functioning is also scarcely explored in this population. The present study aimed at filling these research gaps. Two hundred and sixteen patients diagnosed with IBD filled self-report instruments on an online platform in three times. These waves of assessment occurred at baseline, and 9 and 18 months later. Results revealed that of the 10 measured IBD symptoms, only fatigue, bloody stools and abdominal distension at baseline were negatively associated patients' level of psychological health at Wave 3. Nevertheless, a hierarchical regression analysis demonstrated that none of these symptoms were significant predictors of psychological health measured 18 months later. When cognitive fusion at baseline was added to the model, it became the only significant predictor of psychological health at Wave 3, with an effect of -0.34 ($P < 0.001$). These findings suggest that it is not the experience of physical symptomatology that directly leads to lower psychological health in IBD patients, but rather the way patients deal with adverse internal experiences, i.e., the type of emotion regulation involved. This study reveals cognitive fusion as a harmful process for the determination of IBD patients' psychological functioning. Future studies should thus explore the meditational effect of cognitive fusion in the association between IBD symptomatology and decreased psychological health.

The presence of a subthreshold autism spectrum is associated with greater prevalence of mental disorders in parents of children with autism spectrum disorders

C.C.C. Gesi*, A. Lagomarsini, F.M. Barberi, A. Guzzetta, S. Calderone, G. Cioni, F. Muratori, L. Dell'Osso

Department of clinical and experimental medicine, university of Pisa, Pisa, Italy

* Corresponding author.

Introduction Autism spectrum disorders (ASD) are highly heritable and first degree relatives (especially fathers) of autistic probands have been shown to often manifest a set of subthreshold

autistic features. It is not known, however, the clinical significance of this subthreshold autism spectrum.

Objectives – to evaluate the prevalence of a subthreshold autism spectrum respectively in fathers and mothers of children with ASD; – to describe clinical correlates of parents with and without a subthreshold autism spectrum respectively.

Methods 36 fathers and 39 mothers of preschoolers with ASD were administered the autism-spectrum quotient (AQ), the adult autism subthreshold spectrum (AdAS spectrum), the trauma and loss spectrum (TALS), the SCID-5 and the social and occupational functioning assessment scale (SOFAS).

Results Fathers and mothers did not differ for both AQ and AdAS spectrum total and subscale scores. Overall, 13 parents (17.3%) scored higher than 45 on the AdAS spectrum, as indicative of the presence of a subthreshold autism spectrum. This group showed greater prevalence of mood, anxiety and feeding/eating disorders, greater utilization of antidepressants and higher scores on the TALS and the SOFAS than the group scoring lower than 45 (all $P < 0.05$).

Conclusions Fathers and mothers of children with ASD show autistic traits in equal measure. The presence of a subthreshold autism spectrum is associated to greater prevalence of mood, anxiety and feeding/eating disorders, to greater susceptibility to traumatic events and to lower levels of functioning.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁶ CIBERSAM, mental health, Madrid, Spain

* Corresponding author.

Introduction Social cognition enables the processing of social information and is needed to adapt one's behaviour to the perceived social scene. Its assessment is a very controversial issue, tests currently available often use unhelpful stimuli from the ecological point of view.

Aims To develop a test based on genuine social stimuli—not on their representations—and to do so, a controlled social situation is created in which participants can be evaluated on their abilities to perceive and process such information.

Method A script was prepared, consisting of several interactions which are staged before the participants by two members of the research team. The sample comprises 50 subjects, being on average 22 years old (56% women), who took this test, the MSCEIT and the MASC.

Results The application showed no incidence, no one detected that it was a previously prepared situation and they were not upset when this fact was revealed. A final selection of 18 items obtained a reliability of 0.701. Multidimensional scaling, partly showed the subdomains taken into account. The correlation matrix confirms the validity of the instrument. ($r = 0,465$ alpha $< 0,001$ with MASC. $r = 0,106$ alpha $> 0,05$ with MSCEIT).

Conclusions The instrument is applicable and tolerated by participants being evaluated with it. It is feasible to use it as a test to assess social cognition. It is mid-high reliability allows its use for research purposes. The correlation matrix confirmed validity, showing a significant and moderate connection with MASC and no association with any of the scales of MSCEIT.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Constantine the philosopher university in Nitra, department of psychology sciences, Nitra, Slovak Republic

* Corresponding author.

Background The views of one's self-stigma and quality of life in patients with schizophrenia and depressive disorders are significant subjective notions, both being proven to affect patient's functioning in life. The objective of this research was to find out the quality of life and self-stigma in connection with demographic factors and compare the two groups of patients in those variables. **Method** In a cross-sectional study, the outpatients with the schizophrenia spectrum disorders and depressive disorders completed the quality of life satisfaction and enjoyment questionnaire, the internalized stigma of mental illness scale and a demographic questionnaire during a routine psychiatric control. Furthermore, both patients and their psychiatrists evaluated the severity of the disorder by clinical global impression-severity scale.

Results The quality of life of patients with depression or schizophrenia spectrum disorders did not significantly differ between the two groups. In both groups, unemployment was perceived to be a significant factor decreasing the quality of life. Self-stigma was detected to be higher in patients with schizophrenia as compared to the depressive patients. A strong correlation was found between the two scales, meaning that those with higher levels of self-stigmatization were less prone to see their life as fulfilling and joyful.

Conclusions The present study shows that the degree of the internalized stigma can be an important aspect linked to the quality of life irrespective of the diagnostic category.

Birth order and psychiatric morbidity

J. Hussain

Indus medical college, psychiatry, Tando Muhammad Khan, Pakistan

Objectives: – to determine the frequency of sociodemographic factors (birth order) among subjects attending a psychiatric clinic; – to establish psychiatric diagnosis of subjects; – to bring out dominating frequencies of birth orders of the patient in relation with related diagnosis.

Methodology This cross-sectional study was conducted at outpatient clinic of Liqueate university hospital Hyderabad during 1st January 2012 to 31st January 2012. One hundred consecutive subjects attending a psychiatric OPD with psychiatric symptoms, were assessed for the total siblings, birth order among siblings and their psychiatric diagnosis. The socio-demographic data was recorded through a designed semi-structured proforma, and diagnosis was

established by diagnostic and statistical manual-IV text revised criteria (DSM-IV TR).

Results The age range remained 9–60 years and numbers of siblings were in the range of 1–12 siblings and fourth birth order was found to be dominant in this study to have psychiatric morbidity (38%). While, frequency of first order birth was 18%. Generalized anxiety disorder and depressive (GAD) disorders were dominant diagnosis (55%), while GAD was more in the male gender. **Conclusion** This study shows that psychiatric morbidity was more common in the lower birth order. This study may be carried out at different centers of psychiatry for the better assessment of psychiatric morbidity.

Cultivating the compassionate self against depression: An exploration of processes of change

M. Matos^{1,*}, J. Duarte¹, C. Duarte¹, J. Pinto-Gouveia¹, P. Gilbert²

¹ University of Coimbra, cognitive and behavioral centre for research and intervention CINEICC, Coimbra, Portugal

² Derbyshire Healthcare NHS foundation trust, centre for compassion/mental health research unit, Derby, United Kingdom

* Corresponding author.

Introduction Compassion and self-compassion can be protective factors against mental health difficulties, in particular depression. The cultivation of the compassionate self, associated with a range of practices such as slow and deeper breathing, compassionate voice tones and facial expressions, and compassionate focusing, is central to compassion focused therapy (Gilbert, 2010). However, no study has examined the processes of change that mediate the impact of compassionate self-cultivation practices on depressive symptoms. **Aims** The aim of this study is to investigate the impact of a brief compassionate self training (CST) intervention on depressive symptoms, and explore the psychological processes that mediate the change at post intervention.

Methods Using a longitudinal design, participants (general population and college students) were randomly assigned to one of two conditions: Compassionate self training ($n=56$) and wait-list control ($n=37$). Participants in the CST condition were instructed to practice CST exercises for 15 minutes everyday or in moments of stress during two weeks. Self-report measures of depression, self-criticism, shame and compassion, were completed at pre and post in both conditions.

Results Results showed that, at post-intervention, participants in the CST condition decreased depression, self-criticism and shame, and increased self-compassion and openness to receive compassion from others. Mediation analyses revealed that changes in depression from pre to post intervention were mediated by decreases in self-criticism and shame, and increases in self-compassion and openness to the compassion from others.

Conclusions These findings support the efficacy of compassionate self training components on lessening depressive symptoms and promoting mental health.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The prevalence of post-traumatic stress disorder (PTSD) in Korean parents lost their children by the tragic sinking of ferry Sewol

S.J. Kim

Ajou university school of medicine, department of psychiatry, Suwon, Republic of Korea

A South Korean passenger ferry, the Sewol, carrying 476 people, capsized and sank in 2014 resulting in 295 deaths and 9 missing. Most were high-school students on a school trip (246 deaths, 83.4%) and many parents who lost their children had suffered from a wide range of mental and physical health consequences. This research examines the extent and intensity of ongoing psychological distress and PTSD symptoms among the parents 2 years after the disaster. The 141 parents of the high-school victims agree with research participation were surveyed using a questionnaire on sociodemographic data. We conducted the structured clinical interview including PTSD and suicide assessment for them. Among the 141 subjects, 56.0% ($n=79$) meet the PTSD diagnostic criteria, suggesting that, after two full years, more than a half of them are still suffering from chronic psychological pains. This result is higher than any other PTSD study about indirect victims. In particular, 42.6% ($n=60$) reported suicidal ideation and 4.3% ($n=6$) actually attempted suicide but failed. These figures are on the order of 10 to 100 times higher than the national prevalence. This research is characterized by homogeneity of the subjects in that they were all the parents of young adolescent victims. After two years of traumatic experiences, more than a half of the interviewed parents who lost their children are still suffering from the PTSD. These findings suggest that post-disaster PTSD can be larger and last longer when the relationship was more intimate and the death of the victim was less expected.

The effect of the mental health improvement programs in firefighters

T.Y. Choi^{1,*}, J. Kim¹, J. Lee¹, S. Chang², S. Jung³¹ Catholic university, Daegu school of medicine, psychiatry, Daegu, Republic of Korea² Kyungpook national university school of medicine, psychiatry, Daegu, Republic of Korea³ Keimyung university school of medicine, psychiatry, Daegu, Republic of Korea

* Corresponding author.

Objectives The purpose of this study was to investigate the effectiveness of the mental health improvement programs in Korean firefighters through cooperation with the urban fire station. And we assessed the firefighter's degree of traumatic events and psychopathologies including depression, anxiety, suicidal ideation and insomnia.

Methods A mental health improvement program was provided to 502 firefighters working at Daegu, Gumi and Ulsan during 8-week period. The program included not only an evaluation and treatment of psychiatric symptoms through counseling but also a psychoeducation for mental health awareness. The validated Questionnaires to measure psychiatric symptoms were used; symptoms included depression, anxiety, suicidal thoughts and insomnia. Subjects were

divided to two groups; PTSD high-risk group and non-high risk group. Psychopathological levels were compared before and after the program.

Results PTSD high-risk group included 57 subjects (11.35%) and non-high risk group included 445 subjects (88.65%). Before the program, PTSD high-risk group showed higher depression, anxiety, insomnia scores statistically significant. Multiple logistic regression analysis with PTSD high-risk group as a dependent variable showed depression as a factor for firefighters to become PTSD high-risk group compared to those not depressed. Insomnia turned out to be another variant. The program resulted in significant decrease total scores of BDI and ISI for PTSD high-risk group.

Conclusions The results on this study showed that higher levels of depression and insomnia especially influenced the manifestation of PTSD in firefighters. The evaluation and management of psychopathologies including depression, insomnia with traumatic events for firefighters can be helpful.

Perinatal dissociation during premature childbirth: A comparative study

S. Ellouze¹, J. Aloulou¹, A. Ben Thabet², N. Halouani^{1,*}, A. Gargouri², O. Amami¹¹ Hedi Chaker university hospital, psychiatry "B", Sfax, Tunisia² Hedi Chaker university hospital, neonatology department, Sfax, Tunisia

* Corresponding author.

Premature childbirth is sometimes perceived as a painful and traumatic experience, in which mothers can manifest dissociative symptoms. Our study aims to evaluate dissociative symptoms during premature childbirth compared with full-term delivery and to identify predictors of perinatal dissociation. We conducted a cross-sectional, descriptive and analytical study, including 97 mothers of premature infants who presented to the outpatient unit of neonatology at the UH Hedi Chaker of Sfax in Tunisia. For each mother, we collected sociodemographic and obstetric data. We used the peritraumatic dissociative experiences questionnaire (PDEQ) for screening dissociative symptoms during labor. We assessed severity of prematurity by the perinatal risk inventory (PERI). Responses were compared with a control group of 80 mothers of full-term infants. Average age of mothers was 30.2 years. Average gestational age was 32.82 weeks. Pregnancies were single (83.5%) or twins. 77.3% of mothers gave birth by caesarean section. Prematurity was unexpected by 56.7% of them. According to the PERI, 47.4% of newborns were considered as high-risk preterm infants ($PERI \geq 4$). The average score of PDEQ was 16. The prevalence of perinatal dissociation for this sample (20.6%) was significantly higher compared with the control group ($P=0.014$). It was also correlated to unexpected prematurity ($P<0.001$) and a PERI score ≥ 4 ($P=0.023$). Our results show that perinatal dissociation is more frequently occurring in preterm childbirth, especially when prematurity is severe and unexpected. Early interventions providing adequate information and support during delivery for mothers at risk of developing perinatal dissociation can alleviate such distress and prevent the development of subsequent post-traumatic stress disorder.

Gender differences in overgeneralized autobiographical memory in survivors of torture with posttraumatic stress disorder

V. Giannouli^{1,*}, S. Popa²

¹ Aristotle university of Thessaloniki, school of medicine, Drama, Greece

* Corresponding author.

Introduction Persons suffering from PTSD show less episodic specificity in recalling autobiographical memories producing what is often referred to as “overgeneralized memories” as it is shown by scientific studies.

Objective In this research, we are focusing our attention on whether this phenomenon is the same for both men and women or it shows gender specificity.

Method The rehabilitation center for torture victims “Memoria” provided information about people who have recently experienced torture. Some of these victims of torture volunteered to participate in the current research. The participants were assessed with the Harvard trauma questionnaire in order to identify whether they suffer from PTSD or not. A sample of 40 torture survivors with PTSD was selected for the research—20 men and 20 women. The age range is between 20 and 45. On a computer screen, we presented the cue words with the task to recall a past event and time period (month or 5–20 years). The participants pressed a computer key indicating when an event had been recalled, and then, it was described in an audio recorder. The responses were scored 3 for a specific event, 2 a repeated over time event, 1 a general event, 0 none.

Results Both sexes revealed a significant correlation between specificity for autobiographical memories and episodic simulations, only in case of women this correlation is higher compared with men ($r=0.83$ $P<0.001$).

Conclusions Further research is needed in order to eliminate causalities and to extend the results on other populations.

Neuroeconomic approach to trauma related psychopathology: A version to ambiguous losses in PTSD

I. Harpaz-Rotem^{1,*}, R. Jia², L. Ruderman³, R. Pietrzak¹, I. Levy⁴

¹ Yale university, psychiatry, New Haven, USA

² Yale university, interdepartmental neuroscience program, New Haven, USA

³ Yale university, comparative medicine, New Haven, USA

⁴ Yale university, comparative medicine and neuroscience, New Haven, USA

* Corresponding author.

Psychiatric symptoms typically cut across traditional diagnostic categories. In order to devise individually-tailored treatments, there is a need to identify the basic mechanisms that underlie these symptoms. Behavioral and neuro-economics methods provide a framework for studying these potential mechanisms. We utilized this framework to examine aspects of trauma-related symptomatology and its potential link to individual uncertainty attitudes. We distinguish between attitudes towards uncertain outcomes with known (“risk”) and unknown (“ambiguity”) probabilities, and between attitudes towards uncertain gains and uncertain losses. fMRI data were obtained from 57 combat veterans (30 with PTSD, and 27 without PTSD) who made choices involving risky and ambiguous options, which were used to estimate risk and ambiguity attitudes

in the gain and loss domains. Veterans with PTSD were more averse to ambiguity, but not risk, compared to veterans without PTSD, when making choices between possible losses, but not gains. The degree of aversion was associated with anxious arousal symptoms, as well as with the degree of combat exposure. A whole brain analysis indicated association between activation in specific brain areas implicated in decision-making and severity of PTSD. Moreover, ambiguity attitudes fully mediated the association between combat exposure and anxious arousal symptoms. These results provide a foundation for the causal association between ambiguity attitudes and trauma-related symptoms, as well as etiology of the neural underpinnings of these behavioral outcomes. Results demonstrate the potential of neuroeconomic and behavioral economic techniques for devising objective and incentive-compatible diagnostic tools, and investigating the etiology of psychiatric disorders.

Trauma and the unborn child: PTSD, major depression and relationship quality following late pregnancy loss

D. Horesh^{1,*}, M. Nukrian², Y. Bialik¹

¹ Bar Ilan university, psychology, Ramat Gan, Israel

² Hadassah Ein-Karem medical center, obstetrics and gynecology, Jerusalem, Israel

* Corresponding author.

Background and objective Late pregnancy loss (PL) is recognized as a very difficult life experience. Often, PL is regarded as a “feminine” trauma, experienced individually by the woman, thus neglecting the role of the parental dyad in coping with the loss. This study aimed to examine:

- the prevalence of PTSD and major depressive disorder (MDD) following late PL;
- the role of spousal relationship measures in vulnerability and resilience following PL.

Methods Participants were 100 women, ages 24–49 ($M=35.07$, $SD=5.28$), who have experienced late PL. The mean pregnancy week of loss was 27.29, with the average woman being 22 months post-loss. 84.6% experienced stillbirth. Participants completed self-report questionnaires assessing PTSD, MDD, dyadic adjustment and dyadic self-disclosure.

Results We have found high rates of both PTSD (32.7%) and MDD (53%) among women following late PL, as well as high PTSD-MDD comorbidity rates. Interestingly, a negative association was found between the number of previous pregnancy losses and the severity of MDD, perhaps indicating an inoculation process. Both PTSD and MDD were negatively associated with the levels of dyadic consensus, dyadic self-disclosure regarding guilt and shame, and dyadic affectional expression.

Conclusions Late PL entails a heavy burden of PTSD and MDD, presumably since mothers are already strongly attached to their unborn child. PL is often experienced by both expecting mother and father. Thus, the quality of the spousal relationship following PL is an important protective factor. Therefore, there is a pressing need for novel interventions in couples therapy following PL.

Introduction Patients with post-traumatic stress disorder (PTSD) have shown disturbances in visual information treatment. However, most of studies demonstrated attentional bias towards emotional stimuli by using non-ecological paradigm. The paradigm of change blindness offers the possibility of studying sensitivity to the sudden interruption of visual information with ecological stimuli. **Objectives/Aims** To compare the explicit detection with the implicit detection by using respectively motor response and eye tracking in patients with PTSD and controls.

Methods Fifteen patients with PTSD and fifteen healthy controls had to detect changes in 96 scenes with (1) no change, (2) one neutral change or (3) one emotional pleasant or unpleasant change. We measured the participant's speed and accuracy in explicitly reporting the changes via motor responses, and their capacity to implicitly detect changes via eye movements.

Results The patients showed a trend towards slower explicit detection for the emotional change ($P=0.06$) and more specifically for unpleasant change ($P=0.054$). The two groups did not differ for implicit detection.

Conclusion Patients tend to explicitly detect more slowly emotional change (but not neutral), especially for unpleasant change. This could be the result of a lack of access to consciousness of the emotional information. The emotional visual information treatment in PTSD could require more attentional processes than the non-emotional visual information and then lead to a decrease of the available attentional resources for the explicit task.

Comparison of ten-years risk of fatal cardiovascular events calculated by heartscore in diabetic patients with and without post-traumatic stress disorder (PTSD) comorbidity

N. Lucev^{1,*}, A. Vuk¹, I. Simunovic Filipic², I. Filipic¹

¹ Psychiatric hospital Sveti Ivan, department of psychiatry, Zagreb, Croatia

² The university hospital centre Zagreb KBC Zagreb, department of psychological medicine, Zagreb, Croatia

* Corresponding author.

Introduction Cardiovascular diseases (CVD) are the leading cause of death and disability-adjusted life years lost globally. Recent studies have shown that post-traumatic stress disorder (PTSD) predicts higher risk of cardiometabolic diseases, specifically cardiovascular disease and diabetes type 2.

Aims To assess cardiovascular event risk differences between diabetic patients with and without PTSD comorbidity.

Objectives To explore a ten-year risk of fatal CVD events in diabetic patients with and without PTSD; to gain better insight in potential different functioning patterns in these patient subgroups.

Methods We investigated a cross-sectional sample consisting of 390 psychiatric inpatients and outpatients. Ten-years risk of fatal CVD events calculated by HeartScore, European society of cardiology. Europe high-risk version was used. The risk estimation is made based on: gender, age, smoking, systolic blood pressure and total cholesterol.

Results By analysis of covariance, we controlled possible confounding effects of gender, age, education, marital status, number of household members, work status, average monthly income per household member, body mass index (kg/m^2), number of somatic comorbidities, number of psychiatric comorbidities, duration of PTSD, clinical global impression scale-severity of PTSD at diagnosis. After the adjustment for all these variables, interaction of PTSD and T2DM was significantly associated with CVD risk ($P<0.001$; $\text{Eta}^2=0.04$).

Conclusion A significant fatal CVD event risk differences between diabetic patients with and without PTSD comorbidity were found. Better awareness of possible underlying determinants provides better optimal individual approach planning, likewise effective prevention and control of cardiovascular diseases.

Benefits of EMDR therapy on the memory in the treatment of PTSD

S. Sassi Andrade Vieira, M. Di Giorgio, E. Cohen, M. Caurand, A. Manchon, A. Quaderi, J. Palazzolo*

Université de Nice, psychology, Nice, France

* Corresponding author.

According to some studies, 80% of subjects suffering from post-traumatic stress disorder (PTSD) present twice the risk of developing an insanity as they age because of the high level of stress that has been induced. Indeed, the triggered trauma has a deleterious effect on the establishment of the stress' axis (the hypothalamic pituitary adrenal axis) which is then not able to regulate itself. As a consequence, the hippocampal neurons will be attacked by an excess of cortisol. Memory's dysfunction is central in the symptomatology of PTSD, particularly in respect to encoding and recall. The hippocampus is able to transfer information to the prefrontal cortex. Actually, subjects with PTSD present less activity in the prefrontal cortex triggered by a decrease of encoding and recall capacities. EMDR therapy (eye movement desensitization and recruitment) allow for a fast relief of symptoms by a bilateral alternate stimulation (SBA). Indeed, saccadic eye movements stem affect related to the traumatic event and process the associated cognitions. During the desensitization phase in EMDR, we noticed an increase in activity of the brain's prefrontal, ventromedial, amygdala and thalamic regions. Indeed, the recall of traumatic memories goes through implicit emotional valence regions and associative areas for which the experience is already deeply integrated. After comparing cerebral activity before and after the therapy, researches on EMDR shows that a reduction of stress' symptoms has some sensitive link to PTSD (in prevention to dementia).

* Corresponding author.

The aim of this study was to analyse frequency of embitterment in war veterans with Posttraumatic stress disorder (PTSD) as well as the potential impact of embitterment on the development of chronic PTSD.

Patients and methods It was analyzed 174 subjects (from Health Center Zivinice/mental health center) through a survey conducted in the period from March 2015 to June 2016, of which 87 war veterans with PTSD and control subjects 87 war veterans without PTSD. The primary outcome measure was the post-traumatic embitterment disorder self-rating scale (PTED Scale) who contains 19 items designed to assess features of embitterment reactions to negative life events. Secondary efficacy measures included the clinician-administered PTSD scale–V (CAPS), the PTSD checklist (PCL), the combat exposure scale (CES), the Hamilton depression rating scale (HAM-D), the Hamilton anxiety rating scale (HAM-A) and the World health organization quality of life scale (WHOQOL-Bref). All subjects were male. The average age of patients in the group war veterans with PTSD was 52.78 ± 5.99. In the control group, average age was 51.42 ± 5.98. Statistical data were analyzed in SPSS statistical program.

Results Comparing the results, *t*-tests revealed significant difference between group veterans with PTSD and control group ($t = -21.21$, $P < 0.0001$). War veterans group with PTSD ($X = 51.41$, $SD = 8.91$), control group ($X = 14.39$, $SD = 13.61$).

Conclusion Embitterment is frequent in war veterans with PTSD.

Keywords Embitterment; Posttraumatic embitterment disorder; Posttraumatic stress disorder; War veterans; Bitterness

The role of personal value preferences in predicting army stress

E. Tartakovsky^{1,*}, N. Rofe²

¹ Tel-Aviv university, social work, Tel-Aviv, Israel

² IDF, mental health, Tel-Aviv, Israel

* Corresponding author.

Background The military is a stressful environment, and many service persons experience army stress. Therefore, it is important to understand the factors affecting army stress and stress resiliency.

Objective The present study examines the connections between personal value preferences and army stress, applying the value congruency paradigm.

Method Male soldiers serving in three combat units in the Israeli Defense Forces participated in the study ($n = 257$).

Results The results obtained demonstrated that personal value preferences explained a significant proportion of the variance in army stress beyond the socio-demographic variables. A lower stress level was associated with a higher preference for the values of societal security, conformity, achievement, and universalism, and with a lower preference for the face and personal security values.

Conclusions The research promotes our understanding of the relationships between general motivational goals expressed in personal value preferences and stress in the military context. In addition, the results obtained indicate the possible relevance of using values for selecting and preparing recruits who will most likely adjust well to the army framework. Finally, some value-oriented interventions that may be used for promoting the soldiers' psychological adjustment during their army service are suggested.

* Corresponding author.

Introduction Intrusive traumatic reminiscences are among the most distressing and salient characteristics of post-traumatic stress disorder (PTSD). Associated with involuntary onsets, emotional disturbances and consciousness-related impairments, such symptoms suggest that memory functioning could be impaired in PTSD. While there is a growing body of research on experimental assessments of memory in patients with PTSD, inconsistent results remain.

Objective Using an experimental methodology, this study aims to measure memory in PTSD in consideration of central features of intrusive symptoms, especially emotional, inhibitory and consciousness-related memory impairments.

Method 34 patients diagnosed with PTSD were compared with 37 non-PTSD controls on an item-cued directed forgetting paradigm for emotional words combined with a remember/know recognition procedure.

Results Results confirmed prior findings of an increased and peculiarly conscious recognition of trauma-related words in PTSD. Interestingly, our results showed that, despite general memory inhibitory deficits, PTSD patients, if requested, presented a preserved ability to inhibit this improved recollection of trauma-related words.

Conclusion While our findings highlight a biased memory functioning in favour of threatening stimuli in PTSD, inhibitory deficits for such information was not reported to play a role on this effect. Conversely, it seems that instead of inhibitory deficits, patients presented a preferential treatment of threat concordant with vigilant-avoidant models of information processing. Focusing on memory impairment in treatment for PTSD appears of prime importance. Our findings regarding preserved inhibitory skills for threat memories in the disorder could be an interesting clue for therapeutic interventions on intrusive symptoms.

* Corresponding author.

Grief is a normal response to loss of someone to whom a bond was formed; however, prolonged grief is considered pathological. Persistent complex bereavement disorder (PCBD) is defined as a persistent longing for the deceased over 12 months. Several treatment ways have been used for traumatic loss including eye

movement desensitization and reprocessing (EMDR). In the current case series, effectiveness of EMDR on three PCBD patients will be indicated. Three patients applied to the clinic with similar complaints based on different traumatic backgrounds; commonly, all experienced death of a first-degree relative. Complaints of the patients were over-thinking about the deceased, sleep disturbances, self-blaming, social isolation, avoiding talks about lost relative, and loss of interest in activities. After pre-interviews, they were advised EMDR therapy. One session of EMDR was applied to two of the patients, and two EMDR sessions were conducted on one of them. After the sessions, the patients reported not feeling guilty about the loss anymore, returning their normal routines, feeling better, and showing decreased avoidance. Additionally, the scores of scales (CAPS, BAI, BDI, and IES-R) significantly declined. EMDR therapy can show successful results in a shorter time than other treatment ways used for PCBD treatment [1].

* Corresponding author.

Introduction Pereira et al. (2013) adapted to the antenatal period and validated a shorter version of the original 35-items Postpartum Depression Screening Scale (PDSS [1]), composed of 24 items, selected from the exploratory factor analysis matrix. In their study, the researchers considered this version a useful alternative to evaluate depressive symptoms in pregnancy, taking into account its reliability, concurrent validity and satisfactory combinations of sensitivity and specificity to screen for antenatal depression.

Aim To confirm the four dimensions' structure of the PDSS-24 using confirmatory factor analysis.

Methods 616 women (mean age: 32.29 ± 4.466) in the second trimester of pregnancy (mean weeks of gestation = 17.13 ± 4.929), with uncomplicated pregnancies, completed the PDSS-24 while waiting for their routine prenatal consultation at local health medical centers.

Results The 4-dimensional model of PDSS-24 presented good fit ($\chi^2_{[242]} = 893,275$; RMSEA = 0.067, CFI = 0.934, TLI = 0.94, PGFI = 0.717; $P < .001$). The PDSS-24 Cronbach's alpha was $\alpha = 0.90$; all factors presented good/excellent reliability: Derealization and failure ($\alpha = 0.87$); Concentration difficulties and anxiety ($\alpha = 0.81$); Suicidal ideation ($\alpha = 0.94$), and sleeping difficulties ($\alpha = 0.89$).

Conclusion This further validation study emphasizes that PDSS-24 is an adequate measure of antenatal depressive symptoms. To better distinguish it from the version to use in the postpartum (PDSS-21 [2]), from now on, we will denominate it perinatal depression screening scale-24.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Background When new mothers do not understand how to interact with their newborn babies, they would increase anxiety, even decrease the quality of parent-infant interactions. Previous studies indicate that the postpartum parenting education for first-time-mothers can improve the quality of mother-infant interactions in first two months. This study aimed to evaluate the long-term effectiveness of parenting education for postpartum women during the first year.

Methods The study recruited 81 healthy first-time-mother infant dyads from the medical center in Taipei city. The experimental and control groups received extra education by way of a 40-minute videotape and normal postpartum care, respectively. Data from around first week (T1), followed by the third (T2), sixth (T3), ninth (T4), and twelfth (T5) month postpartum are collected. Assessment scales such as the Edinburgh perinatal depression scale (EPDS), the Chinese version of the parenting sense of competence scale (C-PSOC), and the Nursing child assessment teaching scale (NCATS) used for videotaped mother-infant interactions measurement were used in the study.

Results The analytical results show that the quality of mother-infant interaction increased at T2, T3, T4, and T5 in the experimental group (Fig. 1). No different change in maternal sense of competency was found in the experimental and control groups from T1 to T4. However, a positive change in sense of parenting competency at T5 was found in the experimental group (Fig. 2). No difference in postpartum depression was found between the two groups (Fig. 3).

Conclusions The first-time-mothers parent education has long-term effectiveness in the mother-infant dyad interaction quality.

Prevalence and risk factors of postpartum depression

R. F Cherif*, I. Feki, R. Sellami, D. Trigui, I. Baāti, J. Masmoudi
CHU Hédi Chaker Sfax, psychiatrie A, Sfax, Tunisia

* Corresponding author.

Introduction Childbirth represents for women a time of vulnerability to postpartum mood disorders. These disorders range in severity from the early maternal blues to postpartum psychosis. Along this spectrum is postpartum depression (PPD) that may have many risk factors.

Objectives The study aims to examine the prevalence of PPD and associated risk factors among a sample of Tunisian women receiving cares in the hospital of Sfax.

Methods This is a descriptive cross-sectional study regarding 150 parturients examined during the first and the sixth week post-delivery. The EPDS (Edinburgh postnatal depression scale) was used to assess PPD.

Results The total sample had a mean age of 29.61 years. During the sixth week study period, 126 of 150 were examined. Almost all of the women have a low school level (82.7%). Only 9.3% had a personal psychiatric history. Multiparity was found in 43.3% of cases. The current pregnancy was undesired in 15.3% of cases. Sympathetic signs of pregnancy were reported by 64.7% of women. The prevalence of PPD in the first week was 14.7% and 19.8% in the sixth week after delivery. The PPD was associated with the maternal age (> 35 years), the low school level, the existence of mood personal background, the parity, the difficulty to accept the pregnancy and sympathetic signs of pregnancy.

Conclusion Postpartum depression is common on our sample. Identifying risk factors of PPD allows clinicians to detect subgroups of women with an increased vulnerability who might receive early psychiatric care.

The impact of harassment and discrimination on the mental health of lesbian, gay and bisexual people

H. Pereira

University of Beira interior, psychology and education, Covilhã, Portugal

Introduction Despite growing acceptance of same-sex sexuality in the Western World, identity development of lesbian, gay and bisexual (LGB) individuals is still restricted by negative societal attitudes, which maintain the experience of stigmatization and discrimination.

Objectives The purpose of this study was to document the frequency of discriminatory events experienced by sexual minorities and their association with indicators of mental health in a Portuguese self-identified LGB sample.

Aims To determine the association of harassment and discrimination with levels of mental health, and to establish a predictive relation between these variables.

Methods A total of 610 LGB participants completed an online survey (mean age = 34.48, SD = 11.54). Most participants were single and self-identified as gay (73.8%). The survey included the following categories of survey items: demographic information, mental health, and discrimination experiences. Mental health was measured using the subscale of Emotional Wellness from the SF-36 questionnaire and the K10 questionnaire.

Results Between one-fifth and one-fourth of the participants in this sample frequently felt the need to hide their sexual orientation to prevent discrimination experiences. Close to 20% reported having suffered from verbal abuse, followed by close to 10% who suffered from written threats, harassment, and physical threats. A hierarchical multiple regression analysis was performed to assess the effects of anticipated and actual discrimination on mental health. The analysis explained 17% of the overall variance.

Conclusions Stigma/discrimination create discriminatory experiences which impact LGB people's mental health.

Gender differences and temperaments affective, impulsivity, sensation seeking and traits of schizotypal personality

F. Ricci*, A. Ventriglio, M. Pascucci, A. Bellomo
 University of Foggia, institute of psychiatry, Foggia, Italy
 * Corresponding author.

Background In the literature, the growing interest to the gender such as variable expression and treatment of psychiatric disorders, it is emerged in a considerable number of fields. Gender differences have become the subject of numerous investigations, in order to verify how the sex variable might affect the psychopathology.

Aims We propose to evaluate the role of gender differences in the development of traits of schizotypal personality, impulsivity, SS and their influence in the definition of temperamental component.
Materials We recruited 173 healthy subjects, between 18 and 65 years, who completed the following tests: BIS-11; SPQ; SDS; SAS; HCL-32; TEMPS-A; SSS.

Results The bivariate analysis by gender shows scores for the hyperthymic temperament significantly higher among males compared to the scores for the female sex, which, in turn, presents higher scores for cyclothymic. The levels of anxiety and depression are higher among women while levels of sensation seeking are higher among men. Although the male gender is associated with a greater sensation seeking, compared to women, it is not showed a higher correlation with the different types of impulsivity. We can find significant differences to the subscales for the SPQ between the two genders.

Conclusions The examination of these data may suggest the existence of differential specific features of gender that, in the presence of psychopathology, become more easily detectable; particularly in the male gender, it seems to emerge more impulsive behavior and activation compared to the female gender in which instead it seems to prevail a tendency to emotionality and introversion.

Systematic risk assessment in a mother-baby unit (MBU)–Importance for maternal and infant safety

G. Saraf^{1,*}, P. Chandra², G. Desai², H. Thippeswamy²

¹ Bhopal memorial hospital and research centre, psychiatry, Bhopal, India

² National institute of mental health and neurosciences, psychiatry, Bangalore, India

* Corresponding author.

Introduction Systematic assessment of risks is an essential component of care in psychiatric mother baby units. Self-harm, infant neglect and harm or the vulnerable physical health of both mother and infant may all pose risks.

Aim Development of a risk assessment tool and risk assessment among mother–infant dyads at a MBU in Bangalore, India.

Methods Based on data from 200 admissions, doctors and nurses of the unit developed a 15-item tool for risk assessment. Risk was assessed by both nurses and doctors among 58 consecutive mothers admitted to the unit. Risk domains included risks to self, to infant, related to infant health and feeding and violence faced by mother. Frequencies of various risks were calculated. Nurses' risk assessments were compared to the residents' risk assessments.

Results The mean age of the mothers was 25 (± 4) years, age of infant 4 (± 4) months and duration of episode was 4 (± 14) months.

Diagnoses included acute polymorphic psychosis (30%), BPAD (27%) and depression (21%). 47% had high suicidal risk and 28% had made an attempt in the current episode. 22% had expressed ideas of infant harm and 24% had physically harmed the infant. 48% of mothers had been physically violent. Multiple risks were seen in 47%. Doctors were able to identify risks more often than nurses.

Conclusion Risks for self-harm, infant harm and related to infant health were high. Systematic risk assessment by both nurses and doctors is important in an MBU to ensure adequate care for the mother infant dyad.

Prevalence and related factors of postpartum depression

A.A. Sayin^{1,*}, B. Burcak Annagur¹, A. Annagur²

¹ Selcuk university, department of psychiatry, Konya, Turkey

² Selcuk university, department of neonatology, Konya, Turkey

* Corresponding author.

Objective The aim of this study was to investigate the prevalence of postpartum depression among women and determine which factors are related this clinical condition.

Methods The study included 206 women who were admitted to the department of child health and diseases neonatal intensive care unit in Selcuk university faculty of medicine within six weeks postpartum period. First SCID-I and demographic data form for the participants who were volunteer to participate the study were filled. Then, Edinburgh postpartum depression scale, multidimensional scale of perceived social support, Beck anxiety inventory and maternal bonding scale were applied to all participants.

Results We found that 6.8% ($n = 14$) of mothers have postpartum depression. Then we compared the two groups postpartum depression (PPD) and non-postpartum depression (NPPD). In terms of socio-demographic characteristics and found a significant difference only in the level of economic status. Socio-economic status was lower in the group with PPD. In addition, social support received during pregnancy was significantly lower in the group with the PPD. Peripartum or any time depression history and comorbid psychiatric disorders were related factors with PPD. EPDS scores were significantly higher and MSPSS scores were significantly lower in the group with PPD.

Conclusion Postpartum depression has many negative consequences for both mother and baby. In the present study, we found that postpartum depression rates were consistent with previous studies. Early detection, prevention and treatment of postpartum depression is very important for the postpartum women who have a higher risk for depression.

Prenatal exposure to maternal depression and its influences on infant development and behaviour

N. Shakel*, N. Shakel

Latvian university, medicine faculty, Rīga, Latvia

* Corresponding author.

Introduction Depression is one of the most common mental disorders worldwide. Women are more at risk of depression while they are pregnant, and during the first weeks and months of postpartum period. Perinatal depression, might influence the children's development during pregnancy as well as it can have negative affect and delay in child postnatal development.

Materials and methods Pregnant women undergoing antenatal care in Latvia, Riga were interviewed using PHQ-9 and GAD-7 scales, the obtained data from the scale's results were analyzed and summarized in an analytic cross-sectional study. Literature overview.

Results There is a high correlation between the depressive episodes before pregnancy, during pregnancy and postpartum depression, as well as it have negative effects and delay in child postnatal development. Using Patient Health Questionnaire-9 and Generalised Anxiety Disorder Assessment-7 screening scales, was set up an inquiry among 200 pregnant women in Riga, Latvia. Depressive symptoms have 45% of pregnant women. 36% of pregnant women have mild depression symptoms, 3% moderate symptoms, 5% moderate severe symptoms and 1% severe depression symptoms.

In its turn anxiety disorder screening results are following: 35% of pregnant women have mild anxiety symptoms, 9% moderate anxiety symptoms; 3% severe anxiety symptoms. Anxiety disorder symptoms note 47% of pregnant women. 36% of respondents note both depression symptoms and anxiety disorder symptoms.

Conclusion HQ-9 and GAD-7 scales are informative, quick and easy for patients to complete. Children development and behavior has association with maternal depressive state during pregnancy. There is high prevalence of depression symptoms among pregnant women in Latvia.

⁵ Hospital provincial de la misericordia, Psiquiatria, Toledo, Spain

⁶ Hospital Universitario de Alava, Psiquiatria, Vitoria-Gazteiz, Spain

* Corresponding author.

Introduction Depression is a disease with high prevalence all over the world. Selective serotonin reuptake inhibitors (SSRIs) and dual antidepressants (DA) are worldwide used to treat the different types of depressive episodes. Between the adverse events of these compounds, an unusual but potentially severe side effect is the syndrome of inappropriate antidiuretic hormone secretion (SIADH). **Results and discussion** Several cases published, and an amount of cases series have documented the association of SIADH to the use of SSRIs and DA. All SSRIs and DA are at risk of producing SIADH (fluoxetine, paroxetine, fluvoxamine, sertraline, citalopram, escitalopram, venlafaxine and duloxetine). Old age has been found as a risk factor for developing SIADH. There are not enough data to conclude that other risk factors can play a role in the development of this adverse event. Treatment should include the immediate withdrawal of the antidepressant. The introduction of other antidepressants is controversial, as SIADH has been related with all antidepressive treatments; but the risk of relapse into a depressive episode must be considered also. Between symptomatic treatments, the control of water intake and the use of low doses of loop diuretics can be recommended. Severe cases can be treated with higher doses of loop diuretics and saline hypertonic solution.

Conclusions SIADH has been related with SSRIs and DA antidepressants and it is an infrequent but severe adverse event. Its risk must be considered when prescribing treatment with them. If this adverse event is produced, the substitution of the antidepressant should be done.

Anti-inflammatory properties of brilliant blue G on chronic unpredictable mild stress-induced changes in rat hippocampus

F. Aricioglu^{1,*}, T. Bastaskin¹, C. Kandemir², S. Sirvanci², C. Ozkartal¹, T. Utkan³

¹ Marmara University School of Pharmacy, Department of Pharmacology and Psychopharmacology Research Unit, Istanbul, Turkey

² Marmara University School of Medicine, Department of Histology Embriology, Istanbul, Turkey

³ Kocaeli University School of Medicine, Department of Pharmacology, Kocaeli, Turkey

* Corresponding author.

Objective Purinergic 2X7 receptor (P2X7R) activation has recently been considered to be involved in depression at least partially by triggering microglial activation. The aim of the present study was to examine whether the chronic administration of brilliant blue G (BBG), a highly selective P2X7R antagonist, has antidepressant-like effects and microglial (Iba-1) immunoreactivity in chronic unpredictable mild stress (CUMS) model in rats.

Methods Male Wistar Albino rats (290–360 g) were divided into groups such as control (saline), CUMS, CUMS + Imipramine (20 mg/kg; i.p.), CUMS + BBG25 (25 mg/kg; i.p.), CUMS + BBG50 (50 mg/kg; i.p.) groups ($n = 10-12$ in each). In CUMS model, various stressors were applied for 40 days. On day 20, the treatment of BBG was started for 20 days. At the end, sucrose preference and forced swimming tests were performed. Then brains were removed with paraformaldehyde perfusion for Iba-1 immunohistochemical analysis in hippocampus. One-way analysis of variance and Tukey's test were used for statistical analysis.

Results The time of immobility in forced swim test was significantly reduced while sucrose preference was increased in Imipramine and CUMS + BBG50 groups compared to control and

CUMS groups, respectively. In immunohistochemical experiments, Iba-1 was overexpressed in CUMS group and BBG significantly reduced the overexpression of Iba-1.

Conclusion Our results suggest that chronic administration of BBG has an antidepressant-like activity supporting the notion of P2X7 receptors involvement in depression by modulating microglial activation.

Harmane suppresses microglial neuroinflammatory response and induce antidepressant-like effect in rats

F. Aricioglu^{1,*}, G. Arkan¹, C. Kandemir², S. Sirvanci², C. Ozkartal¹, T. Utkan³

¹ Marmara University School of Pharmacy, Department of Pharmacology and Psychopharmacology Research Unit, Istanbul, Turkey

² Marmara University School of Medicine, Department of Histology Embriology, Istanbul, Turkey

³ Kocaeli University School of Medicine, Department of Pharmacology, Kocaeli, Turkey

* Corresponding author.

Objective Harmane is a beta-carboline, which binds to imidazoline receptors and it has been previously shown that it may have an antidepressant effect when administered acutely. This study is planned to investigate the effect of harmane on chronic unpredictable mild stress (CUMS) model and microglial (Iba-1) immunoreactivity in the same model as markers of neuroinflammation.

Methods Male Wistar Albino rats (290–360 g) were divided into groups such as control (saline), CUMS, CUMS + Imipramine (20 mg/kg; i.p.), CUMS + Harmane5 (5 mg/kg; i.p.), CUMS + Harmane10 (10 mg/kg; i.p.) groups ($n = 10–12$ in each). In CUMS model, various stressors were applied for 40 days. On day 20, harmane administration was started for 20 days. At the end, sucrose preference and forced swimming tests were performed. Then, brains were removed with paraformaldehyde perfusion for Iba-1 immunohistochemical analysis in hippocampus. One-way analysis of variance and Tukey's test were used for statistical analysis.

Results The time of immobility in forced swim test was significantly reduced while sucrose preference was increased in Imipramine and CUMS + harmane10 groups. In immunohistochemical experiments, Iba-1 were overexpressed in CUMS group and Harmane significantly reduced the overexpression of Iba-1.

Conclusion Our results suggest that chronic administration of harmane has an antidepressant-like activity in chronic stress model of depression. These results support the notion of imidazoline receptors involvement in depression by modulating neuroinflammation and at least a part of its antidepressant effect might be through modulating microglial activation as a reflection of neuroinflammation.

* Corresponding author.

Introduction Dopamine receptors perform various functions essential to vertebrate central nervous systems and they are the major targets of antipsychotic drugs. Our recent studies pioneered to perform molecular modeling studies of the dopamine D2 receptor (D2R), describing the mechanism and binding affinities of marketed antipsychotics into the active sites of the D2^{high}R and D2^{low}R [1]. Another study provided significant information about changes of binding cavity properties of D2R [2].

Objectives Since the marketed antipsychotics have serious side effects, we aim to explore ligands with better inhibition profiles on D2R with less unwanted outcomes. For this aim, we compare the effectiveness of the marketed drugs with small peptides and vitamin substances.

Aims The main goal of the research is to explore novel small molecules that inhibit D2R to be used in schizophrenia.

Methods In this study, we used a large number of endogenous vitamins and peptides with dopamine D2R active-inactive forms in monomeric-dimeric patterns to understand their interactions at the active sites of targets. Nineteen of antipsychotic drugs, which are widely used in schizophrenia treatment are selected as reference molecules. Molecular docking, molecular screening and molecular modeling approaches were used.

Results Some of these endogenous molecules showed similar or better inhibition profiles on D2R compared to the known standard inhibitors of the target.

Conclusions Proposed molecules may be potent for D2 receptor inhibition with less side effects for the use for schizophrenia.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Given the poor compliance of schizophrenic patients to antipsychotic therapies, are been developed drugs in long-acting formulation that for their pharmacokinetic ensures prolonged therapeutic activities. Currently, we consider that their efficacy depends on hereditary tracts, influencing both pharmacodynamic and pharmacokinetic parameters.

Objective Investigate relationships between clinical efficacy and genetic polymorphisms of long-acting drugs' pharmacodynamic targets.

Methods Seventy-eight psychotic patients, treated with atypical long-acting antipsychotics (olanzapine pamoate, paliperidone palmitate, risperidone and aripiprazole), were examined. We carried out a blood sampling to evaluate dopaminergic DRD2 and glutamatergic GRM3 genetic receptors polymorphisms. PANSS and BPRS scales were used to assess clinical condition.

Results Regarding the GRM3 genes, the study of rs2228595 and rs6465084 polymorphisms showed a prevalence of wild type genotypic frequency of 81.2% and 56.2%, respectively. The prevalence of the patients with mutated heterozygote genotype (rs6465084 polymorphisms) resulted high (40.6%). Considering rs1989796 e rs274622 polymorphisms, the sample showed a prevalence of mutated heterozygote genotype in the 53.1% e 45.3%, respectively, with a percentage of 43.7% of patients with a mutation in homozygosis. Considering the rs146812 polymorphism, the 53.1% of patients resulted with a wild type genotype. Finally, findings showed a prevalence of 56.2% for the mutated heterozygote genotype in the DRD2 rs6277 polymorphism. The genotypic categorization analysis demonstrated a significative association between the GRM3 rs274622 polymorphism and higher BPRS scores.

Conclusions The relationship between rs274622 polymorphism and worse clinical conditions could indicate a major resistance to long-acting antipsychotics in patients with genotypic frequency CT (mutated heterozygosis) for this polymorphism.

⁶ University of London, Imperial College, London, United Kingdom

* Corresponding author.

Introduction The multicenter, cross-sectional survey summarizes the current prescription patterns of psychopharmacological medications in patients with major depressive disorder (MDD) treated in European university psychiatric centers.

Methods The study included a total of 1181 MDD patients who were recruited in 9 academic sites across 8 European countries. Socio-demographic, clinical, and psychopharmacological characteristics were collected within a detailed clinical interview and the current depressive symptom severity was measured by the Montgomery and Åsberg Depression Rating Scale (MADRS). Symptom reduction during the present MDD episode was analyzed by calculating retrospective MADRS scores. Descriptive statistics, analyses of variance (ANOVAs), and Spearman correlation analyses were performed to examine the impact of various features on the applied pharmacological strategies.

Results Regarding first-line antidepressant medication, the most frequently prescribed drug classes were selective serotonin reuptake inhibitors (SSRIs) (53.4%), serotonin-norepinephrine reuptake inhibitors (SNRIs) (23.6%), noradrenergic and specific serotonergic antidepressants (NaSSAs) (8.2%), tricyclic antidepressants (TCA) (5.1%), and the melatonergic antidepressant agomelatine (5.0%). The most commonly used individual antidepressants were escitalopram (18.4%), venlafaxine (15.2%), sertraline (12.9%), paroxetine (9.1%), mirtazapine (8.2%), duloxetine (7.0%), and fluoxetine (6.5%). Among the patients, 59.4% were treated with polypharmaceutical medications (mean: 2 drugs) and for the number of individual drugs, we found a significant correlation with the present MADRS total score and the MADRS total score change during the current depressive episode.

Conclusion Consistent with surveys investigating primarily municipal psychiatric treatment centers, we could replicate the observation that SSRIs are the most commonly used antidepressants in MDD for the first time for European university centers.

The regulation of orexins and their cognate receptors in two distinct rat models of depression and effects of treatments

A.J. Harpøth*, B. Elfving, O. Wiborg, G. Wegener, H.K. Müller
Aarhus University Hospital, Translational Neuropsychiatry Unit,
Institute of Clinical Medicine, Risskov, Denmark

* Corresponding author.

Introduction Depression has sleep disturbances as a key symptom and recently sleep has been suggested as a new area to optimize treatment in depression. Orexin is produced in the hypothalamus and projected throughout the brain innervating a number of structures important in depression. It controls a number of physiological processes including sleep, arousal, cognitive processes and stress, which are affected during depression.

Objective The study examines the possible implications for abnormalities in the orexinergic system in depression. We aim to determine whether treatment targeting this system relieves depressive symptoms.

Methods Using real-time qPCR and Western blotting optimal sampling time is determined by an assessment of the diurnal variation of orexin expression. Expression of orexin and its receptors are investigated in the hypothalamus, the hippocampus, and the prefrontal cortex of the Flinders Sensitive Line (FSL) and the Chronic Mild Stress model of depression. Behavioral and molecular response to treatment with a conventional antidepressant and an orexin receptor antagonist will be addressed in FSL rats. In addition, we will include exercise as a noninvasive treatment, which has shown positive effects on both sleep and depression in humans.

Results Real-time qPCR analysis showed increased expression of the orexin-1 receptor (40%) and the orexin-2 receptor (39%) in the prefrontal cortex of FSL rats compared to the control rats, the Flinders Resistant Line rats.

Conclusion This study may provide a platform for screening of drugs with effects on both sleep and depressive symptoms with perspectives for the development of novel strategies for treatment of depression.

* Corresponding author.

Introduction Patients with schizophrenia have 3-fold higher mortality from lifestyle diseases, and a long-lasting exposure to antipsychotic medication may contribute to the development of somatic illnesses. Region of Central Jutland was inspired by European initiatives to establish a lifestyle intervention program in an attempt to reduce mortality among individuals with severe mental illness.

Objectives To investigate whether this intervention could possibly lower the need for antipsychotic treatment, and to provide a unique view of actual medication practice.

Aims To investigate the influence of a lifestyle intervention program on changes in antipsychotic medication and polypharmacy in an unselected cohort of patients with newly diagnosed schizophrenia.

Methods Observational study of outpatients participating in a program with individual consultations, group sessions and exercise groups.

Results One hundred and eleven patients were eligible for analysis. Fifty-four percent of the patients were subject to antipsychotic monotherapy. Median Defined Daily Dose (DDD) of antipsychotics was 1.3 at index (interquartile range [IQR] 0.67–2.00). Fifty-two percent of the patients experienced a decrease in DDD during the period with median change of –0.33 DDD (IQR –1.00 to 0.43). We found no significant difference in baseline variables or extend of participation between patients with decrease in doses and patients with increase (Fig. 1).

Conclusions Most patients decreased or stabilized their doses of antipsychotic medication during the study period. Half of the patients were subject to antipsychotic polypharmacy. Extend and type of participation in the lifestyle intervention program did not correlate to changes in dosing of antipsychotic medication.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychiatric comorbidity in patients affected by fibromyalgia and/or autoimmune rheumatic diseases: Preliminary results of an observational study

A. Bellomo¹, A. Zendoli¹, A. La Marca¹, E. Cuzzo¹, M. La Montagna^{1,*}, A. Rinaldi¹, N. Melillo², A. Mele², F.P. Cantatore²

¹ University of Foggia, Department of Psychiatry, Foggia, Italy

² Ospedale Riuniti Foggia, Struttura Complessa Reumatologia Universitaria, Foggia, Italy

* Corresponding author.

Introduction Fibromyalgia is characterized by skeletal muscle pain and axial stiffness, with elective multiple points of tenderness (tender points). According to scientific literature, the prevalence of depression, anxiety and a worse quality of life is higher in patients with fibromyalgia. Trauma (sexual abuse and physical aggression) has a key role in the pain perception.

Objectives To describe the clinical characteristics of patients with fibromyalgia and/or autoimmune rheumatic diseases admitted to O.O.R.R. Foggia (Department of Rheumatology), to detect correlation between fibromyalgia and psychiatric disorders.

Aims To underline psychiatric comorbidity in patients affected by fibromyalgia and/or autoimmune rheumatic diseases.

Methods Diagnostic tests at Baseline (T0): Mini International Neuropsychiatric Interview and Structured Clinical Interview for DSM Disorder 2 to assess psychopathology, 12-Item Short Form survey for the quality of life, Diagnostic Criteria for Psychosomatic Research for disorders of somatic symptoms, Insight Scale for the awareness of the disease, Davidson Trauma scales to assess the presence of a post-traumatic stress disorder, Pittsburgh Sleep Quality Index about the quality of sleep. After 3 months (T1): further psychodiagnostic assessment for patients with positive mental status exam in drug treatment.

Results Affectivity disorders, feelings of anger, irritability, hostility, impaired stress response, increased vulnerability to traumatic events are very frequent in patients affected by fibromyalgia.

Conclusions The preliminary results of this study show that patients with fibromyalgia have diagnoses of major depression, anxiety disorders, post-traumatic stress disorder and personality disorders (cluster B). Multidisciplinary interventions are needed integrating the rheumatologic therapy with the psychiatric one, based on the detected diagnosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Switching to paliperidone palmitate in an outpatient sample: Preliminary results of a 43-month follow-up

R. Martín Gutierrez*, R. Medina Blanco, D. Sierra Biddle, M.J. Cuesta Nuñez, P. Suárez Pinilla

Hospital Universitario Marqués de Valdecilla, Psychiatry, Santander, Spain

* Corresponding author.

Introduction Patients with psychosis are treated in outpatient community clinics during most of their lifetime. Antipsychotic treatments are commonly used in regular clinical practice. However, the non-adherence is one of the main causes of relapses.

Fig. 1 Change in total DDD from index to follow-up (111 patients).

Long-acting injectables (LAIs) could be a safe option to guarantee the efficacy.

Aim and objectives Our purpose is to evaluate the efficacy of the switch to paliperidone palmitate from other oral or LAI antipsychotics, in terms of hospital and emergency admissions.

Methods We performed a mirror-image study in an outpatient mental health clinic, comparing patients before and after paliperidone palmitate change over 43 months. Fifty-seven patients were included, most of them ($n=47$) were diagnosed with psychotic disorders (82.5%) while 4 were bipolar patients (7%), and the remained patients ($n=6$; 10.6%) were classified as behavioral disorders. The following variables were studied before and after the switching: number of admissions, days of stay and emergency visits.

Results From those 57 patients, 44 were previously treated with other LAIs, whereas 13 were taking oral antipsychotics. The median age at switch was 49 years ($SD=12.31$). The reasons for switching were: inefficacy (26.3%), non-adherence (19.3%), side effects (38.6%), and non-specified (15.8%). We found significant differences between the three main variables: number of admissions ($t=4.59$; $P\leq 0.001$), days of stay ($t=2.27$; $P=0.027$) and emergency visits ($t=3.74$; $P\leq 0.001$).

Conclusions Paliperidone palmitate seems to be an effective treatment in order to guarantee the adherence. Our preliminary data show that paliperidone palmitate might reduce the sanitary cost in outpatients.

Web search query data and prescription volumes of antidepressants

M. Gahr^{1,*}, Z. Uzelac¹, R. Zeiss¹, B.J. Connemann¹, D. Lang², C. Schönfeldt-Lecuona¹

¹ University Hospital of Ulm, Psychiatry and Psychotherapy III, Ulm, Germany

² University Hospital of Ulm, Psychosomatic Medicine and Psychotherapy, Ulm, Germany

* Corresponding author.

Introduction Persons using the Internet generate large amounts of health-related data, which are increasingly used in modern health sciences.

Objectives/aims We analysed the relation between annual prescription volumes (APV) of several antidepressants with marketing approval in Germany and corresponding web search query data generated in Google to test, if web search query volume may be a proxy for medical prescription practice.

Methods We obtained APVs of several antidepressants related to corresponding prescriptions at the expense of the statutory health insurance in Germany from 2004–2013. Web search query data generated in Germany and related to defined search-terms (active substance or brand name) were obtained with Google Trends. We calculated correlations (Pearson's r) between the APVs of each substance and the respective annual "search share" values; coefficients of determination (R^2) were computed to determine the amount of variability shared by the two variables.

Results Significant and strong correlations between substance-specific APVs and corresponding annual query volume were found for each substance during the observational interval: agomelatine ($r=0.968$; $R^2=0.932$; $P=0.01$), bupropion ($r=0.962$; $R^2=0.925$; $P=0.01$), citalopram ($r=0.970$; $R^2=0.941$; $P=0.01$), escitalopram ($r=0.824$; $R^2=0.682$; $P=0.01$), fluoxetine ($r=0.885$; $R^2=0.783$; $P=0.01$), paroxetine ($r=0.801$; $R^2=0.641$; $P=0.01$), and sertraline ($r=0.880$; $R^2=0.689$; $P=0.01$).

Conclusions Although the used data did not allow to perform an analysis with a higher temporal resolution our results suggest that web search query volume may be a proxy for corresponding prescription behaviour. However, further studies analysing other pharmacologic agents and prescription data that facilitates an increased temporal resolution are needed to confirm this hypothesis.

Underreporting of adverse drug reactions: Results from a survey among physicians

M. Gahr^{*}, J. Eller, B.J. Connemann, C. Schönfeldt-Lecuona
University Hospital of Ulm, Psychiatry and Psychotherapy III, Ulm, Germany

* Corresponding author.

Introduction Drug safety surveillance strongly depends on the spontaneous and voluntary reporting of adverse drug reactions (ADR). A major limiting factor of spontaneous reporting systems is underreporting (UR) which describes incorrectly low reporting rates of ADR. Factors contributing to UR are numerous and feature country-dependent differences.

Objectives/aims Understanding causes of UR is necessary to facilitate targeted interventions to improve ADR reporting and pharmacovigilance.

Methods A cross-sectional questionnaire-based telephone survey was performed among physicians in outpatient care in a federal state of Germany.

Results From $n=316$ eligible physicians $n=176$ completed the questionnaire (response rate=55.7%). Most of the physicians ($n=137/77.8\%$) stated that they report ADR, which they have observed to the competent authority rarely ($n=59/33.5\%$), very rarely ($n=59/33.5\%$) or never ($n=19/10.8\%$); the majority ($n=123/69.9\%$) had not reported any ADR in 2014. Frequent subjective reasons for ADR non-reporting were (specified response options): lack of time ($n=52/29.5\%$), the subjective evaluation that the required process of reporting is complicated ($n=47/26.7\%$) or requires too much time ($n=25/14.2\%$) or the assessment that reporting of an ADR is needless ($n=22/12.5\%$); within free answers the participants frequently stated that they do not report ADR that are already known ($n=72/40.9\%$) and they only report severe ADR ($n=46/26.1\%$).

Conclusions Our results suggest a need of interventions to inform physicians about pharmacovigilance and to modify the required procedure of ADR reporting or to offer other reporting options.

Treatment attitude and hospitalization: Comparison of oral therapy and long-acting injectable (LAI) antipsychotics in patients with schizophrenia

L. Montemagno^{*}, M. Ludovico, A. Distefano, M. Marta Valentina, B. Mariacatena, C. Maria, M. Antonio, P. Antonino
University of Catania, Department of Clinical and Experimental Medicine, Catania, Italy

* Corresponding author.

Background Adherence to prescribed antipsychotic drugs is a crucial factor in predicting medium- to long-term clinical out-

come in schizophrenia. A helpful approach to promote adherence in schizophrenia is the use of long-acting injectable (LAI) antipsychotics.

Object To evaluate:

– the global functioning and the hospitalization rate occurred in the year before and in the year following the switch from a low-efficacy oral antipsychotic to either a LAI once-monthly therapy (palmitate paliperidone or olanzapine pamoate) or the corresponding oral compound (paliperidone, risperidone or olanzapine) in schizophrenic patients;

– the treatment attitude and the insight in patients treated with second-generation antipsychotic (SGA)-LAIs and with the corresponding oral compounds.

Method Sixty adult schizophrenic outpatients: thirty were switched to LAIs and thirty to the corresponding oral antipsychotic. We used the following scales: Drug Attitude Inventory (DAI), Schedule for the Assessment of Insight (SAI), Life Skill Profile (LSP).

Results Number of hospitalizations per year decreased in both groups (LAIs: from 1.3 ± 0.5 to 0.3 ± 0.5 ; oral: from 1.3 ± 0.5 to 0.6 ± 0.5). We found a direct association between the “hospitalization event” and the oral drug compared to the corresponding LAI formulation ($P=0.049$; OR: 3.05; 95% IC: 1.01–9.26). Patient receiving LAIs achieved a more significant improvement at the LSP score compared to the oral group ($P<0.001$ vs. $P=0.0034$) and higher DAI (5.9 ± 4.3 vs. -1.1 ± 4.3) and SAI (8.7 ± 2.9 vs. 5.6 ± 2.1).

Conclusions Our data suggest that SGA-LAIs, improving the adherence to the treatment, may sensitively reduce costs in mental health services.

Analysis of big data shows haloperidol with a decreased level of serum potassium

J.S. Noh^{1,*}, M.Y. Park², K.Y. Lim¹

¹ Ajou University School of Medicine, Department of Psychiatry, Suwon, Republic of Korea

² Mibyeong Research Center, Korea Institute of Oriental Medicine, Daejeon, Republic of Korea

* Corresponding author.

Introduction Haloperidol has been used for the treatment of schizophrenic disorders and other disorders with psychotic symptoms in psychiatric cares. It has been reported that haloperidol can cause QT-prolongation as well as Torsades de Pointes, especially in hypokalemic condition. Here, we tested the usefulness of the large clinical electronic medical record system data from a hospital located in South Korea and further investigated any change in potassium levels before and after an exposure to haloperidol.

Methods The dataset used in this study is derived from open access database with information such as admission, discharge, diagnosis, prescribed drugs and selected laboratory data for the period 1 June 1994 to 31 July 2013. This database contains information of total 461,170 patients with 4,920,758 prescriptions and 3,811,812 data about serum potassium levels.

Results Extracting a dataset from this database to compare the levels of serum potassium before and after haloperidol usage, we selected 3661 cases of data, 2476 of them (67.6%) were males and 1185 (32.4%) were females. More than 98.5% (3606) was Asians, and mean age of the patients was 68.63 ± 17.3 years old. The levels of serum potassium before and after haloperidol usage were 4.93 ± 2.53 and 3.86 ± 0.6 mEq/L, respectively, and *t*-tests revealed that those levels were significantly different (<0.001).

Conclusions Findings showed that an exposure to haloperidol could lead to a decrease in levels of serum potassium. We suggested

that EMR data can be a valuable tool to investigate the effects of treatment on several clinical data.

Effectiveness and tolerance of treatment with Aripiprazole LAI in a group of schizophrenics patients

N. Olmo López (Psychiatrist)^{1,*}, M. García Nicolás (Psychiatrist)¹, L.A. Núñez Domínguez (Psychiatrist)²

¹ Mental Health Centre, Navarra, Tudela, Spain

² Medical Center, Navarra, Pamplona, Spain

* Corresponding author.

Introduction In the pharmacological treatment of schizophrenia, more and more authors suggesting the use of injectable antipsychotics long-term these patients, since it increases adherence to treatment, one of the risk factors for relapse that argues most often to explain the failure of the treatment of these patients.

In the present study, it is to observe the evolution of a group of such patients to assess efficacy and tolerability of treatment with Aripiprazole LAI.

Material and method Data from 17 patients treated at a mental health center in Navarra (Spain), diagnosed with schizophrenic disorder, followed over a year after beginning treatment with Aripiprazole LAI are collected.

The data collected are:

- date of treatment change (month and year);
- antipsychotic previous;
- reason for change;
- aripiprazole LAI dose;
- number of income before and after the start of Aripiprazole LAI (mirror);
- effects adverse pre and post start of treatment with Aripiprazole LAI: metabolic, endocrine, extrapyramidal;
- treatment antipsychotic concomitant pre and post start Aripiprazole LAI.

Results The results show a decrease in the number of income after the start with Aripiprazole LAI, with very good retention of treatment, and a low number of side effects, which were mild.

Conclusions Treatment with Aripiprazole LAI is a good therapeutic alternative to the use of antipsychotic drugs by mouth, with good adherence, tolerability and efficacy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ University of Padova, Department of Neurosciences, Padova, Italy

* Corresponding author.

Antipsychotic drugs are currently used in clinical practice for a variety of mental disorders. Clozapine is the most effective medication for treatment-resistant schizophrenia, in controlling aggression

and suicidal behavior in psychosis. Although clozapine is associated with a low likelihood of extrapyramidal symptoms and other neurological side effects, weight gain and metabolic side effects are well known in clinical practice exposing the patient to a greater risk of cardiovascular disorders, premature death, as well as psychosocial issues leading to non-adherence. The mechanisms underlying this pharmacologically activated disorders are still controversial. Based on our in vitro results, we have characterized in vivo the effects of the selective PKC β inhibitor, Ruboxistaurin (LY-333531) on a preclinical model of long-term clozapine-induced weight gain. Cell biology, biochemistry and psychomotor tests have been performed on wild type and PKC β (-/-) mutant mice to investigate the contribution of endogenous PKC β and its pharmacological inhibitor on the neuroleptic effect of clozapine. Lastly, we also shed light on a novel aspect of the mechanism underlying of clozapine-induced weight gain, demonstrating that the clozapine-dependent PKC β activation promote the inhibition of the lipid droplet-selective autophagy process, opening the way to new therapeutic intervention approach.

* Corresponding author.

Introduction An increasing body of evidence suggests that antipsychotic medication can cause immunological changes that could be attributed to the amelioration of psychotic symptoms or the metabolic side effects of the drugs. So far, the results of the studies remain controversial.

Objective Our aim was to compare the levels of interleukin (IL) IL-2, IL-6 and transforming growth factor- β 2 (TGF- β 2) in drug-naïve, first-episode patients with psychosis before and after six weeks of antipsychotic medication.

Methods Thirty-nine first episode patients with psychosis were enrolled in the study. Serum levels of IL-2, IL-6 and TGF- β 2 were measured by enzyme linked immunosorbent assay (ELISA) before and six weeks after the initiation of antipsychotic medication. In addition, clinical psychopathology was assessed using Positive and Negative Syndrome Scale (PANSS) before and after treatment.

Results Serum levels of IL-2 were significantly higher in the study group six weeks after the initiation of antipsychotic treatment ($P < 0.001$) while TGF- β 2 levels were decreased ($P < 0.001$) and IL-6 levels were slightly reduced ($P < 0.004$).

Conclusion The changes in cytokine levels may be attributed to the action of antipsychotic medication and the remission of psychopathology. The reduction in TGF- β 2 levels is observed in all patients and with all antipsychotic medications used. TGF- β 2 may be a marker of clinical efficacy.

Amelioration of impaired hippocampal cognitive performance in Alzheimer's disease via long-term intervention with ghrelin

B. Sadeghi

Shahid Beheshti University of Medical Sciences, Physiology, Neuroscience Research Center, Tehran, Iran

Introduction Alzheimer's disease (AD) is a neurodegenerative disorder characterized by loss of memory and cognitive deficits. Ghrelin is a peptide hormone which has been linked to neuroprotection, memory and learning processes.

Objectives This study investigated the effects of ghrelin-induced memory retention on amelioration of cognitive deficits via restoration of long-term potentiation (LTP) and induction of synaptic plasticity in hippocampal CA3, using a rat model of AD induced by amyloid- β (1-42) injection.

Methods Five groups of male rats (230–270 g) including ghrelin-treated (200 ng/rat, [ICV], daily for two weeks), A β 1-42 injected (5 μ L/rat) and A β 1-42 plus ghrelin-treated animals were designed. Ghrelin was administered after an ICV injection of A β 1-42. To assess cognitive performance and the motor dysfunction, passive avoidance tests and open-field were performed, respectively. Step-through latency (STL) was evaluated as learning and memory index. Intrahippocampal field potential recordings were done.

Results Results showed that following A β 1-42 injection, STL and induction of LTP were significantly decreased whereas ICV injection of ghrelin significantly enhanced memory retention by improvement of STL and restitution of LTP in the CA3 with increased EPSP slope and PS amplitude, suggesting the involvement of ghrelin in postsynaptic mechanisms of hippocampal LTP.

Conclusions It was revealed that neuroprotective effects of chronic ghrelin not only can enhance but also can restore LTP in the CA3 area in A β -induced AD. Results suggest that ghrelin may be considered as a promising therapeutic agent to alleviate cognitive deficits of AD.

Introduction In healthy volunteers, light acting through serotonin pathways, decreases the threshold for sweet, but not salt taste; similar to SSRI paroxetine. In depressive disorders, there is deficiency of serotonin throughput, which is remedied by SSRI medications, and results in improvement in symptoms of depression. Thus, we report on taste thresholds before and after SSRI treatment.

Objectives To study the variation in thresholds for sweet with SSRI treatment in depressed patients in short- and long-term.

Aims To compare the threshold for sweet (test) and salt (control) after 1 and 4 weeks of SSRI escitalopram therapy in depressed patients.

Methods The project was approved by the institutional ethics committee. Following informed consent, depressed patients were initiated on escitalopram 10 mg/d (increased to 15 or 20 mg, if required after 1 week). Taste recognition threshold, intensity and pleasantness were measured for sweet and salt. Each tastant was made –1 to –3 (100 mM–1 mM). Regional recognition thresholds were determined at the tip of the tongue using a cotton bud well soaked in the tastant.

Results Three males and 4 females of mean ages 39.1 years completed the study. There was significant shift to the left for sweet thresholds between days 0 and 7, and 7 and 28 [F(Dfn, Dfd)=9.242 (4.162) $P < 0.0001$]. A similar shift to the left was seen for salt but day 7 only [F(Dfn, Dfd)=6.213 (4.162)].

Conclusion The increase in serotonin throughput as envisaged through SSRI treatment was paralleled by decrease in sweet thresholds.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Metabolic outcomes of Red yeast rice administration in patients treated with second-generation antipsychotics

G.M. Troili*, A. Bruno, G. Pandolfo, M. Crucitti, R.A. Zoccali, M.R.A. Muscatello

University of Messina, Psychiatric Unit, Department of Biomedical and Dental Sciences and Morphofunctional Imaging, Messina, Italy

* Corresponding author.

Rationale Second-generation antipsychotics (SGAs) are notoriously associated with a wide range of metabolic adverse effects, and their chronic use is related with an increased risk for the development of metabolic syndrome (MS). The nutraceutical approach to the management of MS might be a promising strategy in the prevention of cardio-metabolic risk. In this context, Red yeast rice (RYR) have been shown to have a lipid lowering effect in an increasing number of clinical studies.

Objectives The present study was aimed to explore the efficacy and safety of RYR treatment on metabolic parameters in a sample of subjects receiving atypical antipsychotics.

Methods Ten outpatients treated with atypical APs assumed RYR at single daily dose of 200 mg/day for 30 days. Total cholesterol, high-density lipoprotein cholesterol (HDL), low-density lipoprotein cholesterol (LDL), triglycerides, fasting levels of glucose, and glycated hemoglobin were determined.

Results RYR administration non-resulted in a statistically significant reduction of metabolic parameters in the study sample. However, a trend for total cholesterol (T0 vs. T1: 159.6 vs. 145.6) and LDL (T0 vs. T1: 94.1 vs. 77.6) decrease was observed.

Conclusions Our findings in patients receiving atypical antipsychotics did not confirm the beneficial effect of RYS on lipemic profiles previously found in subjects who do not take this class of drugs. Further clinical trials with adequately-powered and well-designed methodology are needed to better explore the RYS effectiveness on the SGAs-induced metabolic side effects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Modulators of the brain renin-angiotensin system (RAS) have been shown to improve cognitive functioning in several animal models of neuropsychiatric disorders. Moreover, the brain RAS has been considered a new target for the treatment of Alzheimer's disease (AD). However, there are no population-based follow-up studies supporting this hypothesis.

Objectives Cross-sectional and prospective relationships between cognitive decline and ARB treatment were examined in the population-based Kuopio Ischemic Heart Disease Risk Factor Study.

Aims To evaluate procognitive/antidementia capacity of orally delivered angiotensin II receptor blockers (ARB).

Methods The study was conducted on a sample of 1774 subjects (920 females, 854 males; age range at baseline: 42–61 years) from Eastern Finland. An established cutoff score of at least 2-point decrease in the Mini Mental State Examination over a 9-year follow-up was used to detect age-related cognitive decline in the cross-sectional setting. In the prospective setting, a hospital discharge diagnosis of dementia/AD was used as outcome variable. Cross-sectional relationships were determined with logistic regression and prospective analyses were conducted with the Cox proportional hazards model (both adjusted for relevant background variables).

Results Cross-sectional analysis displayed a decrease of the odds of cognitive decline ($n = 87$; 4.9% of participants) in those with ARB treatment; OR = 0.445, 95% CI: 0.22–0.90, $P = 0.024$. Furthermore, in the prospective setting, the risk of dementia/AD diagnosis ($n = 149$; 8.4% of participants) was significantly reduced in ARB treated participants; HR = 0.621, 95% CI: 0.40–0.98, $P = 0.038$.

Conclusions ARB treatment is associated with a decreased risk for age-related cognitive decline and dementia/AD manifestation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The effect of Qing Huan Ling on the hypoglutamatergic schizophrenia model in mice

Y. Zhang^{1,*}, F. Liu², Z. Dai², Q. Wu¹

¹ Xi'an Mental Health Center, Pharmacy Lab, China

² Xi'an Mental Health Center, Science and Education Department, China

* Corresponding author.

Objective To investigate the effect of Qing Huan Ling and (or) risperidone on activity and preferences behavior of the hypoglutamatergic schizophrenia model in mice.

Methods Seventy kunming mice were randomly divided into 5 groups, one group as placebo group. The rest groups intraperitoneal injection MK-801 continuously 14 day, then randomly numbered: model group, Qing Huan Ling group, risperidone group and Qing Huan Ling combined risperidone group. Intra-gastric administration give corresponding drugs for each group one month, at the same time observe high activities and changes in the preferences of five groups.

Results Compared with the blank group, activity of the rest model groups induced by MK-801 was increased ($P < 0.05$). After intra-gastric administration one month, model groups of high activity was decreased, especially risperidone combined Qing Huan Ling group. There was no statistical meaning in inquiry activity of five groups ($P > 0.05$). Compared with model group, latent period of step-through test was prolonged 35.5 s ($P < 0.05$), of step-down test was prolonged 11.4 s in risperidone combined Qing Huan Ling group.

Conclusion The combination of Qing Huan Ling and risperidone can suppress the high activity; also can protect harmed memory of the preference behavior in the hypoglutamatergic schizophrenia model in mice.

Description of anesthetic drugs used in hospital del Mar and their impacts on convulsion duration and blood pressure in electroconvulsive therapy

M. Angelats^{1,*}, A. Leila¹, C. David¹, P. Laia¹, M. Laura¹, E. Itziar¹, B. Adinson², S. Purificación¹, P. Víctor¹, B. Dani¹

¹ Instituto de Neuropsiquiatria y Adicciones INAD, Parc de Salut Mar, Psiquiatria, Barcelona, Spain

² Fellow of the Royal College of Physicians of Canada, Psychiatry, Quebec, Canada

* Corresponding author.

Introduction The electroconvulsive therapy (ECT) is an effective treatment used for several psychiatric disorders. However, there are multiple enigmas about the mechanisms of action and factors that improve its results. Some frequent questions are if the anesthetic drug makes a difference in the time of convulsion and blood pressure.

Aims Our principal aim is to describe the utilization of anesthetic drugs among the patients that are being treated with ECT in hospital del Mar. We also want to know the differences in the time of convulsion and systolic arterial pressure for every anesthetic drug (propofol, thiopental and etomidate).

Material and methods We have used the database of ECT in hospital del Mar. It contains information like age, principal diagnosis, medical background and pharmacological treatment at the moment of starting ECTs; it also contains information of each indi-

vidual ECT session as basal, 2 and 5 minutes arterial pressure; the anesthetic drug used, and convulsion duration.

We made an analysis of general conditions of the population, the differences of convulsion time and arterial pressure between the three anesthetic drugs.

Results Propofol was used in 1140 sessions, thiopental in 61 sessions and etomidate in 54 sessions. The differences in the means of convulsion times between propofol and etomidate are statistically significant ("P" value < 0.05). Etomidate or thiopental increases the difference of arterial pressure more than propofol.

Conclusions Further research about the factors that improve convulsion duration and minimize adverse effects on blood pressure is needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

An evaluation of the use of electroconvulsive therapy in a United Kingdom high secure psychiatric hospital

H. Blott*, S. Bhattacharjee, E. Harris

West London Mental Health trust, Forensic Psychiatry, London, United Kingdom

* Corresponding author.

Introduction Electroconvulsive therapy (ECT) is an effective NICE-approved treatment for severe depression, treatment-resistant mania and catatonia; the Royal College of Psychiatrists' (RCPsych) guidelines also support its use fourth line for treatment-resistant schizophrenia.

Objectives Evaluate the use of ECT at Broadmoor High Secure psychiatric hospital, focusing on the indications for its prescription and patients' capacity to consent.

Method Analyse case records of all patients who received ECT, and of all patients referred for Second Opinion Appointed Doctor (SOAD) certified ECT treatment under Section 58 of the Mental Health Act 1983 (MHA) due to incapacity, between 01.09.11 and 30.07.15.

Results All patients lacked capacity to consent to treatment during this time. Thirty-three referrals were made to the SOAD service for 15 patients, and of these 30 resulted in certification (T6) of which 10 were not subsequently used. Improvements in mental state and agreement to take clozapine were common reasons for T6s either not being certified or used. Urgent treatment under Section 62 of the MHA was employed 7 times for 4 patients during this period. Of the referrals to the SOAD service, 25 were for treatment-resistant schizophrenia, 5 for mania, 3 for catatonia and none for depression.

Conclusions Those patients requiring ECT within this population tended to be the most unwell and all lacked the capacity to consent to it. The majority (76%) of patients receiving ECT at Broadmoor do so outside of NICE (but within RCPsych) guidelines. ECT may be an effective strategy for promoting compliance with clozapine.

* Corresponding author.

Introduction Repetitive transcranial magnetic stimulation (rTMS) is a neurostimulation technique used in many indications, especially in psychiatry in the treatment of mood disorders. Although its efficacy in this treatment has been demonstrated, the study of predictive response factors currently remains a major challenge.

Method We conducted a retrospective study from the cohort of treatment-resistant depressed patients that received rTMS treatment in Esquirol Hospital in Limoges in order to identify response predictors at three months. Of the 416 patients treated between January 2007 and November 2015, 107 subjects have been included. The clinical characteristics of responders and non-responders at three months after treatment, but also at the end of treatment and after one month were compared. Predictors of clinical improvement objectified by the Hamilton Depression Rating Scale (HDRS) were identified using a logistic regression model.

Results In our cohort, the response rates were 52% at the end of treatment, 61% at 1 month and 57% at 3 months. Psychiatric family history and the recurrence of thymic episodes were found to be negative predictors of response to rTMS treatment. Similarly, high subscore of depression core symptoms in HDRS could also predict a poorer response.

Conclusion Our data from a naturalistic cohort tended to prove that a number of clinical features should be taken into account in determining the profile of the treatment-resistant depressed patients that could respond to rTMS treatment.

Prolonged theta burst stimulation: A novel rTMS paradigm in neuropsychiatry

M. Klírová^{1,*}, M. Hejzlar¹, T. Novák¹, R. Rokyta²

¹ National Institute of Mental Health, Neurostimulation Department, Klecany, Czech Republic

² 3rd Faculty of Medicine, Charles University, Department of Normal, Pathological and Clinical Physiology, Prague, Czech Republic

* Corresponding author.

Introduction Repetitive transcranial magnetic stimulation (rTMS) has important role in treatment of neuropsychiatric disorders. Theta burst stimulation (TBS), a modification of rTMS, seems to produce greater changes in cortical excitability (CE) than those observed in conventional rTMS protocols. TBS is used in different protocols: intermittent TBS (iTBS) and continuous TBS (cTBS). While iTBS facilitates CE, cTBS leads to CE inhibition. However, a prolonged cTBS produces facilitatory effect similar to that of iTBS. Prolonged TBS (pTBS), a novel rTMS paradigm, is of great clinical interest for its short duration, but also because it may induce stronger effect.

Aim To prove the effect of pTBS of motor cortex on changes of motor threshold (MT), CE and pain threshold (PT) in healthy volunteers (HV). To compare the effects of two different forms of active pTBS (pcTBS, piTBS) with placebo.

Methods A double-blind, placebo-controlled, cross-over study compared the effects of different pTBS of contralateral M1 area on MT, CE and PT. We enrolled 24 HV to the study, who underwent all types of pTBS in randomized order and were assessed before and

after each pTBS application. We used MagPro R30 (with coil focused to contralateral M1 area, 1200 pulses/session, 90% MT).

Results A significant changes in CE and MT were found after application of continuous pTBS. Intermittent and placebo pTBS did not confirm the effect. There were no significant changes on PT after pTBS. Continuous pTBS was better tolerated than intermittent pTBS.

Conclusion pTBS should be considered as an effective and safe treatment option for neuropsychiatric disorders.

Transcranial direct current stimulation: Adverse effects and the efficacy of a commonly utilised sham protocol

A. Kortteenniemi^{1,*}, T. Ali-Sisto¹, J. Wikgren², S. Lehto¹

¹ Institute of Clinical Medicine, University of Eastern Finland, Department of Psychiatry, Kuopio, Finland

² Centre for Interdisciplinary Brain Research, University of Jyväskylä, Department of Psychology, Jyväskylä, Finland

* Corresponding author.

Introduction Transcranial direct current stimulation (tDCS) is a promising neuromodulation method that has, for example, been used to treat depression. Nevertheless, the adverse effects of tDCS and the validity of the current standard tDCS sham protocols have received limited attention.

Objectives To evaluate the extent and types of tDCS adverse effects and to assess the reliability of sham stimulation as a control procedure for tDCS in a double-blind setting.

Aims To compare adverse effects between tDCS and sham stimulation groups, and to determine how well the participants and the experimenter are able to distinguish tDCS from sham stimulation.

Methods A sample of healthy volunteers received a 20-minute session of either tDCS ($n=41$; 2 mA) or sham stimulation ($n=41$; ramp up 15 s, ramp down 15 s; no current in between). The anode was placed over F3 and cathode over F4. Both the participants and the experimenter reported immediate adverse effects and the perceived likelihood for the participant to receive tDCS. Analyses were conducted using the Mann-Whitney U-test.

Results The tDCS group reported more erythema compared with the sham group ($P=0.016$, Cohen's $D=0.444$). No other significant differences in adverse effects were observed. In the tDCS group, both the participants ($P=0.034$, Cohen's $D=0.612$) and the experimenter ($P=0.006$, Cohen's $D=0.674$) reported a higher perceived likelihood of the participant receiving tDCS than in the sham group.

Conclusions tDCS has only modest adverse effects. Nevertheless, the current standard sham protocol appears insufficient.

From theory to practice: The contribution of John Farquhar Fulton (1899–1960) to psychosurgery

P. Michielsen^{1,*}, L. De Jonge², S. Petrykiv³, M. Arts⁴

¹ Mental Health Western Northern Brabant, Department Clinical Psychiatry, Halsteren, The Netherlands

² Mental Health Western Northern Brabant, Department Neuropsychiatry and Old Age Psychiatry, Halsteren, The Netherlands

³ University of Groningen, University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands

⁴ University of Groningen, University Medical Center Groningen, Department of Old Age Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction John Farquhar Fulton was an American neurophysiologist and historian, who pioneered psychosurgery based on animal experiments. Together with psychologist Carlyle Jacobsen, Fulton presented the results of bilateral frontal lobe ablation in chimpanzees. This study prompted neurologist Egas Moniz and neurologist Walter Freeman to perform similar brain surgery on human subjects.

Objectives To present the scientific papers of John Farquhar Fulton on psychosurgery.

Aims To review available literature and to show evidence that John Farquhar Fulton made a significant contribution to the development of psychosurgery.

Methods A biography and research papers are presented and discussed.

Results Fulton and Jacobsen experimented with 'delayed response tasks' in chimpanzees. The aim was to test the animal's capability to memorize the correct location of the food. They found that after sequential ablations of the left and right frontal association cortices these memory tasks became significantly difficult for the monkeys to perform. The researchers saw parallel conclusions in clinical cases of human frontal lobe damage.

Conclusions An investigation into the role of the limbic system is one of the crowning achievements of John Farquhar Fulton, as this has influenced even today's thinking about the role of the limbic system. We should thank Fulton for his pioneering work as modern psychosurgery has gradually evolved from irreversible ablation to reversible stimulation techniques, including deep brain stimulation.

Analysis of ECT indications in the hospitalized psychiatric patients

A. Mihaljevic Peles^{1,*}, M. Bajsi Janovic¹, A. Strucic², S. Janovic¹

¹ University Hospital Zagreb, Department of Psychiatry, Zagreb, Croatia

² School of Medicine, University Hospital Zagreb, Department of Psychiatry, Zagreb, Croatia

* Corresponding author.

Introduction Electroconvulsive therapy (ECT) has been considered a treatment option for the treatment resistance, mania, depression, suicidality and schizophrenia. It has been still controversial due to the lack of controlled clinical trials and unknown biological basis but also because of the negative image from the history of the treatment.

Objective Specifics of the clinical judgement on when and for which patients' indications, ECT was a treatment choice.

Aim of the study was to evaluate indications for the ECT treatment in the hospitalized psychiatric patients at the psychiatric department.

Method For all the patient cases in the last 7 years at the department ($n = 326$), data was analyzed regarding age, gender, number of hospitalizations, age of first episode, diagnose, previous treatment, leading indication for ECT and outcome after the ECT, regarding following treatment.

Results The leading indication for ECT was psychosis and/or pharmacological treatment resistance, followed by suicidality. Patients with psychosis were younger than patients with other diagnoses when receiving ECT treatment. Regarding the results, indications for ECT had been partially differentiated from expected guidelines. Outcomes after the ECT were favorable in terms of better control-

ling the symptoms, lowering exacerbation frequency and intensity and partially, functioning.

Conclusion Studies on ECT indications and outcome could provide further insight on efficacy of the treatment, and possible improvements in clinical assessment on eligible patients who could benefit from the ECT treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A systematic review and meta-analysis of the mortality rate of electroconvulsive therapy (ECT)

N. Topping¹, S.N. Sanghani², G. Petrides², C.H. Kellner³, S.D. Ostergaard^{1,*}

¹ Aarhus University Hospital, Psychosis Research Unit, Risskov, Denmark

² The Zucker Hillside Hospital, Hofstra Northwell School of Medicine, Department of Psychiatry, Glen Oaks, NY, USA

³ Icahn School of Medicine at Mount Sinai, Department of Psychiatry, New York, NY, USA

* Corresponding author.

Introduction Electroconvulsive therapy (ECT) is an efficacious treatment for many mental disorders, but is underutilized because of fears of adverse effects, including the risk of death.

Objectives and aims To provide a full picture of the magnitude of ECT-related mortality worldwide.

Methods We performed a systematic review and meta-analysis (PubMed and Embase) in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guideline. Only publications reporting on a specific number of ECT treatments as well as specific number of ECT-related deaths were included in our analysis. The ECT-related mortality rate was calculated by dividing the total number of ECT-related deaths by the total number of ECT treatments. The 95% confidence interval (95% CI) of this estimate was calculated using Bernoulli's principle of distribution.

Results Fourteen studies with data from 32 countries reporting on a total of 757,662 ECT treatments met the predefined inclusion criteria. Fifteen cases of ECT-related death were reported – yielding an ECT-related mortality rate of 2.0 per 100,000 treatments (95% CI: 1.0–3.0). In the eight studies published after 2001 (covering 406,229 treatments), no ECT-related deaths were reported.

Conclusions The ECT-related mortality rate was estimated at 2 per 100,000 treatments. For comparison, a recent meta-analysis on the mortality of general anaesthesia in relation to surgical procedures reported a mortality rate of 3.4 per 100,000. Thus, our systematic review and meta-analysis documents that death caused by ECT is extremely rare. This information can be used to reassure patients in need of ECT.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Objectives The purpose of this study was investigating the effectiveness of rTMS (repetitive transcranial of magnetic stimulation) on increase social performance in patients with recurrent major depression.

Method It was used a quasi-experimental, pretest–posttest design with control group, a sample consisting of 32 patients who had depression on the basis of DSM-IV diagnostic criteria, SCID and BDI-II scales and were randomly assigned to two groups.

The experimental group underwent 20 sessions of rTMS as the independent factor and both groups (control & experimental) had 12-session psychotherapy and drugs treatment. Upon the intervention, both groups were tested with two tests (BDI-II & SASS). To determine the effect of the independent factor on the dependent factor of rTMS.

Data were analyzed by *t*-test.

Results The comparison between pre- & posttest of all the tests showed the reduction of signs & symptoms of depression, ($\alpha = 0/05$) (Beck scale $P \leq 0/001$ & $F = 30$) and increase social performance in participants ($P \leq 0/001$ & $F = 83$).

Conclusion The rTMS is effect in the reduction of signs & symptoms of depression and increase social functioning in recurrent major depression.

The research of electroconvulsive therapy effect on cognitive function in rats with depressive-like disorder formed by ultrasound

V. Ushakova^{1,*}, E. Zubkov², A. Morozova², A. Gorlova¹, D. Pavlov¹, A. Inozemtsev¹, V. Chekhonin²

¹ Lomonosov Moscow State University, Department of Biology, Moscow, Russia

² Serbsky State Federal Medical Research Centre for Psychiatry and Narcology, Department of Fundamental and Applied Neurobiology, Moscow, Russia

* Corresponding author.

Electroconvulsive therapy (ECT) is effective method of resistant depression treatment. ECT activates neurotransmitter systems, increases neurotrophic factors production, induces neurogenesis. Nevertheless, ECT side effects, expressed as temporary amnesia, limit its application in clinical practice.

The objective of our work was to estimate rat's memory after ECT in the behavioral test: "Object recognition", "Morris water-maze". The aim of the work was to research the effect of ECT on cognitive function in rats with depressive-like disorder and in normal rats.

Methods The research was conducted with Sprague-Dawley rats ($n = 41$, 2 month age). Experimental stages:

– control group ($n = 10$) compared to control + ECT group ([70 mA, 50 Hz, 500 μ sec; 10 days] $n = 10$);

– control group ($n = 9$) compared to group with depressive-like disorder, formed by ultrasound ([20–45 kHz; 21days] US, $n = 6$) and group with depressive-like disorder received ECT ($n = 6$).

Memory was estimated in the "Object recognition" and "Morris water-maze" tests.

Results (1) ECT did not decrease cognitive function in the "Object recognition" test in normal rats ($P = 0.1217$). Also, it did not lead to cognitive impairments in the "Morris water-maze" test: time of platform searching did not differ significantly from the control group ($P = 0.8573$).

(2) ECT produced recovering effect on memory impairments of the US group in the "Object recognition" test ($P = 0.0066$). In the "Morris water-maze" ECT decreased time of platform searching by 7 times compared to the US group ($P = 0.0025$). That demonstrates the absence of ECT negative effect on rat's memory.

Conclusion ECT does not produce negative effect on cognitive function in rats with depressive-like disorder and even recovers memory impairments.

Glucocorticoid activeness in patients with mitral valve prolapse and autonomic dysfunction

E. Pervichko^{1,*}, A. Martynov², Y. Zinchenko¹

¹ Lomonosov Moscow State University, Faculty of Psychology, Moscow, Russia

² Moscow State University of Medicine and Dentistry, Faculty of General Medicine, Moscow, Russia

* Corresponding author.

Background Urgency of psychophysiological examination of mitral valve prolapse (MVP) patients is suggested by a high incidence of anxiety disorders among these patients.

Objectives To study glucocorticoid function activity and emotional stress resistance in MVP patients with autonomic dysfunction (AD).

Methods The trait anxiety level (TA) was assessed with the State-Trait Anxiety Inventory (Spielberger). Emotional stress resistance was undertaken with our modified version of Rosenzweig Picture-Frustration Test (Zinchenko, Pervichko). The cortisol level in blood plasma was measured by radioimmunoassay technique with radioimmune assay kit of cortisol in human blood plasma 'KORT-3N' (Belarus). There were 32 MVP patients (mean age was 28.5 ± 1.6 years) and 15 healthy people (mean age was 27.5 ± 1.3 years) who took part in the study.

Results Among reactions to frustration revealed by MVP patients the following categories are dominating: extrapunitive (E), ego-defensive (ED), and obstacle-dominance (OD). There was revealed a direct correlations: TA and E ($r = 0.49$, $P < 0.001$); TA and ED ($r = 0.46$, $P < 0.01$); TA and indexes of AD ($r = 0.43$, $P < 0.01$).

There was displayed a higher level of cortisol in MVP patients with severe grade of AD, against the level revealed by patients with average grade of AD (433.9 ± 78.0 mmol/L vs. 299.3 ± 42.9 mmol/L; $P < 0.05$). Direct correlations were established between the cortisol level and the level of TA ($r = 0.45$; $P < 0.01$); between the frequency of E-reactions in Modified Rosenzweig Test and cortisol level ($r = 0.42$; $P < 0.01$).

Conclusion Along with low stress resistance, registered AD and high level of TA, MVP patients reveal higher indexes of cortisol in blood plasma.

* Corresponding author.

Background Psychological distress is considered as a component of the cardiovascular risk. The present study aims to determine which psychophysiological, electrocardiographic and anthropometric factors are correlated with life events, depression and quality of life in healthy adults.

Method A total of 114 adults were examined using the Social Readjustment Rating Scale, the EuroQol Group 5-Dimension Self-Report Questionnaire, Beck Depression Inventory – Second Edition, Zung Self-Rating Depression Scale. Physiological measures included heart rate variability, skin conductance level and skin temperature. Anthropometric characteristics included weight, height, hip size, waistline, blood pressure, heart rate at rest and after mental activity, muscle mass, fat stock, percentage of the body fat, segmental distribution of muscle and fat mass, fat-free mass and the water content in the body. Finally, data from electrocardiographic examination included aortic pulse wave velocity, central aortic pressure and augmentation index.

Results Life events in last two years correlate with worse quality of life and a higher level of depression. Life events in last two years also correlate with the increase of the risk factors for cardiovascular problems in terms of several anthropometric and physiological measures. Finally, life events in last two years was also related with the overweight.

Conclusions Results suggest some possible mechanisms by which stress may exert adverse effects on cardiovascular morbidity and mortality in healthy persons. Primary preventive strategies with the stress management training may prove beneficial.

Art therapy for patients in acute psychotic episodes

T. Aladashvili

Center for Mental Health and Prevention of Addiction, Adult Psychiatry, Tbilisi, Georgia

Purpose Evaluate the efficacy of art therapy during acute psychotic episodes.

Methods Thirty-six inpatients with ICD-diagnoses of schizophrenia (F20.0–F20.9) age between 20–60 were randomised to either 12 twice-weekly sessions of psychodynamic group art therapy plus treatment as usual or to standard treatment alone. Art therapy was administered in 12 sessions of 90 minutes for 6 weeks. At 12 weeks, 55% of patients randomised to art therapy, and 66% of patients receiving treatment as usual were examined. Scales used: 17 – Item Hamilton Rating Scale for Depression (HRSD) for depression and Scale for the assessment of negative symptoms (SANS).

Interventions The approach was non-directive – patients could choose to create whatever they wanted and use any available material. Interventions by the art therapist aimed at supporting the art

process and helping to understand the image. The last 30 minutes of a session were reserved for a shared viewing and reflecting on the images.

Results With post-treatment and follow-up scores of SANS and HRSD patients who had received AT had a significantly greater mean reduction of positive and negative and also depressive symptoms at 12-week follow-up than patients treated as usual. Social functioning was significantly higher in the AT group. There were no significant interactions between intervention group and gender.

Conclusion Evidence on the efficacy and effectiveness of AT in patients with schizophrenia is far from being conclusive and benefits might be limited to a subgroup of patients. Results of this study suggest AT can be implemented in routine hospital settings for patients experiencing acute psychotic states.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

³ Institute Polytechnic of Coimbra, ESTESC, Coimbra Health School, Coimbra, Portugal

⁴ Coimbra Hospital and University Centre, Psychiatric Department, Coimbra, Portugal

* Corresponding author.

Introduction Perseverative Negative Thinking (PNT) is a transdiagnostic cognitive process [1] characterized by repetitiveness, intrusiveness and difficulties to disengage (Ehring, 2011). The Perseverative Thinking Questionnaire (PTQ-15; [2]) is a self-reported instrument, developed to evaluate these characteristics. The Portuguese version assess two meaningful dimensions – Repetitive thoughts (RT); and Cognitive interference and unproductiveness (CIU) [3].

Aim To confirm the bi-dimensional structure of the PTQ-15 using Confirmatory Factor Analysis, in two distinct samples.

Method A sample composed of 256 students (Mean age = 20.58 ± 1.870; 78.1% girls) and a sample composed of 480 adults from the community (parents of the students; mean age = 50.84 ± 5.310; 53.1% women) filled the PTQ-15. We used software AMOS.

Results The second-order model of PTQ-15 with two dimensions presented good fit, in both students (CMIN = 2.449; RMSEA = 0.075; CFI = 0.958, TLI = 0.949, PGFI = 0.776; $P < 0.001$) and their parents (CMIN = 3.46; RMSEA = 0.072, CFI = 0.955, TLI = 0.942, PGFI = 0.632; $P < 0.001$). Internal consistency of the total scale, measured through Cronbach's alpha was $\alpha = 0.95/0.94$; both factors presented good/excellent reliability: repetitive thoughts ($\alpha = 0.93/0.92$); cognitive interference and unproductiveness ($\alpha = 0.88/0.92$).

Conclusion Taken together, both CFAs provided additional evidence that PTQ-15 is an adequate measure for perseverative thinking.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The medical model of rehabilitation treatment of drug addicts with psychiatric comorbidity: Efficacy evaluation

Z. Bereza

The Saint-Petersburg State Medical University n. a. Acad. I. P. Pavlov, Department of Psychiatry and Rehabilitation, Saint-Petersburg, Russia

Introduction The medical model assumes the professional psychotherapeutic assistance at all stages of the rehabilitation process and pharmacological treatment of comorbid mental disorders.

Aim Evaluation of the efficacy of the medical model rehabilitation based on the clinical, psychological, and social characteristics of patients at the all stages of the treatment.

Subjects Eighty-five drug-addicted patients with psychiatric comorbidity. The inclusion criteria were: age above 18 years, withdrawal status. The patients were examined four times:

- 1 – during the first weeks of treatment;
- 2 – after 45 days;
- 3 – after 6 months;
- 4 – after 12 months.

Results and conclusions The primary evaluation the highest scores noted in the sections: “family and social connections”, “health status”, “psychiatric status” and “legal aspects” received lower scores. In the second measurement, the results established a significant improvement on the scale of “health status”, “mental status”, “alcohol”, “drug use” compared with original values. Early retired patients the most high-end performance observed on the scale of “drug alcohol using”, “job/livelihood”, “health status”, “legal aspects”, the “psychiatric status”, “family and social connections” recorded lower scores. Indicators on the scale of “drug use”, “alcohol” in this group of patients was significantly higher than patients who remain on treatment, which may indicate a possible updating of the attraction to the drugs. The third measurement showed a significant improvement ASI according to the all scales as compared to the previous ones. In the course of the rehabilitation process revealed positive changes in clinical, psychological and social characteristics of patients.

Predictive biomarkers in clozapine-treated patients: Assessment of the evidences and suggestion for research methodology

F. Cerrato^{1,*}, L. Guizzaro², P. Scudellari¹, A.R. Atti¹, D. De Ronchi¹

¹ Psychiatry, Department of Biomedical and Neuromotor Sciences, Bologna, Italy

² Second University of Naples, Medical Statistic, Napoli, Italy

* Corresponding author.

Introduction Predictive biomarkers are tools that identify a sub-population of patients who are most likely to respond to a given therapy. In order to identify them a strict methodology is necessary (RCT's studies). In consideration of its cost in economic and medical terms, predictive biomarkers would be useful to distinguish clozapine-resistant patients before its administration.

Aims The evidence concerning genetic biomarkers was reviewed with the aim of assessing whether there is enough evidence to claim for predictive biomarkers useful in practice. Secondary aims were the assessment of the evidence concerning genetic prognostic biomarkers and predictors of side effects in clozapine-treated schizophrenic patients.

Methods One hundred and twenty-eight studies, searched on the Pubmed database or referenced in other studies, were included in this review. Sixty-five papers were related to clozapine efficacy and explored 167 genetic variants.

Results Fifty-four variants were supported as prognostic biomarkers, three were successfully replicated: rs6280, rs6314 and rs4680; 49 papers were related to clozapine weight gain and explored 216 different genetic variants. Forty-five of which were positively related to weight gain during clozapine treatment. Among these 45 variants, only two, Rs3813929 and Rs779039, were successfully replicated.

Fourteen studies explored 111 genetic variants potentially correlated to Clozapine-induced agranulocytosis. Thirty-four variants were found to be associated with agranulocytosis. Five variants had positive results, successfully replicated. In particular, HLA B38.

Conclusions To date there is no evidence to support a modification of clinical practice towards predictive medicine. The research could ideally progress with RCTs involving the prognostic factors found in association studies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Loss of motivation and frustration for visitor surgeons in provincial health centers or psychiatric hospitals in Greece

I. Christodoulou^{1,*}, E. Pogonidou², C. Pogonidis², C. Charalambous³

¹ G. Papanikolaou General Hospital, B'surgical Department, Thessaloniki, Greece

² Democritus University of Thrace, Master Program in Health and Safety in the Workplace, Alexandroupolis, Greece

³ General Psychiatric Hospital, Internal Medicine Department, Thessaloniki, Greece

* Corresponding author.

Introduction The core workplace for a surgeon is the operating theatre. Secondary duties may include visits to small health centers for outpatient examinations and visitor work to psychiatric hospitals.

Objective The objective of our study is to highlight the mistakes of management that lead to half-empty provincial health centers and psychiatric hospitals.

Methods Presentation of the 2-year-experience of a surgeon visitor in provincial health centers and in a large psychiatric hospital in Greece.

Results The provincial health center of Lagada needs at least 4 surgeons to serve; too many patients to be examined or/and operated in 2–3 hours only. Subsequently problems arise, as simultaneously in the emergencies department a surgical eye for an abdominal pain or a bad looking leg is needed every 15 minutes. The health center of Koufalia needs 3 hours of driving per day for 3–8 surgical patients only. The psychiatric hospital offered work for 3 surgeons 5 days a week for a long period of time. During 2012–2014, only one surgeon visited the hospital once a week. The work needed to be done may kill the surgeon or force him to receive antidepressants in order to keep his functions alive.

Conclusions Not a hint of scientific motivation for two years is a strong reason for a surgeon to avoid the duty to provincial health centers and psychiatric hospitals which is obligatory according to

our national health system Laws until two years are completed for newly appointed surgeons. Managers might encourage surgeons if some balancing convenience was offered.

A grounded theory of service providers' perceptions of a recovery-oriented transformation of a mental health service

G. Eikmeier^{1,*}, T. Junghans², T. Kruse², A. Lacroix¹

¹ Klinikum Bremerhaven, Psychiatry, Bremerhaven, Germany

² Klinikum Bremerhaven, Management Board, Bremerhaven, Germany

* Corresponding author.

Recovery-oriented mental health service programs are often rather based on ideological or political considerations than on empirical evidence.

At Klinikum Bremerhaven Reinkenheide, we have included peer support workers in our teams in order to improve the quality of our treatment program and the recovery attitudes of the staff members. To control and evaluate this process an independent investigator conducted 13 (T1: February 2012), respectively 15 (T2: September 2013) interviews with different stakeholders of the change process. The interviews were transcribed and analysed for the categories level of information, confidence, participation and profession/working conditions/team structure.

The main result of T1 was that nursing staff fostered the projected transformation while physicians and psychologists focused on risk management and worried about losing their role. As implication of the T1 results, we offer a continuous in-house-training to improve interprofessional teamwork and social psychiatric expertise. At T2 all interviewed participants judged the involvement of the peer support workers positively. Many of the interviewees expressed though that from their point of view their participation had decreased and/or, the reorganisation was already terminated. As implication of T2, we now try to improve our internal communication and cooperation and strengthen the involvement of all stakeholder groups.

Besides the employment of peer support workers, it is essential in a recovery-oriented transformation of mental health services:

- to train staff members continuously and;
- to involve all stakeholder groups continuously in the change management.

A third survey is projected for 2017 to implement further requirements for a successful change process.

⁴ Faculty of Health Sciences, University of Aalborg, Department of Health Science and Technology, Aalborg, Denmark

* Corresponding author.

Introduction Individual placement and support (IPS) is an evidence-based intervention where IPS consultants support people with severe mental illness in achieving competitive employment. IPS is a recovery-oriented intervention, but vast evidence regarding its ability to influence recovery-oriented outcomes challenges this position.

Aim To investigate how an IPS-intervention influences the personal recovery process in people with severe mental illness.

Method A qualitative phenomenological study including interview of 12 participants in an IPS-intervention. Analysis was made using a four-step phenomenological analysis method.

Results IPS contributed to personal recovery in a number of ways: The IPS consultants' ability to create an equal, acknowledging and safe relationship where participants' needs were taken into consideration in the search and support for job or education was found valuable. In combination with employment, the role of the IPS consultant contributed to normalization and stabilisation of participants' daily lives, changed their behaviours and beliefs about maintaining new achievements, personal goals and dreams.

Conclusion Individual placement and support provides opportunities to gain personal goals and contributes to stabilisation and normalization of participants' daily lives. This study supports the notion that the individual placement and support positively influences personal recovery in people with severe mental illness.

Healthy lifestyles programme in an acute psychiatric inpatient unit

I. Ganhaio^{1,*}, M. Trigo², A. Paixao³, J. Cardoso²

¹ Centro Hospitalar Psiquiátrico de Lisboa, Serviço de Psiquiatria Geral e Transcultural, Qta do Anjo, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Serviço de Psiquiatria Geral e Transcultural, Lisbon, Portugal

³ Centro Hospitalar Psiquiátrico de Lisboa, Serviço de Alcoolologia e Novas Dependências, Lisbon, Portugal

* Corresponding author.

Introduction Mental health issues and illnesses are associated with poor self-care and unhealthy lifestyles that contribute to morbidity, mortality and overall decrease in quality of life when compared to the general population. Healthy lifestyle promotion is infrequently considered a priority in mental healthcare services, especially in acute psychiatric inpatient units.

Objectives To present a healthy lifestyles promotion programme implemented in an acute psychiatric inpatient unit.

Aims To reflect on how to design an adequate programme for patients with complex needs.

Methods In a general psychiatric inpatient unit, a team of two psychologists and one psychiatrist, ventured to introduce weekly activities that included drawing, colouring, painting, crafts and games, that provided a context for patients and the team to sit down together or to gradually "drift" together and make possible conversations focusing on tobacco smoking, caffeine consumption, weight control, physical activity and health promoting activities.

Results Instead of individual or group psychoeducation talk interventions, play and art strategies, in closer proximity with the patients, made it far easier to engage difficult patients and made psychoeducation possible and fun.

Conclusions Patients with severe mental illness are frequently reluctant to engage in activities targeting healthy lifestyles, especially in acute psychiatric inpatient units, when insight and motivation for change may be low due to illness and consequences

of illness. Play and art therapy interventions led by a team of mental healthcare professionals who participate directly with the patients, may be an innovative, more effective and enjoyable strategy.

Population attributable fraction (PAF) in repeated measures design: Childhood traumas as predictors of psychotherapy outcomes

T. Härkänen*, O. Lindfors, E. Heinonen, P. Knekt
National Institute for Health and Welfare THL, Department of Health, Helsinki, Finland

* Corresponding author.

Introduction Population attributable fraction (PAF) represents the proportion of treatment failure, which could be avoided, if the individuals at high risk were similar to the individuals at low risk. The PAF, however, has not been available for repeated measures designs.

A relatively prevalent and strong risk factor for many adulthood disorders, such as depression and anxiety, are adversities and traumas experienced in childhood. Little is, however, known of their implications for common treatments such as psychotherapy.

Objectives To develop PAF for repeated measures, and to provide a useful tool in various research fields to provide decision-makers results, which are easier to interpret.

This study will examine the relative importance of different childhood traumas as predictors of psychotherapy outcome in a patient population with depressive and anxiety disorders.

Methods PAF was calculated using generalized linear mixed models and Bayesian predictive distributions.

The data is based on 326 outpatients, randomized in one long-term and two short-term psychotherapies by the Helsinki Psychotherapy Study. Patients were assessed up to 10 times during a 5-year follow-up. A combination of psychiatric symptoms measured, is used as the outcome measure.

Results The repeated measures PAF will provide a useful aggregate measure over the follow-up time and over the patient population.

Conclusions The repeated measures PAF will provide insight on the relative importance of the different domains of childhood traumas on therapy outcome. Associations of individual-level risk factors do not provide guidelines for policy decisions, which should acknowledge also prevalences of the risk factors in the patient population.

Characterizing the inpatient care of young adults experiencing early psychosis

R. Kamieniecki^{1,*}, B. Vaughn¹, J. Danielson¹, K. Bonnie¹, M. Carter¹, T. Mihic¹, S. Williams², J. Puyat³

¹ St. Paul's Hospital, Mental Health, Vancouver, Canada

² Simon Fraser University, Public Health, Burnaby, Canada

³ University of British Columbia, Centre for Health Evaluation and Outcome Sciences, Vancouver, Canada

* Corresponding author.

Introduction/objectives The available literature suggests that treatments and health services for psychosis are considered to be poorly organized and highly variable. Little is known, however,

about how inpatient care is provided to individuals experiencing early psychosis. To facilitate quality improvement activities, we characterized the care this patient group receives in an inner city hospital.

Methods We performed chart reviews of individuals admitted to psychiatric inpatient units at St. Paul's Hospital, Vancouver, British Columbia between 01/04/2014 and 31/03/2016. Those who were 17–25 years of age and hospitalized for psychotic symptoms at the time of admission were included. Demographic and health service use were summarized using descriptive characteristics.

Results We identified 73 inpatients (mean age = 22; males = 78%; Caucasian = 41%) that met study inclusion criteria, having a combined total of 102 care episodes and an average length of stay of 30.7 days (median = 18; min = 3; max = 268). Half of the care episodes were repeat admissions, with up to 30% of the patients readmitted within 28 days of discharge. Physical and mental status examinations (MSE) were performed in virtually all care episodes, although frequency is low (31.4% had daily physical examinations and 18.6% had MSE every nursing shift). In 49% and 50% of care episodes, patients were given oral antipsychotics and discharged on depot medications. Even when indicated, not all care episodes had follow-up appointments (60%) or referrals to income assistance (35%), community mental health teams (61%), and housing support (38%).

Conclusions Specific programs are needed to address current gaps in inpatient care for patients with early psychosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Objectives Mental health conditions (MHC) have been associated with restrictions in daily life participation and functioning affecting health and well-being. Substantial numbers of people with MHC experience hospitalizations, however, there is limited evidence supporting functional interventions in the in-patient setting to promote recovery. The OC is an intervention implemented during sub-acute hospitalization, which attempts to promote activity and participation of people with MHC, both during the in-patient stay and upon return to the community, with a view to enabling recovery. To facilitate its implementation, we investigate the OC effectiveness.

Aims Investigate the OC contribution to cognition, symptoms and functional capacity among inpatients with schizophrenia.

Methods This is a quasi-experimental, prospective, pre/post-designed study with convenience sampling. Inpatients with schizophrenia were enrolled into the study group participating in the OC intervention ($n = 16$); or the control group participating in hospital treatment as usual ($n = 17$). The study participants completed evaluations at baseline and at discharge or after 10 weeks with: Neurocognitive State Examination, Trail Making Test, Ray Complex Figure, and Category Fluency Test for aspects of cognition; Positive and Negative Syndrome Scale for symptoms severity, and Observed Tasks of Daily Living-Revised for functional capacity.

Results Statistically significant improvement in cognitive functioning, symptoms severity and functional capacity was found in the study group after the intervention. These changes were not observed in the control group.

Conclusion The results support the OC effectiveness for cognitive and functional capacity improvement and symptomology relief. The findings advance the body of evidence for functional interventions in hospital settings.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Compare “family atmosphere” in informal caregivers of patients with psychotic symptoms compared to their inclusion or not in self-help associations

M. Mentis^{1,*}, M. Gouva², E. Kotrsotisiou³, N.V. Angelopoulos¹, E. Dardiotis¹

¹ University of Thessaly, Postgraduate Program “Primary Health Care”, Larisa, Greece

² Technological Educational Institute of Epirus, Research Laboratory Psychology of Patients Families and Health Professionals, Ioannina, Greece

³ Technological Educational Institute of Thessaly, Research Laboratory of Care, Larisa, Greece

* Corresponding author.

Introduction The participation of informal caregivers in the café of patients with psychotic symptoms in coordination with self-help groups have been found to reduce the expressed emotion in combination with psychoeducations interventions help create a supportive environment.

Objectives This study investigates the differences in the family atmosphere of informal caregivers of patients with psychotic symptoms.

Aims To compare whether or not the participation of informal caregivers of patients with psychotic symptoms in self-organized associations helps to foster a supportive family environment, hence reducing the risk of relapse.

Methods Snowballing sampling consisting of 510 informal caregivers of patients with psychotic symptoms was used in the current study. The Family Environment Scale of Moos and Moos and socio-demographic questions were implemented to collect the data. Control Cronbach's Alpha reliability of scale gave value $\alpha = 0.795$.

Results The comparison showed that informal caregivers of patients with psychotic symptoms irrespective of their participation or not in self-help associations do not show significant differences in Family Environment Scale. Significant statistical difference between the two groups ($P < 0.05$) only occurred in the subcategory “organization”, as the first group ($m = 4.68$, $df = \pm 2.233$) were found to have lower values compared to the other group ($m = 5.21$, $df = \pm 2.233$).

Discussions The study demonstrated that informal caregivers of patients with psychotic symptoms involved in self-help groups do not show to have a particular difference in the family atmosphere than families who do not participate in self-help associations.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A randomized controlled study: The effects of self-referral to inpatient treatment on patient activation

I.E.O. Moljord^{1,*}, M. Lara-Cabrera²

¹ St. Olavs University Hospital, Nidaros DPS, Trondheim, Norway

² St. Olavs University Hospital, Tiller DPS, Trondheim, Norway

* Corresponding author.

Introduction Self-referral to inpatient treatment (SRIT) has recently been implemented in Norway in several community mental health centers (CMHC) in an effort to increase activation and to improve access to mental health services and timely treatment.

Objective To examine the effect of having a contract for self-referral to inpatient treatment (SRIT) in patients with severe mental disorders. This intervention was based on personalized care planning, legislation regarding patients' rights and is intended to enhance user participation.

Aims To assess the 12-month effect on patient activation measure-13 (PAM-13).

Methods A randomized controlled trial with 53 adult patients; 26 participants got a SRIT contract which they could use to refer themselves into a CMHC up to five days for each referral without contacting a doctor in advance. Preliminary results on the primary outcome after 12 months with the self-report questionnaires Patient Activation Measure (PAM-13), will be analyzed using linear mixed and regression models.

Results The preliminary results showed no significant effect on PAM-13 (estimated mean difference [emd] -0.41 , 95% CI [CI]: -7.49 to 6.67). A post hoc analysis found an effect of SRIT on PAM-13 in those with baseline PAM-13 scores below ≤ 47 .

Conclusion There were no group differences.

Trial design Clinicaltrials.gov NCT01133587.

Treatment profiles in a Danish psychiatric university hospital department

N. Okkels^{1,*}, R.B. Mogensen², L. Crean³, S. Skadhede², C.H. Vestergaard², C. Rasmussen², J.W.D. Shanmuganathan², K.B. Hansen², P. Munk-Jørgensen²

¹ Aarhus University Hospital Risskov, Aarhus University Hospital, Clinic for OCD and Anxiety, Risskov, Denmark

² Aarhus University Hospital Risskov, Department of Organic Psychiatric Disorders and Emergency Ward, Risskov, Denmark

³ Aarhus University, Department of Mathematics, Aarhus, Denmark

* Corresponding author.

Introduction Despite concerns about rising treatment of psychiatric patients with psychotropic medications and declining treatment with psychotherapy, actual treatment profiles of psychiatric patients is largely unknown.

Aims To describe patterns in the treatment of patients in a large psychiatric university hospital department.

Methods A descriptive mapping of treatment of in- and outpatients in a psychiatric department at Aarhus University Hospital Risskov, Denmark. Information was collected by health care staff using a 25-item survey form. The P -value was calculated with a χ^2 test and $P < 0.05$ was considered significant. The study was preceded by a pilot study on 41 patients.

Results Over a 1 month period we assessed a total of 343 consecutive patients and hereof included 200 in the age range 18–90 years (mean 53.76); 86 men and 114 women. One hundred and eighty-eight patients (94%) used psychotropic medication, 37 (19%) as monotherapy and 148 (74%) in combination with non-pharmacological therapy. Ninety-seven (49%) had psychotherapy and 104 (52%) social support. Among inpatients, 21 (64%) had physical therapy, and 10 (30%) electroconvulsive therapy. In total, 163 (82%) had non-pharmacological therapy. Fifty-two (26%) patients had monotherapy and 148 (74%) polytherapy. Mean number of

treatment modalities used pr. patient was 2.07 for all patients and 3.23 for inpatients.

Conclusions In our department, polytherapy including non-pharmacological modalities is applied widely across all settings and patient categories. However, psychotropic medication clearly dominates as the most frequently applied treatment.

H-index may influence more than methodological variables for publication in high impact psychiatry journals – A systematic review

L. Primo de Carvalho Alves*, A.A. Rodrigues, F. Moreira Lima, N. Janovik, L. Sanguinetti Czepielewski, K.M. Mendes Ceresér, N. Sica da Rocha

Universidade Federal do Rio Grande do Sul, Programa de Pós-graduação em Psiquiatria e Ciências do Comportamento, Porto Alegre, Brazil

* Corresponding author.

Objectives The scientific community assumes that rigorous methodology research is more likely to be published in high impact psychiatry journals (HIJ). We aimed to test which methodological variables could predict publication in HIJ.

Methods We conducted a systematic review of the MEDLINE and EMBASE databases from 2013, January 1st to 2015, June 15th. Inclusion criteria were studies that were RCTs whose at least one arm of the study should be fluoxetine regarding adult patients (>18 years old) with MDD. We performed logistic regression regarding the number of participants, intention-to-treat analysis, blinding, multicenter study, sample losses, positive result, sponsorship of pharmacy's industry, and h-index of the last author. A HIJ was considered if journal impact factor was above the median or 3rd quartile of our sample.

Results Forty-two studies were considered for the final analysis. The results of the univariate logistic regression found no differences between HIJ and low impact psychiatry journals for all methodological variables, except the h-index of the last author. By considering HIJ when impact factor was above the mean, h-index had an odds ratio = 1.09 (1.01–1.17), $P=0.02$; considering HIJ when impact factor was above the 3rd quartile, h-index had an odds ratio = 1.07 (1.01–1.14), $P=0.02$.

Discussion Our results indicate that the author productivity may be a relevant predictor for publication in a HIJ in the psychiatry/psychology field. Our study proposes that journals focus on identifying what are the relevant criteria for publication approval in the peer-review process.

Disclosure of interest The authors have not supplied their declaration of competing interest.

¹ University of Naples SUN, Department of Psychiatry, Naples, Italy

² University of Salerno, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Section of Neurosciences, Salerno, Italy

* Corresponding author.

Introduction Family members of patients with EDs report high levels of burden, psychological distress and the need to receive information on the disease of their ill relative. There is the need to provide family members and patients with psychoeducational family intervention in order to satisfy their care needs.

Objective To develop a new psychoeducational approach for patients with Eating Disorders (EDs) and their relatives according to the Falloon model.

Aims (1) To develop a family psychoeducational intervention for patients with EDs. (2) To implement the experimental intervention in the clinical routine care. (3) To evaluate efficacy of the approach in terms of reduction of family burden and improvement of relatives' coping strategies.

Results The Department of Psychiatry of the University of Naples SUN has developed a new psychoeducational family intervention for patients with EDs and their family members. The intervention consists of 6 sessions, scheduled weekly. The sessions deal with several topics such as information on EDs (e.g., causes, symptoms, clinical characteristics), communication skills (e.g., how to express an unpleasant feeling) and problem solving skills. The intervention is led by trained mental health professionals, such as psychiatrists, psychologists or rehabilitation technicians.

Discussion This is the first example of psychoeducational intervention for families of patients with EDs developing according to the Falloon approach.

Conclusions Family intervention represents an essential tool to provide to patients with EDs and their family members in order to promote a global recovery.

Impact of communication on family satisfaction and anxiety in critical care

K. Sundararajan

Royal Adelaide Hospital, Intensive Care Unit, Adelaide, Australia

Objective The objectives of this study were to explore the impact of a communication course for doctors on family satisfaction and anxiety in an Australasian ICU and to elucidate the determinants of family satisfaction and anxiety.

Design Prospective observational study. Pre- and post-study design.

Participants One hundred and three consecutive family members of patients staying in the ICU for more than 48 hours were identified. Eighty-six subjects were evaluated and analysed.

Methods Ten-point Likert scale (FS-ICU Questionnaire) used to measure satisfaction. Hospital Anxiety and Depression Scale was used to measure anxiety. Study performed over a 12-week period (9 weeks pre- and 3 weeks post-course) in a 34-bed intensive care unit before and after a communication course for junior medical officers.

Results Fifty-six subjects were approached for the purpose of this study. Forty-three family members were included, 40 of patients who survived, and 3 whose relative died in ICU. Overall family satisfaction was high (mean scores 9.44 ± 0.91). Post-course, 47 subjects were approached for the purpose of this study and 43 family members consented to participate. Overall family satisfaction was high (mean scores 9.84 ± 0.97). There was a statistically significant difference in the frequency of doctors' communication before and after the course ($P < 0.01$) and anxiety levels ($P = 0.0001$)

Conclusion The majority of families are happy with their care in the ICU. A communication course aimed at junior medical officers was effective in improving satisfaction and reducing anxiety among family members.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Using junior doctors to improve patient care: Creating a clinic to monitor the physical health of patients prescribed clozapine

M. Tonkins, P. Hardy, S. Foster*, S. Mullins
Sheffield Health and Social Care NHS Foundation Trust, West Community Mental Health Team, Sheffield, United Kingdom
* Corresponding author.

Introduction In the United Kingdom, compliance with guidelines on physical health monitoring of patients prescribed clozapine is poor. Our community team established a 'clozapine clinic', led by junior doctors, to monitor the physical health of this population.

Aims The aims of this audit were:

- to ascertain levels of compliance with guidelines on the physical health monitoring of patients taking clozapine;
- to compare the current level of compliance with that prior to the establishment of the clinic.

Methods Eleven standards were drawn from National Institute for Health and Care Excellence guidelines and the Maudsley Prescribing Guidelines in Psychiatry.

Three audit cycles were conducted: two prior to the establishment of the clinic and one after. In each cycle, searches of patient records were conducted and blood results were reviewed. This was supplemented by telephone calls to general practitioners to ensure a complete data set.

Analysis was conducted in Microsoft Excel™ and changes between the cycles were analysed using a two-tailed Z-score.

Results Each audit cycle included 28–30 patients. In the current cycle compliance levels varied between 66% (annual ECG recording) and 100% (monthly full blood count). The average compliance level was 73% across all standards. This represents an overall improvement on previous audit cycles. Since the clinic was established there has been a statistically significant improvement in compliance with annual monitoring of weight ($P=0.147$), body mass index ($P=0.0178$), and ECG monitoring ($P=0.0244$).

Conclusions Improvements in the care of a vulnerable population may be achieved through setting clear standards, regular audit, and harnessing the leadership and enthusiasm of junior doctors.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Enhancement of flexible cognition in autism

C. Varanda, F.D.M. Fernandes*
University of São Paulo, Department of Physical Therapy, Speech, Language Pathology and Audiology, and Occupational Therapy, São Paulo, Brazil

* Corresponding author.

Autism is defined by qualitative deficits in communication, social interaction and restricted patterns of interests and behavior. There are also reported difficulties in the dynamic activation and modification of cognitive processes in response to changes in tasks demands. It is assumed that poor flexible cognition is related to those difficulties. This research aimed to assess and intervene in cognitive flexibility in subjects with autism.

Ten subjects diagnosed with autism by psychiatrists, aged 5y to 13y5m, were assessed in cognitive flexibility through WCST in pretest and in patterns of social interactions, behaviors and com-

munication through ADI-R. An intervention program with 14 to 21 sessions designed to enhance cognitive flexibility through activities of local coherence inference, constructive praxis, attentional shifting, inhibitory control, besides drama games after reading stories. In posttest, they were assessed in WCST and ADI-R. Raw scores of categories completed and perseverative errors and responses were used.

Regarding flexible cognition, perseverative errors and responses were lower in posttest ($P=0.028$). Categories completed were improved in posttest ($P=0.049$). Total scores on ADI-R were lower in posttest ($P=0.051$) and as well as scores on communication abilities ($P=0.033$).

The qualitative improvement showed by the individuals of this research concerning flexible cognition and also patterns of restricted behavior, social interaction and communication abilities suggests that individuals with autism can benefit from the development of strategies for the rehabilitation of flexible cognition and more research is suggested with a larger sample among subjects on the autism spectrum.

Awareness of and satisfaction with available treatment options in schizophrenia: Results from a survey of patients and caregivers in Europe

P. Cherubin^{1,*}, C. Maria², L. Hargarter³, A. Wooller⁴

¹ Janssen, Medical Affairs, Issy-les-Moulineaux, France

² Janssen, Communication & Public Affairs, Bucharest, Romania

³ Janssen, Medical Affairs, Neuss, Germany

⁴ Janssen, Medical Affairs, High Wycombe, United Kingdom

* Corresponding author.

Introduction Understanding beliefs and concerns of patients with schizophrenia and their caregivers, regarding treatment options, is key to improving their care. Perceived fears can impact adherence to therapy and represent a barrier to prescribers when discussing treatment decisions.

Objectives Explore patient and caregiver awareness of and satisfaction with available treatment options.

Methods Independent market research agency commissioned by Janssen, performed an online European survey in 2016 to capture demographics, awareness of available therapies, current treatment satisfaction and adherence from patients with schizophrenia and caregivers.

Results Results from 166 patients with schizophrenia and 468 caregivers from 12 European countries (France, Germany, UK, Italy, Spain, Denmark, Russia, Sweden, Austria, Belgium, Switzerland, and the Netherlands). One-fifth of patients reported they have not discussed alternative treatment options with their healthcare professional (HCP) despite 37% of patients being dissatisfied or very dissatisfied with their current therapy. HCPs were considered as the primary information source for the majority of patients (73%), although 27% of patients and 25% of caregivers believed that HCPs were not fully aware of all available treatment options. Moreover, 68% of patients treated with oral antipsychotics confirmed they would consider switching to a long-acting antipsychotic treatment, though 32% reported they have not been made aware of it as an

option. Many caregivers (46%) reported dissatisfaction with their level of involvement in treatment decisions.

Conclusions This survey underlines the critical role HCPs play in providing relevant information on treatment alternatives and emphasize the need for an open dialogue on available treatment options between HCPs, patients and caregivers.

Disclosure of interest Pierre Cherubin is a full-time Janssen employee working within the Medical Affairs Department. The other authors have not supplied their declaration of competing interest.

Lack of insight as a third variable between subjective appraisal of cognitive impairment and psychotic symptoms

R. Rossi^{1,*}, V. Santarelli¹, C. Marucci¹, D. Gianfelice², F. Pacitti¹

¹ University of L'Aquila, Department of Applied Clinical Sciences and Biotechnologies DISCAB, L'Aquila, Italy

² S. Salvatore Hospital, Community Mental Health Department, L'Aquila, Italy

* Corresponding author.

Background The relationship between subjective appraisal of cognitive deficits and symptom severity in schizophrenia is unclear. Insight reportedly impacts on both factors. Our aim is to further assess the relationship between the subjective perception of cognitive deficits, symptom severity and lack of Insight as a mediator variable.

Methods A total of 109 subject diagnosed with schizophrenia. Positive and Negative Syndrome Scale (PANSS) was modelled as dependent variable; Subjective Scale to Investigate Cognition in Schizophrenia (SSTICS) was modeled as independent variable and "Lack of Insight" (LoI) PANSS Item was tested as a mediator variable. Mediation was assessed using the Sobel Mediation Test.

Results LoI acts as a suppressor variable (i.e. it enhances the relation between the independent and dependent variable) between SSTICS and negative symptoms, while showing a mediator effect between SSTICS and depressive symptoms.

Discussion LoI has a central role in mediating the relationship between subjective appraisal of cognitive deficits on the one hand and positive and depressed symptoms on the other. Its suppressor role between SSTICS and depression is consistent with several reports of an enhanced risk of depression in patients fully aware of their disability. Its mediator role between SSTICS and positive symptoms supports the centrality of LoI as a metacognitive function whose failure may worsen psychotic symptoms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Biometrika Healthcare Research, Zagreb, Croatia

* Corresponding author.

Introduction Increased somatic morbidities in schizophrenic patients and their association with HRQoL are well documented. Less is known about their association with schizophrenia treatment outcome.

Objective To explore whether the number of somatic comorbidities is associated with poorer psychosis treatment outcome independently of psychiatric comorbidities and other clinical and socio-demographic parameters.

Aim To improve understanding of association of somatic morbidities on treatment outcome of schizophrenic patients.

Methods This nested-cross-sectional study was done during 2016 at Psychiatric hospital Sveti Ivan, Zagreb-Croatia on the sample of 301 patients diagnosed with schizophrenia spectrum disorder. Outcomes were the number of psychiatric rehospitalizations since primary psychiatric diagnosis and the composite of significant improvement measured by CGI-S and the best self-rated health defined as 4th quartile of EQ-5D-5L VAS. Predictors were number of somatic and psychiatric comorbidities. By logistic regression, we controlled socio-demographic and clinical confounders.

Results Having two or more somatic comorbidities was significantly associated with the failure to achieve the composite of improvement. The number of somatic comorbidities was significantly associated with increase in psychiatric hospitalizations, even after the adjustment for psychiatric comorbidities and large number of clinical and socio-demographic variables.

Conclusions Chronic somatic comorbidities are associated with poorer psychosis treatment outcome independently of psychiatric comorbidities and other factors. Therefore, to treat psychosis effectively it may be essential to treat chronic somatic comorbidities promptly and adequately. The integrative approach should be the imperative in clinical practice.

Predictors of insight in patients with schizophrenia

R. Softic^{1,*}, A. Sutovic¹, E. Osmanovic², E. Becirovic¹, E. Avdibegovic¹, M. Mirkovic Hajdukovic¹

¹ University Clinical Center Tuzla, Psychiatry Clinic, Tuzla, Bosnia and Herzegovina

² BH Heart Center Tuzla, Cardiovascular Unit, Tuzla, Bosnia and Herzegovina

* Corresponding author.

Aim To establish predictors of insight in patients with schizophrenia with regard to symptoms severity, executive functioning, level of education, marital status, age, and number of hospitalizations.

Subjects and methods A cross-sectional study was conducted on 60 consecutive outpatients with schizophrenia. Positive symptoms were established with 4-item Positive Symptom Ranking Scale (PSRS), and negative symptoms with Brief Negative Symptoms Assessment (BNSA). The level of insight was established with Self-Appraisal of Illness Questionnaire (SAIQ). Executive functions were established with Wisconsin card sorting test, and three verbal subtests from Wechsler's Intelligence Test: information, similarities, and calculating. All neuropsychological tests were administered by psychologist educated in administration of these and other neuropsychological tools.

Results Predictive statistical model identifies age and illness duration as negative, and higher level of education, and being married as a positive predictors of insight with 38.5% variance

explained. Scores on subscales “Similarities” and “Calculating” had positive association with insight score. Model explains 24.7% of variance. When model was adjusted on alpha 5% level of concluding only three significant positive predictors appears: higher level of education, higher score on “Similarities” subscale, and being married. Model explains 38.5% of variance.

Conclusion Level of education and marital status, among all other factors, have important impact on level of insight in patients with schizophrenia.

Can neuropsychological testing facilitate differential diagnosis between at-risk mental state for psychosis and adult attention deficit hyperactivity disorder?

E. Studerus

University of Basel Psychiatric Hospital, Center for Gender Research and Early Detection, Basel, Switzerland

Introduction Patients with an at-risk mental state (ARMS) for psychosis and patients with attention deficit hyperactivity disorder (ADHD) have many overlapping symptoms and hence can be difficult to differentiate clinically.

Objectives The aim of this study was to investigate whether the differential diagnosis between ARMS and ADHD could be improved by neuropsychological testing.

Methods A total of 157 ARMS and 122 adult ADHD patients were recruited via the Basel Früherkennung von Psychosen (FePsy) study and the ADHD Special Consultations Unit of the University of Basel Psychiatric Hospital, respectively. Verbal learning and memory was tested with the California Verbal Learning Test (CVLT), sustained attention with the Continuous performance test (CPT) and problem solving abilities with the Tower of Hanoi task. Group differences in neuropsychological performance were analyzed using generalized linear models, which included age and gender as covariates.

Results Adult ADHD patients recalled significantly fewer words in the CVLT (both after short and long delay) and had significantly more false alarms and omissions and longer reaction times in the CPT than ARMS patients.

Conclusions Adult ADHD patients show larger deficits than ARMS patients in the domains of verbal memory and sustained attention, but not in problem solving abilities. This in line with current meta-analyses, which found that impairments in the domains of attention and verbal memory are of medium effect size in adult ADHD patients and of small effect size in ARMS patients. Our results suggest that measures of these domains can be exploited to improve the differential diagnosis between adult ADHD and ARMS patients.

Clozapine augmented with risperidone in treatment-resistant schizophrenia

G. Sulejmanpasic^{1,*}, S. Bise²

¹ Clinical, Psychiatric Clinic, Sarajevo, Bosnia and Herzegovina

² Cantonal Psychiatric Hospital of Sarajevo, Clinical, Sarajevo, Bosnia and Herzegovina

* Corresponding author.

Introduction The evolution of various pharmacological therapies for schizophrenia has given rise to several pharmacological models for the neuroreceptor targets of antipsychotics and the influence of various neuroreceptors on specific symptoms and side effects.

Objectives Experience in clinical practice affirms clozapine's position as the treatment of choice for patients with treatment-refractory schizophrenia. Unlike clozapine, risperidone has a more targeted profile of neurotransmitter binding, with particular predilection for dopamine and serotonin receptors. Risperidone is, to date, the most extensively documented clozapine augmentation agent.

Aim The aim was to evaluate clinical efficacy, safety and tolerability of augmenting clozapine with risperidone in patients with treatment-resistant schizophrenia.

Methods In a randomized, double-blind, placebo-controlled 8-week trial, 10 patients unresponsive or partially responsive to 300 mg/day of clozapine monotherapy ($n=5$) received a steady dose of 450 mg/day clozapine combined with or up to 4 mg/day of risperidone ($n=5$). Patient psychopathology was assessed at 2-week intervals with the Brief Psychiatric Rating Scale (BPRS), the Scale for the Assessment of Negative Symptoms (SANS) and Clinical Global Impression (CGI) improvement scale.

Results From baseline to week 4 and week 8, mean BPRS total and positive symptom subscale scores were reduced significantly in both groups, but the reductions were significantly greater with clozapine/risperidone treatment. Reductions in SANS scores were also significantly greater with clozapine/risperidone treatment than with clozapine monotherapy group. Clozapine/risperidone treatment did not induce additional weight gain or agranulocytosis compared with clozapine monotherapy treatment.

Conclusions Clozapine augmentation with risperidone appears to be well tolerated, safe and may provide additional clinical benefit for patients who are nonresponsive or only partially responsive to clozapine alone.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The association of schizophrenia symptoms clusters with obsessive compulsive symptoms

E. Theochari^{1,*}, E. Tsaltas², D. Kontis³

¹ Psychiatric Hospital of Attica “Dromokaiteio”, Tarsi, Athens Chaidari, Greece

² Athens University Medical School, Experimental Psychology Laboratory, 1st Department of Psychiatry, Athens, Greece

³ Psychiatric Hospital of Attica, Cognitive Rehabilitation Unit, Athens, Greece

* Corresponding author.

Introduction Thirty percent of individuals with schizophrenia demonstrate obsessive compulsive symptoms (OCSs). There is conflicting data on the effects of antipsychotic medication on OCSs in schizophrenia. The delineation of the relationship of OCSs with positive, negative and general psychopathology symptoms has theoretical and treatment implications.

Objectives To investigate the relationship among OCSs with the symptoms clusters in schizophrenia.

Methods We recruited 110 chronic schizophrenia patients and assessed OCSs (Yale-Brown Scale) and schizophrenia symptoms (Positive and Negative Syndrome Scale). In order to investigate the relationship of OCSs with clusters of schizophrenia symptoms, we conducted correlation analyses between YBOCS total scores or obsession or compulsion subscores with the PANSS symptoms scores (total, positive, negative and general psychopathology) and the cognitive scores derived from CANTAB. We re-conducted these

correlations for the sub groups with clinically detectable OCSs (YBOCS > 8) and clinically significant OCSs (YBOCS > 14).

Results The only significant correlation was that of scores of OCSs with PANSS general psychopathology scores ($\rho = 0.190, P = 0.047$). Obsessions and compulsions did not significantly correlate with positive or negative symptom clusters. No significant correlation between OCSs and schizophrenia symptoms were detected in the subgroups with clinically detectable or significant OCSs.

Conclusions OCSs appear to be a separate symptom cluster in the context of schizophrenia, suggesting that OCSs cannot be expected to be influenced by standard antipsychotic treatments.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Obsessive compulsive symptoms, social functioning and executive functions in chronic schizophrenia

E. Theochari^{1,*}, E. Tsalas², D. Kontis³

¹ Psychiatric Hospital of Attica “Dromokaiteio”, Tarsi, Athens Chaidari, Greece

² Athens University Medical School, Experimental Psychology Laboratory, 1st Department of Psychiatry, Athens, Greece

³ Psychiatric Hospital of Attica, Cognitive Rehabilitation Unit, Athens, Greece

* Corresponding author.

Introduction Schizophrenia leads to functional deficits. A third of schizophrenia patients have obsessive compulsive symptoms (OCSs). The existing studies, which have investigated the effect of OCSs on social functioning (SF) of schizophrenia patients have produced contradictory findings and, interestingly, they have not adjusted for the role of executive functioning.

Objectives To investigate the predictive role of OCSs on SF in schizophrenia controlling for the effects of executive functioning.

Methods In a cross-sectional study of 110 chronic schizophrenia patients we assessed OCSs (Yale-Brown Scale), SF (Strauss Carpenter Scale) and composite executive function (cognitive flexibility: Intra-extra dimensional set shifting task and planning: Stockings of Cambridge task) using the Cambridge Neuropsychological Test Automated Battery (CANTAB). We also measured total symptoms (PANSS total scores) and illness duration. Regression analysis tested the predicting role of OCSs (YBOCS total score) on functioning taking into account executive function (composite score) duration of illness and schizophrenia symptoms.

Results OCSs were associated with better SF ($B = 0.099$; 95% CI = 0.019, 0.180; $t = 2.449$; $df = 88$; $P = 0.016$). This result was driven by the association of OCSs with job functioning ($B = 0.043$; 95% CI = 0.006, 0.081; $t = 2.289$; $df = 88$; $P = 0.024$). Executive functions were not significantly associated with social functioning.

Conclusions OCSs and not executive functions are associated with social functioning in schizophrenia. Future studies should examine whether OCSs represent a compensatory mechanism aiming at preserving social functioning in the disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ University of Eastern Finland, Kuopio Research Centre of Geriatric Care, Kuopio, Finland

* Corresponding author.

Introduction The clinical distinction between schizophrenia and affective psychoses is often not clear-cut, and very little is known about the effectiveness of treatments among patients having both schizophrenia and affective symptoms.

Objectives To study the comparative real-world effectiveness of antipsychotic treatments among patients having schizophrenia and affective symptoms.

Methods We studied the risk of all-cause rehospitalization during use of specific antipsychotics during 1996–2012 among all patients who had been previously hospitalized with both schizophrenia and mood disorder diagnoses in Finland since 1987 ($n = 28,015$). We linked nation-wide databases on hospitalization, mortality, and filled prescriptions. The primary analysis was within-individual analysis, in which each individual was used as his/her own control to eliminate selection bias. The effect of concomitant psychotropic medications, and the temporal orders of exposure and non-exposure periods were adjusted.

Results When 22 specific antipsychotic treatments were compared with the most frequently used antipsychotic quetiapine, the lowest rehospitalization risks were observed during the treatment periods of olanzapine long-acting injection (LAI) (HR: 0.52; 95% CI: 0.34–0.80), risperidone LAI (0.67; 0.56–0.81), and clozapine (0.68; 0.63–0.74). The worst outcome was observed for periciazine (1.19; 0.96–1.48) and no antipsychotic use (1.09; 1.04–1.13).

Conclusions Olanzapine LAI, risperidone LAI, and clozapine use are associated with the lowest risk of rehospitalization among patients with schizophrenia and affective symptoms.

Efficacy of F17464, a new preferential D3 antagonist in a placebo-controlled phase 2 study of patients with an acute exacerbation of schizophrenia

I. Bitter, M. Groc, C. Delsol, C. Fabre, M. Fagard, L. Barthe, F. Gaudoux, V. Brunner, F. Brackman, F. Tonner*

Institut de recherche Pierre-Fabre, France

* Corresponding author.

Introduction F17464 is a new highly potent preferential D3 antagonist, 5-HT1A and weak D2 partial agonist, with confirmed antipsychotic-like activity in animal models. In healthy volunteers, F17464 had a good safety and tolerability profile. A PET-scan study determined a high D3 occupancy rate up to 22 h after a single dose.

Objectives The primary objective was to evaluate the efficacy of 40 mg/day of oral F17464 in comparison to placebo.

Methods This double-blind, parallel group, multicenter study included patients with acute exacerbation of schizophrenia treated for 6 weeks as antipsychotic monotherapy. Patients were hospitalized for the first 3 weeks of treatment, then continued as outpatients.

Results The 144 randomized patients had a baseline PANSS mean (SD) total score was 89.6 (9.5). The change from baseline of PANSS total score to Day 43 on the FAS (LOCF), showed a statistically significant difference in favor of F17464 over placebo: adjusted mean (SE) change -13.5 (2.1) on F17464 and -7.8 (2.2) on placebo with a treatment effect estimate -5.7 (2.7). The 20% or 30% response rate was statistically higher in the F17464 group (47.2% and 25.0%) compared to the placebo group (30.6% and 13.9%). The incidence of treatment-emergent adverse events was slightly higher in the F17464 group (70.8%) than in the placebo group (62.5%). There were no clinically-relevant hepatic, metabolic, or cardiovascular abnormalities. No EPS was reported under F17464.

Conclusion This is the first D3 antagonist that proves efficacy. The results of this phase 2 study also demonstrate the favorable safety profile of F17674 when compared to placebo.

Stigma in early detection of psychosis: Subjective experiences of those concerned

M. Uttinger^{1,*}, C. Rapp², E. Studerus³, K. Beck³, A. Riecher-Rössler³

¹ Psychiatric Services Solothurn, Ambulatorium, Olten, Switzerland

² Psychiatric Services Solothurn, Center for the treatment of psychotic disorders, Solothurn, Switzerland

³ University of Basel Psychiatric Hospital, Center for Gender Research an Early Detection, Basel, Switzerland

* Corresponding author.

Introduction Despite the large scientific debate concerning potentially stigmatizing effects of informing an individual about being in an at-risk mental state (ARMS) for psychosis, studies investigating this topic are rare and quantitative assessment of this kind of stigmatization does not exist so far.

Objectives This study presents first results regarding potentially helpful or stigmatizing effects of being informed about an ARMS assessed with a newly developed quantitative self-rating (FePsy-Stigma questionnaire).

Methods Forty ARMS patients participating in the prospective Basel Early Detection of Psychosis (FePsy) study as well as patients clinically assessed in the early detection service of the Psychiatric Services of Solothurn, completed the FePsy-Stigma questionnaire during their follow-up assessments at least six months after they

had been informed about their increased risk of developing psychosis. The questionnaire was constructed based on a previous qualitative study and on adapted versions of formerly used instruments for assessing stigma in mental health (Internalized Stigma of Mental Illness Scale, Personal Beliefs and Experiences Questionnaire).

Results Stigmatization appeared to be low overall except for social withdrawal due to suspected stigma. Stigma resistance, stereotype awareness and expected discrimination scored considerably higher than actually experienced discrimination, alienation and stereotype endorsement.

Conclusions The results suggest that early detection services help individuals cope with symptoms and build certain resilience toward potential stigmatization, rather than enhancing or causing the latter. In line with previous studies, our results indicate that there is a considerable difference between expected and actually experienced discrimination as well as between stereotype awareness and stereotype endorsement.

⁶ Flügelman's Mazor Mental Health Medical Center, Mental Health Medical Center, Acre, Israel

* Corresponding author.

Background Impairments in social behavior and cognition, such as the ability to identify others' emotional state, are important features in schizophrenia. Arginine vasopressin (AVP) and oxytocin (OXT) and are nonapeptides that influence social cognition and behavior. Previous studies have shown that the administration of intranasal AVP or OXT may affect the ability to recognize facial emotions. The primary objective of this study was to investigate the effects of a single dose of AVP or OXT on social cognition in patients with schizophrenia. The secondary objective of the study was to test for sex-specific effects of intranasal AVP and OXT administration on social cognition.

Methods In this double-blind, placebo-control, cross-over study, 34 patients diagnosed with schizophrenia or schizo-affective disorder, received a dose of AVP, OXT or placebo in three separate meetings. Forty-five minutes after administration, subjects performed facial emotion recognition tasks.

Results There were no significant main effects of hormone administration on the ability to recognize facial emotions between treatment conditions. However, AVP administration resulted in sex-specific differences in emotion recognition. Specifically, in men, AVP administration reduced the ability to recognize angry faces. In women, AVP administration reduced the ability to recognize sad faces and improved the ability to recognize fearful faces.

Conclusions These findings indicate that intranasal AVP may affect the recognition of facial emotions differently in men and

women. Thus, AVP may increase the differences between men and women on social cognition.

Long-term metabolic effect of second-generation antipsychotics in first episode of psychosis

J. Vázquez Bourgon^{1,*}, R. Pérez-Iglesias², V. Ortiz-García de la Foz³, B. Crespo-Facorro¹

¹ University Hospital Marqués de Valdecilla, IDIVAL, University of Cantabria, CIBERSAM, Psychiatry, Santander, Spain

² Institute of Psychiatry, King's College London, Psychiatry, London, United Kingdom

³ University Hospital Marqués de Valdecilla, IDIVAL, CIBERSAM, Psychiatry, Santander, Spain

* Corresponding author.

Introduction There is growing evidence indicating that the use of second-generation antipsychotic (SGA) treatments in psychosis is related to potential metabolic side effects. Previous studies have shown clear metabolic side effects at short-term (12 weeks). However, to detect clinically-relevant impairment in metabolic parameters a long-term follow-up is preferred.

Objectives The aim of this study was to investigate the effect of aripiprazole, ziprasidone and quetiapine on metabolic measures in medication-naïve first episode psychosis patients after 1 year of treatment.

Methods One hundred and sixty-eight, drug-naïve patients, suffering from a non-affective first episode of psychosis, were included in the present study. Patients were randomly assigned to quetiapine, ziprasidone or aripiprazole treatment lines. Weight and glucomic/lipid parameters were recorded at baseline and after 1 year of treatment. Other clinical and socio-demographic variables were recorded to eliminate potential confounding effects.

Results Weight ($t = -10.85$; $P < 0.001$), BMI ($t = -11.38$; $P < 0.001$), total cholesterol ($t = -5.37$; $P < 0.001$), LDL-cholesterol ($t = -5.21$; $P < 0.001$), triglycerides ($t = -5.18$; $P < 0.001$) and the triglyceride/HDL insulin resistance index ($t = -4.09$; $P < 0.001$), showed statistically significant increments after 1 year of treatment.

Moreover, on comparing the percentage of patients with pathological levels before and 1 year after the antipsychotic treatment, we detected higher percentages of patients with obesity (5.1% vs. 15.3%; $P < 0.001$), hypercholesterolemia (23.2% vs. 39.6%; $P < 0.001$) and hypertriglyceridemia (5.8% vs. 14.2%; $P = 0.021$) after 1 year of treatment.

Conclusions The primary exposure to SGAs during the first year of psychosis was associated with significant increments in weight and metabolic parameters leading to a significant increment in the proportion of obesity, hypertriglyceridemia and hypercholesterolemia in our sample.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW0818

Lack of differential long-term metabolic profile of aripiprazole, quetiapine and ziprasidone in first episode of psychosis

J. Vázquez Bourgon^{1,*}, R. Pérez-Iglesias², V. Ortiz-García de la Foz³, B. Crespo-Facorro¹

¹ University Hospital Marqués de Valdecilla, IDIVAL, University of Cantabria, CIBERSAM, Psychiatry, Santander, Spain

² Institute of Psychiatry King's College London, Psychiatry, London, United Kingdom

³ University Hospital Marqués de Valdecilla, IDIVAL, CIBERSAM, Psychiatry, Santander, Spain

* Corresponding author.

Introduction The use of second-generation antipsychotic (SGA) treatments in psychosis has been associated with metabolic changes. However, there are differences in metabolic profile between SGAs. In a previous study conducted in our sample of first episode psychosis patients, we observed that the ziprasidone had a more benign metabolic profile compared to aripiprazole and quetiapine, at short-term (12 weeks). However, to detect clinically-relevant impairment in metabolic parameters a long-term follow-up is preferred.

Objectives The aim of this study was to investigate if the differentiated metabolic profile of aripiprazole, ziprasidone and quetiapine observed at short-term is maintained after 1 year of treatment in a sample of drug-naïve patients with a first episode of psychosis.

Methods One hundred and sixty-eight, drug-naïve patients, suffering from a non-affective first episode of psychosis, were included in the present study. Patients were randomly assigned to receive quetiapine, ziprasidone or aripiprazole. Weight and glucomic/lipid parameters were recorded at baseline and after 1 year of treatment. Other clinical and socio-demographic variables were recorded to eliminate potential confounding effects.

Results No significant differences between antipsychotic groups (all $F < 2.61$; $P > 0.05$) were found in any of the metabolic parameters studied after one year of treatment.

Conclusions Despite the metabolic profile differences observed at short-term in our previous studies, we did not find significant differences in the metabolic and weight parameters studied between treatment groups after one year of treatment, concluding that they present similar metabolic profiles at long-term. Other clinical individual interventions (e.g.: diet, exercise), not here controlled, may have influenced possible differences in long-term metabolic outcomes.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Differentiated psychopharmacological treatment in three genetic subtypes of 22q11.2 deletion syndrome

W.M.A. Verhoeven^{1,*}, J.I.M. Egger¹, N. de Leeuw²

¹ Vincent van Gogh Institute for Psychiatry, Centre of Excellence for Neuropsychiatry, Venray, Netherlands

² Radboud University Medical Centre, Department of Human Genetics, Nijmegen, Netherlands

* Corresponding author.

Introduction The 22q11.2 deletion syndrome (22q11DS), mostly caused by the common deletion including the *TBX1*- and *COMT*-genes (LCR22A-D), is highly associated with somatic anomalies. The distal deletion (distal LCR22D) comprises the *MAPK1*-gene and is associated with specific heart defects. The rare central deletion (LCR22B-D) encompasses the *CRKL*-gene and shows predominantly urogenital anomalies. 22q11DS also differs in its neuropsychiatric profile: common deletion accompanied by schizophrenia-like psychoses and autism spectrum disorders, distal deletion by anxiety disorders, and central deletion by autistic-like behaviours.

Objectives Investigating genetic subtypes of 22q11DS.

Aims Achieving a targeted pharmacological treatment based on genetic sub-typing.

Methods Thirty-two patients with genetically proven 22q11DS, referred for detailed neuropsychiatric analysis.

Results Apart from two patients with distal deletion and one with central deletion, common 22q11.2 deletion was detected in

29 patients. Those with the common deletion were typified by a history of relapsing schizophrenia-like psychoses and partial non-response to conventional antipsychotics. In most patients, anxieties and mood instability were also manifest. The two patients with a distal deletion predominantly showed anxiety symptoms, while the behaviour of the patient with a central deletion was characterized by symptoms from the autism spectrum. Most patients with a common deletion could successfully be treated with clozapine or quetiapine, often combined with valproic acid. One patient with a distal deletion showed full remission upon treatment with citalopram (the second refused such a pharmacological intervention). The behaviour of the patient with central deletion improved upon contextual measures only.

Conclusions The genetic subtype of 22q11DS enables targeting of treatment strategy.

Clustering and switching on verbal and nonverbal fluency in patients with schizophrenia

M. Víchová^{1,*}, T. Urbánek²

¹ Psychiatric Clinic, University Hospital in Brno, Department of Psychology, Faculty of Arts, Masaryk University, Brno, Czech Republic

² Faculty of Arts, Masaryk University, Department of Psychology, Brno, Czech Republic

* Corresponding author.

In our study, we focus on the extent of occurrence of switching and clustering during fluency task among patients with schizophrenia compared to healthy controls. The previous studies found that both switching and clustering were affected in patients with schizophrenia. However, it has not clear yet if the decrease is caused by the impairment of executive functions or is related to poorer vocabulary. In our study, participants were tested Verbal Fluency Task (phonological and semantic) and also the nonverbal fluency task (measured by Five Point Test) so that the effect of vocabulary would be removed. Our study included 50 participants: 25 individuals with schizophrenia and 25 healthy controls. We found significant differences in the way of organization between group of psychiatric patients and healthy controls. The absence of clustering is typical for psychiatric population, patients tell the words without closer connection, they neglect association links, switch between clusters. Due to this way of response, they achieved lower score, they told fewer words than healthy controls. However, this manner was found also in nonverbal task where the patients did not follow one-way in drawing patterns and they often change the number of connecting dots or used lines. Our study implies that this condition is probably caused by disruption of the executive functions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Episodic retrieval is characterized by the subjective experience of remembering. Semantic memory, on the other hand, is a more structured record of facts, meanings, concepts and knowledge about the external world that we have acquired. The medial temporal lobe (MTL), especially the hippocampus and parahippocampal cortex, plays a central role in both types of memory process. Published studies suggested that individuals with schizophrenia have deficits in episodic and semantic memory, as well as structural abnormalities of the medial temporal lobe. However, it is not clear whether reported correlations reflect the impact of the disease state or that of underlying genetic influences contributing to the risk. To understand better etiology and effects of psychosis on the global brain structure and cognitive processing, relatives of individuals with schizophrenia can be studied. The aim of our study was to examine the association between abnormalities of the MTL, psychopathology, and memory impairment in schizophrenia. Study sample ($n=60$) consisted of first episode schizophrenia patients, their non-psychotic siblings and matching control subjects. We used high-resolution magnetic resonance imaging and probabilistic algorithms for image analysis. Episodic and semantic memory was measured with neuropsychological tests. Our results showed differences in memory performance between the groups. Neuropsychological data were correlated with MRI findings. The results may provide insight into etiology of schizophrenia and its effects on cognition and help to identify neuroanatomical and cognitive endophenotypes of psychotic disorders.

* Corresponding author.

Introduction Recently, as a result of an increased emphasis on patients' needs, the awareness on the quality of life has been engaged into account in the exploration of schizophrenia.

Objectives The aim of the study was to explore the relations between hope, self-stigma, personality traits and quality of life in patients with schizophrenia spectrum disorder.

Methods Fifty-two stabilized outpatients with schizophrenia spectrum disorders participated in cross-sectional study. The psychiatrist assessed each patient with Mini International Neuropsychiatric Interview and Clinical Global Impression-Severity. The patients completed Quality of Life Satisfaction and Enjoy-

ment Questionnaire, Internalized Stigma of Mental Illness Scale, Temperament and Character Inventory, Adult Dispositional Hope Scale, Drug Attitude Inventory, Liebowitz Social Anxiety Scale, Beck Depression Inventory – II, and Beck Anxiety Inventory.

Results The quality of life was significantly higher in employed patients, and individuals with higher hope, self-directedness, and persistence. The quality of life was lower among the patients with higher number of hospitalizations, those with higher severity of the disorder and individuals who were taking more medication. The patients with more pronounced symptoms of depression, anxiety, and social anxiety had a lower quality of life. Finally, the quality of life was lower among the individuals with higher harm avoidance, and self-stigmatization.

Conclusions Detection of the quality of life in the context of personality traits, hope, self-stigma and demographical and clinical factors may be an important part of the treatment of patients with schizophrenia.

* Corresponding author.

Introduction Most individuals diagnosed with schizophrenia must cope with some form of stigmatization. Different types of public stigma, self-stigma and label avoidance, may have negative consequences for these individuals.

Objectives The aim of the study was to search the degree of self-stigma in schizophrenia and its association with the clinical and demographic factors.

Methods One hundred and ninety-seven stabilized outpatients diagnosed with schizophrenia spectrum disorders participated in the study. The mean age of the sample was 40 years. All individuals completed the Internalized Stigma of Mental Illness Scale (ISMI) and a demographic questionnaire. The disorder severity was assessed both by a psychiatrist (objCGI-S: the objective version of Clinical Global Impression – Severity scale) and by the patients (subjCGI-S: the subjective version of Clinical Global Impression – Severity scale).

Results The total score of the ISMI positively correlated with the severity of the disorder measured by the objCGI-S and the subjCGI-S. Additionally, the self-stigma positively correlated with the treatment duration, and the number of hospitalizations. The regression analysis identified these regressors as the most relevant to the self-stigma – the number of hospitalizations, the severity of the disorder rated by a psychiatrist, and the difference between the objective rating and the subjective rating of the severity of the disorder.

Conclusions Outpatients with psychosis, who have undergone a higher number of hospitalizations, dispose of a higher severity of the disorder and show a bigger discrepancy between their rating of

the severity and the psychiatric rating, display a greater degree of self-stigma.

Therapy initiation during a first acute episode psychosis in the psychiatric department of Mahdia

B. Walid*, I. Marrag, R. Ben Soussia, F. Ellouze, M. Nasr Hospital, Psychiatrie, Mahdia, Tunisia

* Corresponding author.

Introduction The quality of the therapeutic care during a first episode psychosis (FEP) determines the middle- and long-term prognosis.

Objectives The aim of our study is to describe the therapeutic attitudes in front of a FEP and discuss them according to current international recommendations.

Methods This is a retrospective descriptive study. All patients with a FEP, hospitalized in the psychiatric department of the university hospital, Mahdia during the period from 15 May 2000 to 31 December 2013 have been included.

Results We recruited 111 patients. The average age was 27 years, a male predominance was noted. Initially, the majority of patients were treated in monotherapy (55.9%) and mostly with typical antipsychotic drugs (80.2%), by injection. Among those under association, 63.4% received corrective treatment and 26.8% a benzodiazepine. The prescription of a mood stabilizer and an antidepressant was noted in respectively 5.6 and 2.8% of cases. The majority of patients received typical antipsychotic drugs (53.1%) while 39.6% were under atypical antipsychotic. The follow-up period, after which a reduction of the antipsychotic dose was decided, ranged from 1 to 66 months with an average of 8.26.

Conclusion The progression to a chronic psychosis, still has a severe connotation. The Early and adequate therapeutic care in accordance with the international recommendations, determines the prognosis and constitute a decisive moment in the evolutionary trajectory of the disease.

* Corresponding author.

Introduction Annual monitoring of physical health of people with severe mental illness (SMI) in primary or secondary care is recommended in England.

Objective The SMI Health Improvement Profile (HIP) was developed to target physical well-being in SMI through the role of the mental health nurse.

Aim The primary aim was to investigate if health checks performed by community mental health nurses (CMHNs) trained to use the HIP improved the physical well-being of patients with SMI at 12 months.

Methods A single blind, parallel group randomised controlled trial of training to use the HIP (clustered at the level of the nurse). Physical well-being was measured in study patients using the physical component score of the SF36v2 at baseline and at 12 months.

Results Sixty CMHNs (working with 173 patients) were assigned to the HIP programme (training to use the HIP) or treatment as usual. The HIP was completed with 38 (42%) patients at baseline and 22 (24%) at follow-up in the HIP programme group. No effect of the HIP programme on physical health-related quality of life of study patients was identified, a finding supported by per protocol analyses.

Conclusions This study found no evidence that CMHN delivered health checks following training to use the HIP are effective at improving the physical well-being of SMI patients at one year. More attention to methods that aim to enable the delivery, receipt and enactment of evidence-based interventions to improve physical health outcomes in this population is urgently required.

Brainstem audiometry as a diagnostic tool in psychiatry: Preliminary results from a blinded study

V. Wahlström¹, R. Wynn^{2,3,*}

¹ Balsfjord General Practitioner's Office, Balsfjord, Norway

² UiT The Arctic University of Norway, Department of Clinical Medicine, Tromsø, Norway

³ University Hospital of North Norway, Division of Psychiatry and Substance Abuse, Tromsø, Norway

* Corresponding author.

Background Some prior studies of brainstem audiometry have found illness-specific aberrations, suggesting that this procedure can be of use to clinicians in diagnosing certain psychiatric illnesses.

Aims The study aimed to examine the diagnostic properties of a brain stem audiometry procedure (SD-BERA[®]) for patients suffering from schizophrenia and bipolar disorder.

Methods A blinded study including 12 patients with schizophrenia, 12 patients with bipolar disorder, and 12 healthy controls was performed in 2014/2015. The patients were recruited from psychiatric specialist services and a primary care office in the County of Troms, Norway. The patients and controls were examined with brainstem audiometry. The clinical diagnoses were not known to the researchers who analysed the brain stem audiometry data at the Swedish company SensoDetect. Sensitivity and specificity for each group (compared to healthy controls) was calculated.

Results The brain stem audiometry procedure had a high degree of sensitivity (1.00), but a lower degree of specificity (0.45) when patients suffering from bipolar disorder were compared to healthy

controls. For the diagnosis of schizophrenia, the brain stem audiometry procedure had a high degree of specificity (0.91), but a lower degree of sensitivity (0.33) when patients were compared to healthy controls.

Conclusions This method may help clinicians by lending support to a clinically suspected diagnosis of schizophrenia. The relatively low specificity for bipolar disorder could suggest that the method needs further development before it can be useful clinically when the diagnosis of bipolar disorder is suspected. Further scientific testing is needed to verify these findings.

Aripiprazole in treatment of disability in social, professional and family life in schizophrenia patients

N. Zivkovic*, G. Djokic, D. Curcic

Psychiatric Clinic Laza Lazarevic, Emergency Psychiatry Department, Belgrade, Serbia

* Corresponding author.

Introduction Enhancement of overall functioning is one of most important goals in treatment of schizophrenia (SCH) patients.

Objective To assess efficacy of aripiprazole in treatment of disability and impairment in social, professional and family life in SCH patients.

Methods This study included 50 patients with SCH diagnosed by ICD-10 criteria, divided into H (Haloperidol, 5–20 mg/24 h) group (25 patients), and A (Aripiprazole, 10–30 mg/24 h) group (25 patients). Antipsychotics were tested for 12 months with Positive and Negative Symptom Schedule (PANSS), Sheehan Disability Scale (SDS) and the number of withdrawals attributed to adverse event (AE).

Results The mean pretrial PANSS score was 103.6 in A and 105.3 in H group. The mean PANSS score after 12 months was 53.5 in A and 54.4 in H group. There were no significant statistical difference in PANSS pretrial scores and scores after 12 months between groups, $P=0.619$; $P=0.364$. There were significant statistical difference in PANSS score reduction after 12 months in both groups ($P<0.001$). Aripiprazole improved all SDS scores in comparison to Haloperidol with high statistical significance. Work: A vs. H, $P<0.001$; social life: A vs. H, $P<0.001$; family life: A vs. H, $P<0.001$; days lost: A vs. H, $P=0.012$; days unproductive: A vs. H, $P=0.007$; 8.0% AEs occurred in A, and 36.0% in H group.

Conclusions Aripiprazole showed same efficacy as haloperidol in treatment of SCH. Aripiprazole showed significantly better efficacy in treatment of disability and impairment. Number of withdrawals was significantly higher in haloperidol group.

Smoking and tardive dyskinesia in patients with schizophrenia

L. Zouari, N. Smaoui, I. Abida, N. Charfi*, M. Maâlej, N. Zouari, J. Ben Thabet, M. Maâlej

Hédi Chaker University Hospital, Psychiatry, Sfax, Tunisia

* Corresponding author.

Introduction Tardive dyskinesia (TD) is a drug-induced movement disorder that arises with antipsychotics. These drugs are the mainstay of treatment for schizophrenia. Epidemiological studies have shown mixed results on smoking's association with TD.

Objective To study the association between smoking and TD induced by antipsychotics in outpatients with schizophrenia.

Methods This was a cross-sectional study. It involved 89 patients suffering from schizophrenia, followed-up in outpatient psychiatry unit at Hédi Chaker university hospital in Sfax in Tunisia, between April and May 2016. We looked for TD in according to DSM-IV-R criteria. The intensity of TD was assessed with the Abnormal Involuntary Movement Scale (AIMS) and the level of nicotine dependence with the Fagerström Test for Nicotine Dependence (FTND).

Results The prevalence of smoking in patients with schizophrenia was 69.6%. Of these, 54.8% had a high or very high degree of nicotine dependence. The prevalence of TD was 33.7%. The AIMS average score was 12.13 ± 5.6 with extremes ranging from 3 to 26. TD was correlated with tobacco consumption ($P=0.003$), the average number of smoked cigarettes (43.7 vs. 33.8; $P=0.004$) and the Fagerström average score (7.2 vs. 6.1; $P=0.012$).

Conclusion The results of this study showed a correlation between the amount of smoking and severity of TD in patients with schizophrenia. The nature of the relationship between smoking and TD needs to be clarified through an experimental study.

Leptin and ghrelin levels in alcohol-dependent patients and their relationship with withdrawal and craving

S. Mehta^{1,*}, A. Baruah², D. Chetia², S. Das², P. Avinash²

¹ SMI, Psychiatry, Dehradun, India

² LGBRIMH, Psychiatry, Tezpur, India

* Corresponding author.

Introduction Association between leptin and ghrelin plasma levels and alcohol craving have been found in few studies but they have failed to differentiate this correlation with alcohol withdrawal state.

Objectives To research this correlation in a different population and to study this correlation with respect to hyper-excitability state of alcohol withdrawal.

Aim To study levels of leptin and ghrelin in relation with alcohol withdrawal and craving.

Methods Twenty-five indoor patients fulfilling the alcohol dependence criteria were assessed for alcohol withdrawal symptoms and craving. Leptin and ghrelin levels were measured on 1st day, @ the end of 1st week, @ the end of 3rd week of stopping alcohol. Withdrawal was assessed using CIWA-A at day 1 and day 7, craving was assessed using PENN's scale of craving at the end of week 1 and week 3. Control group consisted of 15 first-degree relatives not taking alcohol.

Results It was found that leptin [$t(38)=2.95$, $P=0.005$] and ghrelin [$t(38)=2.56$, $P=0.015$] were significantly higher in alcohol-dependent patients. Levels of hormones had no significant correlation with alcohol withdrawal scores but had positive correlation with craving scores after abstinence.

Conclusions Leptin and ghrelin, known for balancing the energy homeostasis of body, also seem to play a role in pathways of drug dependence and craving. This relation is independent of stress hormone axis as leptin and ghrelin levels are not correlated with

withdrawal scores, which is an indicator of stress hormone axis activation during alcohol withdrawal.

Affective temperaments in medical students using prescription stimulants for neuroenhancement

L. Mineo^{1,*}, Y. Sarraf², S. Hanauer², D. Patel², C. Ingram², L. Montemagno¹, C. Concerto³, F. Battaglia³

¹ University of Catania, Department of Clinical and Experimental Medicine, Psychiatry Unit, Catania, Italy

² New York College of Podiatric Medicine, Department of Preclinical Sciences, New York, USA

³ Seton Hall University, Department of Interprofessional Health Sciences and Health Administration, South Orange, USA

* Corresponding author.

Introduction The non-medical use of prescription stimulants (NMUPS) is a common habit among American college students; It refers to the use of stimulant medications by students who do not qualify for prescription or in higher quantities or manners other than prescribed in order to improve their academic performance. To the best of our knowledge, no studies have examined the role of specific affective, biologically determined and inherited traits that might predict misuse of stimulants for neuroenhancement in graduate education.

Aim To examine the role for individual temperament traits on non-medical use of prescription stimulants (NMUPS) in medical college students.

Methods We investigated 181 students using the short form of the Temperament Evaluation of the Memphis, Pisa, Paris and San Diego Auto-questionnaire (TEMPS-A). Furthermore, we assessed the association of demographic variables and health risk behaviors (drinking, smoking, use other illicit drugs) with NMUPS. Predictors were investigated using logistic regression.

Results The prevalence of NMUPS was 30.06% with 7.1% users being previously diagnosed with ADHD. NMUPS users had higher scores on the hyperthymic scale. The main reason for taking NMUPS was to "Increase ability to stay alert during studying" (80.1%) followed by "Allow studying for longer periods of time" (19.9%). The hyperthymic temperament score and being a user of other illicit drugs increased the odds of becoming NMUPS.

Conclusions Our results suggest that personality profiles can be used to identify students with an increased risk for NMUPS for early personalized counseling and behavioral intervention based on their temperament profile.

Impulsivity and pathological gambling: An Italian study

F. Mucci^{*}, D. Marazziti, S. Baroni, A. Piccinni

Università di Pisa, Dipartimento di Medicina Clinica e Sperimentale, Pisa, Italy

* Corresponding author.

Introduction Pathological gambling (PG) is a behavioral addictive disorder characterized by persistent and problematic gambling behaviors, in presence of impairment of self-regulation and impulsivity. Impulsivity is widely supported by literature in developing and maintaining addictive behaviors and PG.

Aim(s) The aim of this study is to compare PG to impulsivity in a group of Italian outpatients, in order to further explore their appealing relation and to sensitize local public institutions about this problem that is of growing concern amongst our population.

Methods Fifty outpatients were recruited at the psychiatric outpatient ward of the University of Pisa. All of them had a diagnosis of PG, assessed throughout the structured clinical interview for DSM-5 (SCID-5). The sample was compared with a similar group of healthy control subjects. South Oaks Gambling Screen (SOGS) scale and Barrat Impulsivity Scale (BIS-11) questionnaires were used to assess respectively the severity of PG and impulsivity traits of personality.

Results PG patients reported significantly higher total score in BIS-11 than control subjects. In particular, the “motor impulsivity” and “cognitive complexity” scores were significantly higher in PG patients, as well as “motor” and “non-planning” impulsivity subscale scores. A positive and significant correlation was found between BIS-11 and SOGS total scores.

Conclusions These results corroborate the existence of the widely described association between impulsivity and PG. Also they support the notion that impulsivity may represent a core element of PG and, perhaps, to a typical personality trait, that may be particularly related to the development of addictive and impulsive behaviors.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychosis – Different presentation for designer drugs compared to cannabis abusers?

F. Dumitrescu

Alexandru Obregia Psychiatric Hospital, S XVI, Bucharest, Romania

Introduction “Bath salts” target the endocannabinoid system in a similar manner to cannabis. In the case of designer drug misuse, subjects seem to be at higher risk of psychotic symptoms.

Aims To investigate the nature and frequency of psychotic symptoms associated with cannabis and/or bath salts misuse in a male inpatient population.

Method The files of 107 patients admitted to the department of addictions, “Al. Obregia” Psychiatric Hospital Bucharest July 2015–July 2016 were reviewed. Cases had a diagnosis of psychotic disorder with recorded cannabis/bath salts abuse.

Results Mean age was 26.65 years old (STDV=5.9). Mean duration of use was of 83.94 months – cannabis; 60.48 months – bath salts and 33.75 months – both substances (BS). Sixty-three patients (73.3%) presented disorganised behaviour; 55.8% ($n=48$) formal thought disorder; 45% ($n=39$) paranoid delusions. A strong positive association between the length of use of cannabis and disorganised behaviour ($n=33$; $r=0.05$; $P<0.05$) was found. Grandiose ideation was frequent in cannabis users. ($X^2=4.1$; $n=0.03$; $P<0.05$). Multidrug abuse was associated with increased formal thought disorders compared to subjects with cannabis abuse ($X^2=10.9$; $n=0.001$; $P<0.05$). Negative symptoms were more frequent with bath salts users than with users of both substances ($X^2=13.4$; $X^2=23.21$; $X^2=16.8$; $P<0.05$).

Conclusion Positive psychotic symptoms were associated with cannabis and BS abuse, while bath salts promoted negative symptoms.

A multidisciplinary team (MDT) approach to managing alcohol-dependent patients with comorbid depression in an acute hospital setting

L. Owens^{1,*}, K. Patterson², G. King³, P. Richardson²

¹ The Royal Liverpool University Hospital, Hepatology, Liverpool, United Kingdom

² Royal Liverpool & Broadgreen university Hospital Trust, Hepatology, Liverpool, United Kingdom

³ Royal Liverpool & Broadgreen University Hospital Trust, Alcohol Services, Liverpool, United Kingdom

* Corresponding author.

Introduction Alcohol-dependent patients have a significantly increased risk of depression, contributing a cycle of relapse and attendance at acute hospital services seeking help. Care is often focused on the alcohol dependence treatment with little consideration of concomitant psychiatric disorders.

Aim To help bridge this gap in care planning and aim toward multidisciplinary long-term support.

Method We collected data on all patients referred to our alcohol complex patient MDT. We investigated the range of disciplines involved in patient care. We spoke to our patients about why they had chosen to attend hospital. We then developed a referral system to our alcohol MDT where a bespoke pathways of care was developed with all current and future care providers.

Results Our patients were often being cared for by multiple services, however much of this work was happening in isolation and was at times conflicting. Importantly, the patients were unclear where to go for what, and were utilizing the ED as a fail-safe when they were troubled.

Of 15 patients referred to MDT, 7 (50%) had a diagnosis of depression (DSM-IV). These patients had an average of 5.1 hospital attendances and 2.2 hospital admissions in the 3 months prior to MDT. At 3 months post-MDT, we were able to demonstrate a reduction in hospital admissions and attendances (average 2.2 & 1.4, respectively).

Conclusions An MDT for alcohol-dependent patients with depression facilitates effective and collaborative working for the benefit of patients and services.

Fenethylamine (Captagon) abuse: Case report and literature review

M. Preve*, S. Casigliani, M. Godio, N.E. Suardi, R. Traber, R.A. Colombo

Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

* Corresponding author.

Introduction Novel psychoactive drugs (NPS) has rapidly increase in the last years in the drug market as a recreational use. Fenethylamine is a theophylline, an amphetamine-like drug, having stimulant effects similar to those of other amphetamine-type derivatives. Fenethylamine was used as medicament for hyperactivity disorders in children, narcolepsy and depression, but it has also been used as a drug of abuse under the common name of ‘captagon’. The purpose of this report is to review the clinical evidence for the potential of abuse of fenethylamine. We propose a case report and literature review.

Method We conducted a systematic review of the literature with the principal database (PubMed, Enbase, PsychInfo) and we present a case report.

Results The effects of fenethylamine is characterized by euphoria, derealization, autopsychic and somatopsychic depersonalization, hallucination, agitation and decrease of pain perception.

Discussion and conclusion The primary drug market for fenethylamine (as captagon) has traditionally been countries located on the Arabian Peninsula but also North Africa since 2013. To our knowledge, there is no report on the recreational use of fenethylamine in literature. The clinical features of fenethylamine intoxication were also similar to effects from other amphetamine-like drugs. In our case report, dissociative symptoms are the core of fenethylamine intoxication. Further research is warranted to replicate our clinical and qualitative observations and, in general, quantitative studies in large samples followed-up over time are needed. Methodological limitations, clinical implications and suggestions for future research directions are considered [1,2].

Disclosure of interest The authors have not supplied their declaration of competing interest.

Dysregulation of emotions among pathological gamblers: The role of savoring

G. Rogier^{1,*}, P. Velotti²

¹ University of Rome, La Sapienza, Department of Dynamic and Clinical Psychology, Rome, Italy

² University of Genoa, Education Sciences, Psychology Unit, Genoa, Italy

* Corresponding author.

Introduction Theories have conceptualized pathological gambling as an attempt to cope with emotional states. However, there is a lack of research about emotion dysregulation in this population. In a similar way, few is known about the nature of emotion regulation strategies used by pathological gamblers. Furthermore, it is not clear if pathological gamblers have difficulties to regulate negative emotions (as sadness) or positive ones (as excitement).

Objectives We sought to explore the associations among pathological gambling, emotion dysregulation and different types of emotion regulation strategies, comparing a clinical sample with community participants.

Aims To highlight similarities and differences in emotion dysregulation between pathological gamblers and healthy participants.

Methods A sample of pathological gamblers and a sample of healthy men, were administered the South Oaks Gambling Screen (SOGS), Difficulties in Emotion Regulation Scale (DERS), Difficulties in Emotion regulation Scale-Positive (DERS-P), Emotion Regulation Questionnaire (ERQ) and the Ways of Savoring Checklist (WOSC).

Results As expected, both levels of emotion dysregulation and suppression were significantly higher in the clinical sample while levels of savoring and reappraisal were significantly higher in the community sample.

Conclusions Such results confirm the theorization of pathological gambling as a dysfunctional response to emotional states and underline the role of positive emotions. Specifically, pathological gamblers may be prone to suppress negative emotions instead to engage in functional strategies as reappraisal. Gamblers also fail to regulate positive emotions showing a poor capacity of savoring positive moments.

Impulsivity and self-esteem in pathological gambling: What is the link?

G. Rogier^{1,*}, P. Velotti²

¹ University of Rome, La Sapienza, Department of Dynamic and Clinical Psychology, Rome, Italy

² University of Genoa, Educational Sciences, Psychology Unit, Genoa, Italy

* Corresponding author.

Introduction In empirical literature, impulsivity is identified as a core feature of gambling addiction. Furthermore, pathological gamblers are prone to have a poor self-esteem. Previous researches studied the link between impulsivity and self-esteem bringing contrasting results. However, relationships between such constructs among pathological gamblers have not been investigated.

Objectives We sought to explore the associations among pathological gambling, self-esteem and different facets of impulsivity comparing a clinical sample of pathological gamblers with community participants.

Aims To highlight patterns of associations between self-esteem and impulsiveness in pathological gambling.

Methods A sample of pathological gamblers and a sample of healthy men, were administered the South Oaks Gambling Screen (SOGS), the UPPS Impulsive Behavior Scale (UPPS) and the Rosenberg Self-Esteem Scale (RSES).

Results As expected, levels of impulsivity were significantly higher in the clinical sample while levels of self-esteem were significantly lower. A significant and negative correlation between impulsivity and self-esteem was found among pathological gamblers. Different patterns of associations were found between self-esteem and dimensions of impulsivity.

Conclusions Coherently with others results, our study confirmed that pathological gamblers showed high impulsivity and low self-esteem. The peculiar patterns of associations between impulsivity and self-esteem could be informative to tailor treatment programs for pathological gamblers.

Outcome and characteristics of patients in methadone maintenance program depending on whether they are or not drug consumption room users

A. Romaguera^{1,*}, R. Martínez¹, L. Bádenas¹, I. Novell¹,

C. Castillo¹, M. Torrens^{1,2}

¹ Parc de Salut Mar, Institut de Neuropsiquiatria i Addiccions, Barcelona, Spain

² Universitat Autònoma de Barcelona, Departament de Psiquiatria, Barcelona, Spain

* Corresponding author.

Introduction In January 2012, a drug consumption room (DCR) opened in an outpatient treatment center for alcoholism and drug abuse (CADA) to reach people who inject drugs (PWID) who did not seek treatment.

Objectives/aims To evaluate the characteristics and evolution of 76 patients undergoing methadone maintenance treatment (MMT) during a year in a CADA, depending on whether they are DCR users or nonusers.

Methods A retrospective cross-sectional observational study was conducted by reviewing data collected from patients in MMT during 2015, performing a statistical comparison between DCR users

and nonusers. Outcome was evaluated through urine controls, considering a poor outcome when positive to heroin > 20%.

Results Of the 76 patients in MMT, the average age was 40 years, 21% were women, mean dosage of methadone was 48.2 mg/day and more than a half were DCR users (52.63%). Of the 40 patients, which formed the DCR user subgroup, the average age was 36.4 years, 20% were women and mean dosage of methadone was 47 mg/day. The outcome of all the patients in PMM was successful in 48.68% of the cases, presenting differentially the nonusers a 91.67% of good response and the users only a 10%.

Conclusions Inclusion of a drug consumption room in an outpatient treatment center for alcoholism and drug abuse, which facilitates accessibility for people who inject drugs to treatment, poses new challenges in order to improve the effectiveness of the PMM.

U-47700: The new emerging opioid drug

D. Sanagustin Bosqued*, M. De Dios Felis, E. Monteagudo Gimeno, S. Pérez González, A. Trabsa Biskri, L. Galindo Guarín, M. Grifell Guardia, P. Quintana Mathe, M. Torrens Melich

Institut de Neuropsiquiatria i Adiccions, Psychiatry, Barcelona, Spain

* Corresponding author.

Introduction The trans-3;4-dichloro-N-(2-(dimethylamine) cyclohexyl) labelled as U-47700 has a high affinity with the selective receptor, considered to have 7.5 times the binding affinity of morphine; as a result, it is sold as a recreational drug because of its analgesic and euphoric effects. Several toxicity cases and some fatalities have been reported during 2016.

Objectives To describe the presence of trans-3;4-dichloro-N-(2-(dimethylamine) cyclohexyl) in samples delivered to Energy Control during 2016 in Barcelona.

Methods From January 2016 to October 2016, 4031 samples were delivered and only those samples containing trans-3;4-dichloro-N-(2-(dimethylamine) cyclohexyl) were studied, 6 of them were analysed as U-47700 (0.148%). Samples were analysed by energy control, a Spanish harm-reduction NGO that offers users the possibility of analysing the substances they intend to consume. Analysis was done by gas chromatography-mass spectrometry.

Results From the 6 samples that were analysed as trans-3;4-dichloro-N-(2-(dimethylamine) cyclohexyl), the presentation of 4 of them was white powder and the rest were not described. The precedence of the samples was Canada (2), USA (1), Sweden (1), Holland (1) and the remaining sample was not described. All samples were received during 2016.

Conclusions The use of trans-3;4-dichloro-N-(2-(dimethylamine)cyclohexyl) is progressively increasing in Barcelona. Its harmful effects are being reported in recent medical literature and consumption represents an emerging issue, gaining popularity among recreational opioid users. It is potentially lethal when mixed with depressants like alcohol or benzodiazepines and overdose risk is higher compared to other opioids. This drug is not being detected by routine in medical test.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Substance use and quality of life in young adult psychiatric patients

J. Silva Ribeiro*, S. Morais, P. Oliveira, O. Mendes, A. Botelho, L. Vale, A. Bessa, P. Renca, V. Santos, N. Madeira
Centro Hospitalar e Universitário de Coimbra, Centro de Responsabilidade Integrado de Psiquiatria e Saúde Mental, Coimbra, Portugal

* Corresponding author.

Introduction It is known that several factors can influence the quality of life such as age, gender, socioeconomic status, the presence of mental illness or substance abuse.

Objectives/aims Assess quality of life of outpatients observed in Young Adult Unit of our Psychiatry Department (Coimbra Hospital and University Centre – Portugal) and its relation with substance use.

Methods Socio-demographic characterization of youth psychiatric outpatients observed during between 1st January 2015 and 31st July 2016. Portuguese versions of The Alcohol, Smoking and Substance Involvement Screening Test (ASSIST) and The World Health Organization Quality of Life scale (WHOQOL-BREF) were administered. A Spearman correlation coefficient between ASSIST and WHOQOL-BREF scores was calculated.

Results A total of 255 outpatients were observed: 64.3% females and 35.7% males; ages between 17 and 39 years old. ASSIST and WHOQOL-BREF were administered in 57 patients. Average ASSIST total score was 16.81 (median: 13.50), with tobacco and alcohol scoring higher. Average WHOQOL-BREF total was 13.74 (median: 13.67), with physical and psychological domains scoring less. We found a significant negative correlation between WHOQOL-BREF physical domain and ASSIST tobacco scores; and between WHOQOL-BREF social domain and ASSIST sedatives score.

Conclusions Quality of life is influenced by several factors. Studies showed that consumers of psychoactive substances have lower WHOQOL-BREF scores than nonusers. In our sample, we did not find a significant correlation between global quality of life and different substances. This may be due to existence of low consumption of substances in the sample as well as the existence of other factors that might have influenced quality of life.

Efficiency of Cocarnit preparation in clinical course of alcohol dependence at withdrawal syndrome stage

I. Sosin^{1,*}, O. Goncharova², Y. Chuev²

¹ *Kharkov Medical Academy of Postgraduate Education, Narcology, Kharkov, Ukraine*

² *Kharkiv Medical Academy of Postgraduate Education, Narcology, Kharkiv, Ukraine*

* Corresponding author.

Introduction Recently scientific attention of Ukrainian narcology was focused on the group of new complex pharmacological preparations with polymodal pathogenic effect option (Cocarnit, World Medicine, Great Britain).

Aims and objectives To ground feasibility of Cocarnit application in complex treatment of alcohol withdrawal syndrome (AWS).

Method Eleven patients with alcohol addiction were examined. An integrated research of relieving and adjuvant effects of pharmacological preparation Cocarnit in complex with traditional detoxication therapy in clinical course of alcohol dependence at AWS stage was carried out. One to 2 ampoules of Cocarnit were injected intramuscularly once per 24 hrs, № 6.

Methods Clinical-psychopathological, clinical-laboratory, consulting of specialists, methods of psychological investigation (CIWA; CAH; SF-36) at day 1, 7 and 14 of treatment.

Results AWS quantification score on admission was 41. Further therapeutic regress of all AWS components was registered. At day 1 the patient's condition started improving, clinical score was 32; at day 3 – 17; day 5 – the score was 13, insignificant tremor remained. At day 7 of treatment, practically complete relieving effect of the therapy was ascertained. With CAH method at day 7 of the treatment, an increase of figures in all scales was registered: state of health 2.7, activity 2.4, mood 2.5. SF-36 method: at day 1 – the score was 24, day 7 – 32, day 14 – 49.

Conclusions Thus, the developed by us method of integrated treatment with inclusion of Cocarnit for withdrawal state in alcohol addicts allows to stop acute signs of pathology within 3–5 days.

³ Institute of Psychiatry, University of Foggia, Department of Clinical and Experimental Medicine, Foggia, Italy

⁴ Section of Hygiene, Catholic University of the Sacred Heart, Department of Public Health, Rome, Italy

* Corresponding author.

Introduction The addictive behaviors can be seen as attachment disorders. In literature studies about the relationship between attachment styles and addictions are few. However, in addicted patients the identification of secure or insecure attachment styles seems to have serious implications for the therapeutic alliance and the treatment.

Objectives To study the relationships between different attachment styles and types of addiction (chemical or behavioral).

Aims To examine the role of attachment styles in patients with alcohol dependence (AD) or pathological gambling (PG).

Materials We recruited 29 with AD and 33 with GP according to DSM-IV-TR criteria; all patients were abstinent from addictive behaviors at least since one month, the experiences in close relationships (ECR) was administered for the study of attachment styles.

Results PG compared to AD has higher raw scores both anxiety factor ($P < 0.001$) and avoidance factor ($P = 0.003$) at ECR. ECR ambivalent correlates with the diagnosis of PG ($P = 0.010$); ECR avoidant correlates with AD ($P = 0.006$); ECR anxiety shows a trend of correlation with the diagnosis of AD ($P = 0.052$). The subjects showed the following attachment styles (Table 1).

Conclusions This is the first study that compares the attachment styles of patients AD and PG. We found differences in attachment styles of the two types of addiction, confirming the need of different approaches and then different types of treatment. Our findings need to be replicated in larger groups, also widening the target of other addictions.

Table 1

	Secure	Ambivalent	Anxious	Avoidant
PG	2	27	–	4
AD	1	13	6	9

⁴ Section of Hygiene, Catholic University of the Sacred Heart, Department of Public Health, Rome, Italy

* Corresponding author.

Introduction The addictive behaviors can be seen as attachment disorders. To our knowledge, the literature on the relationship between pathological gambling (PG) and attachment styles is still poorly represented. However, in addicted patients, the identification of secure or insecure attachment styles seems to have serious implications for the therapeutic alliance and the treatment.

Objectives To examine the clinical role of attachment styles in the PG patients.

Aims To study the relationships between the different attachment styles and PG and the severity of PG.

Materials We recruited 33 patients with GP according to DSM-IV-TR criteria; all patients were abstinent from addictive behaviors at least since one month, the experiences in close relationships (ECR) was administered to investigate attachment styles, the South Oaks Gambling Screen (SOGS) to investigate the severity of gambling.

Results The subjects showed the following attachment styles (Table 1). Ambivalent attachment style correlates with high scores to the SOGS ($P < 0.001$), and with a shorter period of abstinence from PG ($P = 0.022$). Patients with ambivalent attachment style have increased severity of PG at SOGS, correlating with higher raw score on the anxiety factor of ECR and lower raw score on avoidance factor (for both $P = 0.036$).

Conclusions Patients showed ambivalent attachment, and anxiety factor correlates with a greater severity of PG. Attachment style could be a severity index of PG. Our findings need to be replicated in larger groups, also widening the target of other addictions both chemical and behavioral.

Table 1

	Secure attachment	Ambivalent attachment	Anxiety attachment	Avoidant attachment

Incidence of Internet addiction in adult attention deficit hyperactivity disorder

B. Tuzun Mutluer^{1,*}, T.G. Yener Orum¹, S. Sertcelik²

¹ Bakirkoy Prof. Dr. Mazhar Osman Training and Research Hospital for Psychiatry, Psychiatry, Istanbul, Turkey

² Haydarpasa Numune Research and Training Hospital, Psychiatry, Istanbul, Turkey

* Corresponding author.

Objective In this study, it was aimed to determine the internet use properties of Adult Attention Deficit Hyperactivity Disorder (ADHD) patients who were followed-up at Haydarpasa Numune Research and Training Hospital, Psychiatry Department; ADHD Outpatient Clinic.

Method Thirty participants who were diagnosed with adult ADHD aged between 18–31 years rated their ADHD symptoms in childhood retrospectively, using Wender Utah Rating Scale. Patients rated current adult ADHD symptoms with the Adult ADHD DSM-IV-Based Diagnostic Screening and Rating Scale (DSRS) and severity of symptoms measured by Adult ADHD Self-Report Scale (ASRS). Internet addiction (IA) was assessed with Young's Internet Addiction Scale (IAS). It was determined that, none of 30 Adult ADHD patients have been diagnosed with IA. 29 of patient have moderate internet use although 1 of patients have risky internet use. The results revealed that total ASRS score ($P=0.020$), total Adult ADHD DSM-IV-Based DSRS score ($P=0.036$) and the Attention Deficit related properties subscale total score ($P=0.042$) were significantly correlated with the IAS total score. Subscale of the self-report scales including; failing to finish schoolworks, chores, or duties at workplace, difficulty of following through on instructions ($P=0.017$), restiveness; impaired inhibitory performance ($P=0.017$), feeling not confident ($P=0.017$), difficulty of managing time ($P=0.047$), failing to give close attention to details or making careless mistakes ($P=0.037$) are closely relevant to IAS total score.

Result In conclusion, clinical features, which are characteristic of Adult ADHD could have same shared etiology with IA. Furthermore, ADHD patients are more likely to have an IA diagnosis. However, it was thought that this result had to be supported with studies including larger samples.

Internet addiction and impulsivity among university students

B.Ö. Ünsalver^{1,*}, H. Aktepe²

¹ Uskudar University, Medical Documentation and Secretariat, Istanbul, Turkey

² Uskudar University, Psychology, Istanbul, Turkey

* Corresponding author.

Introduction The progress in technology adds to the new ways of communication between people. In our age, online communication has taken the place of face to face communication. People express themselves, become friends and in a way become who they are through the tools of social media. Many biological and psychological factors may affect the choice of people for communicating through social media.

Objective Main objective of this research is to measure the frequency of Internet addiction and its relationship to social media use and impulsivity.

Methods The population of the study is composed of 117 female (58.5%) and 83 male (41.5%) students between 18–25 years of age from Uskudar University. Barratt Impulsivity Scale and Internet Addiction Scale were used for data collection and measurement of variables.

Results Among the participants, 97.5% were found to go online everyday. Among the participants, 74.5% went online for social media use. Only 5% of the subjects fitted the criteria for Internet addiction. Thirty-six percent had limited symptoms for Internet addiction. Internet addiction symptoms and impulsivity were

positively related. The tool for Internet access did not affect Internet addiction. Those who used a smart phone went online for social media use more commonly than those who used a computer.

Conclusion It has been debated that social media and the increase in smart phone use may be affecting young people and increase internet addiction rates, however we have found that impulsivity is an important factor for internet addiction as in other types of addiction.

Cognitive-behavioral therapy in young adults with major depression and alcohol dependence

D. Vasile*, O. Vasiliu

Central University and Emergency Military Hospital "Dr. Carol Davila", Psychiatry, Bucharest, Romania

* Corresponding author.

Background Adolescents and young adults are a vulnerable population to both alcohol use disorders and depressive major disorder. Use of cognitive-behavioral therapy (CBT) could help in diminishing depressive symptoms severity as well as alcohol dependence severity.

Objective To evaluate CBT efficacy in young adults diagnosed with major depressive disorder and alcohol dependence.

Methods A number of 12 patients, age 23–35, 7 male and 5 female, outpatients, diagnosed with alcohol dependence and major depressive disorder, moderate or mild episodes, according to ICD-10 criteria, were included in a 3 months CBT oriented program. All subjects were evaluated using a Visual Analogic Scale (VAS) for self-evaluation of alcohol problems severity (score ranging from 0 – absent to 10 – extremely severe), AUDIT scale, Hamilton Depression Rating Scale (HDRS) – 17 items, and Global Assessment of Functioning (GAF). Patients participated in 30 minutes individual CBT sessions, twice per week, for 12 weeks. Cognitive restructuring based on patients' diary, coping skills training, and activation techniques have been applied in the CBT sessions.

Results After 12 weeks all patients reported decreases on VAS and AUDIT scores, with mean percentages of 55 and 50, while GAF increased with 45%. HDRS scores decreased with 65%. These changes were considered significant when compared to initial values ($P=0.007$ for VAS, $P=0.009$ for AUDIT, $P=0.012$ for GAF and $P<0.001$ for HDRS), according to dependent samples t -test $P<0.05$, bivariate.

Conclusion Cognitive-behavioral therapy, focused on cognitive restructuring, coping skills training, and activating techniques is an efficacious intervention in young patients with comorbid depressive and alcohol dependence.

Relationship between insomnia and tobacco smoking in alcohol-dependent patients

A. Wnorowska^{1,*}, A. Jakubczyk¹, A. Klimkiewicz¹, A. Mach¹, K. Brower², M. Wojnar¹

¹ Medical University of Warsaw, Psychiatry, Warsaw, Poland

² University of Michigan, Psychiatry, Ann Arbor, MI, USA

* Corresponding author.

Introduction Insomnia and tobacco use are frequent and important problems in alcohol-dependent patients. However, the relationship between sleep problems and cigarette smoking was not thoroughly investigated in this population.

Aim The purpose of the study was to investigate the relationship between tobacco smoking and severity of insomnia in alcohol-dependent patients in treatment. We also aimed at assessing other predictors of insomnia in this population.

Methods The study group comprised 384 alcohol-dependent patients. Standardized tools were used to assess: tobacco dependence (Fagerström Test for Nicotine Dependence [FTND]), sleep problems (Athens Insomnia Scale [AIS]), severity of alcohol dependence (Michigan Alcohol Screening Test [MAST]) and drinking quantities before entering treatment (Timeline Follow Back [TLFB]). Other comorbid psychiatric symptoms were assessed using Brief Symptom Inventory (BSI) and Barratt's Impulsiveness Scale (BIS-11).

Results The study group included 79.1% of current smokers, 62% of participants reported insomnia (AIS). The mean FTND score was 6.05 ± 2.18 . The multivariate regression analysis revealed that the severity of tobacco dependence was significantly associated with the severity of insomnia (FTND, $\beta = 0.140$, $P = 0.013$). Other factors associated with insomnia that remained significant in multivariate model were severity of psychopathological symptoms (BSI, $\beta = 0.422$, $P < 0.0005$) and intensity of drinking (TLFB, $\beta = 0.123$, $P = 0.034$).

Conclusion Tobacco use may predict severity of insomnia in alcohol-dependent patients. This finding may have important clinical implications and influence strategies applied in treatment of alcohol use disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The effect of aripiprazole on nicotine dependency in patients under methadone maintenance therapy

S.M. Zamir*, H. Javdani, A. Massoudifar, M. Naghdipour, A. Mehrnami

Qazvin University of Medical Sciences, Psychiatry, Qazvin, Iran

* Corresponding author.

Introduction The prevalence of smoking in patients under methadone maintenance therapy is high (85–98%). Most of these patients tend to quit smoking, but only a few of them receive treatment or referred to quit smoking. Recent study on aripiprazole, has been shown to reduce smoking.

Aims The aim of this study was to evaluate aripiprazole on smoking in patients under methadone maintenance therapy.

Material and method This study was a double-blind intervention study. Patients under Methadone maintenance therapy in 22 Bahman Hospital randomly divided into two intervention and control group. First with the FTQ questionnaire, nicotine dependency assessed in all patients. Then, 6-week aripiprazole administered to intervention group. Data were analyzed by SPSS version 21.

Results The age range of patients was 67–25 years. Two groups were matched in demographic characteristics. Finally, mean num-

ber of FTQ questionnaire in case group before intervention was 8.9 ± 1.4 and after intervention was 8.4 ± 1.6 . This difference was statistically significant ($P = 0.0007$).

Conclusion The study results show the aripiprazole effect in reducing the desire to smoke in patients under methadone maintenance therapy. The overall level of dependency on nicotine on the basis of test FTQ has decreased. By choosing aripiprazole as adjunctive therapy to quit smoking, by reducing the tendency of patients to smoking, can decrease cardiovascular complications and other problems caused by smoking and we can reduce the mortality rate of these patients.

Motivations behind suicide attempts: A study in the ER of Maggiore hospital – Novara

D. Marangon^{1,*}, C. Gramaglia², E. Gattoni², M. Chiarelli Serra², C. Delicato², S. Di Marco², A. Venesia², L. Castello², G.C. Avanzi², P. Zeppegno²

¹ Azienda Ospedaliero Universitaria, S.C. Psichiatria, Novara, Italy

² Università del Piemonte Orientale, Translational Medicine, Novara, Italy

* Corresponding author.

Introduction A previous study, conducted in the province of Novara stated that, from an epidemiological and clinical point of view, being a female, being a migrant, as well as being in the warmer months of the year, or suffering from an untreated psychiatric disease are associated with suicide attempts. Literature suggests there is a positive relation between negative life events and suicidal behaviours. In this study, we intend to deepen knowledge, individuating motivations and meanings underlying suicidal behaviours. This appears a meaningful approach to integrate studies and initiatives in order to prevent suicide and suicidal behaviours.

Aim To examine possible correlation between socio-demographic and clinical characteristics and motivations underlying suicide attempts.

Methods Patients aged > 16 years admitted for attempted suicide in the Emergency Room of the AOU Maggiore della Carità Hospital, Novara, Italy, were studied retrospectively from the 1st January 2015 to the 31st December 2016. Each patient was assessed by an experienced psychiatrist with a clinical interview; socio-demographic and clinical features were gathered. Analysis were performed with SPSS.

Results and discussion Data collection are still ongoing; results and implications will be discussed. We expect to find different motivations in relation to socio-demographic and clinical characteristics [1,2].

Disclosure of interest The authors have not supplied their declaration of competing interest.

Predictors of a suicidal behavior in patients with dementia

N. Maruta^{1,*}, I. Mudrenko²

¹ “Institute of Neurology, Psychiatry and Narcology of National Academy of Medical Science of Ukraine” SI, Borderline Pathology, Kharkiv, Ukraine

² Sumy State University, Medical Institute of the Sumy State University, Department of Neurosurgery and Neurology, Sumy, Ukraine

* Corresponding author.

Introduction Cognitive disorders are associated with a wide range of psychopathological syndromes and behavioral disorders, and suicidal manifestations in dementia are understudied nowadays.

Objectives To investigate clinical-psychopathological predictors of a suicidal behavior in patients with dementia.

Methodology Forty-four patients with dementia were examined: 23 patients with suicidal manifestations and 21 patients without them (control group). Clinical and psychometrical methods were used: Mini Mental State Examination (MMSE) scale; Assessment of Suicide Risk scale; Hamilton Rating Scale for Depression (HDRS), and statistical ones.

Results It was determined that male patients with dementia had suicidal behavioral manifestations more often than female patients (69.6%; $P < 0.05$). An average age of the patients was 69.88 ± 1.85 years with no significant difference between the main and control groups.

The majority of the patients with dementia (52.3%) had suicidal manifestations. Real suicidal intentions were the most frequent (25%; $P < 0.05$); 20.5% of patients expressed passive thoughts (antivital sentences, fantasies, ideas concerning death); 2 patients (6.82%; $P < 0.05$) had suicidal attempts. Patients with suicidal tendencies in their clinical picture more often had hallucinatory syndrome (39.1%; $P < 0.05$); features of severe depression (35.04 ± 1.54 points; $P < 0.01$); a high level of suicidal risk (26.34 ± 1.68 points; $P < 0.01$); a severe cognitive deficit (MMSE score 0–10); and a significantly lower level of self-awareness of death (18.53 ± 0.72 points; $P < 0.05$) in comparison with the control group.

Conclusions A high suicide risk in dementia correlated with a level of depressive symptoms ($r = 0.6$), moderate and/or severe grades of dementia ($r = 0.45$), and a low level of self-awareness of death ($r = 0.35$).

The burden of attempted suicide: The attitude of emergency services workers

G. Cuoghi¹, M. Venuta², G. Mattei^{2,3,*}, A. Sacchetti², S. Ferrari²

¹ Villa Rosa, Modena, Italy

² University of Modena and Reggio Emilia, Clinical, Diagnostic and Public Health Medicine, Modena, Italy

³ Association for Research in Psychiatry, Association for Research in Psychiatry, Castelnovo Rangone, Italy

* Corresponding author.

Introduction The great global burden of suicide requires specific preventive strategies focused on emergency services (ES) workers, providing first aid after attempted suicide.

Objectives To investigate the approach of ES workers toward attempted suicides, and to assess work-related stress and team-work attitude as variables likely to influence suicide risk perception.

Methods A total of 265 ES workers (73 medical doctors, 130 nurses, 62 health and social care workers) from 3 hospitals in the area of Modena (Northern Italy) were involved. In a group setting, titles from local newspapers reporting about suicides were read, and ES workers were asked to fill in 3 psychometric scale questionnaires (SUIATT, MBI and SAQ).

Results The questionnaires returned were 88 (33%), 47% ($n = 42$) were filled by women, median age was 40 years. Doctors group had the highest response rate (60%). Burnout levels were intermediate at the Emotional Exhaustion subscale, severe at the Depersonalization subscale and mild at the Professional Efficacy subscale. Eighteen percent recorded a good team perception, 33% had a good perception of their work conditions. SUIATT subscales showed a restrictive attitude toward suicide, regardless of hospital and task.

Discussion No associations emerged among SUIATT, MBI and SAQ subscales; male sex alone correlated to the SUIATT factor “rationality/mental alteration”, suggesting more “tolerance” of suicidal behaviour.

Conclusions It is crucial to raise awareness among ES workers on this issue, since those workers considering suicide as “more acceptable” are more likely to recognise its signs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Attempted suicide: Study of the phenomenon in a sample of patients in the province of Modena

L. Bisi, M. Bolondi, G. Mattei*, A. Sacchetti, S. Ferrari

University of Modena and Reggio Emilia, Diagnostic, Clinical Medicine and Public Health, Modena, Italy

* Corresponding author.

Introduction Attempted suicide consists in a self-damaging non-fatal behaviour, with an explicit or implicit evidence of the intent to die. It has a multifactorial aetiology: presence of psychiatric disorder, particularly major depression and other non-psychiatric components, like a series of stressful events.

Aim To describe suicidal behavior among patients who attempted suicide.

Methods Cross-sectional study. Patients admitted to three hospitals in the Province of Modena (Italy) after having attempted suicide were enrolled. Observation time: August 2015–August 2016 (13 months). Descriptive statistics made with STATA 13.0.

Results A total of 187 subjects (female 65%) were enrolled in the period of time considered. Forty-one percent were aged 45–64; 43.7% had higher education; 50.4% were unemployed; 49.6% had regular income. Common means to attempt suicide were drugs (64%), weapons (11%), precipitation (10%), other (6%), choking (4%). Recent stressful events were reported by the 83.4% of respondents, namely: family conflicts (29%), economic problems (17%), personal health problems (11%), health problems affecting a family member (5%), emotional separation (9%), job loss (7%), other (22%), alcohol abuse (27%), substance abuse (4%). The main psychiatric diagnoses were: depressive disorder (56.67%), personality disorder (20%), psychotic disorder (6.67%), bipolar disorder (5.33%), behavioural disorders (2.67%), anxiety disorders (2%), dementia (1.33%).

Conclusions Findings of the present study are consistent with available literature and could help to identify “high risk” groups to plan future targeted programmes.

Mental health profile of suicide victims in an Irish urban population

G. Udoh

Saint Patrick's University Hospital, Young Adult, Dublin, Ireland

Objectives To describe demographic and psychiatric characteristics of suicide victim cases.

Method Retrospective, case file psychological autopsy of deaths registered at the coroner's court, Dublin. Cases with a verdict of suicide and open verdicts registered in 2007, 2012 and 2013 were included.

Results Two hundred and five cases of suicide/open verdicts were registered the 3-year period. Seventy four percent ($n = 152$) were males. Mean age – 42.87 years old (STD = 15.44) with no significant difference between genders. Sixty-four percent ($n = 132$) were single at the time of death, while 32.2% had children. One hundred and ninety-eight had a stable accommodation; 37.5% ($n = 77$) living alone, and 36.6% ($n = 75$) actively employed.

One hundred and twelve subjects (54.6%) suffered from mental illness; 53.6% – affective disorder; 15.2% – alcohol and substance misuse; 12.5% – psychotic disorder. Seventy-nine (70.5%) were not in contact with mental health services at the time of death; 32 (28.6%) were attending as outpatients. Illness onset was recorded for 68.7% cases ($n = 77$); 35.7% ($n = 40$) had a length of illness of more than 5 years. Psychiatric comorbidity was present in 29.5% ($n = 33$); 54.5% ($n = 18$) presented also alcohol/substance misuse.

Conclusion Suicide victims were single, middle-aged male, suffered mental health difficulties, most frequently affective disorder. A small number of subjects an additional comorbid diagnosis. Few were in contact with outpatient services at the time of death. No significant differences in demographic characteristics were found between the group suffering from mental illness and the group with no mental illness.

Suicide and drug and alcohol addiction: Self-destructive behaviours. An observational study on clinic hospital population

A. Nardella^{1,*}, G. Falcone¹, G. Giordano¹, D. Erbuto², M. Migliorati², M. Innamorati³, P. Girardi⁴, M. Pompili⁴

¹ Psychiatry Residency Training Program, Faculty of Medicine and Psychology, Sapienza University of Rome, Rome, Italy

² Faculty of Medicine and Psychology, Sapienza University of Rome, Department of Neuroscience, Mental Health and Sensory Organs NESMOS, Rome, Italy

³ European University of Rome, Department of Human Sciences, Rome, Italy

⁴ Faculty of Medicine and Psychology, Sapienza University of Rome, Sant'Andrea Hospital Rome, Department of Neuroscience, Mental Health and Sensory Organs NESMOS, Rome, Italy

* Corresponding author.

Introduction Suicidal behaviour and drug and alcohol dependence represent two different aspects of self-destructive behavior. **Objectives** We evaluated the relationship between suicidal behavior and substance and alcohol addiction. It was investigated the role of childhood trauma in these self-destructive behaviors and in the development of the two mental constructions of hopelessness and mentalization.

Aims We also assessed how a high level of hopelessness could affect suicidal ideation and how low or absent capacity of mentalization could influence the development of substance and/or alcohol addiction.

Methods This naturalistic, observational study included 50 patients (mean age = 46.54; S.D = 14.57) recruited from the department of psychiatry ($n = 18$) and the centre for suicide prevention ($n = 32$) of Sant'Andrea Hospital (Rome). Different questionnaires were administered to each patient from February to May 2016.

Results There was not a statistically significant relationship between suicidal behavior and addict behavior. Childhood trauma resulted a risk factor for alcohol abuse with a relationship that tended to significance ($P = 0.07$). Physical and sexual abuses were significantly associated with addiction (respectively $P = 0.014$; $P = 0.033$). It was showed a statistically significant interaction between high level of hopelessness and suicidal ideation ($P = 0.037$). The absence of mentalization was related to the absence of alcohol abuse ($P = 0.061$). Finally, trauma experienced during childhood was associated with high level of hopelessness ($P = 0.005$).

Conclusions Suicidal behavior is influenced indirectly by a childhood traumatic experience that conditioning the level of hopelessness. Childhood trauma affected directly the development of drug abuse and alcoholism. The capacity of mentalization was not related with childhood trauma.

Cyberbullying and suicidal ideation: Relationship with mood states and consumption of psychoactive substances

D. Silva¹, J. Nunes^{1,*}, T. Ferreira², A. Pissarra da Costa¹

¹ Hospital Sousa Martins, Department of Psychiatry and Mental Health of Sousa Martins Hospital, U.L.S. Guarda, Guarda, Portugal

² Hospital Prof. Doutor Fernando Fonseca, Amadora, Portugal, Department of Psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction Cyberbullying is an emergent problem associated to terrible consequences, especially in young adults.

Objectives To analyse the levels of behaviours of victimization and aggression of cyberbullying, suicidal ideation, mood states and consumption of psychoactive substances in a sample of college students from the University of Beira Interior (UBI), as well as to analyse the relationship between these variables.

Methods Analytical cross-sectional study that integrates quantitative methodology. Data collection took place via online survey in the population of students at the UBI ($n = 475$, 329 females, mean age 22.2 ± 4.1 years). The questionnaire consisted of socio-demographic, mental health and internet use data and the Portuguese versions of self-reported scales to measure mood states, consumption of psychoactive substances, the levels of behaviours of victimization and aggression of cyberbullying and the levels of suicidal ideation.

Results The levels of aggression of cyberbullying were significantly higher in male students and in users of social networks. There was a significant positive correlation between behaviours of victimization and aggression of cyberbullying, and between them and suicidal ideation and negative affect. The levels of both behaviours of cyberbullying and suicidal ideation were significantly higher in students consuming alcohol with drugs, just drugs and sedatives. There was a significant positive correlation between suicidal ideation and negative affect and a significant negative correlation between suicidal ideation and positive affect.

Conclusions Both behaviours of cyberbullying were significantly associated with suicidal ideation and negative affect. Thus, stands out the relevance of an earlier identification of these behaviours and an adequate intervention by health professionals.

Unexpected variations in official UK statistics related to rates of suicide and those of undetermined intent: An exploration of causes

D. O'Reilly^{1,*}, M. Rosato²

¹ Queen's University Belfast, Centre for Public Health, Belfast, United Kingdom

² Ulster University, Bamford Centre for Mental Health and Well-Being, Belfast, United Kingdom

* Corresponding author.

Background Official rates of suicide are perhaps the most important and enduring measures of population mental health. They are however prone to variations in reporting usually relating to deaths where the intention was uncertain, though most official statistics circumvent this by including 'events of undetermined intent' (ICD10 Y10-34 and Y87.2) along with 'intentional self-harm' in their official statistics. It is however unclear how successful this strategy has been and whether significant sources of bias still persist.

Aim To systematically examine the dramatic change in rates of death from suicide (and undetermined intent) in Northern Ireland, that coincided with a major overhaul and reorganisation of the Coroners Service in 2005/6, to understand the extent to which the initial investigation by the coroners' office, legal processing, registration and coding practices can influence official suicide statistics.

Methods In the space of one year, Northern Ireland went from having a standardised rate of suicide (incl undetermined intent) of 12.6/100,000 in 2004 to 26.6/100,000 in 2006 (a 111% increase) and in doing so went from having consistently the lowest to consistently the highest registered rate of suicide in the UK.

Results Initial analyses rules out changes in the police service, pathology service or registration coding practices as causative and suggest that the introduction of a coroner's liaison officer (with a formal data gathering role) was the most likely factor. The centralisation of the coroners' service also reduced variations according to age, sex, geography and coding.

Conclusions The process underpinning official statistics need to be routinely scrutinised.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW0856

Alcoholic psychoses and suicide trends in Russia, Belarus and Ukraine

Y. Razvodovsky

Grodno State Medical University, Pathological Physiology, Grodno, Belarus

Introduction The dramatic fluctuations in suicide mortality in the countries of the former Soviet Union (fSU) over the past decades have been widely discussed in the scientific literature and are still relatively unexplored. Accumulated evidence suggests that the mixture of cultural acceptance of heavy drinking, high rate of distilled spirits consumption, and binge drinking pattern is major contributor to the suicide mortality burden in fSU countries.

Aims The present study aims to analyze whether binge drinking is able to explain the dramatic fluctuations in suicide mortality in Russia, Belarus and Ukraine from the late Soviet to post-Soviet period.

Method Trends in alcoholic psychoses incidence and suicide rates from 1980 to 2015 in Russia Belarus and Ukraine were analyzed employing a Spearman's rank-order correlation analysis.

Results The estimates based on the Soviet data suggest a strong positive association between alcoholic psychoses and suicide rates in Russia, Belarus and Ukraine. This positive relationship was less evident in the post-Soviet period.

Conclusion Collectively, these findings indicate that alcohol has played an important role in the fluctuation of suicide mortality rates in the former Soviet republics during the last decades. Further monitoring of suicide mortality trends in the former Soviet countries and detailed comparisons with earlier developments in other countries remain a priority for future research.

Attentional bias toward suicide-relevant information in suicide attempters: A cross-sectional study and a meta-analysis

S. Richard-Devantoy*, D. Yang, T. Gustavo, J. Fabrice

McGill University, Psychiatry, Montreal, Canada

* Corresponding author.

Objective Previous studies using a modified Stroop test suggested that suicide attempters, in contrast to depressed patients with no suicidal history, display a particular attentional bias toward suicide-related cues. However, negative results have also been reported. In the present study, we collected new data and pooled them as part of a meta-analysis intended to shed further light on this question.

Method We conducted:

- a cross-sectional study comparing performance on the modified Stroop task for suicide-related, positively-valenced and negatively-valenced words in 33 suicide attempters and 46 patient controls with a history of mood disorders;

- a systematic review and a meta-analysis of studies comparing performance on the modified Stroop task among patients with vs. without a history of suicidal acts in mood disorders.

Results The cross-sectional study showed no significant difference in interference scores for any type of words between suicide attempters and patient controls. A meta-analysis of four studies, including 233 suicide attempters and 768 patient controls, showed a significant but small attentional bias toward suicide-related words (Hedges'g=0.22; 95% CI [0.06 to 0.38]; Z=2.73; P=0.006), but not negatively-valenced words (Hedges'g=0.06; 95% CI [-0.09 to 0.22]; Z=0.77; P=0.4) in suicide attempters compared to patient controls.

Limitations Positively-valenced words and healthy controls could not be assessed in the meta-analysis.

Conclusion Our data support a selective information-processing bias among suicide attempters. Indirect evidence suggests that this effect would be state-related and may be a cognitive component of the suicidal crisis. However, we could not conclude about the clinical utility of this Stroop version at this stage.

Neurocognitive functions in inpatient suicide attempters and non-attempters: A comparison

R.P. Sant'Angelo^{1,*}, F. Ambrosini², M. Pacetti³, R. Raggini¹, G. Piraccini¹

¹ S.P.D.C., Ospedale Bufalini, Cesena, Italy

² Dipartimento di Psicologia, Università di Bologna, Bologna, Italy

³ C.S.M. di Forlì, AUSL ROMAGNA, Forlì, Italy

* Corresponding author.

Introduction According to many studies, suicide attempters, compared to healthy general population, exhibit some neurocognitive deficits, which are considered promising endophenotype of suicidal behavior disorder. A similar pattern of impairment is widespread in individuals affected by psychiatric disorders.

Objectives To compare neurocognitive functions of hospitalized suicide attempters (A) with those of an inpatient group without history of suicidal behavior (NA), likewise affected by psychiatric disorders.

Aims The purpose of the study is to evaluate if neurocognitive impairment is associated to suicidal behaviors, regardless of underlying psychiatric diagnosis.

Methods The whole sample is composed of 70 adult psychiatric inpatients (34 males, 36 females), divided into two groups (A and NA) of 35 patients with diagnosis of Psychotic, affective and personality disorders. Neurocognitive functions were assessed using Tower of London Test (TOL), Modified Wisconsin Card Sorting Test (MCST), Stroop Test (ST) and Attentional Matrices (AM). Differences between A and NA groups were analyzed using U-test of Mann–Whitney and cross tabulations, taking into account the three diagnostic areas.

Results Statistically significant differences were found between A and NA with regard to the ability of categorization (MCST), planning, problem solving and inhibition of automatic response (TOL), which proved to be more preserved in A individuals. No significant differences were found on selective attention tasks (ST and AM).

Conclusions These preliminary findings show statistically significant differences on executive functions between suicide attempters and psychiatric non-attempter individuals. Further research on larger samples is needed to investigate these associations.

Zero suicide southwest UK initiative – Steps to mitigate suicide risk in local populations using quality improvement methodology and a whole life approach

R. Shankar^{1,*}, E. Wilkinson², S. Roberts³, O. Rebecca⁴

¹ Cornwall Foundation NHS Trust, ID Neuropsychiatry, Truro, United Kingdom

² Cornwall Foundation NHS Trust, Psychiatry, Truro, United Kingdom

³ Cornwall Council, Public Health, Truro, United Kingdom

⁴ Kernow Clinical Commissioning, Mental Health, St Austell, United Kingdom

* Corresponding author.

Background Only 25% of people who die by suicide see mental health services. Suicide is not just a health issue. Its causation and consequences lie within all of society. Many erroneously believe that suicide is inevitable and not preventable, because its cau-

sation is too complex. Underlying associations with suicide are largely social. There are programmes in the USA, which have combined interventions to reduce suicides. The 2014 UK suicide rate per 100,000 was 10.8 but 11.1 in South West (SW) England (pop: 5 million). A whole system approach is necessary. Zero Suicides SW is a project to address this.

Aim (1) To develop a regional strategy to reduce and prevent suicide. (2) To make whole populations suicide risk aware. (3) Reduce regional suicide rates.

Method A collaborative involving national and local 60 organisations including charities and voluntary sector was formed. Five collaborative meetings used narratives of suicide survivors, national experts led themed workshops, etc. to come up with a regional strategy. Quality Improvement (QI) Methodology was used to develop and examine the success of all projects.

Outputs Initiatives such as using local radio stations for mental health promotion, collaboration via a poster campaign with local breweries and pubs to make men more self-aware of risk, suicide risk counselling for relatives/carers of patients admitted to psychiatric care, improving scrutiny to access to medication for recently discharged psychiatric patients have developed from the project. The QI model demonstrated how localised changes at person and organisation level could combine and have a powerful role in suicide prevention.

Suicide risk assessment in the elderly

N. Smaoui, I. Baati, T. Dorsaf, S. Mkaouer, I. Abida, J. Masmoudi*

Hédi Chaker University Hospital, Psychiatry A, Sfax, Tunisia

* Corresponding author.

Objectives To assess suicide risk in elderly psychiatric outpatients and to identify potential suicide risk factors in this population.

Methods This was a cross-sectional, descriptive and analytical study, including 50 psychiatric outpatients, aged 65 years or more and attending the Hédi Chaker University Hospital, in Sfax (Tunisia), between November and December 2015. We used a hetero questionnaire including epidemiological and clinical data and three scales: the Suicidal Risk Assessment Scale of Ducher (RSD), the Hospital Anxiety and Depression Scale (HADS) and the Mini Mental State Examination (MMSE).

Results The sex ratio (M/F) was 1. The average age of patients was 68.62 years. The majority of them were married (68%), unemployed (98%), living in urban area (58%) and within their family (88%); they had at most a primary degree (80%) and a low socioeconomic level (74%).

The prevalence of patients at risk of suicide (RSD ≥ 3) was 26%. This risk was high (RSD ≥ 7) in 18% of cases.

The presence of suicidal ideation (RSD ≥ 3) was correlated with: a family history of suicide attempt (58.3% vs. 15.8%; $P=0.003$), a personal history of suicide attempt (80% vs. 12.5%; $P<0.001$), depressive symptoms (HAD-D ≥ 11) (36.7% vs. 10%; $P=0.05$) and anxiety (HAD-A ≥ 11) (52.4% vs. 6.9%; $P=0.001$).

Conclusion Our study showed that among older psychiatric outpatients, one in four had suicidal thoughts. This high rate encourages us to search systematically these suicidal thoughts in this population, especially in patients with risk factors such as a family history of suicide attempt, depressive or anxious symptoms.

The impact of trait emotional intelligence and resilience on suicidal behavior in university students

P. Sojer^{1,*}, S. Kainbacher¹, G. Kemmler¹, H. Freudenthaler², E. Deisenhammer¹

¹ Med. Universität Innsbruck, Psychiatrie, Innsbruck, Austria

² University of Graz, Psychologie, Graz, Austria

* Corresponding author.

Introduction Suicidal ideation has repeatedly been reported as a predecessor of suicidal behavior. Several neuropsychological parameters have been associated with suicidal ideation. Emotional intelligence (EI) and resilience, which play an important role in the emergence of psychiatric disorders may also be related with suicidality.

Objectives The main objective of this study was to investigate the relationship of trait EI and resilience with suicidal ideation. Moreover, we hypothesized that EI and resilience would be correlated with each other and that they were moderating variables between stressful life events and suicidal ideation.

Methods A total of 277 male and female students without current psychiatric diseases were recruited per online questionnaire asking for lifetime and 4-weeks suicidal ideation and demographic data and containing the Resilience Scale of Wagnild and Young, the Connor Davidson Resilience Scale and, for the measurement of trait EI, the Self-Report Emotional Ability Scale. Additionally, we applied the Social Readjustment Rating Scale to assess stressful life events.

Results We found significant negative correlations between lifetime and in part 4-weeks suicidal ideation and intrapersonal trait EI as well as resilience. Trait EI and resilience were interrelated. There was no significant moderating effect of trait EI or resilience on the relationship between SRRS score and suicidality.

Conclusion Assessing EI and resilience as trait factors might be helpful in the prospective identification of suicidal individuals.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Medical University, Forensic Medicine, Pleven, Bulgaria

⁴ Medical University, Forensic Medicine, Plovdiv, Bulgaria

⁵ University Hospital "Dr G. Stranski", Psychiatry, Pleven, Bulgaria

* Corresponding author.

Introduction Suicidality is still an understudied problem in Bulgaria especially on a subnational (regional) level.

Objectives To collect data on suicidality in two major regions of Bulgaria with a population over 250,000 each (Plovdiv and Pleven) for a six years period (2009–2015).

Aims To analyze demographic, health-related and other characteristics associated with suicidal behavior as well as motives and methods of suicide.

Methods Data were extracted from relevant documentation (medical records, public health reports, etc.) and statistically processed upon collection.

Results Majority of suicide victims were males between 45 and 64 years while most suicide attempts occurred among 18–29 years old females.

Leading method of suicide was hanging, followed by jumping from high places and use of firearm.

Prevailing suicidal motives were psychotic symptoms, serious somatic illnesses and family problems. Depression accounted for 25% of all suicide cases and in another 25% motivation could not be identified because of insufficient data.

The proportion of unemployed among suicide committers was not significantly higher than that of employed and retired.

Conclusions Severe mental disorders are a major trigger of suicidal behavior.

Personal relationships should be targeted by suicide prevention interventions.

Somatic illnesses are increasingly important suicide risk factor driven by the ongoing process of population aging.

Frontline healthcare professionals should be trained to explore underlying suicidal motives and actively probe for depression in each case of suicidal behavior.

Unemployment related suicide risk is most likely mediated through an adaptation crisis mechanism induced by the abrupt change of social status.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Risk factors for multiple suicidality in Hungary

M.D. Toth^{1,*}, P. Osváth², V. Vörös², K. Futó³, N. Ágnes², A. Székely⁴, G. Purebl⁴, S. Fekete²

¹ National Public Health and Medical Officer Service, Office of the Chief Medical Officer, Budapest, Hungary

² University of Pécs, Department of Psychiatry and Psychotherapy, Pécs, Hungary

³ INDIT Foundation, Alcohol Outpatient Unit, Pécs, Hungary

⁴ Semmelweis University, Institute of Behavioural Sciences, Budapest, Hungary

* Corresponding author.

Introduction Suicide rate in Hungary is among the highest in the European Union (2015: 18.9/100,000 inhabitant). Although there is no national registration system of suicide attempts in Hungary, according to previous studies Hungarian Romas have three times higher suicide attempt rate than non-Romas.

Objectives The aim of this study was to explore socio-demographic and mental health risk factors of multiple suicide attempts in Hungary.

Methods A total of 1547 suicide attempts were assessed via retrospective data analysis using patient records. Data on socio-demographic variables, psychiatric diagnoses, methods and reported reasons of suicide attempts were investigated. Binary logistic regression analyses were performed to identify potential risk factors for multiple suicide attempts.

Results The ratio of multiple attempters were 37.7% in the sample, with a Roma predominance (Roma: 51.8%, non-Roma: 34.8%, $\chi^2_{(1)} = 27.64$; $P < 0.001$). Of the potential factors examined, Roma ethnicity (OR: 2.03; CI: 1.53–2.70; $P < 0.001$), economic inactivity (OR: 1.7; CI: 1.36–2.18; $P < 0.001$), mood disorders (OR: 1.58; CI: 1.25–1.99; $P < 0.001$), personality disorders (OR: 2.09; CI: 1.45–3.01; $P = 0.00$), organic mental disorders (OR: 1.76; CI: 1.01–3.07; $P = 0.44$) and mistreatment as reported reasons (OR: 3.95; CI: 1.17–13.32; $P = 0.02$) were found as significant risk factors of multiple suicide attempts.

Conclusion National registration of suicide attempts would be necessary for a more thorough analysis. Beside the more advanced treatment of mental health disorders, increased efforts in prevention are recommended with a special focus of low SES groups and Roma ethnicity. The specific background factors in Roma ethnic group should be further examined.

Suicide-related Internet use among university students

V. Voros*, P. Osvath, Z. Szabo, Z. Nagy, S. Fekete
University of Pecs, Department of Psychiatry, Pecs, Hungary

* Corresponding author.

Introduction Nowadays, mobile and Internet communication is widely used and has a special role in mental health prevention. Besides, websites targeting suicide prevention, pro-suicide contents (methods for suicide, suicide pacts) are also easily available, which may increase the risk for suicide in vulnerable people.

Aims Our aim was to assess the relation between Internet use and suicidal behaviour among university students and also to assess online activity regarding suicidal contents and help-seeking behaviour.

Methods Self-administered questionnaires were completed by university students.

Results Most of the 101 students who completed the survey use the Internet 3 hours or more a day. They are facing suicidal contents numerous times. Professional websites providing information and the common popular sites were mainly visited, sites providing help were less screened (10%). More than quarter of the students felt discomfort when looking at sites dealing with suicide. Almost one-third of the subjects had suicidal thoughts during their lives and 15% already planned suicide. In case of suicidal thoughts, subjects would seek help mainly from friends and family, but online help-seeking was not preferred.

Conclusions Despite of the extensive Internet use, students rarely seek help for emotional problems on the Internet. Development of websites controlled by professionals is essential, especially for those who would not benefit from traditional psychological/psychiatric care. Future research is needed regarding the characteristics of Internet use and the potentials and limits of help-seeking via the Internet in order to prevent people from pro-suicide websites and to improve professional websites.

Differential diagnostic of self-destructive behaviour via structural-dynamic model

G. Pyliagina

Shupyk National Medical Academy of Postgraduate Education,
Department of Psychiatry, Psychotherapy and Medical Psychology,
Kyiv, Ukraine

Objectives Structural-dynamic model (SDM) of self-destructive behaviour (SdB) is needed for differential diagnostic of numerous features of SdB. SDM is based on an awareness that self-destructiveness has different variants with diversity of psychophysical damage as its outcome. SDM describes whole continuum of SdB variations and helps to differentiate them, to assess risk of suicidal or non-suicidal activity and to do long-term prognosis for SdB development as well.

Methods SDM of SdB is a generalized conception, which is a result of consequent scientific researches. The clinical criteria by ICD-10 and semi-structured suicidological interview were used in all of the surveys. In general, we observed 860 patients with suicidal attempt, suicidal ideas and self-destructive injuries.

Results Our researches proved that SDM of SdB determine suicidological diagnosis implementing all-round assessment of SdB features of patient using kinds, forms and clinical-pathogenetic types as main categories of this concept. The kinds of SdB are: self-aggressive behaviour, self-destructive behaviour (it includes non-suicidal or psychotic variants) and suicidal behaviour. Each kind of SdB helps to detect pathogenetic mechanisms and dynamic tendencies in development of it. The form of SdB discloses behavioural specification in each case. There are equivalent, internal and external forms. The clinical-pathogenetic types of SdB are: suicidal, parasuicidal, pseudosuicidal or asuicidal. Each of them discloses significant clinical characteristics of actual self-destructive episode (nosology, syndrome, psychological traits, situation peculiarities, etc.). The differential diagnostic of SdB by SDM concept will allow doctors to treat patients more accurately and effectively.

Cross cultural aspects of OCD in Islam and clinical practice

W.I. Abouhendy

Faculty of Medicine, Zagazig University, Psychiatry, Zagazig, Egypt

Introduction Religious obsessions and compulsive acts compromise approximately two thirds of all obsessive compulsive disorder symptomatology in Muslim patients. Imam's mosque is consulted before a psychiatrist.

Objectives To explore the Islamic jurist's views and methods in dealing with obsessions and compulsions.

Aims Introduction of guidelines for managing OCD in some Muslim patients.

Methods We began studying the different opinions of scholars in defining obsessive compulsive behaviour focusing on the tight criteria required by the Maliki Jurists to consider the individual being obsessed. This was followed by a thorough review of other Islamic doctrines.

Results The jurisprudential therapeutic approach includes:

- obsessions are satanic whispers not originating from the self, which is equivalent to "It is not me but my OCD" in modern cognitive behavioural approach;
- diverting attention from the obsessive thought rather than engaging with it;
- not to respond to the obsessional thought (response prevention);
- listing of religious permits;
- focusing attention on acts of worship;
- thought stopping.

At the end we added various jurisprudential rules to be remembered by patients such as certainty does not fade with scepticism, no defiles by doubt, there are no doubts for a man with excessive doubts.

Conclusion Exposure and response prevention techniques are deeply rooted in Islamic jurisprudence and are practised with conviction by OCD Muslim patients. We produced specific guidelines that could be used by clinical psychologists and other mental health professionals in dealing with OCD patients to ensure their engagement in therapy.

University Psychiatry Clinic, Day Hospital, Skopje, The Former Yugoslav Republic of Macedonia

* Corresponding author.

Introduction World statistical data show that a large number of mothers suffer from antenatal or postnatal depression and that it is linked with difficulties in personal and emotional development in child.

Aim To present the importance of treatment of antenatal depression.

Material and methods We present is a 32-year-old woman man, with completed high level of education, married, mother of one child, pregnant in first trimester, who suffered of depression several years ago. Diagnosis was made in line with the ICD 10 (F33), and the following diagnostic instruments were used: HAMA, HAMD, clinical interview.

We present is a 32-year-old woman man, with completed high level of education, married, mother of one child, pregnant in first trimester, severe depression with depressive mood, weight lost, insomnia, agitation, suicidal thoughts.

She was treated in the day hospital of our clinic with SSRI antidepressants, individual and group psychotherapy.

Results During the day hospital stay patient was treated with pharmacologic agents (SSRI anti-depressants – tbl. Sertraline), which showed a great success, that is reduction in the depression, sleep improvement, normal gain weight and regular pregnancy and baby birth with APGAR score 9/9.

Discussion Literature shows that antenatal depression is associated with poor mother self-care during pregnancy including poor visit of antenatal clinics, substance misuse, low birth weight, preterm delivery and significant intellectual and emotional deficits in children whose mothers were suffered of antenatal or postnatal depression.

Conclusion Treatment of antenatal or postnatal depression is very important for mothers' mental health and for the normal develops of child also.

The burnout's prevalence among Tunisian military consultants in psychiatry

H. Belhadj*, W. Krir, C. Bencheikh, H. Elkefi, A. Oumaya

Military Hospital, Psychiatry, Tunis, Tunisia

* Corresponding author.

Introduction Burnout causes a considerable human cost. Army employees are, in fact, particularly exposed to this risk.

Objective To determinate the prevalence of burnout syndrome among military consultants in psychiatry and to study its socio-familial repercussions.

Method A cross-sectional study was conducted in a military outpatient clinic in Tunis and included 30 military patients with a seniority of more than 15 years. Burnout and major depression were assessed with the instrument Burnout Measure Short version (BMS-10) and the Patient Health Questionnaire "PHQ-9", respectively.

Results Eighty percent of participants ($n = 24$) had a very high degree of burnout exposure according to BMS-10. Twenty of these (83.3%) had a moderate to severe depression. All married patients ($n = 22$) having burnout syndrome reported a conjugopathy and a tendency to physical and verbal aggressiveness against their children.

Conclusion Military employees are particularly vulnerable to burnout. Detecting burnout in time is therefore essential in order to prevent its undeniable socio-familial repercussions.

Muscular strain as risk factor of somatic symptom of mix anxiety and depression

M. Bhadar^{1,*}, S. Asghar¹, Z. Mukhtar²

¹ Sexual Health Institute Pakistan, Psychiatry, Lahore, Pakistan

² Azm Center, Sexual Health, Sargodha, Pakistan

* Corresponding author.

Introduction Somatic symptoms in depression are not uncommon. There is increased suicidality, poor prognosis, and increased risk of relapse. Neurological and musculoskeletal symptoms can be explained on basis of increased muscular tension in the body.

Methods An internet search was made using key words muscular tension, SSRIs depression, anxiety, somatic symptoms.

Results Ninety-eight percent patients reported at least one of somatic symptoms. Forty-five percent reported six somatic symptom. GIT symptoms in 67% patients. Fatigue in 78% of patients. Weakness in body parts 45% and headache in 43% to 65%. Chest pain more common in male. Patient over 40 showed pain in limbs or joints. Number of symptoms was directly related to severity of depression.

Discussion Increased muscular tension is one component of mix anxiety and depression. Main nerves and their branches pass in between muscular bellies. When there is increased muscular tone, it puts extra compression on major nerves and their branches. This will cause dysesthesia in body parts. Stretching of muscles produce pain due to hypoxia. This produces headache, strain neck and backache pain in chest. Fatigue is result of over consumption of energy due to hypertonia. One of their side effect is of SSRIs is muscular hypertonia which will not be very helpful for these symptoms. Drugs like tricyclics, SNRI can have better results when used alone, gabapentine, pregabline tinazidine used as adjunct can alleviate symptoms. Non-pharmacological treatment includes massage, relaxation technique, and warm water therapy.

Conclusion Somatic symptoms of mix anxiety and depression should be important consideration in its treatment.

* Corresponding author.

Language anxiety is a distinct complex of self-perception, beliefs, feelings, and behaviors related to classroom language learning arising from the uniqueness of the language learning process. Effects of foreign language anxiety are particularly evident in the foreign language classroom, and this anxiety is a strong indicator of academic performance. So, the study aimed to investigate relationships between personality traits with language anxiety among bilinguals. The research method was correlation. The population was included all upper intermediate language learners and higher levels in language institutes, that 250 learners were selected by cluster sampling method, and responded to McCare & Costa's NEO personality traits (neuroticism, openness to new experience, extroversion, agreeableness, and conscientiousness) and Horwitz's language anxiety inventory. The data were analysed by Pearson correlation formula. The results showed that there is positive and significant relationship between neuroticism and openness to new experience with language anxiety, and positive and significant relationship between extroversion, agreeableness, and conscientiousness with language anxiety. Thus, it can be concluded that personality traits have important impact on language anxiety.

Gynecological symptoms in somatization disorder

C.M. Calahorro^{1,*}, M. Guerrero Jiménez², B.M. Girela Serrano²

¹ Hospital Universitario San Cecilio, Unidad de Salud Mental, Granada, Spain

² Santa Ana Hospital, Psychiatry, Motril – Granada, Spain

* Corresponding author.

Background Medically unexplained symptoms are common in ambulatory medical patients. Such disorders are consistently more prevalent in women than in men and occurs up to 10 times more frequently in women.

Main objective To review published literature about gynecological symptoms related to somatic disorder and which percentage of these patients diagnosed as Somatoform Disorder are referred from gynecologist consultations.

Methods We present the case of a 31-year-old woman diagnosed of a somatic symptom disorder whose first consultation was gynecological. She is referred to Mental Health Unit from Primary Care Center because of having been referred to five different specialists and been diagnosed as "functional somatic syndromes" in all cases. She started a selective serotonin reuptake inhibitor, and attended

a relaxation group during two months with good recovery afterwards.

She is asymptomatic nowadays and has not been visited by any other specialist.

Conclusions Women report more intense, numerous, frequent bodily symptoms than men. This difference appears in samples of medical patients and in community samples, whether or not gynecologic and reproductive symptoms are excluded, and whether all bodily symptoms or only those, which are medically unexplained are examined.

Women may be more aware of and more attentive to weak or diffuse bodily stimuli, which men do not perceive, and some studies suggest that women have greater bodily vigilance and awareness. This could result from the experiences of menstruation, menopause, pregnancy, and lactation which all serve to repeatedly call women's attention to their anatomy and physiology and to sensitize them to bodily changes.

Nursing consultation and the care to depression in elderly

C.M. Carvalho*, T.V. Cardoso Vernaglia, D. de Assis Correa Sória, T.D.J. Espirito Santo da Silva, S.R. Souza, R. Mello
Universidade Federal do Estado do Rio de Janeiro, Alfredo Pinto
School of Nursing, Rio de Janeiro, Brazil

* Corresponding author.

Depression is a major mental illness affecting the elderly. About 15% of the elderly have some depressive symptoms and about 2% have severe depression. This study was conducted in an Extension Program of the Federal University of the State of Rio de Janeiro (UNIRIO) and the aims are: to identify the prevalence of depression in the elderly attended by the community center "Project Rebirth" in Rio de Janeiro-RJ, and discuss strategies developed in consultation to care the depression.

Methodology The elderly are registered in the program and accompanied by a multidisciplinary team. In nursing consultations, whose base is in the realization of Nursing Process, there is the application of the Geriatric Depression Scale named Yesavage - reduced version (GDS-15) held by students under the supervision of the teacher. After classification of the patient on the scale, they develop the care plan based in the Nursing Interventions Classification (NIC), and the nursing diagnoses that have among their factors related to depression and its symptoms.

Results and conclusions In addition to interventions carried out in consultation, involving recovery of self-esteem, encouragement of leisure and recreational activities, and supported self-care, the program staff (psychologists, doctors, nurses and occupational therapists) works in partnership in support group health education, encouraging the integration of the elderly. The well-being and self-esteem of the elderly, thus, reduce the triggers of depression, with the integration of participants, students and professionals.

Anxiety in elderly can be diagnosed based on a detailed history and cognitive examination using various instruments. These instruments aim to obtain information that supports both the syndromic and etiological diagnosis and the planning and execution of therapeutic and rehabilitation measures to be used in each case. During the nursing consultation with elderly people in the Federal University of State of Rio de Janeiro (UNIRIO), many patients with cognitive impairment showed anxious behavior. The study objectives to describe the factors related to the nursing diagnose anxiety in elderly patients attended in the nursing consultation. The consultations are based in the application of the nursing process. After the symptoms analysis, the nursing diagnosis anxiety is complemented with the related factors. The principals are death threat (64%), stressors (19%) and not needs met (17%). The data found are associated with cognitive impairment. Cognitive impairment in the elderly can lead to anxiety, depression and hopelessness, according to many studies.

Conclusions Working the cognitive needs, and reducing stressors are appropriate strategies to reduce the anxiety. The care with the health professionals is important to notice the related factors early and improve the strategies.

"Mom, there is a monster in the closet": The impact of early attachment trauma (EAT) on the development of anxiety disorders and treatment possibilities

D. D'Hooghe (Clinician)

Traumacentre Belgium, Bruges, Belgium

Objectives In this workshop, I want to broaden the vision on attachment trauma and highlight the importance to acknowledge EAT as a hidden epidemic.

The significance of EAT in the development of anxiety symptoms becomes more and more apparent.

Methods Recognizing the effect, that the quality of the attachment relationship has on the development of a secure attachment bond, is important to understand the factors underlying the development of anxiety symptoms.

The availability, responsiveness, mentalizing possibilities. . . of the parent create a secure base from which the child can explore and develop.

The absence of those features in the child-parent relationship, causes traumatic stress in the child and impacts his psychological and neurological well-being.

Results Insecure attachment influences the neurobiology and results in dissociative processes (hyper- and hypo-aroused) expressed in different types of anxiety disorders.

Derived from the neurobiology there is a clear link between anxiety, depression and aggression.

The internal working model (IWM), rises from insecure attachment, influences adversely the child's capability to regulate and relate.

From an intergenerational point of view, an insecure attachment style of the parent implements the absence of affect en stress regulation capabilities and leave the child with the inability to regulate his anxiety.

Conclusion There is a clear link between EAT and different types of anxiety disorders.

Treatment strategies should integrate neurobiological, attachment and trauma insights resulting in body oriented therapy, development of affect – and stress – regulation strategies, restructuring the internal working model, the therapeutic relationship as attachment bond. . .

Does depression explain poor effort on Symptom Validity Tests (SVT)?

J. De Jonghe^{1,*}, T. Schoemaker², S. Meyer¹, D. Lam³

¹ Noordwest Ziekenhuisgroep, Geriatric Medicine/Medical Psychology, Alkmaar, Netherlands

² Noordwest Ziekenhuisgroep, Medical Psychology, Den Helder, Netherlands

³ Slotervaart Hospital, Medical Psychology, Amsterdam, Netherlands

* Corresponding author.

Background and aims Valid assessments require sufficient effort from the part of the testee. Motivation may be compromised, particularly in psychiatric conditions. We examined associations between response bias on free recall and self-reported symptoms in depressed and PTSD patients.

Participants and methods This is a cross-sectional study. Patients had depression ($n = 48$), or PTSD or other anxiety disorders ($n = 37$). A control group ($n = 47\%$) had chronic pain disorder, fibromyalgia or chronic fatigue. The Green Word Memory Test (GWMT) was administered to all subjects. The Structured Inventory of Malingered Symptomatology (SIMS), and the Beck Depression Inventory (BDI-II) were administered in subsamples. Study outcome was self-reported depressive symptoms in Symptom Validity Test (SVT) negative cases.

Results Average age of the participants was 45.1 years (SD 9.5), 48.5% were female. GWMT was positive in 52.3% of all cases, GWMT and SIMS were positive in 33.8%, and GWMT and SIMS were negative in 37.7%. No significant group effects on GWMT were found. Average BDI-II scores were 32.8 (SD 13.9) for depressed patients, 28.3 (15.5) for those with anxiety disorders, and 27.6 (14.1) for controls ($P = 0.43$). Seventy-eight percent of depressed GWMT negative cases reported at least moderate depressive symptoms (BDI-II > 18), and 44.4% severe symptoms (BDI-II > 29). Approximately half of the GWMT negative cases with anxiety disorders and controls scored BDI-II > 18.

Conclusions Non credible test performance is prevalent in disability claimants with affective, mood disorders. However, depressive symptoms per se do not explain poor effort on cognitive tasks.

The cortisol awakening response in anxiety disorders and personality disorders and changes in salivary cortisol level after psychotherapy

E. Dembinska*, K. Rutkowski, J. Sobanski, K. Cyranka, M. Mielimaka, A. Citkowska-Kisielewska

Jagiellonian University Medical College, Department of Psychotherapy, Krakow, Poland

* Corresponding author.

Introduction The hypothalamus–pituitary–adrenal axis (HPA axis) dysregulation plays an important role in the pathophysiology

of anxiety disorders. Salivary cortisol level is a useful indicator of HPA axis dysfunction.

Objectives Most data suggests elevated cortisol awakening response (CAR) in anxiety disorders, but there are studies indicating opposite pattern (flat CAR).

Aim Goal of this study was to determine whether patients with anxiety and personality disorders show a specific daily cortisol patterns and weather this pattern changes after 12 weeks of intensive predominantly psychodynamic combined group and individual psychotherapy.

Method The studied population comprised 77 patients, mainly females (72.7%), with primary diagnosis of anxiety disorder 40.9% or personality disorder 59.1%. The Symptom Checklist "0" was used to assess the pre- and post-treatment levels of patients' symptoms. Pre- and post-treatment cortisol levels were measured in three saliva samples collected during one day (at awakening, 30 min after awakening, at 22.00).

Results The obtained results were partly similar to previous research. We found four different daily CAR patterns: decreased (drop 30 min after awakening), flat (rise 0–49% 30 min after awakening), normal (rise 50–75% 30 min after awakening) and elevated (rise over 75% 30 min after awakening), two of them (flat and elevated) were considered as typical for anxiety disorders. Groups of CAR pattern differed significantly in the level of sleep symptoms, dysthymia symptoms and avoidance/dependency symptoms. The changes in the CAR pattern after psychotherapy were not significant.

Conclusions Anxiety disorders and personality disorders are characterized by more than two specific daily salivary cortisol patterns.

EV0012

Neurotic personality dysfunctions as factors predisposing for reacting with suicidal ideation to intensive psychotherapy

P. Rodzinski, A. Ostachowska, K. Cyranka, K. Rutkowski, E. Dembinska*, J. Sobanski, A. Citkowska-Kisielewska, M. Mielimaka

Jagiellonian University Medical College, Department of Psychotherapy, Krakow, Poland

* Corresponding author.

Introduction Identifying patients' risk of reacting with suicidal ideation (SI) to psychotherapy is an important clinical problem that calls for empirical verification.

Objectives Analysis of associations between patients' initial neurotic personality dysfunctions not accompanied by SI and emergence of SI at the end of a course of intensive psychotherapy conducted in integrative approach with predominance of psychodynamic approach in a day hospital.

Methods Neurotic Personality Questionnaire KON-2006 and Life Inventory were completed by 680 patients at the time of admission to a psychotherapeutic day hospital due to neurotic, behavioral or personality disorders. Symptom Checklist KO "0" as a source of information about emergence of SI was completed both at the admission and at the end of the treatment. Among 466 patients without SI at the admission, in 4% SI occurred at the end of the treatment.

Results A number of neurotic personality dysfunctions (demeanors declared) that significantly predisposed to SI emergence at the end of the treatment were found: physical aggression against close ones ($P < 0.001$), grandiose fantasies ($P = 0.043$), tendencies to resignation ($P = 0.022$) and resignation-related

feeling of loss of life opportunities ($P=0.037$), tendency to follow predominantly ones intuition ($P=0.035$).

Conclusions In patients who declared the above-mentioned demeanors increased risk of SI emergence than in others (10–30% vs. 4%) indicate that there are particular vulnerable areas of neurotic personality that require especially careful approach during intensive psychotherapy—dealing with those areas may result in distress or anxiety that may lead to SI.

EV0013

Blood levels of patients with profound refractory OCD who are on supra-normal dosages of sertraline

L. Drummond*, V. Robert

South West London and St Georges Mental Health NHS Trust, National OCD/BDD Service, London, United Kingdom

* Corresponding author.

Introduction Patients with OCD usually require higher dosages of serotonin reuptake inhibiting (SRI) drugs than is used for the treatment of depression. This observation resulted in treatment-refractory patients being occasional prescribed selective SRI drugs above the normal upper limit of prescribing. Previous studies have shown that these high doses are well tolerated.

Objectives We decided to investigate the blood levels of patients on dosages of sertraline that were above the normal therapeutic range.

Method Successive patients treated by the National Inpatient Service for OCD/BDD who were treatment refractory and prescribed > 200 mg sertraline per day were included. All had previously received 2+ trials of different SRIs for > 3 months each as well as been offered augmentation with dopamine blockers and at 2+ trials of exposure and response-prevention. All patients scored in the profoundly ill range of the Yale Brown Obsessive Compulsive Scale.

Sertraline was titrated in 50 mg increases every 2–4 weeks up to a maximum of 400 mg. Blood samples were taken after their morning dose. This was after the patients had stabilised for at least 2 weeks on the higher doses.

Results Seventeen patients were included in the study and received sertraline dosages ranging from 225 mg to 400 mg per day. Blood levels were within therapeutic range or below for all patients. Following treatment within the service, these patients generally showed an improvement of an average of improvement of 43% on the YBOCS.

Conclusions A subgroup of patients with profound refractory OCD seem to either malabsorb or rapidly metabolise sertraline resulting in lower than therapeutic blood levels.

* Corresponding author.

Objective The main objective of the present study is to investigate effectiveness of mindfulness-based stress reduction in anxiety and depression in patients with multiple sclerosis.

Methods This study is in kind of semi-experimental research in form of pretest–posttest pattern with control group. Statistical population of the study consists of all patients with multiple sclerosis referred to Iran MS Association by 2016. Sampling method in this study is available sampling and based on having inclusion criteria. Among depressed and anxiety patients 30 individuals were selected randomly and were classified in two groups with 15 people in each group. Experimental group was under mindfulness-based training on stress reduction for 8 sessions. Control group was also in waiting list. All patients in experimental and control groups fulfilled depression and anxiety inventories before and after intervention. Obtained data was analyzed using MANCOVA and in SPSS22 software.

Finding Obtained results show that there is significant difference between the two groups in terms of anxiety and depression after intervention ($P<0.001$).

Conclusion Mindfulness-based stress reduction can help reduction of symptoms of anxiety and depression in patients with MS.

Neuroimaging correlates of insight in obsessive compulsive disorder: A fMRI study

A. Gadad*, D.Y.C.J. Reddy, D.G. Venkatasubramanian, D.J. C.N National Institute of Mental Health & Neurosciences, Psychiatry, Bangalore, India

* Corresponding author.

Aim of the study To study the neural substrates of insight in OCD by comparing patients with good insight, patients with poor insight and matched healthy controls using functional MRI.

Methodology Subjects were recruited from among patients attending OCD clinic, adult psychiatry services and psychiatry ward inpatients of National Institute of Mental Health And Neurosciences (NIMHANS), Bangalore. They were further divided into 'good insight' ($n=30$) and 'poor insight' ($n=14$) using Brown's assessment of belief's scale. Control subjects ($n=30$) were recruited from consenting volunteers. 3 T MRI was used mental rotation task was paradigm used for fMRI and analysis was done by SPM 8.

Results Poor insight patients and good insight patients comparison revealed differential activation in left superior/medial frontal gyrus (corresponding to the DLPFC). A negative correlation between BABS score and activation of right inferior parietal lobule. Mental rotation task behavioural data results: OCD patients as a group had significantly lower accuracy compared to healthy controls. Poor insight group had significantly decreased accuracy ratio compared to good insight group and healthy controls. A negative correlation was noted between BABS score and accuracy ratio, indicating that poorer the insight, greater the errors during the active task.

Conclusion Insight has been important prognostic factor in OCD. Poor insight patients had specific deficits in left medial frontal gyrus and right inferior parietal lobule as compared to good insight patients and healthy controls. Together, these indicate that insight has a strong neurobiological underpinning in OCD.

Objective Negative attitudes and the inability of emotion regulation can make individuals vulnerable against addiction. In this field, the main objective of this study is to investigate effectiveness of teaching positive psychology on dysfunctional attitudes and emotional self-regulation of withdrawing addicts.

Methods This study is conducted using semi-empirical method in form of pretest posttest. Statistical population consists of all addicted people referred to Addiction Treatment Camps of Karaj by 2015. Among these camps, Vardavard Camp is selected randomly and among the referees, 30 people of those who were qualified to participate in this study and were satisfied for this action were selected and were placed in two experimental and control groups. Experimental group received positive psychology intervention and control group was in waiting list. Both groups fulfilled dysfunctional attitude scale and emotional self-regulation scale in baseline and after treatment. Obtained data have been analyzed using independent *t*-test and covariance in SPSS-22.

Finding There is significant difference between two groups at the end of intervention in terms of dysfunctional attitudes and emotional self-regulation ($P < 0.05$).

Conclusion Teaching positive psychology can lead to change in dysfunctional attitudes and emotional self-regulation of addicted people.

Acceptance and commitment therapy and anxiety disorders: Clinical case

R. Guijarro^{1,*}, M. Cerviño², P. Castrillo²

¹ Complejo Hospitalario Universitario de Granada, Servicio Andaluz de Salud, Unidad de Salud Mental Comunitaria, Granada, Spain

² Complejo Hospitalario Universitario de Granada, Servicio Andaluz de Salud, Unidad de Rehabilitación de Salud Mental, Granada, Spain

* Corresponding author.

Acceptance and commitment therapy (ACT) is a third-generation therapy that relates to human suffering as an inherent part of life in the human condition. Concerning personal values, ACT is focused on the acceptance of suffering, by doing away with the avoidance of things that cause us discomfort.

The goal of the therapy is to make a person's reactions to suffering more flexible, working with the role of the symptoms rather than with the eliminating the symptoms themselves.

This paper shows how the application of this therapy to a person with generalized anxiety disorder helps to reduce symptoms

such as uncontrollable worrying, lack of concentration and muscular tension that these patients often suffer. The modification of symptoms has been measured by a single case study, where the symptoms are assessed by questionnaires before and after the treatment's application. Diagnosis was made according to the Diagnostic and Statistical Manual of Mental Disorders' (DSM-IV) criteria.

Patterns of dissociative (conversion) disorder cases in private psychiatric facility and the effectiveness of an indigene model of psychotherapy

M.I. Hussain

Khyber Pakhtunkhwa Health Care Commission, Iftikhar Psychiatric Hospital, Peshawar, Pakistan

This is descriptive study was carried out on newly diagnosed dissociative (conversion) disorder patients admitted in private health care facility, Iftikhar Psychiatric Hospital Peshawar.

The studied was carried out from January 2012 to December 2012. Cases were diagnosed according to international classification of disease (ICD-10) diagnostic criteria. Subjects were selected through purposive sampling. A total of 139 patients were included in this study. Patterns of and disorder and demographic will be presented in presentation.

Due to sociocultural sensitivity of applying dialectical and CBT an indigenes model of psychotherapy was applied.

Stage 1: admission of conversion disorder cases for four days admission with informed consent, supportive psychotherapy, and brief psycho-education of attendants to avoid reinforcement of the patient's behavior. Parental single dose medication to break the cycle of fits.

Stage 2: it involves exploratory session with the patient and her/his family members focusing on what is the problem with the patient nature of stressors, and the family environment. Meanwhile, we involve the patient in the recreational and occupational therapy to avoid sick role and illness behavior.

Stage 3: psychotherapy session with the patient to give psycho-education and insight of her/his mental problem. Discussing different options, and facilitating the patient to come up with the best possible desirable option. Psychotherapy of the family members involved psycho-education about the patient's mental illness, its association with the prevailing stressors, and avoiding reinforcement. Responses have been 85% improvement in conversion disorder, 90% in sensory symptoms, 98% in motor symptoms, 95% in mixed symptoms.

The prevalence and risk factors of anxiety disorders in an Egyptian sample of school and students at the age of 12–18 years

A. Ismail

Alazhar University, Psychiatry, Cairo, Egypt

Background generalized anxiety disorder (GAD) are highly prevalent and impairing conditions among children and adolescent. There are some general population studies that have examined these conditions during the early life course.

The primary objectives of this study were to examine the prevalence, and socio-demographic factors related to GAD in

representative sample of Egyptian school students (prep, middle and secondary students), and the correlation between adolescence and socio psychological factors that lead to anxiety disorders in adolescents.

Methods The study included 1200 student (600 from rural area, and 600 from urban area), their age ranged from 12–18 years m we used GHQ (28 items with cut point 14), the anxiety scale and SCID I.

Results The positive clinical cases represent 20.6%, depression is the most prevalent 23.8%, anxiety was (6.69%), body dysmorphic disorder (15.2%), adjustment disorder (13.8%); GAD (9.2%); obsession (7.4%)

Conclusions Findings demonstrate the clinical significance socio demographic factors related to GAD among adolescent youth, and highlighting on the paternal relations.

Recep Tayyip Erdogan University Training and Research Hospital, Psychiatry, Rize, Turkey

* Corresponding author.

Medical and mental health professionals have long been interested in understanding both the motivations for seeking a change in physical appearance as well as the psychological outcomes of cosmetic surgery. By time to time researchers began to incorporate standardized psychometric tests and psychiatric evaluation into their studies. Psychiatrists have studied the personality characteristics and psychological state of these patients with the hope of identifying patients who may be psychologically inappropriate for surgery or those who are likely to be dissatisfied with a technically successful surgical outcome. There were some degree of congruence in the factors that appeared to be associated with poor outcome, demographic factors like being male, younger age, psychological/psychiatric factors such as history of depression or anxiety, dysmorphophobia, personality disorder as narcissistic or borderline, previous surgical procedure with which the patient was dissatisfied and minimal deformity. As a cosmetic surgery, prominent ear deformity is the most common abnormality of the external ear. We have used both clinical interview and psychometric assessments in three cases who want to go surgery because of their prominent ear. Two of the cases have used cyanoacrylate adhesive to their postauricular skin for camouflage of their prominent ear deformity. We have evaluated the patients' psychiatric state with psychosocial viewpoint of the deformity.

A mixed approach: Posttraumatic obsessive compulsive disorder

R. Landera Rodríguez^{1,*}, M. Gómez Revuelta², M. Juncal Ruíz¹, O. Porta Olivares¹, R. Martín Gutiérrez¹, L. Sánchez Blanco¹, D. Abejas Díez¹, G. Pardo de Santayana Jenaro¹, M. Fernández Rodríguez³, L.A. Giraldo Vegas³

² Hospital Universitario de Álava-Sede Santiago, Psychiatry, Vitoria-Gasteiz, Spain

³ Hospital Universitario Marqués de Valdecilla, General Medicine, Santander, Spain

* Corresponding author.

Introduction Several studies along the last two decades provide information indicating the relationship between posttraumatic stress disorder (PTSD) and obsessive compulsive disorder (OCD). The particular features described in patients who developed OCD symptoms closely after the onset of PTSD, may suggest the existence of a specific subtype of OCD more likely to be suffered after a traumatic event. The few studies focused on evaluating treatment efficacy for the association between OCD and PTSD seem to predict poor response to pharmacologic or behavioral cognitive (BCT) monotherapy.

Objectives Despite the evidence, most widely used guidelines propose the employment of either a psychotherapeutic or psychopharmacologic approach. We propose to combine intensive BCT and serotonin profile antidepressants in order to optimize PTSD-OCD subtype.

Material and methods We present two detailed case reports offering the results of combining intensive BCT and serotonin profile antidepressants as soon as the comorbid diagnosis for both disorders was established. These two patients were recruited from outpatient care centers.

Results Our limited experience supplied promising outcome results. Significant improvement regarding to functional impairment appeared from early stages of the treatment in both patients.

Discussion Despite logistic difficulties, an intensive and coordinated psychopharmacologic and psychotherapeutic approach might constitute another treatment choice which may be taken into account in those cases monotherapy fails to reduce PTSD-OCD subtype patients' impairment.

Conclusions A mixed treatment approach might be taken into account as a first line treatment in PTSD-OCD disorder.

Regression models for biopsychosocial factors affecting patients with haemoglobinopathies in a Greek hospital

G. Lyrakos^{1,*}, E. Aslani², V. Spinaris¹, M. Drossou-Servou³, M. Tsironi²

¹ General Hospital Nikaia "Ag. Panteleimon", Psychiatric, Nikaia, Greece

² University of Peloponnese Faculty of Human movement and Quality of Life Sciences, Department of Nursing, Sparta, Greece

³ General Hospital Nikaia "Ag. Panteleimon", Thalassemia Transfusion Unit, Nikaia, Greece

* Corresponding author.

Introduction Sickle cell and thalassemia (haemoglobinopathies) are autosomal recessive inherited conditions that affect haemoglobin and as chronic diseases, stress, anxiety and depression are comorbid conditions.

Objectives To examine possible biopsychosocial factors affecting stress, anxiety and depression symptoms in these patients.

Aims To investigate whether different condition related markers, contribute to the psychological symptomatology.

Methods A total of 97 patients participated in the study, 21 males (21.6%) and 76 females (78.4%), with a mean age of 44.35. Convenience sampling method was used and participants were recruited from the General Hospital of Nikaia, 'Ag. Panteleimon', in Athens, Greece. DASS and MFI scales were used to measure the dependent and independent variables. Data were analysed with the SPSS 21 software.

Results Multivariate analysis revealed that days between transfusions ($\beta = -0.454$), reduced activity ($\beta = 0.350$) and age ($\beta = -0.207$) explained 30.1% of the variance in Stress [$F(3.91) = 13.04$ $R^2 = 0.301$ $P = 0.03$]. Reduced activity ($\beta = 0.417$) and days between transfusions ($\beta = 0.318$) explained 30.3% of the variance in Anxiety [$F(2.92) = 19.96$ $R^2 = 0.301$ $P = 0.03$]. Finally reduced activity ($\beta = 0.334$), days between transfusions ($\beta = 0.364$), and reduced motivation explained 41.3% of the variance in Depression [$F(3.91) = 21.34$ $R^2 = 0.413$ $P = 0.03$]. Levels of ferritin, haemoglobin, age and present condition of health had a NS effect in the models.

Conclusions Similar factors were found to affect stress, anxiety and depression in the sample, with days between transfusions and reduced activity being the major factors affecting the psychological symptoms in haemoglobinopathy patients. More research is needed in order for all the biopsychosocial factors to be revealed in this field.

Depression, anxiety and stress symptoms among students in Albania explored by DASS-42

A. Pilika^{1,*}, A. Simaku²

¹ University Hospital Center “Mother Tereza”, Department of Neuroscience, Psychiatric Service, Tirana, Albania

² Institute of Public Health, Department of Public Health, Tirana, Albania

* Corresponding author.

Introduction In Albania, at the current time, no research has been conducted to assess students' risk for depression, anxiety and stress.

Objectives To explore which group of students are at risk for depression, anxiety and stress.

Aim The aim of this study is to explore the symptoms of depression, anxiety and stress among students according to the 42-item Depression Anxiety and Stress Scale (DASS-42).

Material and methods The DASS-42 was translated from English to Albanian, culturally verified, back-translated and administered to 570 students in university campus of Tirana district. Exploratory factor analyses (EFA) and Cronbach's alpha, were performed to identify the psychometric properties of the Depression, Anxiety, and Stress subscales and the overall scale.

Results EFA with equamax rotation indicated that the 42 items loaded on three factors accounting for 53.2% of the total variance, 19.9% for depression, 17.6% for anxiety and 16.7% for stress subscale. The internal consistency coefficients were high, ranging from 0.90 to 0.93 for subscales and 0.96 for the scale. The mean score of females for the overall scale $M = 28.0 (\pm 36.3$ SD) was significantly higher as compared to males $M = 22.9 (\pm 36.5$ SD), ($t = 2.6$, $P < 0.01$). Females also had a significant higher score $M = 11.5 (\pm 12.8$ SD), for depression as compared to males $M = 8.7 (\pm 12.6$ SD), ($t = 2.4$, $P = 0.02$), whereas no difference was found with regard to anxiety ($P = 0.2$) and stress subscales ($P = 0.07$).

Conclusions Female students, students from rural areas and married individuals have more total scores for depression, anxiety and stress symptoms.

Somatic-type delusional disorder and comorbidity mood disorder

V. Martí Garnica^{1,*}, M.D. Ortega García², M.Á. Bernal López², J.R. Russo De León³, S. García Marín⁴

¹ Servicio Murciano de Salud, CSM San Andres, Murcia, Spain

² Servicio Murciano de Salud, CSM Cartagena, Murcia, Spain

³ Servicio Murciano de Salud, Hospital Reina Sofía Murcia, Murcia, Spain

⁴ Servicio Murciano de Salud, CSM Lorca, Murcia, Spain

* Corresponding author.

Chronic delusional disorder encompasses what classical termed as paranoia and paraphrenia. This disorder is characterized by the presence of one or more non-bizarre, permanent and systematized delusions. Cognitive functions of the patient not affected, judgment and reason are not affected if the subject is not addressed delirious. Delusional theme includes life-like experiences, including: persecution – persecutory type –, suffering from a disease – somatic type –, to be loved by someone famous – erotomaniac type –, the partner is unfaithful – jealous type – or having a special quality or gift – megalomaniac type –. Usually, patients lack awareness of mental illness and often prior to contact with mental health, made a pilgrimage by different specialists looking for an organic explanation.

The description of a case report of a 47-year-old male who has a delusional belief body deformity secondary to manipulation by a physiotherapist suffering a muscular pain in the lumbar region is performed. Prior to psychiatric diagnosis, begins a long journey by different specialists.

As a consequence, somatic-type delusional disorder is a challenge in the diagnosis and treatment in the medical field because it is required a multidisciplinary approach for these patients.

How painful is this? Idiosyncrasies of attention in irritable Bowel syndrome

M. Martin^{1,*}, S. Chapman²

¹ University of Oxford, Experimental Psychology, Oxford, United Kingdom

² University of Bath, Pharmacy and Pharmacology, Bath, United Kingdom

* Corresponding author.

Introduction Theoretical controversy surrounds the issue of the extent to which cognitive processes can be identified which are characteristic of patients with irritable Bowel syndrome (IBS). The issue is important because particular patterns of idiosyncrasies would suggest tailored therapeutic interventions.

Objectives To map the processing of pain information in IBS and healthy participants in relation to physical and social threat, using latency as well as frequency metrics.

Methods Participants (20 with IBS and 33 controls) were tested in an extended exogenous cuing paradigm whose derived measures included assessments of bias, engagement and disengagement. They also completed a battery of health and illness activity tests.

Results There was a significant interaction between bias in processing of pain (physical threat) and of neutral stimuli, as shown on Fig. 1. Further significant idiosyncrasies were observed in the relations between measures of attention and levels both of symptoms and of illness behaviour.

Conclusions Detailed evidence was obtained of anomalies in attention in IBS. The results may be interpreted in terms of interactive feedback between pain perception in relation to the gut, pain-specific attentional processes, and health behaviour. It will be

discussed how mindfulness based cognitive therapy can be used as an intervention to disrupt this feedback.

Fig. 1 Attentional bias in IBS and healthy groups with pain and neutral stimuli. Target in the same (valid) or different (invalid) position as the cue, bias = (RT invalid – RT valid).

Conversion disorder: Unexplained symptoms of silenced emotions?

C.P. Martins^{1,*}, S. Carvalho¹, F. Silva², H.S. Almeida¹

¹ Hospital de Magalhães Lemos, Service B, Porto, Portugal

² Hospital de Magalhães Lemos, Service C, Porto, Portugal

* Corresponding author.

Introduction Conversion disorder is a condition defined by the presence of symptoms of altered voluntary motor or sensory function, not intentionally produced or feigned, presumed to be the expression of a psychological conflict or stressor, but mimicking neurological diseases or other medical conditions, that must be excluded before this diagnosis is made. The suspicion of conversion disorder arises when clinical findings are incompatible with the suggested neurological or medical conditions and there is a temporal relation between the onset of the symptoms and a psychological stressor. However, when these hints are absent, diagnosis may not be clear and require wider workup.

Objectives/aims To make a brief review on conversion disorder and present an illustrative clinical-vignette.

Methods We collected information from medical records and interview with the patient and made a research on PubMed with the MeSH terms “conversion disorder”.

Results We present a 51-years-old female outpatient with episodes of paralysis of left upper and lower limbs. Some months before the onset of these symptoms, her daughter came to live with her. Their relationship became very conflictual. Electroencephalogram, laboratory and imaging studies were normal. She did not tolerate the antidepressants tried (SSRI, SNRI and trazodone), but reported to feel better with amisulpride and alprazolam.

Conclusions Widely discussed in the past as “hysteria”, conversion disorder is still intriguing, because little is known about the link between body and mind, making the management of patients with this disorder challenging and highlighting the need for more studies on the topic.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Diagnosis of generalized anxiety disorder in Russia: The results of a web-based survey of psychiatrists

I. Martynikhin^{1,*}, N. Neznanov¹, S. Mosolov²

¹ Pavlov First Saint Petersburg State Medical University, Psychiatry and Narcology, St-Petersburg, Russia

² Moscow Research Institute of Psychiatry, Serbsky State Medical Research Center of Psychiatry and Narcology, Department of Pharmacotherapy, Moscow, Russia

* Corresponding author.

Introduction There is a lack of attention on generalized anxiety disorder (GAD) in the psychiatrists' education programs in Russia. The consequence of this is difficult to estimate because of insufficiency of the GAD epidemiology in Russia.

Objectives Are estimation of the comparative prevalence of diagnosis of GAD among other anxiety and stress related disorders; psychiatrists' knowledge about GAD and their therapeutic approaches.

Methods The invitations to survey were sent by e-mail to members of the Russian Society of Psychiatrists; 888 psychiatrists took part in the survey. Twenty-six percent of them worked in inpatient departments, 43% – in outpatient departments, 15% – in somatic services, 17% – researchers and university professors.

Results A total of 83% of respondents have diagnosed GAD at least once during last year. Most often GAD was diagnosed by psychiatrists of somatic services. Mixed anxiety and depressive disorder was diagnosed in 2.5 times more often than GAD; adjustment disorders – in 2.1 times. Doctors have noted that among their patients with other mental disorders 26% have chronic anxiety, but most of doctors do not establish the comorbid diagnosis of GAD for these patients. Only a quarter of doctors consider that detachment of GAD from other anxiety disorders is based on the features of etiology and pathogenesis. In the treatment of GAD together with SSRIs, SNRIs, and pregabalin prescribing, doctors often prescribe benzodiazepines, atypical anxiolytics (hydroxyzine, buspirone) and low-potency antipsychotics (alimemazine, chlorprothixene).

Conclusions Increasing attention to GAD in the psychiatrists' education programs may improve diagnosis and treatment of this disorder in Russia.

* Corresponding author.

Introduction Deep brain stimulation (DBS) is a neurosurgical procedure under investigation for a range of psychiatric and neurological disorders. One of them is obsessive compulsive disorder (OCD), which is a neuropsychiatric illness that often develops in childhood, affects 2% of the general population and causes significant impairment across the lifespan. Some cases are refractory to pharmacotherapy and psychotherapy and that is why new treatments have been investigated over the last decades.

Objectives/aims In this paper, we intent to do a review of the literature about the efficacy of DBS in the treatment of OCD.

Methods We present a literature review of some scientific articles found on Pubmed search using “deep brain stimulation and obsessive compulsive disorder/DBS and OCD”.

Results Clinical outcome of DBS for OCD shows robust effects in many studies. It appears that most patients regain a normal quality of life after DBS, reporting changes in perception, feeling stronger and more confident, and doing things unreflectively. It seems that DBS is a valid alternative to lesional ablative neurosurgery for severe, therapy-refractory OCD patients, although with partially discrepant results probably related to differences in anatomical targeting and stimulation conditions.

Conclusions DBS seems to be a promising modality for the treatment of some refractory psychiatric disorders such as OCD, but the search for the best target still continues. Randomized studies with larger samples are needed to establish the optimal targeting and stimulation conditions.

⁴ 1st Psychiatric Clinic Athens University, Aiginition Hospital, Athens, Greece

⁵ 1st Cardiology Clinic Athens University, Hippokration Hospital, Athens, Greece

* Corresponding author.

Introduction Whether anxiety and depression are associated with hypertension and to what extent is not clear.

Aims The aim of the present study was to assess any differences in the prevalence of anxiety and depression among different groups of hypertensive patients.

Methods The study cohort comprised of 127 patients (75 male, mean age 54 ± 14) who underwent assessment of their blood pressure levels and were divided in four groups: group I (normotensives, $n = 34$), group II (stage 1 HTN, $n = 33$), group III (stage 2 HTN, $n = 30$) and group IV (stage 3 HTN, $n = 30$). The evaluation of anxiety disorder was made by means of Hospital Anxiety Depression Scale (HADS), while the evaluation of depression was made with the Beck Depression Inventory (BDI). Statistical analysis was done with SPSS for windows. *P*-value was set at 0.05 for differences to be considered significant.

Results Comparing the four groups of patients there was a significant difference both in BDI (8.6 ± 7.0 vs. 11.6 ± 10.4 vs. 27.1 ± 5.8 vs. 32.4 ± 3.9 , $P < 0.0001$) and HADS (10.2 ± 7.2 vs. 9.7 ± 7.0 vs. 16 ± 4.7 vs. 27 ± 5.1 , $P < 0.0001$). We proceeded to comparison among the 4 groups and there was a significant rise in the BDI and HADS in three of the four groups group II > group III > group IV, $P < 0.0001$.

Conclusion These data suggest that there is a clear burden of anxiety and depression as the levels of BP increase. This finding is of important clinical significance as it could contribute to a different approach of hypertensive patients. A larger cohort study could enlightened the mechanisms involved.

Association of arterial stiffness burden with anxiety and depression in different stages of hypertension

A. Mermerelis^{1,*}, S.M. Kyvelou², V. Akke³, C. Papageorgiou⁴, C. Stefanadis², A. Douzenis¹

¹ 2nd Psychiatry Clinic, Athens University, Attikon Hospital, Athens, Greece

² 1st Cardiology Clinic, Athens University, Hippokration Hospital, Athens, Greece

³ Epidemiology Department, Galway University, Galway, Ireland

⁴ 1st Psychiatry Clinic, Athens University, Aiginition Hospital, Athens, Greece

* Corresponding author.

Introduction There has been an attempt to associate anxiety and depression with arterial stiffness. In the present study, we assessed differences in arterial stiffness among 3 groups of hypertensive patients compared to control normotensives as well as possible association with anxiety and depression scoring system.

Methods The study cohort comprised of 127 patients (75 male, mean age 54 ± 14) who underwent assessment of their blood pressure levels and were divided in four groups: group I (normotensives, $n = 34$), group II (stage 1 HTN, $n = 33$), group III (stage 2 HTN, $n = 30$) and group IV (stage 3 HTN, $n = 30$). The evaluation of anxiety disorder was made by means of Hospital Anxiety Depression Scale (HADS), while the evaluation of depression was made with the Beck Depression Inventory (BDI). Arterial stiffness evaluation was done with Cardio-Ankle Vascular Index (CAVI). Statistical analysis was done with SPSS for windows. *P*-value was set at 0.05 for differences to be considered significant.

Results Both CAVI R and CAVI L indices were significantly higher as the severity of hypertension progressed ($P < 0.001$). BDI score was significantly correlated with CAVI R (Pearson $r = 0.53$, $P < 0.0001$) and CAVI L (Pearson $r = 0.39$, $P < 0.0001$). HADS score was also significantly correlated with both CAVI R (Pearson $r = 0.53$, $P < 0.0001$) and CAVI L (Pearson $r = 0.43$, $P < 0.0001$).

Conclusions There is a burden in the arterial stiffness of this population with the increase of the levels of BP which is not surprising. However, the new finding is that there is a strong correlation with arterial stiffness indices and both anxiety and depression scoring system.

Rafsanjan, Iran

* Corresponding author.

Social anxiety disorder, pervasive and debilitating disorder with a high rate that affects many aspects of human life. The aim of the study was to assess the relation between social phobia and personality traits of Rafsanjan University of medical sciences students. By using Cochran formula and random stratified sampling, 284 person of Rafsanjan University of medical sciences students selected. Participants responded to questions of the NEO Personality and Social Phobia questionnaire. Data analyzed with Pearson correlation coefficient, analysis of variance and regression. Among the individuals, 11.6% had severe social phobia and 4.6% very severe. The relationship between social phobia and neuroticism was reversed and significant and other personality characters were significantly. Neuroticism and openness predicted social phobia

significantly. The academic courses in terms of social phobia had not different with them but there were significant differences in the character of personality. It seems that dimensions of personality associated with Social phobia and be able to explain it.

Duloxetine augmentation in resistant obsessive compulsive disorder: Surveying a new medication for challenges in treatment of OCD

A. Mowla

Shiraz University of Medical Sciences, Psychiatry, Shiraz, Iran

Introduction Up to 50% of patients with OCD have failed to respond in SSRI trials, so looking for pharmacological alternatives in treatment of obsessive compulsive disorder (OCD) seems necessary.

Objectives Surveying duloxetine augmentation in treatment of resistant OCD.

Aims Study the effects of serotonin-norepinephrine enhancers for treatment of OCD.

Methods This augmentation trial was designed as an 8-week randomized controlled, double blind study. Forty-six patients suffering from OCD who had failed to respond to at least 12 weeks of treatment with a selective serotonin reuptake inhibitor (fluoxetine, citalopram or fluvoxamine) were randomly allocated to receive duloxetine or sertraline plus their current anti OCD treatment. Yale-Brown Obsessive Compulsive Scale (Y-BOCS) was the primary outcome measure.

Results Forty-six patients (24 of 30 in duloxetine group and 22 of 27 in sertraline group) completed the trial. Both groups showed improvement over the 8-week study period (mean Y-BOCS total score at week 8 as compared with baseline: $P < 0.001$ and $P < 0.001$) without significant difference ($P = 0.861$). Those receiving duloxetine plus their initial medications experienced a mean decrease of 33.0% in Y-BOCS score and the patients with sertraline added to their initial medication experienced a mean decrease of 34.5% in Y-BOCS.

Conclusions Our double blind controlled clinical trial showed duloxetine to be as effective as sertraline in reducing obsessive and compulsive symptoms in resistant OCD patients. However, it needs to be noted that our study is preliminary and larger double blind placebo controlled studies are necessary to confirm the results.

¹ Hospital Infanta Leonor, Psiquiatría, Madrid, Spain

² Hospital Clínico San Carlos, Psiquiatría, Madrid, Spain

³ Hospital de Puerta de Hierro, Psiquiatría, Madrid, Spain

* Corresponding author.

As human reproduction has to been seen not only from the biological (gender) but from the social and anthropological perspective, and as long as paternity joins a very important aspect in men identity, we found essential to review actual and past literature in order to explain symptoms and attitudes experienced by some fathers to be.

Couvade syndrome was first described in the mid-sixties by a group of British authors who tried to analyze some typical pregnancy symptoms observed in fathers to be. These symptoms are hetero-

geneous and could be difficultly classified, but must of the authors tend to group them in anxiety or somatophorm-like disorders.

In this oral communication, we will explore into the deep causes of this syndrome and its links to the Couvade ritual described in some ancient cultures like the Greek (year 60 B.C.) as well as analyze an actual case report, with the help of the exhaustive revision of the existing literature.

Couvade has to be contemplated as a way to define the new identity of the father to be, and his bond with the newborn, his couple and the society.

Finally, Couvade could be seen as a proactive and constructive preparation of the male to the paternity, out of psychopathology and recognize these comprehensive reactions as a normal and functional part of the reproductive ritual.

Objective Increased statistics of prostitution and reduced age of prostitutes at the world and as a result, prevalence of diseases such as AIDS and other diseases has gained attention of scholars to the problem of prostitution and relevant problems. Hence, the main objective of this study is to analyze the correlation between object relations and attachment style in prostitutes in Iran.

Method Applied method in this study is correlation. Statistical population in this study consists of prostitutes of Tehran, Mashhad, Kerman, Tabriz and Mazandaran and statistical sample consists of 317 women selected using simple random sampling method in 2015. For purpose of data collection, Bell Object Relations and Reality Testing Inventory (BORRTI) and Hazan and Shaver attachment styles questionnaire are used. The data were analyzed using multivariate regression and Pearson correlation in SPSS-22.

Finding The results showed that there is significant correlation between object relations and attachment styles in prostitutes ($P < 0.01$).

Conclusion Object relations scales (incompetence, self-centeredness and alienation) are correlated to insecure attachment styles in prostitutes.

Keywords Object relations; Attachment styles; Prostitutes

The risk of hypertension in general population with anxiety traits in Russia/Siberia: Gender disparities. WHO survey MONICA-psychosocial

V. Gafarov, E. Gromova, D. Panov*, I. Gagulin, A. Gafarova

FSBI Institute of Internal Medicine SB RAMS, Collaborative laboratory of Cardiovascular Diseases Epidemiology, Novosibirsk, Russia

* Corresponding author.

Objective To determine gender differences in prevalence of anxiety traits in general population and to evaluate its impact on the risk of hypertension in men and women aged 25–64 years in the open population in Russia/Siberia.

Methods Under the third screening of WHO program “MONICA-psychosocial” a random representative sample of the population aged 25–64 were surveyed in Novosibirsk in 1994 ($n=657$ men, $n=870$ women). Anxiety levels were measured by means Spielberger test. Over the 16-year period were identified 229 cases of AH in women and 46 for men. Cox-proportional regression model was used for an estimation of hazard ratio (HR).

Results In general population aged 25–64 years at 99.5% of women and 97.5% of men had moderate and high levels of anxiety traits. In univariate Cox regression analysis model the risk incidence of arterial hypertension in women and men with high level of anxiety was 2.383-fold and 5.18-fold higher, respectively, over 5 years of follow-up. It was 1.853-fold and 5.75-fold higher over 10 years and 1.45 and 3.82 times higher over 16 years after baseline. In the multivariate Cox regression model HR of hypertension was 1.648 in women with high level of anxiety; and it was 4.568-fold higher in men.

Conclusion Despite the higher prevalence of HLA in women, the risk of developing hypertension is much higher in males.

Introduction The Depression, Anxiety and Stress Scales are widely used in clinical and non-clinical populations, both in research and clinical settings. The need for briefer but valid and reliable instruments has motivated the reduction of the original 42-item scale to a short 21-version. On Portuguese samples, Pais-Ribeiro et al. (2004) found that the original 3-factor solution (stress, anxiety and depression) explained 50.35% of the variance and in an exploratory analysis; Xavier et al. (2015) presented a two factor solution and a modified three-factor solution with a sample of pregnant women, both with adequate factors' reliability (<0.70) and explaining above 50% of the variance.

Aims Based on the previous results of factor analysis with Portuguese samples, the present study aimed to perform confirmatory factor analyses (using Mplus software) to evaluate which dimensional structure best fitted the data.

Methods The sample comprised 234 students (78.2% female), between 18–26 years old ($M=20.55$; $SD=1.66$). Eighty-five percent of the participants were on their first three years of college education. Participants filled the Portuguese version of the DASS-21.

Results Our results showed that the original 3-factor structure had the best model fit [$\chi^2_{(186)}=475.465$, $P<0.05$; $RMSEA=0.082$, $90\% CI=0.073-0.091$; $CFI=0.918$; $TLI=0.908$; $SRMR=0.05$]. Good reliability was found for all subscales (0.92 for stress, 0.87 for anxiety and 0.91 for depression subscale).

Conclusions The DASS-21 is a reliable instrument that, with student populations, seems to have better performance when used with a 3-factor structure. Further research is needed to confirm this structure in Portuguese clinical samples.

Psychogenic nonepileptic seizures

L. Queiroga*, R. Rodrigues, J. Mesquita Reis
Child and Adolescent Psychiatry Resident, Hospital Dona Estefania, Lisbon, Portugal

* Corresponding author.

Introduction Psychogenic nonepileptic seizures (PNES) are defined as a somatoform conversion disorder manifesting as paroxysmal events not associated with electroencephalographic (EEG) epileptiform correlates. This entity is poorly understood and often misdiagnosed as epilepsy. It is important to recognize that misdiagnosis leads to inappropriate use of antiepileptic drugs, which may worsen the course of the disease.

Recent studies have suggested that the frequency of psychogenic nonepileptic seizures ranges from 10 to 23% of referrals to a pediatric epilepsy center, as well as 60% of children with PNES achieve symptom improvement and event freedom of symptoms following appropriate treatment.

Objectives The aim of this study is to conduct a literature review of studies which the purpose was better understand the etiologies, features, and care outcomes of psychogenic nonepileptic seizures (PNESs) in a pediatric setting.

Conclusion A early identification of the risk factors for comorbid psychopathology, diagnosis and appropriate care for PNESs reduces inappropriate medical investigation and therapy, expedites rates of remission, and decreases health-care utilization in a pediatric setting.

Emetophobia (a specific phobia of vomiting): A case study

D. Roy
The Prince Charles Hospital Metro North Health Services, Acute Care Team, Department of Psychiatry, Chermside, Australia

Introduction Case presentation of a young woman Ms. A.M., referred by her GP with an eating disorder, who was thereafter diagnosed with an uncommon type of phobia (emetophobia – a specific phobia of vomiting) and treated accordingly.

Objectives To highlight the diagnostic dilemma with such uncommon cases, who are often misdiagnosed as having anorexia nervosa or bulimia nervosa or suffering from other anxiety disorders (like OCD or GAD).

Methods A comprehensive mental state examination was conducted including a diagnostic clarification interview. She was followed up by the mental health team on a regular basis with support and also providing appropriate psychotherapy.

Discussion Ms. A.M. refused medications and only agreed to non-pharmacological treatment. She was therefore commenced on once weekly psychotherapy (CBT), which she undertook for a period of 4 months. She showed good response to the psychotherapy with significant attenuation of her core symptoms, although she still continued to exhibit some avoidance behaviors.

Conclusions This particular patient showcases a relatively uncommon and often misdiagnosed specific phobia (emetophobia)

and highlights the positive response seen in this case with psychotherapy.

Social anxiety as a basic factor shaping anti-vital and suicidal behaviour among contemporary adolescents

O. Sagalakova^{1,*}, D.V. Truevtsev¹, I.Y. Stoyanova², A.M. Sagalakov¹

¹ Altai State University, Barnaul, Russia

² Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk, Russia

* Corresponding author.

Introduction In adolescence, social anxiety (SA) and anti-vital and suicidal behavior (AB and SB) constitute a single syndrome.

Aim The aim is to define the role of SA and its components in shaping adolescent AB, with a subsequent risk of SB.

Materials and methods A total of 981 adolescents participated in the survey. The authors' proprietary Anti-vitality and Resilience Questionnaire and Social Anxiety and Social Phobia Questionnaire; statistic methods: ANOVA, Correlation analysis.

Results and discussion Twenty-four percent from the sample have high SA levels, and 21.8% have clinical SA levels connected with high risk of AB and SB. Adolescents find themselves in unstable conditions of the psychological field reorganization (crisis), and they are in need of actualization of means to satisfy their social motives. It makes them vulnerable to mental disorganization under evaluation conditions, and the situation is aggravated with the absence of internalized mental regulation tools. AB, SB is higher, the higher the SA in adolescents is. SA as a subjective perception of insufficient means to influence the surroundings in order to satisfy social needs can play one of the key roles in the accumulation of negative affect in the system of mental activity, and lead ultimately to its failure.

Conclusion Inability to satisfy their actual motives, lack of strategy for self-realization and dealing with failures, and inability to keep the targeted priority in evaluation situations lead to feeling loss of life purpose and negative evaluation of the future and shape AB, SB.

Disclosure of interest The research was supported by Russian Science Foundation (Altai State University).

Psychological treatment of trichotillomania: A case study

T. Sarmiento Luque*, J.M. Sanchez

Hospital De Mollet, Department of Psychiatry, Barcelona, Spain

* Corresponding author.

This paper presents a clinical case of trichotillomania. Therefore, the aim of this study is to present in detail the procedure followed in a case of trichotillomania in a public health context, using cognitive-behavioral techniques, in order to deepen the knowledge of the efficacy of these treatment procedures and demonstrate the feasibility of implementation.

The results obtained show significant improvements in different clinical aspects: first, the hair pulling behavior disappeared completely; moreover, anxiety diminished significantly and mood normalized. All these results allow us to conclude that the intervention was successful.

Factors associated with professional stress at the teachers

N. Halouani*, F. Smaoui, C. Derbel, R. Naoui, J. Alouloi, O. Amami

CHU Hédi Chaker, Psychiatry B, Sfax, Tunisia

* Corresponding author.

Introduction Teaching, as a profession, is recognized as demanding and stressful.

Objectives (1) Evaluate the professional teacher stress, (2) Identify possible factors associated with it.

Methods This is a cross-sectional study, descriptive and analytical, conducted among teachers of high school Mahmoud Magdich in Sfax. (Tunisia). Participants were asked to complete the anonymous form detailing the socio-demographic, professional characteristics and any work stressors.

The evaluation of occupational stress was evaluated by the scale of "Karasek".

Results Thirty-six teachers replied to the questionnaires. The sex ratio (M/F) was 0.38. The mean age was 48.77 years. The average number of years of exercise was 23.20 years and the average number of hours worked per week was 16.25 hours. The participants stress profile according to the scale of "Karasek" was: 55.6% stressed, 27.8% assets, 11.1% liabilities, and 5.6% relaxed. The main stress factors mentioned were respectively: the inadequate salary (58.3%), difficult working conditions (52.8%), problems with students and parents (25%) and lack of organization at work (22.2%). Factors correlated with the profile "stressed" were: female gender ($P=0.026$), lack of pastime practice ($P=0.034$), teaching high school degree ($P=0.04$), feeling that they work "too hard" in their work ($P=0.005$), they are "the end" at the end of the working day ($P=0.015$) and low social support ($P=0.005$).

Conclusion The occupational stress among teachers was quite important. Knowing how to identify factors and taking action would be interesting for the guarantee development for teachers. Students would be the ultimate beneficiaries.

Personal and pathopsychological features of patients with somatoform disorders in primary care

B. Tsygankov*, A. Kulichenko

Moscow State Medical Dental University, Department of Psychiatry,

Narcology and Psychotherapy, Moscow, Russia

* Corresponding author.

Introduction Somatoform disorders are a therapeutic challenge for primary care physicians. Various studies show low efficacy of psychotherapy for these patients, and the need for differentiated approach to their treatment.

Objective Explore the differences between pathopsychological, personal characteristics of patients with somatoform disorders.

Methods It was carried out psychometric evaluation of 108 patients with different clinical variants of somatoform disorders, using SCL-90-r, Leonhard questionnaire.

Results Patient with somatization disorder (SD) had maximum values on the "somatization", "depression", "hostile", "paranoid" scales; a high level of anxiety. Singularity personality structure of these patients defining feature of exaltation, excitability, emotionality. Patients with undifferentiated somatoform disorder (USD) also showed high levels of somatization, anxiety and obsessive-compulsive, interpersonal sensitivity, phobic anxiety. Patients with stable somatoform pain disorder (SPD), had high levels of depression, obsessive-compulsive. SPD formed in individuals with

features of anxiety, seizing, high emotivity. The maximum values for the scales of anxiety (ANX, PHOB) recorded in patients with somatoform dysfunction of the autonomic nervous system (SDANS). Evaluation of coping strategies showed a preferential use of the “avoidance” strategy by patients with SD, USD, a rare use of social support strategies, responsibility. Patients with somatoform pain disorder often resorted to seek social support.

Conclusion The use of the questionnaire SCL-90-r has identified a number of clinical features of patients with different variants of the SFD. Typologically in all samples of patients revealed moderate accentuation on emotivity trait.

Acupuncture decreases competitive anxiety prior to a competition in young athletes: A randomized controlled trial study

S. Zarei Serkani*, M. Shayestefar, A.H. Memari
Sports Medicine Research Center, Neuroscience Institute, Tehran
University of Medical Science, Department of Sports Medicine,
Tehran, Iran

* Corresponding author.

Introduction Although a certain level of competitive anxiety may increase performance, many athletes with anxiety experience uncontrolled negative feelings and cognition that in turn can have overwhelming effects on their performance.

Objectives Indeed, we aimed to assess the effect of the acupuncture on competitive anxiety in a sample of young football players using physiological biomarkers and subjective anxiety measures.

Methods We aimed to assess the effect of acupuncture on competitive anxiety of the adolescent football players prior to the competition using psychological and physiological markers. A total of 30 athletes were randomly and equally allocated to either acupuncture or sham control group.

Results The results of *t*-test on posttest scores showed that acupuncture had a significant effect on cognitive anxiety ($P=0.001$) and somatic anxiety ($P<0.001$) but not self-confidence ($P>0.05$). Furthermore, the results showed that acupuncture significantly decreased the skin conductance in acupuncture group compared to sham group ($P=0.006$) ($P<0.001$).

Conclusions In conclusion, the results suggested that acupuncture have the capacity to decrease cognitive and somatic anxiety prior to competition in adolescent athletes while this was accompanied by significant physiological changes.

Mental health literacy in bipolar disorder: A cross-sectional survey in Saudi Arabia

F. Alosaimi¹, D. Alateeq^{1,*}, R. AlHenaki², S. Bin Hussain²,
A. Bin Salamah², A. Al-Muhanna², M. AlAngari²

¹ King Saud University, Department of Psychiatry, Riyadh, Saudi Arabia

² King Saud University, College of Medicine, Riyadh, Saudi Arabia

* Corresponding author.

Introduction Stigmatization of individuals with mental illnesses is widespread and serves as a major barrier to treatment. Specific alterations in mental health literacy about a disorder and its perceived treatability can change this social attitude. Assessing awareness of bipolar disorder is important as the WHO ranked bipolar disorder as the sixth cause of disability.

Objectives To assess mental health literacy (knowledge, attitudes and beliefs) in bipolar disorder among Saudi population.

Methods Cross sectional study is currently conducted. We are using valid reliable questionnaire assessing the level of awareness, knowledge, attitude and behavior toward bipolar disorder. It is distributed to adult Saudi citizen (> 17 years of age) in malls, university and hospitals in Riyadh. People who are known to have psychiatric disorder and their caregivers or who works as psychiatrists and psychologists are excluded.

Results There are 200 samples collected, and 14 were excluded according to exclusion criteria. Fifty-two percent of our preliminary sample has heard about bipolar disorder, and more than half of them believe that neurotransmitter disturbances, substance use and psychological trauma are more likely to be causes of bipolar. In contrast, 49% of the sample did not choose psychiatric medication as effective treatment for bipolar, whereas more than half of them chose praying.

Conclusions It is a first-of-its-kind research study in Saudi Arabia determining the current mental health literacy of bipolar disorder in Saudi Arabia. We are aiming to increase the sample size to reach 1000 participants. Further study will be needed to investigate possible interventions to improve such problem.

Demyelination in rat model of mania-like behavior

M. Andrabi^{1,*}, V. Subbiah¹, R. Sagar², R. Mathur³

¹ AIIMS, Neurobiochemistry, New Delhi, India

² AIIMS, Psychiatry, New Delhi, India

³ AIIMS, Physiology, New Delhi, India

* Corresponding author.

Introduction Ample amount of data suggests role of REM sleep deprivation as the cause and effect of mania. In the present model, we have tried to implement behavioral sensitization to sleep deprivation, conditions mimicking natural circumstances, so as to produce an animal model with symptomatology resembling very close to human mania. Pre-clinical and clinical studies have shown that mania is often co-morbid with multiple sclerosis, therefore we sought to find out whether myelin integrity is disrupted and if lithium could protect against such damage.

Objectives (1) To analyse mania-like behavior after REM sleep deprivation. (2) To analyse any damage to myelin under TEM.

Aims We wanted to see if there could be any damage to myelin after behavioral sensitization to stress.

Methods Rats were sleep deprived by classical flowerpot or platform method. OFT was performed to assess behavior of rats. The analysis was performed over 5 min, separated into 5 bins of 1 min each. Behavioral scores included total square entries, inner square entries, time spent in center, rearing frequency, time spent rearing, number of grooming bouts, time spent grooming defecation and time spent still. TEM was performed to study changes in myelination in two distinct regions of brain, DG and VTA.

Results It was observed that the REM sleep deprived rats had mania like symptoms. REM sleep deprivation lead to demyelination in DG and VTA. Lithium treatment restored myelination per se.

Conclusions The result suggests the involvement of myelin damage in the pathogenesis of mania, Li offers protection against such damage.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Valproate used during pregnancy: What should be done?

J.N. Beezhold^{1,*}, D. Fagard², C. Harabaiu³

¹ Norfolk and Suffolk NHS Foundation Trust, Central Norfolk Acute Service, Norwich, United Kingdom

² UEA, Norwich Medical School, Norwich, United Kingdom

³ Norwich School, Sixth form, Norwich, United Kingdom

* Corresponding author.

Background Sodium valproate can cause serious developmental disorders in unborn babies if taken while pregnant, especially in the first trimester.

Aim To review recent literature and advice or treatment for women who have or are using valproate whilst pregnant.

Design Literature review.

Methods Literature review using Pubmed with search terms: 'bipolar'; 'pregnant'; 'valproate' and following up references.

Results There are several small methodologically flawed studies that attempt to address this question and will be reprised. Three key population register studies found high rates of malformations. A retrospective study of longer-term outcomes found high rates of developmental issues. There are several relevant treatment guidelines, including from the National Institute for Health and Clinical Excellence (NICE). There is a 40% risk of developmental disorder, a 10% risk of congenital malformations and a 3% risk of IQ deterioration.

Conclusions Avoid valproate in women of childbearing age if at all possible, and consider effective contraception if used. If already pregnant then consider, with involvement from the patient, stopping or minimizing the dose of sodium valproate. Assess the risks and benefits of using sodium valproate during pregnancy versus stopping the treatment for the first trimester as symptoms of the disorder may return. Seek advice from a perinatal psychiatrist. Add 5 mg of folic acid daily for the remainder of the pregnancy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Assessment of psychotic symptoms in bipolar disorder

F. Cazan^{1,*}, R. Paunescu², A. Tamas¹

¹ Clinical Emergency Hospital for Children Cluj-Napoca, Psychiatry, Cluj-Napoca, Romania

² University of Medicine and Pharmacy Cluj-Napoca, Neurosciences, Cluj-Napoca, Romania

* Corresponding author.

Introduction Bipolar disorder is a disabling condition characterized by the presence of manic, depressive, hypomanic or mixed episodes, affective symptoms that may coexist with several types of psychotic features.

Objectives The purpose is to evaluate the frequency of psychotic symptoms among bipolar disorder.

Method The study included 55 bipolar patients admitted in the Psychiatry Clinical Hospital from January 2012 until May 2013. Inclusion criteria were represented by diagnosis of bipolar disorder, manic or depressive episode, according to DSM-IV-TR and

ICD 10 criteria. Clinical instruments used to assess the severity of the current affective episode were Young Mania Rating Scale (YMRS) for manic patients and Hamilton Depression Rating Scale-17 items – (HDRS) for the depressive ones. Psychotic symptoms were evaluated with the Brief Psychiatric Rating Scale-18 items – (BPRS).

Results Out of the 55 patients, 32 had psychotic symptoms upon admission to the hospital. BPRS results showed delusions of guilt, inutility, hypochondriac and nihilistic delusions for the depressed patients. Delusions of grandiosity and megalomania accounted for most of psychotic symptoms in manic patients. A smaller number of patients showed delusions of invention and reform. Perception disturbances such as auditory hallucinations were present in both diagnosis categories but in a higher percentage in depressive bipolar patients.

Conclusions Even if less frequently than in schizophrenia or schizoaffective disorder, psychotic symptoms are present in bipolar disorder. They influence the general functioning and the outcome of patients diagnosed with this illness.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Profile of depression in women attending antenatal clinics in Blantyre District, Malawi

G. Chorwe-Sungani^{1,*}, J. Chipps²

¹ Kamuzu College of Nursing, Community and Mental Health, Blantyre, Malawi

² University of the Western Cape, School of Nursing, Bellville, South Africa

* Corresponding author.

Introduction Depression is one of major health problems affecting pregnant women in low resource settings. It can lead to poor uptake of antenatal services. Data about prevalence of antenatal depression and associated risk factors remain scanty in Malawi. The study settings were eight selected antenatal clinics in Blantyre district, Malawi. The aim of this study was to assess prevalence of antenatal depression and associated risk factors among pregnant women attending antenatal clinics in Blantyre district, Malawi.

Methods This was a quantitative study which used a random sample of 97 pregnant women. Ethical approval was granted by relevant bodies. Descriptive and inferential statistics were used to analyse data.

Results Prevalence of antenatal depression in Blantyre district was 25.8% (n=25). Risk factors associated with antenatal depression included: "being distressed by anxiety or depression for more than two weeks during this pregnancy"; "feeling that pregnancy has been a positive experience"; "having a history of feeling miserable or depressed for two weeks or more before this pregnancy"; "relationship with partner is an emotionally supportive one"; "experiencing major stresses, changes or losses in the course of this pregnancy"; "having history of physical abuse when growing up", and "having concerns about being or becoming a mother".

Conclusion This study has shown that antenatal depression is prevalent in Malawi. It suggests that psychosocial interventions targeting pregnant women may be necessary to reduce antenatal depression and associated risk factors. However, further research regarding ways for assisting pregnant women to build and strengthen their psychosocial support structures is needed.

EV0049

Intramuscular ketamine in depression, suicidal thoughts and anxiety: A report on two cases

M. Cigognini*, R. Moreno

Institute of Psychiatry, GRUDA, São Paulo, Brazil

* Corresponding author.

Introduction Several studies have shown that ketamine, an antagonist of NMDA receptors, represents a promising alternative in the treatment of depression. The therapeutic use of ketamine, commonly used at a dose of 0.5 mg/kg, and in a single application IV has been short and requires monitoring in a hospital setting. IM use has been shown to be effective in treating depression and suicide risk, and have low side effect profile.

Methods Two patients diagnosed with bipolar depression and suicide risk were submitted to ketamine IM application (0.75 mg/kg), receiving one application of ketamine IM every two days, totaling 4 applications. Patients were under medical monitoring for 2 hours after injection verifying vital signs and potential side effects. Responses were measured using BDI, BAI and BSI.

Aim To evaluate response of ketamine IM injections on depressive, suicidal and anxious symptoms.

Summary Case 1: female, 20 years old, single with three recent suicide attempts, symptomatic for two months. Started lithium 450 mg daily. Side effects of ketamine were nausea, drowsiness and paresthesia. Case 2: female, 24 years old, single with symptoms lasting for six years. Started aripiprazole 5–10 mg and 25 mg lamotrigine concomitantly. Side effects of dry mouth, dizziness and dissociation.

Conclusions The use of ketamine IM showed reduction of 75.5%–83.3%–85.7% (case 1) and 71.4%–77.2%–60.8% (case 2) in BDI, BAI and BSI, respectively as well as safety and tolerability in use.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Reversible cognitive impairment associated with a high free fraction but subtherapeutic total blood level of valproic acid due to hypoalbuminemia in a bipolar patient

G. Dautzenberg^{1,*}, M. Nederlof², E. Heerdink², A. Beekman³

¹ Altrecht GGZ, Old Age Psychiatry, Utrecht, The Netherlands

² Utrecht University, Utrecht Institute of Pharmaceutical Sciences, Utrecht, The Netherlands

³ VU University Medical Center, Department of Psychiatry, Amsterdam, The Netherlands

* Corresponding author.

Valproic acid (VPA) is widely used in the treatment of epilepsy and bipolar disorder. It is largely bound to serum proteins (80–95%) in particular albumin, with a saturable binding capacity. Under conditions of hypoalbuminemia, protein binding of VPA will decrease and its pharmacologically-active free fraction will rise, even to toxic levels while measuring subtherapeutic VPA total blood levels [1].

We present an elderly bipolar patient with (sub)clinical total levels of VPA and a high free fraction of VPA due to hypoalbuminemia (14–24 g/L) leading to severe reversible cognitive impairment.

VPA and the free fraction in particular, was the most likely cause of the cognitive impairment [2]. There was a time-correlation with increasing blood levels of total VPA (68 mg/L, reference 80–120 mg/L [3]), notably the free fraction (37.5 mg/L, reference 5–15 mg/L), and the intoxication.

For therapeutic drug monitoring in laboratories, generally, total VPA concentrations (free + protein-bound) are measured instead of

free fractions, due to technical difficulties, a lack of established reference ranges [4] and (inter)national guidelines [5,6] not requiring it. This presentation and literature points out that it is clinically relevant to measure the free fraction [7,8], especially in patients with hypoalbuminemia [9–11] to prevent unnecessary side effects and toxicity.

We recommend measuring albumin during VPA use; particularly in patients with nephrotic syndrome, liver disease [12] or older adults [13–15]. Hypoalbuminemia demands a free fraction measurement.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Care pathways for patients with bipolar disorders at Psychiatry Clinic Affektiva, Gothenburg: Identifying and solving issues for a more efficient and safe care

M. Dellepiane*, C. Boldt-Christmas, G. Jungestrand, P. Asplund, R. Ahmed, T. Nordin

Sahlgrenska University Hospital, Psychiatry, Gothenburg, Sweden

* Corresponding author.

Introduction The Psychiatry Clinic Affektiva has developed a care pathway for patients with bipolar disorder (BD). It consists of one outpatient clinic and two inpatient wards. Clinical observations suggest that patients with BD benefit from treatment in a dedicated unit with tailored care programs and that better outcomes are achieved in terms of reduced average length of stay and safer transitions to outpatient care for this group.

Aims The aim is to improve the care of bipolar patients by increasing bed-availability and overall continuity in the care pathway and monitoring core aspects in the management of outpatients in order to reduce admissions and to facilitate standardized treatment and collaboration between in- and outpatients unit.

Method We developed a structure to monitor and measure specific outcomes such as readmission within 28 days, relapse within 12 months and the use of lithium in this group. We also developed a standardized care protocol in order to improve the safety and the equality.

Results At this stage our preliminary results from our efforts are promising but further monitoring is needed to confirm our hypothesis. More data will be collected during 2017.

Conclusions Affektiva Psychiatry Clinic has developed a model for continuously monitoring several essential aspects in the care of patients with BD and providing a specific care program.

Risk factors for suicide behaviors in bipolar disorder: A closer look

D. Durães*, J. Martins, R. Borralho

Centro Hospitalar Barreiro-Montijo, Mental Health and Psychiatry Department, Barreiro, Portugal

* Corresponding author.

Introduction Suicide behaviors (suicide acts and suicide attempts) are a major concern for clinicians treating patients with psychiatric disorders. Among them, patients with bipolar disorder (BD) have the highest prevalence of suicide behaviors, accounting for up to one-quarter of all completed suicides. Additionally, suicide remains the leading cause of avoidable death in patients with BD.

Aims This work aims to review the main risk factors for suicide behaviors in patients with BD.

Methods The MEDLINE/Pubmed database was searched using the keywords “bipolar disorder” with: “suicide”; “suicide attempt”; and “suicide risk factors”. Articles published in the last 10 years were considered.

Results It is estimated that 25% to 50% of patients with BD will attempt suicide at least once in their lifetime and, that 10% to 15% will die. The risk factors for suicide behaviors in patients with BD have been widely studied and their knowledge is crucial for identifying patients at risk.

The main risk factors include previous suicide attempts, family history of suicide and hopelessness. Other risk factors have also been identified: depressive polarity of first mood episode; rapid cycling; increasing severity of affective episodes; depressive polarity of the latest mood episode; mixed affective states; early age of onset; and comorbid anxiety disorders, substance use disorders and cluster B personality disorders.

Conclusions Prevention of suicide behaviors is crucial when treating patients with BD. Therefore, the knowledge of these risk factors is of extreme importance in order to promptly identify patients at risk and adopt the proper preventive therapeutic interventions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Background Mindfulness-based cognitive therapy (MBCT) is a psychotherapeutic intervention that has been shown effective in several clinical conditions. Nevertheless, research is still needed on its effectiveness on cognition.

Objective To analyze possible effects on cognition of the addition of MBCT intervention versus a brief structured group psycho-education to the standard treatment of subsyndromal bipolar depression. Our hypothesis was that MBCT could improve some aspects of cognitive function to a higher degree than psycho-education and treatment as usual (TAU).

Methods/design A randomized, multicenter, prospective, versus active comparator, evaluator-blinded clinical trial was conducted. Forty patients with BD and subclinical or mild depressive symptoms were randomly allocated to:

- MBCT added to psychopharmacological treatment ($n = 16$);
- a brief structured group psycho-educational intervention added to psychopharmacological treatment ($n = 17$);
- standard clinical management, including psychopharmacological treatment ($n = 7$).

Assessments were conducted at screening, baseline, post-intervention (8 weeks) and 4-month follow-up.

Results Cognition results point to significant improvement in Stroop Color test as well as processing speed in TMT A test ($P < 0.05$) in the two psychological intervention groups versus TAU.

Conclusion These preliminary findings suggest that the addition of MBCT or psycho-education to usual treatment could improve some cognitive dimensions in subsyndromal bipolar depressive patients.

The blue-eyed man: A case of Waardenburg syndrome type 1 associated with mania and autistic spectrum disorderB. Francis*, S.T. Jambunathan, J.S. Gill, S. Wong
University Malaya, Department of Psychological Medicine, Kuala Lumpur, Malaysia

* Corresponding author.

Waardenburg syndrome (WS) is a rare genetic disorder characterised by varying degrees of sensorineural deafness, dystopia canthorum, musculokeletal defects, pigmentation anomalies such as bright blue iris, greying hair and in some cases intestinal pathology.

A 21-year-old Chinese gentleman, diagnosed with WS type 1 (Figs. 1 and 2) at the age of two, presented at the emergency unit with manic symptoms for the past one month such as irritability, grandiosity, flight of ideas and reduced need for sleep. With regards to social integration, he had features suggestive of autism spectrum disorder (ASD). He often played by himself and was fixated on particular toys. He was eventually admitted to the psychiatric ward for acute management of mania. He was stabilised on olanzapine 10 mg BD and sodium valproate 600 mg BD. His sodium valproate was cross-titrated with lithium in the ward and his manic features gradually subsided. He was discharged well after 2 weeks of admission with lithium 300 mg BD and olanzapine 10 mg BD. WS type 1 has been localised to the locus 2q35 and researchers have identified that a tetranucleotide repeat marker on 2q35 is strongly associated with recurrent mood symptoms.

In conclusion, it is important to note that individuals with WS may be at higher risk to develop ASD and mood disorders.

Late-onset bipolar illness: Literature review and case report

J. García-Jiménez (Psychiatrist)*,
A. Porras-Segovia (Third year resident in psychiatry),

J.E. Muñoz-Negro (Psychiatrist), L. Gutiérrez-Rojas (Psychiatrist)
*Acute Psychiatric Hospitalization Unit, Mental Health Clinical
Management Unit, Granada Hospital Complex, Granada, Spain*
* Corresponding author.

Introduction Late-onset bipolar-illness (LOBI) diagnosis comprises those patients whose first mania episode occurs aged 60 or older. Traditionally, it has been considered as a secondary disorder, accompanying other conditions such as dementia. While this is true for some cases, LOBI is a wider concept, which has its own features and also includes other entities.

Objectives To describe the main features of LOBI.

Methods Critical review of the literature and description of the case of a 72-year-old woman diagnosed with LOBI.

Results While only 6–8% of all new cases of bipolar disorder (BD) occur in people older than 60, recent research suggests an increase of first episodes in this age group. LOBI is less associated with family history compared to early onset BD and seems to occur more frequently in women.

LOBI presents with better premorbid functioning and atypical psychopathology as compared to early onset. Also, there is a higher prevalence of mixed episodes and a higher frequency of episodes per year, with a great risk of suicide. LOBI patients have more cognitive impairment and higher rates of comorbid psychiatric disorders. These patients show some specific neuroimaging signs, including subcortical hyperintensities.

Quetiapine and valproate have proved useful, but the pharmacokinetic and pharmacodynamic characteristics of older patients must be taken into account.

Conclusion The reported case identifies similarities between LOBI and classical BD. However, both this case and the literature review reveal that LOBI has specific features that differentiate it from classical BD. Further research is needed to characterise the condition and improve its management.

Correlation between alterations of inflammatory markers and treatment with atypical antipsychotics in patients diagnosed with bipolar affective disorder

M. Godio^{1,*}, F. Marino², M. Preve¹

¹ Socio-Psychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

² University of Insubria, Research Center of Medical Pharmacology, Varese, Italy

* Corresponding author.

Introduction Clinical evidences suggests that cerebral inflammatory processes are involved in the development of major affective disorders [1].

Obvious correlations exist between changes of inflammatory markers such as acute-phase protein C (PCR) and VES, in patients with bipolar spectrum diagnosis [2].

Objectives Our aim is demonstrating the correlations between changes of PCR and VES and pharmacological treatment with atypical antipsychotics in patients with acute bipolar disorder, highlighting a trend.

Method Twenty patients with bipolar disorder were assessed at the entrance (T0), after three weeks (T1) and after six weeks (T2) of hospitalization using specific rating scales and blood tests routines include PCR and VES.

Results Is possible to appreciate a correlation between the affective phase of bipolar disorder and inflammatory markers with a proportional trend (Table 1).

Discussion and conclusion The scores obtained seem to confirm the effect of antipsychotic in both sense of psychiatric symptomatology reduction and in anti-inflammatory action.

A confirmation of a correlation between the resolution of affective disorders and normalization of inflammatory markers confirm the intrinsic anti-inflammatory activity of such drug compounds [3].

Table 1

	PCR mg/L	VES mm/h	MADRAS	YMRS	CGI	BPRS
t0	17.85 ± 10	13.10 ± 9	9.30 ± 11	24.27 ± 10	3.95 ± 1	84.65 ± 30
t1	4.55 ± 4 ^a	12.65 ± 8 ^b	4.30 ± 5 ^a	3.85 ± 5 ^a	2.65 ± 1 ^a	65.50 ± 21 ^a
t2	1.45 ± 3 ^{c,d}	12.75 ± 8 ^b	2.45 ± 3 ^{c,d}	1.65 ± 2 ^{c,d}	1.80 ± 1 ^{c,d}	54.30 ± 17 ^{c,d}

^a $P < 0.01$ vs. T0

^b $P > 0.01$ vs. T0/T1.

^c $P < 0.01$ vs. T0.

^d $P < 0.01$ vs. T1.

Introduction Within the various cultures and throughout the centuries has observed the relationship between emotional states and heart function, colloquially calling him “heartbroken”. Also in the

medical literature are references to cardiac alterations induced by stress.

Objective Takotsubo is a rare cardiac syndrome that occurs most frequently in postmenopausal women after an acute episode of severe physical or emotional stress. In the text that concerns us, we describe a case related to an exacerbation of psychiatric illness, an episode maniform.

Method Woman 71 years old with a history of bipolar I disorder diagnosed at age 20. Throughout her life, she suffered several depressive episodes as both manic episodes with psychotic symptoms. Carbamazepine treatment performed and venlafaxine. He previously performed treatment with lithium, which had to be suspended due to the impact on thyroid hormones and renal function, and is currently in pre-dialysis situation.

She requires significant adjustment treatment, not only removal of antidepressants, but introduction of high doses of antipsychotic and mood stabilizer change of partial responders. In the transcurso income, abrupt change in the physical condition of the patient suffers loss of consciousness, respiratory distress, drop in blood pressure, confusion, making involving several specialists. EEG was performed with abnormal activity, cranial CT, where no changes were observed, and after finally being Echocardiography and coronary angiography performed when diagnosed Takotsubo.

Results/conclusions In this case and with the available literature, we can conclude that the state of acute mania should be added to the list of psychosocial/stressors that can trigger this condition.

Determination of p11 multifunctional protein in human body fluids by enzyme-linked immunosorbent assay

H. Jiang^{1,*}, R. Quan², Y. Yuan³

¹ Southeast University, Department of Psychosomatics and Psychiatry, Nanjing, China

² ZhongDa Hospital Affiliated to Southeast University, Department of Anesthesiology, Nanjing, China

³ Medical School of Southeast University, Department of Psychosomatics and Psychiatry, Nanjing, China

* Corresponding author.

Objectives The diagnosis of major depressive disorder (MDD) is symptom based due to the lack of biological biomarker. p11 protein was recently found to be an important factor mediating depression-like states and antidepressant responses. The aim of the study was to assess whether p11 protein in urine can serve as a potential biomarker for major depression, and the relationship of its levels among urine, serum and cerebrospinal fluid (CSF).

Methods We obtained urine samples from 13 drug-free MDD patients and 13 age- and gender-matched healthy controls. We also collected urine, serum and cerebrospinal fluid samples from 13 of fracture patients or cesarean section patients in the spinal anesthesia. The concentrations of p11 protein were measured using ELISA.

Results In MDD patients, urine levels of p11 protein were all less than the minimum detectable concentration of the ELISA kit. The urine levels of p11 were detectable only in one healthy control. In the spinal anesthesia patients, we can detect p11 concentrations in both serum and urine in only two patients. Besides, levels of p11 were detectable in the serum of one patient and urine of another patient. We were unable to measure CSF levels of p11 in all patients.

Conclusions Concentrations of p11 protein in the body fluids are very low and unstable. The sensitivity of the current p11 ELISA kit is currently unsatisfactory, requiring the development of an ELISA kit of higher sensitivity to determine whether p11 in body fluids can serve as biomarker for depression.

⁵ Kangbuk Samsung Hospital, Psychiatry, Seoul, Republic of Korea

⁶ Chung-Ang University Hospital, Psychiatry, Seoul, Republic of Korea

⁷ Naju National Hospital, Psychiatry, Naju, Republic of Korea

⁸ The Catholic University St. Mary Hospital, Psychiatry, Seoul, Republic of Korea

* Corresponding author.

Introduction Many guidelines for bipolar disorders have been introduced based on evidences. In contrast, KMAP-BP was developed by an expert-consensus.

Objective To summarize the medication strategies for bipolar depression over four published KMAP-BP (2002, 2006, 2010, and 2014).

Methods The questionnaire using a nine-point scale had covered some clinical situations with many treatment options about the appropriateness of treatment.

Results For mild-to-moderate depression, antidepressant (AD) + mood stabilizer (MS) in early editions and MS or lamotrigine monotherapy and AAP+(MS or lamotrigine) in later editions were preferred strategies. For severe nonpsychotic depression, MS+AD was the only first-line medication in early editions. In 2014, various medications [MS+AAP (atypical antipsychotic), AAP+lamotrigine, MS+AD] were preferred. Valproate and lithium has been rated as first-line MS in all editions. Lamotrigine were positively preferred later. Adjunctive AD was accepted as first-line strategy for severe depression in all editions. Preference of AAP also has been increased remarkably. Adjunctive AAP was not first-line treatment for mild-to-moderate depression in all editions, but was for nonpsychotic depression in 2010 and 2014 and for psychotic depression in all editions. Recommended AAPs have been changed over 12 years: olanzapine and risperidone in 2002 and quetiapine, aripiprazole, and olanzapine in 2014 were first-line AAP.

Conclusion There have been evident preference changes: increased for AAP and lamotrigine and decreased for AD. The high preferences for aripiprazole and lamotrigine in later editions were likely derived from favorable tolerability.

Obesity and quality of life in bipolar disorder

R. Jouini*, H. Ben Ammar, G. Hamdi, N. Smari, A. Aissa, E. Khelifa, Z. El Hechmi

Razi Hospital, Psychiatry F, Tunis, Tunisia

* Corresponding author.

Introduction Overweight and obesity, despite their comorbidities and mortality, could deteriorate the quality of life of people with bipolar disorder.

Objectives The objective of this study is to evaluate the quality of life among patients with bipolar disorder and investigate a possible interaction between obesity and deterioration of the quality of life.

Aims This study aims to highlight the importance of preventing overweight and obesity in people with bipolar disorder to obtain an adequate quality of life subsequently an acceptable control of the illness.

Methods Fifty euthymic bipolar patients (Hamilton Depression Scale score ≤ 8 , and Young Mania Rating Scale score ≤ 6) received the Medical Outcomes Study 36-Item Short-Form Health Survey in Arabic validated version in order to investigate the quality of life.

Results We examined 50 euthymic bipolar patients (60% men, 40% women). The average age was 46, 5 years (23–70). Most patients (69%) were overweight (BMI ≥ 25.0 kg/m²) (body mass index), of whom 40% were obese (BMI ≥ 30.0 kg/m²). Seventy-two percent of the investigated patients had an affected quality of life (score < 66.7). The mental items were deteriorated in 80% of the cases. An affected quality of life was correlated with obesity. The BMI was significantly and negatively correlated with the scores of dimensions D4 (mental health) and D8 (perceived health) ($P < 0.01$).

Conclusion The investigation of quality of life in people with mental disorder enables to reveal the social handicap caused by these illnesses consequently emphasizes health care in mental affections.

Research of thinking and memory at persons with the alcoholic dependence complicated by abuse of preparations of sedative and somnolent group

G. Jumashaeva

Tashkent Institute of physicians post-Graduate study, Academic Department of Addiction Medicine and Adolescent Psychopathology, Tashkent, Uzbekistan

In recent years, abuse of sleeping medicines with the subsequent formation of an inclination and increase of tolerance to preparations of this group has gained distribution in the Republic of Uzbekistan among the persons suffering from alcoholic dependence.

The assessment of thinking and memory functions was carried on by using a pictogram technique at 40 patients with the alcoholic dependence complicated by abuse of a somnolent preparation. Two groups of patients had similar duration of alcohol abuse, but differing in the length of abuse of hypnotic drugs: 20 patients used it not more than 1 year, 20 patients more than 5 years.

Research has shown that with the duration of abuse of somnolent preparation within 1 year patients with alcoholic dependence had no expressed memory violations: by means of pictogram drawings patients could remember all set of words. Twenty-five percent of patients' drawings had the ordered appearance, steady graphic characteristics; the chosen images were followed by exact, laconic comments. The tendency to prevalence of the concrete images associated with alcoholic situations was found in 75% of patients of this group at a graphic representation of abstract concepts.

Abuse of somnolent preparations more than 5 years at 35% of patients has come to light misunderstanding of sense of the task, 40% of patients – insufficient image differentiation with inability of selection of visions to abstract concepts, 10% of patients – had tendency to the stereotypy and a perseveration. All the patients had a decrease in efficiency of the mediated storing.

Bipolar disorders diagnostics in ambulatory medico-psychological service

N. Kornetov*, E. Larionova

Siberian State Medical University, Psychiatry, Addiction and Psychotherapy, Tomsk, Russia

* Corresponding author.

Introduction The difficulties of diagnosis and clinical differentiation of bipolar disorders, schizophrenia and schizoaffective disorder have been repeatedly noted both foreign and Russian authors.

Objectives Full medico-psychological service clinical documentation research, including bipolar disorder patient records.

Aims Determination of bipolar disorders in accordance with the DSM-5 criteria among psychiatric outpatients.

Methods A group of 142 patients with established according to ICD-10 diagnoses: schizophrenia, schizoaffective disorder 137 (96.5%); the average patient's age 50 ± 13 and bipolar disorder and mania episode 5 (3.5%) – 55.4 ± 14.4 has been investigated.

Results It was found that 18 (12.7%) of all patients meet the DSM-5 bipolar disorder criteria compared with the primary diagnosis (3.5%). Structure of the diagnosis of bipolar disorder was represented as follows: bipolar disorder type I – 11 (61.2%), bipolar disorder type II – 7 (38.8%). Consequently, due to formal application DSM-5 bipolar disorder criteria BD determination 3.5 times more.

Conclusion Traditionally, the diagnosis of schizophrenia is preferred over bipolar disorder. Manic episode in bipolar disorder can be evidently regarded as an acute schizophrenia manifestation. The diagnostic criteria for DSM-5 are convenient in diagnostics of manic and depressive episodes in case of their combination in I type bipolar disorder.

Is the use of long-acting injectable antipsychotic extended in the outpatient treatment of bipolar disorder? A brief description

L. Niell*, J. Rodríguez, R.A. Baena, I. Alberdi-Paramo,

G. Montero, M.M. Tenorio, M. Pereira, R. Sanz,

P. Gomez-Merino, F. De Vicente, A. Carrillo

Hospital Clínico San Carlos, Psiquiatría, Madrid, Spain

* Corresponding author.

Aims Obtain and analyze information on treatment guidelines, with particular emphasis on the use of antipsychotics, in patients diagnosed with bipolar disorder I and bipolar disorder II who are treated at a mental health center in a district of Madrid (Spain) under the conditions of habitual clinical practice.

Then, compare with recently published literature.

Methods We performed a descriptive study of a sample of 100 patients diagnosed with bipolar disorder (type I and type II) at any stage of the disease who receive regular treatment in a mental health center in a district of Madrid. Information regarding the treatment used, especially the use of antipsychotics (either in a single therapy or in combination with other drugs such as mood stabilizers, antidepressants, hypnotics or anxiolytics), was collected retrospectively from the data obtained from the medical record.

Results Ninety-four percent of patients are taking mood stabilizer treatment (68% lithium, 24% valproate, 1% and 1% carbamazepine and lamotrigine). Four percent take lithium and valproate in combination. Forty-eight percent of patients are taking some antipsychotic (atypical about 90%). Of these, only 10% in injectable form, and 5% take both oral and injectable antipsychotics.

Conclusions The diminished use of injectable antipsychotics, well below recent publications, draws the attention. You can probably explain this low proportion of injectable medication because we are generally dealing with stable patients with a long-term disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Misdiagnose bipolar disorder: About a case report

C. Novais*, M. Marinho, M. Mota Oliveira, M. Bragança, A. Côte-Real, S. Fonseca

Centro Hospitalar de São João, Psychiatry Department, Clínica de Psiquiatria e Saúde Mental, Al. Prof. Hernâni Monteiro, Portugal

* Corresponding author.

Introduction Early stages of bipolar disorder are sometimes misdiagnosed as depressive disorders. This symptomatology can lead to misinterpretation and under diagnosis of bipolar disorders.

Objectives/aims To describe a patient with a new diagnosis of bipolar disorder after 23 years of psychiatric care.

Methods We report a case of a 66-year-old man, with a previous psychiatric diagnosis of recurrent depressive disorder for the last 23 years, after a hospitalization in a psychiatric inpatient unit because of a major depressive episode. In subsequent years, he was regularly followed in psychiatric consultation with description of recurrent long periods of depressed mood requiring therapeutic setting, alternating with brief remarks of not valued slightly maladjusted behaviour. At 65, he came to the emergency room presenting with observable expansive and elevated mood, disinhibited behaviour, grandiose ideas and overspending, leading to his hospitalization with the diagnosis of a manic episode. In the inpatient unit care, we performed blood tests, cranial-computed tomography (CT) and a cognitive assessment. His medication has also been adjusted.

Results Laboratory investigations were unremarkable. Cranial-CT showed some subcortical atrophy of frontotemporal predominance, without corroboration by the neuropsychological evaluation. The patient was posteriorly transferred to a residential unit for stabilization, where he evolved with major depressive symptoms that needed new therapeutic adjustment. Later he was discharged with the diagnosis of bipolar disorder.

Conclusions Our case elucidates the importance of ruling out bipolar disorder in patients presenting with depressive symptoms alternating with non-specific maladjusted behaviour, which sometimes can be a challenging task.

¹ University Hospital of Ioannina, Psychiatric Clinic, Ioannina, Greece

² Psychiatric Hospital of Thessaloniki, 2nd Psychiatric Clinic, Thessaloniki, Greece

* Corresponding author.

We present an uncommon case of a 46-year-old woman suffering from Munchausen type factitious disorder comorbid with bipolar II disorder.

The patient was diagnosed with major depression disorder 4 years ago during her hospitalization in the internal medicine department after a suicide attempt and SSRI was prescribed.

Since the onset of the disorder the patient started complaining for physical symptoms, migrating from hospital to hospital seeking pathological and surgical interventions, fabricating her medical history. In the last 3 years, the patient visited the emergency room of university hospital of Ioannina 85 times and she was hospitalized in internal medicine or surgical clinics 16 times, performing 19CR, 11 CT and 4MRI.

Many times, she turned to the police suing the treating doctors. During her hospitalizations she refused psychiatric evaluation. Twelve months ago the patient finally visited a psychiatrist, bipolar II disorder was diagnosed and administrated quetiapine with good results to both, mood and ER visits (7 visits in one year and 1 hospitalization).

During the analysis of her mood switches, we observed non-euphoric hypomanic episodes and association of the hypomanic phase with the factitious behavior.

This case report reinforces the importance of maintaining a clinical suspicion of major psychopathology coexistence with factitious disorder.

Aim To assess the clinical outcomes associated with social cognition impairment in euthymic patients with bipolar disorder.

Method It was a cross-sectional study with convenience sample. The diagnose of bipolar disorder was performed by psychiatrist, using DSM-IV criteria, at bipolar disorder program – Hospital de Clinicas de Porto Alegre (Brazil), where the sample was recruited. The social cognition was assessed by psychologists using the Reading the Mind in the Eyes Test.

Results We included 46 euthymic BD patients: BD I ($n=39$), women ($n=32$), age (49.11 ± 13.17), and years of education (10.56 ± 3.80). Patients with social cognition impairment were not different of patients without social cognition impairment regarding socio demographic factors (gender, age, educational level, marital status, and employment status). Patients with social cognitive impairment showed higher rates of BD I patients ($P=0.036$) and higher proportion of hospitalization in the first episode ($P=0.033$), as compared to patients without social cognition impairment.

Conclusion This is a preliminary study demonstrating that BD patients with social cognition impairment show worse clinical outcomes. Severe BD onset seems to be an important predictor of social cognition impairment. However, more studies are needed investigating social cognition impairment in subjects with bipolar disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cognitive impairment and its relation to predominant polarity, number of episodes and illness duration in patients with euthymic bipolar affective disorder (BAD)

S.S. Ratnatunga^{1,*}, I.C. Kulathilake¹, K. Kokila Medhavini¹, M. Dayabandara², I. Rajapakse¹, R. Hanwella², V. de Silva²

¹ NHSL, Psychiatry, Dehiwala, Sri Lanka

² University of Colombo, Psychiatry, Colombo, Sri Lanka

* Corresponding author.

Introduction Previous optimistic assumptions about the prognosis of BAD based on the control of mood symptoms is now challenged as majority of patients continue to have cognitive deficits during the euthymic phase.

Objectives To describe cognitive impairment in euthymic BAD and study the association with clinical characteristics.

Aims Identify the prevalence and severity of cognitive impairment (CI); to correlate CI with the first episode, illness duration, number of episodes and predominant polarity.

Methods Patients attending the psychiatry clinic of the National Hospital of Sri Lanka diagnosed with BAD in the remission phase were recruited. An interviewer-administered questionnaire and Montreal Cognitive Assessment test was used to ascertain clinical characteristics and cognitive functions respectively. Scores of 18–26 described as mild, 10–17 moderate and < 10 as severe cognitive impairment.

Results Total sample size was 58. Mean age=48.84 (SD12.5). Fifty-five percent were females. Mean duration of illness was 179.7 months (SD128.5). A mean of 6 episodes were experienced during the course of illness (min=1, max=18); 58.6% had depression,

37.9% had manic and 3.4% had mixed as their first episode. The predominant polarity was depressive in 65.5%. No cognitive impairment – 8.6%, mild – 63.8%, moderate – 27.6% and none with severe. There was a significant association between the presence of cognitive impairment and the predominant polarity being depressive ($r=10.886$, $df=4$, $P=0.028$). No significant association was found between illness duration, number of episodes or the type of first episode.

Conclusions Patients with a predominant depressive polarity are more likely to experience cognitive impairment. Cognitive impairment had no association with illness duration, type of episode or number of episodes.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Due to recent aviation accidents, like German Wings flight 9525, aviation related mental health disorders have recently received much attention. Several psychological disorders have been associated with aviation ever since its beginning, both in passengers and aviation professionals. A clinical case is revised of a 33 years old air hostess, without previous psychiatric history, who was admitted twice in a manic state, and a third time abroad in Nice, France, after prolonged sleep deprivation due to consecutive transatlantic flights. **Objectives** Scientific revision of psychological disorders in passengers (flight related psychological stress, flight phobia, post-traumatic stress disorders after plane crashes...), aviation professionals (mood changes, sexual function disorders, jet lag, sleep disorders), ground staff, and populations living within close distance to airports (burnout, circadian rhythms disorders due to high noise levels...).

Methods Research in Pubmed, Medscape, scientific literature and other publications, with the following research terms: aviation related mental health disorders, flight related psychological disorders, flight phobia, aerophobia, aviophobia, flight related anxiety, flight related mood disorders, flight induced mania, psychological stress and air travel; articles in English, Portuguese and Spanish.

Results Fifty-eight articles, one book and four publications were considered relevant; the case of the patient is thoroughly described with data retrieved from the clinical file.

Conclusions Several important issues concerning both mental and physical health are highlighted by this clinical case, yet, surprisingly, scientific knowledge has progressed at a rather slow pace and mental health professionals have not given much attention to this issue.

Bipolar versus schizoaffective disorder: Clinical profiles

A.M. Romosan*, L. Dehelean, R.S. Romosan, I. Papava, I. Drut

University of Medicine and Pharmacy “Victor Babes”, Neuroscience, Timisoara, Romania

* Corresponding author.

Introduction Differentiating between bipolar (BD) and schizoaffective disorder (SAD) can be challenging, especially during early stages of the illness.

Objectives Comparing clinical profiles and socio-demographic characteristics of patients diagnosed with BD and SAD.

Methods The study, conducted between 2014–2016, included 67 inpatients from the Timisoara Psychiatric Clinic, diagnosed with either BD ($n=35$) or SAD ($n=32$), according to ICD-10 criteria. The following parameters were analyzed: number of episodes, number of times hospitalized, onset age, frequency and nature of psychotic symptoms, family history of psychiatric disorders and socio-demographic characteristics (age, sex, marital status). Data were obtained by direct interview and patient files. Symptom severity was measured with Brief Psychiatric Rating Scale (BPRS).

Results There were no significant differences between the two samples regarding age or sex distribution. Schizoaffective patients were more frequent unmarried ($P=0.007$). Onset age was significantly lower in SAD patients (22.41 years for SAD, 28.36 years for BD). SAD patients had the highest number of episodes and needed more frequent hospitalization. Bipolar patients had higher percentage of family history of affective disorders when compared to schizoaffective patients (41% versus 36%). Hallucinations were more frequently found in schizoaffective patients than in bipolar patients ($P=0.004$). We found no significant differences between the two samples regarding the presence or the type of delusions. The SAD sample had significantly higher BPRS total scores than bipolar patients ($P=0.035$).

Conclusions Although this study revealed numerous similarities between BD and SAD, it also identified differences that may be helpful in establishing the correct diagnosis.

Temporality in mania: Phenomenological, neurobiological and therapeutic consequences

M. Schwartz^{1,2,*}, M. Moskalewicz³, E. Schwartz⁴, O. Wiggins⁵

* Corresponding author.

Manic disturbances of temporality are underemphasized in present-day accounts. For example, they are not included among criteria for manic episodes in DSM or ICD. Nonetheless, as already claimed by Binswanger (1964), aberrant temporality is core to the disorder. Persons with mania live almost exclusively in the present and hardly into the future. Especially in the larger scheme of things, their future is already here. There is no “advancing, developing or maturing,” anticipations have already been achieved, all that I strive for is present – if you will just get out of my way! A half century ago, Binswanger spelled out this temporal foundation for mania and summed up consequences. The manic self, not living into the future, “is not, to borrow a word, an existential self.”

This presentation will describe phenomenological characteristics of such a manic self and then present correlating findings from contemporary neuroscience. Importantly, such findings clarify present

and future therapeutic interventions. Of critical importance is manic chronobiology: clocks in our brains afford receptor sites for the lithium ion. At these sites, lithium potently inhibits the circadian rhythm regulator glycogen synthase kinase 3 and alters the biological cascade that follows. By taking a close look, we can comprehend implications for mania as well as for treatment with lithium: Neurobiologically, lithium disrupts manic rhythm dysregulation and restores a more “normalized” temporality. The consequence is no less than the return of the existential self.

A receptor mechanism of action for lithium additionally portends future specific and safer treatment options “after lithium.”

Putting it all together: How disordered temporality is core to the phenomenology and neurobiology of mania

M. Schwartz^{1,*}, E. Schwartz², M. Moskalewicz³

¹ Texas A&M Health Science Center College of Medicine, Psychiatry and Humanities in Medicine, West Lake Hills, USA

² George Washington University College of Medicine, Psychiatry, Washington DC, USA

³ University of Oxford, Faculty of Philosophy, Oxford, United Kingdom

* Corresponding author.

Disturbances of temporality in mania, underemphasized in present-day accounts, are nonetheless core to understanding both the phenomenology and the neurobiology of the disorder:

– phenomenology: already in 1954, Binswanger had articulated that persons with mania live almost exclusively in the present and hardly at all into the future. Especially in the larger scheme of things, their future is already here. There is no “advancing, developing or maturing,” anticipations have already been achieved, and all that I strive for is basically present if you will just get out of my way! A half century ago, Binswanger summed up the consequence of manic temporality: the manic self, not living into the future, “is not... an existential self.” This presentation will further describe phenomenological characteristics of such a self in mania;

– findings from contemporary neuroscience correlate remarkably well with the above phenomenology, importantly clarifying present and future therapeutic interventions. Of critical importance in mania, clocks in our brains afford receptor sites for the lithium ion. Once bound to the receptor, lithium potently inhibits the circadian rhythm regulator glycogen synthase kinase 3 (GSK3) and profoundly alters the biological cascade that it initiates. In this presentation, by taking a close look, step-by-step, we will clarify how lithium disrupts mania rhythm dysregulation and restores a more “normalized” temporality. The consequence is no less than the return of the existential self. We will also briefly glance, in this presentation, at the window that lithium cellular efficacy offers for treatment options “after lithium.”

The association of antidepressant therapy with mania in people being treated for unipolar depression reinforces the importance of further clarification of this effect, since it has a huge implication in treatment approach and outcome. With this main objective, authors propose to make retrospective sociodemographic and clinical characterization of a group of patients with antidepressant induced mania in diagnosed unipolar depression, admitted in inpatient unit of Psychiatry and Mental Health Department of Centro Hospitalar de Trás-os-Montes e Alto Douro. Authors also aim to identify features that may increase the risk for mania or hypomania in people who present with an episode of depression, which can guide clinical orientation and improve outcome.

Clinical differences between unipolar and bipolar depression

S. Smaoui*, N. Charfi, M. Maâlej Bouali, L. Zouari, N. Zouari, J. Ben Thabeb, M. Maâlej

Hedi Chaker University Hospital, Psychiatry, Sfax, Tunisia

* Corresponding author.

Introduction Epidemiological studies indicate that the majority of patients with bipolar disorder are diagnosed many years later. Unipolar depression represents the most frequent misdiagnosis.

Objectives This study aimed to examine the symptom profiles of depressed patients in order to identify clinical specificities of bipolar depression.

Methods A total of 31 depressed patients were recruited from psychiatry outpatient department of Hedi Chaker university hospital in Sfax (Tunisia), during October and November 2016. Unipolar and bipolar patients were compared on a broad range of parameters, including sociodemographic and clinical characteristics. Depressive symptoms were rated using the Montgomery Asberg Depression Rating Scale (MADRS) and Bipolar Depression Rating Scale (BDRS).

Results The total sample comprised 31 patients with 16 men and 15 women. It involved 20 with unipolar depression and 11 with bipolar depression. Patients with bipolar depression had more family history of bipolar disorder ($P=0.037$) and a triggering factor had been identified less often ($P=0.03$). MADRS scores were similar in bipolar and unipolar patient (median score 28.22 versus 28.36; $P=0.964$). BDRS scores were significantly higher in bipolar depressed patients (median score 33 versus 25; $P=0.01$). The mixed subscale (item 16 to 20) scores were particularly higher (median 6 vs. 1.2; $P\leq 0.01$) especially concerning irritability ($P=0.001$). Increased motor drive ($P=0.004$) and agitation ($P=0.008$).

Conclusion Our findings suggest that the presence of mixed symptoms is very important to recognize depressed patients as having a bipolar disorder. We also recommend routine use of the BDRS for patients presenting for treatment of depression.

A case report of patient who had two manic episodes with psychotic features induced by nasal decongestant

A. Kandeger, R. Tekdemir*, B. Sen, Y. Selvi
Selcuk University, Department of Psychiatry, Konya, Turkey

* Corresponding author.

Objective Phenylephrine, pseudoephedrine and ephedrine are the sympathomimetic drugs that have been used most commonly in oral preparations for the relief of nasal congestion. These drugs stimulate the central nervous system that is affected by the alpha and beta adrenergic agonism. Sympathomimetic agents used in the treatment of flu and common cold with ephedrine and pseudoephedrine are case reports. That the manic and psychotic episodes are triggered. In this article, we would like to present a bipolar manic disorder with two manic episodes and both of them triggered by influenza drugs.

Case A 25-year-old man patient was admitted to psychiatric outpatient clinic with increasing complaints such as increasing energy, speaking much, decreasing sleep, increasing the libido after using the flu drug that prescribed to him containing phenylephrine. Also, 2 years ago, he has manic attack triggered after the flu drug.

Discussion In recent years the study of epilepsy and bipolar disorder in common suggests that bipolar disorder may affect the kindling phenomenon. In our case, two of reasons in the neurobiology of developing manic attacks the kindling phenomenon is likely to be effective. First, the possibility of using cold medicine containing ephedrine or pseudoephedrine in the first manic episode, in the second manic episode having spent the attack with FAQ stimulant effect of lower phenylephrine. Second, in the first episode after using the 5–6 tablets developing manic attacks. In the second attack to be triggered with just 2 doses may indicate the effect of kindling.

⁴ Necmettin Erbakan University Meram School of Medicine, Child and Adolescent Psychiatry, Konya, Turkey

* Corresponding author.

Objective Elective circumcision operation for male children can affect their psychological status.

Aim We aimed to investigate the traumatic effect of the circumcision procedure and the predictive factors that could contribute to this effect.

Method One hundred and thirty-four children who admitted to urology and child surgery clinics to perform a circumcision procedure were included in the study. The whole group was divided into two groups including general anesthesia (GA) ($n=71$) and local anesthesia (LA) ($n=63$) groups. The procedure was performed under general and local anesthesia in the relevant groups. All of the participants filled the Child Depression Inventory (CDI), State (SA), and Trait (TA) Anxiety and Childhood Anxiety Sensitivity index (CASI) before the operation, and the Child Posttraumatic Stress Reaction index (CPSRI) 1 month after the operation.

Results CDI, CASI and TA scores of the children were similar in both groups, however, SA scores of the LA group were higher than GA group ($P<0.001$), and CPSRI scores of the GA group were

higher than LA group ($P=0.04$). When the other parameters were controlled in regression analysis, only CDI scores predicted CPSRI scores in LA group ($P=0.02$), and TA scores predicted CPSRI scores in the GA group ($P=0.03$).

Conclusion Children who witness the surgical procedure of the circumcision do not develop serious PTSD symptoms. In contrast, children who experience general anesthesia procedure during circumcision develop more serious PTSD symptoms than children operated with local anesthesia. Trait anxiety and depressive symptom severity may be important in developing PTSD symptoms after circumcision operation.

Parenting styles and anxiety disorders in children – A study in an Albanian clinical population

V. Alrikaj^{1,*}, V. Skendi², B. Zenelaj², B. Allkoja²

¹ University of Medicine, Faculty of Medicine, Neuroscience, Tirana, Albania

² University hospital center “Mother Tereza”, Psychiatric service, Neuroscience, Tirana, Albania

* Corresponding author.

Introduction About 20% of children suffer from an anxiety disorder and symptoms may persist in adulthood. About 13 in every 100 children from 9 to 17 years old experience anxiety disorders, girls seem more vulnerable than boys. Theoretical models of anxiety emphasize the effect of parenting on development and maintenance of child anxiety.

Objectives This research aims to study the nature of correlation between parenting styles and anxiety in children who attend Tirana Child & Adolescent Psychiatric Service.

Methods One hundred and seventy-five children and 175 their parents filled Spence Children Anxiety Scale (SCAS) and Parenting Styles & Dimensions Questionnaire (PSDQ) was found a significant correlation between parenting styles and anxiety in children.

Conclusions Parental overprotection produces vulnerable children who become adults ready to give up in front of life difficulties therefore; it is necessary parents' awareness in practicing a balance in their parenting styles, in order to reduce children's anxiety.

Knowledge of kindergarten and elementary schools' teachers regarding attention deficit hyperactivity disorder

S. Almutairi^{1,*}, M. Almutairi¹, A. Al Harbi¹, M. Alsuhaibani¹, N. Alkeaid², T. Albatti³

¹ Qassim University, College of Medicine, Almulayda, Saudi Arabia

² King Fahad Medical City, Rehabilitation Center, Riyadh, Saudi Arabia

³ KFSH & KCUH, Psychiatry Unit, Riyadh, Saudi Arabia

* Corresponding author.

Background Attention deficit hyperactivity disorder (ADHD) is one of the most common mental disorders that manifest among children. Despite the fact that the teacher's role is essential in the assessment and management of pupils with ADHD and the recommendation of participation of teachers for the success and efficiency of diagnoses and treatment, the vast majority of teachers have neither understanding nor knowledge of ADHD.

Objectives The current study explores the kindergarten and elementary school teachers' knowledge regarding early detection and management of ADHD.

Methods Cross sectional survey using stratified random sampling technique was carried out in governmental and private elementary and kindergarten schools in four cities of Qassim region, Saudi Arabia.

Results The study included 1095 teachers, 711 (59.3%) did not get information about ADHD during undergraduate studies. Teachers' overall ADHD knowledge mean was 21.7 + 5.5 out of 38 marks. Teachers with high qualification degree and kindergarten specialty scored 56.4% and 60.2%, respectively. Teachers who attended conferences related to ADHD scored 64.5%, while teachers who read about ADHD or have been ever asked to diagnose/teach an ADHD student had 59.4% and 62.1%, respectively. The sources for those who got their information through reading were statistically significant in overall knowledge, general knowledge and treatment dimensions. As scientific studies and books were the highest with percentage of 24.6% and 23.3%, respectively, 4% and 3.6%, respectively, 3% and 3%, respectively. The level of ADHD knowledge perception showed that 76% of teachers were knowledgeable in relation to overall ADHD perception.

Conclusion Teachers who have higher qualifications or training in identifying ADHD children scored higher in our study.

Affective attitudes towards health are more ambivalent among older adolescents

G. Arina^{1,*}, M. Iosifyan², L. Pechnikova¹, V. Nikolaeva¹

¹ Lomonosov Moscow State University, Department of Psychology, Moscow, Russia

² National Research Center for Preventive Medicine, Laboratory of Psychosocial Factors, Moscow, Russia

* Corresponding author.

Introduction Attitudinal ambivalence is a mediator between attitudes and health behaviors. The present study contributes to our understanding of affective attitudes ambivalence.

Objectives We studied the ambivalence of affective attitudes towards health among adolescents.

Aims We compared the affective attitudes ambivalence between younger (10–14 years) and older (15–16 years) adolescents.

Methods Older ($n=51$, $M_{age}=15.09 \pm 0.30$) and younger adolescents ($n=28$, $M_{age}=12.96 \pm 0.99$) performed a modified Etkind Color Test. We calculated the associations between 13 factors related to health (e.g. sport, risky behavior) and positive emotions, as well as the associations between same factors and negative emotions. Thompson, Zanna and Griffin ambivalence index was a measure of attitudinal ambivalence.

Results Among younger adolescents all 13 correlations between negative and positive attitudes towards health related factors were significant and negative: $-0.402 < r < -0.804$ (which means the greater is the association between a word and positive emotions, the smaller is the association between the same word and negative emotions; and vice versa). Only 5 correlations were significant and negative among older adolescents ($-0.209 < r < -0.463$): environment, risky behaviors, family, sleep, my psychological well-being. The difference in ambivalence indexes was significant in two groups of adolescents [$F(14,64)=5.97$, $P=-0.0001$]. Younger adolescents had significantly lower ambivalence indexes in affective attitudes towards all 13 factors.

Conclusions Older adolescents had more ambivalent affective attitudes towards health related factors compared to younger adolescents.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clinical case: Gynecological side effects caused by methylphenidate

A. Ballesteros*, Á.S. Rosero, F. Inchausti, E. Manrique, H. Sáiz, C. Carrión

Red de Salud Mental de Navarra, Psychiatry, Pamplona, Spain

* Corresponding author.

Introduction Methylphenidate drugs is prescribed in attention deficit disorder and hyperactivity. Among its rare side effects, include alterations in the gynecological. We report a clinical case and review current evidence regarding the tolerability this drug in this area.

Methods We performed a PubMed search of articles published in English of different types (case reports or case/controls studies). We collected the clinical practice guidelines conclusions regarding adverse drug reactions.

Case presentation Our patient is a 14-year-old male diagnosed of ADHD treated with methylphenidate (0.8–1 mg/kg). He developed bilateral and asymmetric gynecomastia under this treatment plan so a referral was made to rule out other causes of this event. After performing several work up tests, it was concluded that this clinical presentation was caused by methylphenidate. Hence, we initiated crossed titration swapping this drug to atomoxetine. Four months later, he was mentally stable and he experimented a volumetric decrease as concerns his gynecomastia.

As regards methylphenidate, in 2009 a couple of cases in which alterations in the sexual sphere presented with the oros presentation were reported. There are series of reported pharmacological side effects (gynecomastia) and also denoted an improvement of the same months after drug discontinuation.

Conclusions Gynecological clinic secondary to the use of psychotropic drugs in ADHD is uncommon. In line with our case, the current evidence suggests a drug suspension as adverse effects are usually reversible (although it may take several months to complete recovery). Further studies are needed to understand the mechanisms underlying these tolerability issues.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clinical case: Phelan–McDermid and pharmacological management

A. Ballesteros*, Á.S. Rosero, F. Inchausti, E. Manrique, H. Sáiz, C. Carlos, Z. María

Red de Salud Mental de Navarra, Psychiatry, Pamplona, Spain

* Corresponding author.

Introduction The Phelan–McDermid syndrome is a chromosomal disorder consisting of a selection on chromosome 22q13.3 associated psychiatric and emotional level, behavioral and traits of autism spectrum disorders. During the neurodevelopmental such chromosomal deletion, which associated with haplo insufficiency Shank 3 causes alterations in the synaptogenesis altering the balance of activating and inhibitory transmission. Throughout the various studies, it is considered that this syndrome has a psychiatric disorder bipolar like.

Case presentation Here, we present s 13-year-old female diagnosed with autism spectrum disorders in childhood and presented regression with catatonia features and behavioral disorders. Interestingly, she presented mutation/microdeletion of the *SHANK3* gene, inducing a premature stop codon in exon 21. Different pharmacological treatments (antipsychotics at high doses and

benzodiazepines) failed to improve clinical symptoms and lead to multiple adverse events. In contrast, lithium therapy reversed clinical regression, stabilized behavioral symptoms and allowed patients to recover their pre-catatonia level of functioning. After the first menstruation there was a cycling psychiatric worsening with a similar clinical pattern so risperidone as adjunctive therapy. As a result of this, this patient recovered clinical and socio-functional stability.

Conclusions They are previous cases where there affective and behavioral improvement after use of mood stabilizer molecules such as valproate or lithium. There is also evidence of the benefit of risperidone low to have a beneficial effect on the balance of activatory and inhibitory transmission level doses of NMDA receptors.

Is there a relationship between Gilles de la Tourette and psychosis? A case report considering the continuum psychosis perspective and vulnerability model

R. Barbagelata*, J.E. Muñoz Negro

Campus de la Salud Hospital, Psychiatry, Granada, Spain

* Corresponding author.

Introduction There has been no evidence so far about significant relationship between Gilles de la Tourette and psychosis. Perhaps a continuum psychosis perspective and the vulnerability model could improve the comprehension of our patients.

Objectives To describe a case in which motor and obsessive symptoms evolve to schizophreniform symptoms and important psychosocial deterioration.

Methods Single case report and literature review.

Results A 20-year-old man, with clinical record of Gilles de la Tourette, and a psychosis episode 6 months before, is brought by his family with a syndrome consistent in motor retardation, whispered speech, poor visual contact, social withdrawal, hygiene neglect, abulia, apathy and blunted affect. In the one-year tracing conceptual disorganization and poor idea association are in the first place. Within child history, we found symptoms congruent with Gilles de la Tourette, obsessive symptoms and others that may be called mild psychotic symptoms (which did not fit in any diagnosis at that moment). We also found a pathological relationship between his parents and among him, as well as a poor economic and social condition.

Conclusions According to the continuum perspective, psychotic symptoms could be found within the obsessive spectrum. Related to the vulnerability model, we found in our case external factors that affected the clinical evolution: family dynamics affected, communication deviation, social and economic impairment, social withdrawal and vital aim loss. These factors should be attended in first place, as they are not only related with the triggering of illness but they also are the main way to recovery.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Features of pubertal patients with schizophrenia neurocognitive profile

Y. Baryluk*, S. Pakhomova, D. Samoylova, J. Abrosimova, E. Kolesnichenko, S. Sizov, E. Bachilo, A. Antonova, M. Deeva, N. Filipova

Saratov State Medical University, Department of Psychiatry, Narcology, Psychotherapy and Clinical Psychology, Saratov, Russia

* Corresponding author.

Identifying the patterns of neurocognitive disorders in pubertal schizophrenia is actual.

Methods Benton Test of visual retention, methods of forward and reverse bills, Bourdon correction sample, Wechsler's subtests (subtest 11 – "Encryption", subtest 12 – "Labyrinths" 1, 2, 3, 4, 5), Trail Creating a Test Part A.

Results All patients were divided into 3 groups. The first group (schizophrenia) and second group (other psychic disorders) showed the worst results than healthy subjects. Qualitative analysis of the "Benton Test" results showed similar variations of difficulty and types of errors in the subjects of the first and second groups – ignoring the number of the figure sides, as well as difficulties in the structuring element of the image corners. The "Methods of forward and reverse bills" demonstrated the fatigue and attention instability. "Bourdon test" showed a high level of the stability index ($K=0.09$). Wechsler's subtest "Encryption B" obtained poor results, indicating a pathological decrease in visual-motor speed. During the subtest "Labyrinths 1, 2, 3, 4, 5" the subjects of first and second groups exceeded the allowable time limit, but the first group of schizophrenia patients allowed more blunders during pubertal study (ignored the walls of the maze, torn pencil despite the given instructions). The test groups 1 and 2 while passing "Trail Creating a Test Part A" have shown good results – job data did not cause difficulties and carried out in accordance with the specified instructions.

Conclusions Neurocognitive disorders allow to confirm the presence of morphological and functional brain changes when endogenous mental illness occurs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Does gender matter? A comparative study of post-traumatic stress disorder among children and teenager

N. Ben Mabrouk, S. Bourgou, N. Staali*, M. Hamza,

A. Ben Hammouda, F. Charfi, A. Belhadj

Mongi Slim Hospital, Child and Teenager Psychiatry, La Marsa, Tunisia

* Corresponding author.

Introduction Post-traumatic stress disorder (PTSD) symptomatology seems to depend of many variables like age, exposition to trauma, environment. . .

Objectives Compare, basing on gender, socio-demographic and symptomatology of patients with PTSD.

Methods A retrospective and comparative study was conducted at the Child and Adolescent Psychiatry Department of Mongi Slim Hospital (Tunisia) from January 2013 until July 2016. We included all cases of patients followed for PTSD (DSM-5). They were divide into 2 groups according to the gender. Data was collected from patients' records.

Results Our study featured 30 patients: 16 boys and 14 girls. The average age was similar for both teams (boys: 8.43 years; girls: 8.53 years). Boys had twice more personal history of somatic, psychiatric illness (70%), and low socioeconomic status (62.5%). The beginning of the facts were significantly later for the female group ($P<0.001$). Females were more likely to be a witness, while males tented to be directly exposed to the trauma. Physical abuse was the major aggression for both groups.

Female gender was associated to parental trauma exposure ($P=0.023$) and to an ongoing event ($P=0.004$). Meanwhile, male gender was associated to a maternal history of psychiatric illness ($P=0.012$), a single traumatic event ($P=0.010$), and to a school

located aggression (0.04). Girls have developed more hypervigilance, guilt symptoms and aggressive behaviors. Low self-worth, regression, specific phobia and suicidal ideations occurred more frequently among boys.

Conclusions Health professionals must be aware of the youth PTSD warning signs in order to have the earlier right intervention.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Lifestyle factors and internet addiction among school children

A. Bener

Istanbul University, Biostatistics & Public Health, Istanbul, Turkey

Aim The aim was to determine the association between internet addition [IA] and fatigue, sleep disturbance, depression, and life style factors among school children.

Subjects and methods A cross-sectional survey based on multi-stage stratified random sampling and 1188 students (73.3%) gave consent during October 2011 to December 2012. Data including socio-demographic details, lifestyle and dietary habits Internet Addiction Test (IAT), Fatigue Scale, Epworth Sleepiness Scale [ESS] and Beck Depression Inventory (BDI) test. Univariate and multiple logistic regression analysis were performed.

Results The overall prevalence of IA among school children was 19.8%. The proportion of IA was significantly more among males (56.4%) as compare to females (43.6%; $P=0.035$), school performance ($P<0.001$) and family income ($P=0.032$). Those with IA had significantly less number of sleep hours (6.16 ± 0.80 vs. 6.58 ± 1.29 ; $P<0.001$) as compared to normal. Those with IA had significantly high number of hours internet use (3.82 ± 1.64 vs. 3.03 ± 1.64 ; $P<0.001$) as compared to normal. A significantly larger proportion of IA than normal subjects reported having headaches ($P=0.010$), double vision ($P=0.037$), eye hurt ($P=0.021$), eye tired ($P=0.005$), dizziness (34.4% vs. 27.3%; $P=0.002$), fatigue, and hearing problem ($P=0.048$). A significantly larger proportion of students with IA most frequently gratifying site (19.9% vs. 11.6%; $P<0.001$), browsed games (38.6% vs. 29.9%; $P=0.010$), chat sites (29.7% vs. 22%; $P=0.013$), email (54.2% vs. 63.1%; $P=0.36$), and research (61.0% vs. 69.2%; $P=0.017$).

Conclusion The current study confirmed the of evidence linking problematic internet use with negative fatigue, greater numbers of symptoms, anxiety, sleeping disturbances, depressive and lifestyle risk factors, among vulnerable young children.

Emotion regulation during looking in the mirror in patients with eating disorders

T. Bernátová^{1,*}, M. Světlák²

¹ Faculty of Medicine, Masaryk University and University Hospital Brno, Department of Psychiatry, Brno, Czech Republic

² Faculty of Medicine, Masaryk University and University Hospital Brno, Department of psychology and psychosomatics, Brno, Czech Republic

* Corresponding author.

Emotion regulation is complex ability involving many emotional processes. One of the main assumptions of adaptive emotion regulation is emotional awareness, or the ability to identify and interpret own emotions. The absence of these fractional skills at patients with eating disorders can lead to rigid maladaptive control

strategies that are underlying etiological factor of eating disorders. Sixteen patients underwent a psychological diagnostic focused on work with emotions. In the experimental part, patients were exposed to their own image through the mirror, during which were supposed to regulate their emotions, according to specific instructions. While patients were looking into the mirror, we monitored psychophysiological activity. Latest results based on the data processing of averages excitation of skin conductance describe the course of the experiment as we expected. Calming phases alternated with mirror exposure were clearly noticeable and consistent during changes in skin conductance and varies almost significantly [$F(3,6) = 2.5, P = 0.068, \eta^2 = 0.22$], which supports the suitability of the selected eliciting material. The difference between mirror exposures with instructions on how to regulate emotions and without them is not statistically significant, but the continuance of the skin conductance describes the phases of the experiment consistently. The most striking response was detected at the first exposure to the mirror, which may suggest a lack of internal resources to regulate such an important stimulus as their own body. The results indicate that exposure to mirror is a negative emotional stimulus, with whom the patient can hardly cope.

Prospective predictors of onset, maintenance and cessation of self-injurious behavior during adolescence

R. Brunner*, J. König, P. Parzer, F. Resch, M. Kaess
University of Heidelberg, Child and Adolescent Psychiatry,
Heidelberg, Germany

* Corresponding author.

Introduction Epidemiological studies indicate a high prevalence of self-injurious behavior in adolescents in the general population. So far, there are only very few studies on the course of self-injurious behavior in adolescents and young adults.

Objectives The aim of the present population-based study was the analysis of prospective predictors of onset, maintenance and cessation self-injurious behavior in adolescents.

Methods A representative sample of the normal population of adolescents from Germany (initial sample: $n = 1444$; mean age = 14.7, $SD = 0.80$, 52% female adolescents) was studied over a two years period on 4 consecutive points of measurement in the context of the European school-based intervention study SEYLE.

Results There was a high remission rate (70.4%) of self-injurious behaviors at 24-month follow-up investigation. However, there was a substantial rate (29.6%) of adolescents who continued the self-injurious behavior, as well as a group of “new starters”. Self-injurious behavior during the baseline examination proved to be the strongest predictor of self-injurious behavior 2 years later. The extent of depressive symptoms and quality of peer relationships were significantly associated with maintaining self-injurious behavior two years later. Furthermore continued self-injurious behavior over the first 12-month was highly associated with suicide plans/suicide attempts at 24-month follow-up investigation.

Conclusions While both, onset and maintenance of SIB are prospectively associated with an increased risk for suicidal behaviour in late adolescence, SIB cessation significantly reduces the risk for later suicidal behaviour.

⁴ Russian Children's Clinical Hospital, Psychoneurology Department, Moscow, Russia

* Corresponding author.

Introduction Opsoclonus myoclonus syndrome (OMS) in childhood still remains unexplored from the perspective of clinical psychology.

Objectives and aims The research was aimed at defining types of psychological development in the group of children with OMS. The study included 18 children between ages 2 years 4 months and 9 years with OMS (8 boys, 10 girls).

Methods The following methods were used: analysis of patient's development and medical record, psychological interview with parents, neurological state assessment and pathopsychological assessment.

Results Patients were divided into three groups according to cognitive development level:

- group with normal intelligence level ($n = 4$);
- group with developmental delay ($n = 11$);
- group with intellectual disability in different forms ($n = 3$).

Several children in group 1 ($n = 3$) and in group 2 ($n = 4$) expressed neurotic behavior with increased levels of anxiety and fear of trying unusual actions during psychological assessment. Children with delay in psychoverbal development ($n = 7$) and with developmental delay ($n = 1$) expressed psychopathy-like states with verbal aggression and had difficulties controlling their emotions. In some cases ($n = 2$), the psychological state of the patient was defined as borderline state with emotional instability, especially in mother–child interaction.

Conclusion Psychological features of children with OMS indicate heterogeneity of their development types that implies different prognosis and developmental dynamics for each type. The results point out the necessity of detailed psychological examination aimed at correlation of psychological help to children with OMS and their families with their psychological state.

* Corresponding author.

Introduction Further research is still needed to demonstrate the benefits of animal-assisted therapy (AAT) for specific participant profiles, such as children with behavioural disorders.

Objectives We wanted to find out if AAT could be considered an efficient therapeutic strategy for the treatment of children with behavioural disorders.

Aims We wanted to study the effects of a preestablished AAT program on the behaviour of children with emotional and behavioural issues in 6 different reception centres for children under government guardianship.

Methods Forty-five children (12 to 17 years old) with emotional and behavioural issues participated in a 14-session AAT program. Behavioural measures were those routinely scored as part of therapy; an observational report of 3 different problematic behaviours (such as impulsivity, lack of social skills or lack of personal recognition) was made twice a week for each child (with a score of frequency and intensity). A pre- and post-treatment “global behaviour score” was calculated for each child, as an average value of the 3 problematic behaviours measured during the month pre-treatment and the month post-treatment.

Results The 45 participants attended, on average, 72.8% of AAT sessions. Independent behaviour scores differed between the pre- and post-intervention evaluations ($n = 135$ behaviours) (Wilcoxon test; $P < 0.0001$). Based on the global behaviour score for each child ($n = 45$), significant change was found between pre- and post-intervention evaluations (Wilcoxon test; $P = 0.0011$).

Conclusions Our results suggest AAT could be a beneficial intervention for children with behavioural issues in terms of program adherence and behaviour improvement.

Exercise for depression in adolescents: A meta-analysis of randomised controlled trials

T. Carter^{1,*}, I. Morres², O. Meade³, C. Patrick³

¹ The University of Nottingham, School of Health Sciences, Nottingham, United Kingdom

² University of Thessaly, School of Physical Education and Sport Science, School of Physical Education and Sport Science, Greece

³ University of Nottingham, School of Health Sciences, Nottingham, United Kingdom

* Corresponding author.

Background The reported lifetime prevalence of depression in adolescents has increased drastically in recent decades. Depression in this population can be particularly damaging and can frequently have a long-lasting adverse impact. The common treatment approach includes psychological therapy and/or anti-depressant medication. However, the efficacy of these approaches, both singularly and combined, is far from conclusive. Recently, there have been an increased number of studies investigating the effect of exercise and physical activity on adolescent depression, however, despite this increased attention, there are no recent reviews and meta-analyses synthesising such studies.

Aim The review examines the treatment effect of exercise on depression symptoms for adolescents aged 13–17 years of age.

Methods A systematic search of seven electronic databases identified relevant randomised controlled trials. Screening, data extraction and trial methodological quality were undertaken by two independent researchers. Standardized mean differences were used for pooling post-intervention depressive symptom scores.

Results Eleven trials met the inclusion criteria, eight of which provided the necessary data for calculation of standardized effect size. Exercise showed a statistically significant moderate overall

effect on depressive symptom reduction. Sensitivity analyses were also conducted and will be presented.

Discussion Exercise and physical activity appear to improve depression symptoms in adolescents, especially in clinical samples, suggesting that exercise may be a useful treatment strategy for adolescents with depression.

Conclusion Despite the positive findings, large clinical trials that adequately minimise bias are required for firmer conclusions on the effectiveness of exercise as an antidepressant treatment.

Sixteen-year population-based cohort study of main class International Classification of Diseases associated with psychiatric disorders in a sample under the age of two years

D. Cawthorpe

The University of Calgary, Psychiatry/Community Health, Calgary, Canada

Introduction This paper illustrates the use of cohort data from a population to describe the early life prevalence and odds ratios (ORs) of the main classes of International Classification of Diseases (ICD) associated with any mental disorder arising at any time during the 16 year study period.

Objectives The main ICD disorder classes were examined in relation to psychiatric disorders over 16 years in a cohort under the age of two years between April 1st, 1993, and January 1st, 1995.

Aims To demonstrate the utility of studying the complete profile of associated diagnoses over time in a population cohort.

Methods The total number of individuals under the age of two years before 1995 ($n = 17,603$) were tallied within each main class of ICD disorder by year and expressed as ORs of those with and without any 16-year psychiatric disorder.

Results The greatest annual rates observed in the early years of life were for the following main ICD classes of disease: respiratory system, sense organs, symptoms signs ill-defined conditions, no diagnosis, injury poisoning, and skin subcutaneous tissue disorders. These disorders also had the highest ORs in early life given the presence of a mental disorder at any time during the study period.

Discussion Knowing the early life main class diagnoses associated with psychiatric disorders could guide both basic science research as well as early intervention social and health investment policies.

Drawing in autistic spectrum disorder children

S. Cepedello*, A.S. Adrian, G.B. LAura, M.T. Eduardo, D.U.V. Nieves, D.L.R. Henar, Á.A. Aldara

Hospital Clinico Universitario, Psiquiatria, Valladolid, Spain

* Corresponding author.

Introduction Drawing can be a tool to complete the psychodiagnose process, especially in children with expression and verbal problems.

The autistic spectrum disorder (ASD) children have problems to describe their feelings and emotions, they can provide us many information drawing their own world.

Objective The purpose of this study was to discover the psychopathology of children with ASD through their drawings.

Methods A4-sized booklets were given for ASD children from 6 to 16 years to draw an imaginary family (L. Corman), a human figure (Buck) or a free drawing.

Results In most of the drawings of ASD children, we could find at least one of the three criteria of ASD: social deficits, communication difficulties and restricted interests.

Conclusions A projective technique as drawing could help us to discover additional information about our patients, specially children and mainly the ones who had problems with the expression of feelings like ASD children.

The act of drawing can be used to understand children's struggles, their internal world. Moreover, it could also help the children gain insight and review progress through drawing records.

Reconceptualizing agitation in autism as primary affective dysregulation: Case report and literature review of use of quetiapine in a patient with Treacher–Collins syndrome and autism

R. Cosme*, S. Dharmapuri

Rush University Medical Center, Psychiatry/Child and Adolescent Psychiatry, Chicago, USA

* Corresponding author.

This case report describes the successful use of low dose quetiapine in the treatment of agitation in a patient with Treacher–Collins syndrome (TCS) and suspected autistic spectrum disorder (ASD). Results from this case report found better efficacy in controlling symptoms of agitation in ASD utilizing lower doses of quetiapine. TCS is a genetic disorder that is characterized by a mandibulofacial dysostosis but is not associated with developmental delay, nor is it associated with a high risk of co-morbid autism, and to our knowledge, there are no previous reports of a co-occurrence of TCS and ASD in the extant literature. There are reports of mandibulofacial dysostosis associated with co-morbid developmental delay that are similar but distinct from TCS, however these reports do not comment on the treatment of agitation in this patient population. The results described in this case report demonstrate a reduction of agitation with low dose quetiapine, and offers support for the reconceptualization of agitation in ASD as a primary affective dysregulation which is also in line with evidence from the extant literature regarding the neurobiologic basis of aggression.

Compassionate Attributes and Action Scale for adolescents: Adaptation and validation

M. Cunha^{1,*}, C. Rodrigues¹, M. Matos², A. Galhardo¹, M. Couto¹

¹ Miguel Torga Institute, Clinical Psychology, Coimbra, Portugal

² FPCE, University of Coimbra, Cognitive-Behavioural Research Centre, Coimbra, Portugal

* Corresponding author.

Introduction Compassion can be defined as an intentional sensitivity to the suffering, with a motivation and commitment to try to relieve it, which can have a positive impact on individuals' emotional and psychological well-being. The relevance of compassion focused therapies is well established and this makes the development of reliable instruments for the assessment of the

different facets of compassion targeting different age groups crucial for research and clinical practice. The Compassionate Attributes and Actions Scale (CAAS) aims to assess compassion on three directions: self-compassion, compassion for others or compassion received from others. Each of the scales assesses one's compassionate attributes and compassionate actions separately when dealing with difficult or painful situations.

Objective/aim This study aimed to adapt the CAAS for adolescents and to explore its factor structure and psychometric properties in a sample of Portuguese adolescents.

Methods A total of 336 Portuguese adolescents with ages ranging from 12 to 19 years old participated in the study. Several exploratory factor analyses were conducted.

Results Exploratory factor analysis showed that, except for the attributes section of the self-compassion scale (that showed to be bi-factorial), all the other scales (and their sections) presented a single-factor structure. The three scales, and its sections, demonstrated a good reliability and excellent test-retest reliability and good convergent and discriminant validity.

Conclusion Results were in line with the factor structure found in the adults' version. The scales and its sections have shown good psychometric characteristics and constitute a useful instrument to assess and investigate the three directions of the compassion.

Assessment of test anxiety in Portuguese adolescents: Psychometric properties of the Cognitive Test Anxiety Revised

J. Silva^{1,*}, M. Cunha², A. Galhardo², M. Couto¹, I. Massano-Cardoso¹

¹ Miguel Torga Institute, Clinical Psychology, Coimbra, Portugal

² Miguel Torga Institute/CINEICC-UC, Clinical Psychology, Coimbra, Portugal

* Corresponding author.

Introduction Test anxiety represents a considerable personal burden due to its interfering nature and is associated with a range of deleterious life trajectories, encompassing school difficulties and health consequences. Although test anxiety seems to be highly prevalent and the pathological symptoms are similar to those of other childhood anxiety disorders, there are specificities that deserve a more in-depth approach. Given that adolescents seem to experience test anxiety in several school grades there is a need for a valid and reliable scale to measure test anxiety in school age students.

Objective This study aims to adapt and analyse the psychometric properties of the Cognitive Test Anxiety Revised (CTAR25) for Portuguese adolescents. In addition, the convergent and divergent validities were examined with related constructs.

Methods Participants were 279 adolescents, with ages between 12 and 19 years old, attending middle and high schools. Together with CTAR₂₅, participants also filled out self-report questionnaires assessing tests anxiety (TAI), self-esteem (RSES), procrastination (QPE) and worry (PSWQ-C).

Results The scale showed good internal consistency, good test-retest reliability, and good validity. Factor analysis revealed the existence of two factors with good internal consistency.

Discussion Results showed that the Portuguese version of CTAR-25 is a valid and reliable self-report instrument for the assessment of test anxiety in adolescents, replicating the findings of the original version.

Sensory processing in children with and without attention deficit hyperactivity disorder: A comparative study using the Short Sensory Profile

M. Dalpatadu^{1,*}, S. Wijetunga², K. Kapugama², S. Kotalawala², C. Suraweera³

¹ Cumberland Hospital, Psychiatry, Westmead, Australia

² Psychiatry, Colombo, Sri Lanka

³ Colombo, Sri Lanka

* Corresponding author.

Background Attention deficit hyperactivity disorder (ADHD) is one of the sensory modulation disorders among others like autism, Asperger syndrome and Fragile X syndrome. Little is known about patients with ADHD and their sensory processing issues in Sri Lanka.

Aims To investigate differences in sensory processing among children between (3–10) yrs with attention deficit hyperactivity disorder and those who are typically developing in Sri Lanka.

Methods A descriptive cross sectional study of 75 children aged (3–10) yrs attending child guidance clinic at Lady Ridgeway Hospital (LRH) were compared with 75 age matched peers who were typically developing, using the Short Sensory Profile (SSP).

Results Out of the sample population of 150, there was a significant difference in sensory processing total score ($P=0.001$) (df=29) of children with ADHD when compared to the typically developing group. The greatest differences were reported on the tactile ($P=0.013$), taste ($P=0.000$), under responsiveness ($P=0.002$), auditory filtering ($P=0.002$) & low energy ($P=0.017$). Out of the raw items commonest sensory processing problems were difficulty standing in line, distractibility if there is a lot of noise around, being unable to work with background noise & difficulty paying attention due to auditory deficits.

Conclusions Majority of children in this sample were reported to have difficulties with processing and responding to sensory input on the SSP. Further studies are needed to assess sensory issues in children with ADHD, to carry out effective interventions.

* Corresponding author.

Introduction The study of the oral and written language delayed at the school makes possible the early detection of scholar, behavioral and psychiatric disorders. These difficulties could affect to the personal and professional development.

Objectives To confirm the relationship between language oral and written delayed for the early detection of developmental disorders.

Method A sample of 350 subjects among 5 and 23 years of age is analyzed with oral and/or written language difficulties. It is studied diagnosis, gender, age, reason for treatment, grade and submitter.

Results The specific learning disabilities (SLD) request a 62.3% of the treatment among 7–10 years. The percentages of SLD

are: reading comprehension difficulties (17.4%), dysorthography (13.4%), reading fluency and reading comprehension difficulties (12.9%), reading fluency (11.7%) and, dysorthography and reading fluency (6.9%). There exist percentage differences between repeaters (39.4%) and no repeaters (22.9%) students with DALE. The oral/written language provides the early detection of Intellectual disabilities (8.6% of the simple). The relation between the reason for treatment and diagnosis do not coincide: the consults was 3.7% for oral language delay, 2.6% for reading comprehension difficulties, 1.4% for dysorthography and 0.9% for reading fluency. The school demand more treatment (50.9%), next to medical centers (22.3%) and family initiative (15.7%).

Conclusions The oral/written language delayed – especially the reading comprehension difficulties – are a good early detection for the developmental disorders (intellectual disabilities minor, SLD and TDAH at the primary stage). There is more percentage of boys than girls (2:1) with language delayed, except at Intellectual disabilities, because there is an identical percentage (4.3%).

Executive functions disorders in high functioning autism and rehabilitation implications

A. Di Santantonio^{1,*}, M. Manfredini², N. Varucciu¹, M. Fabbri², M.C. Cutrone², M. Villanova², F. Resca², R. Di Sarro¹

¹ Local health authority, Health and Disability Integrated Program, Bologna, Italy

² Local health authority, Department of Mental Health and Addictions, Bologna, Italy

* Corresponding author.

Introduction The term executive functions (EFs) includes a set of cognitive processes such as planning, working memory, attention, problem solving, inhibition, mental flexibility, multi-tasking, and initiation and monitoring of actions. EFs are the higher order control processes to guide behaviour.

Some studies on the relationship between EFs and autism spectrum disorder (ASD) showed deficit in the cognitive flexibility and speed processing, particularly with Asperger syndrome. Recently, Merchán-Naranjo et al. [1] supported that children's and adolescents with autism without intellectual disability are insufficient in at least 5 domains: attention, working memory, cognitive flexibility, inhibitory control and problem-solving.

Aims Our work is aimed at verifying if the presence of a dysexecutive syndrome significantly impacts on the adaptive functioning of people with high functioning autism.

Methods A group of young adults with ASD were administered traditional neuropsychological assessment, specific assessment, focusing on the planning strategies for solving problems (Test Tower of London), abstraction and categorization (Wisconsin Card Sorting Test), and the Dysexecutive Questionnaires.

Results The results showed the presence of a specific deficit in the executive functioning in an average cognitive functioning.

Conclusions Integrate the standard cognitive screening with a specific EFs assessment resulted to be very useful for the clinician to realize neuropsychological and psychotherapeutic individualized treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Adolescence and self-injuries

A. Dörr*, S. Viani, Q. Yamil

Faculty of Medicine, Universidad de Chile, Psiquiatría y Salud Mental Oriente, Santiago, Chile

* Corresponding author.

This article is a reflection on the current affairs and an invitation to think about worrying phenomena in youngsters: self-injuries or cuts in the arms in eight young adolescent patients. We try to figure out the underlying cause of such behavior, which is more common every day and reveals some characteristics of society. Sociocultural, individual and family changes are analyzed, showing possible connections among these instances, identity and self-injuries. We suggest that the difficulties in identity development may be related to practices such as self-injury or others, which are related to mentalization problems. In the sociocultural level we find a way to socialize in which subjective discomfort has increased, there is overabundance, mass consumption, and the traditional social institutions (family, school and religion) have failed. Youngsters do not know themselves nor their projects. This difficulty is accompanied by an individual's failure in mentalization capacities (name one's feelings), leading the suffering youngster to practices such as self-injuries, which become permanent. Finally, the particulars of family relationships are described: distance between parents and their offspring, with the life experiences of the former being less appreciated by their offspring while forming their own identity, this is, they are responsible of becoming the architects of their own identities. They are orphans without traditions, which are sources of identity and innovation; to know who we are we must know where we come from.

Determining the influence of game treatment on decreasing divorce children's stress

F. Ebrahimi

Islamic Azad University, Kermanshah Branch, Clinical Psychology, Kermanshah, Iran

Introduction One of the main challenges facing the fact that every society has always called divorce. Phenomenon in modern societies is growing at a rapid rate and adverse effects of economic, social and especially psychological, parents and children.

Aim This study pays to determining the influence of game treatment on decreasing divorce children's stress.

Methods The method of study is of testing in which statistical society of study includes all children (girl and boy) of divorced parents. From all statistical society, we have selected a sample about 26 persons by randomly sampling. The instrument for gathering information in this study includes children stress test (SCARED) in which has been studied sample after measuring its narration and stability.

Result The result of dependent *t*-test and covariance analysis showed game treatment has meaningful and positive influence on children stress.

Conclusions The amount of its interference on decreasing divorce children stress is about 83%. It means 83% of the whole remained scores variance is related to game treatment interference.

A validation study of the Mood and Feelings Questionnaire, Danish version

J. Eg Frøkjær*, N. Bilenberg, R. Wesselhoeft

Institute of Clinical Research, University of Southern Denmark, Department of Child, and Adolescent Psychiatry Odense, Odense C, Denmark

* Corresponding author.

Introduction The Mood and Feelings Questionnaire (MFQ) was developed to measure depressive symptoms in children and adolescents. It includes a child self-report part and a parent report on child part. The MFQ has been validated and proven clinical useful in several countries.

Objectives To validate the MFQ in a population of Danish children and adolescents.

Aims There is a need of a standardized questionnaire for Danish children and adolescents tapping into affective symptoms. Before routine use the MFQ must have been validated in Denmark. This study examines the validity of MFQ in Danish children and adolescents.

Methods The study included two samples of probands aged 8–18 years. A population-based sample of school children and their parents, and a clinical sample including two subsamples:

– patients referred for Child and Adolescent Mental Health Services with depressive symptoms;

– in-patients at the paediatric department of a University Hospital. All included probands and their parents filled out the MFQ and the clinical samples in addition answered the depression section of the Beck Youth Inventories, and were interviewed using the depression part of "K-SADS-PL".

Results Preliminary results from both samples will be presented at the EPA 2017 in Florence.

Conclusions Depending on the results of this study, the MFQ might be used as a screening instrument and as a clinical tool to monitor depressive symptoms in Danish children and adolescents.

Mind your anger habits: For teen (group CBT for teens with anger behavioral problems)

S. Eraky

Egyptian Association of Cognitive Behavior Therapy, Child and Adolescent, Cairo, Egypt

Problematic anger behaviors of children and adolescents represent a significant challenge to the clinical community. Although a number of direct and indirect factors are theorized to contribute to the etiology of aggressive behavioral problems, the cognitive-behavioral model focuses on the cognitive processes that play a significant role in the generation of anger and the aggressive responses to provocation. "Mind your anger habits: for teen" manual, is based on the cognitive-behavioral conceptualization of anger and anger management problems functions, it consists of 10 group sessions for teens and 8 group sessions for their parents.

In the "Mind your anger habits: for teen"; anger is identified as a stress reaction with three response components: cognitive, physiological, and behavioral. The cognitive component is characterized by one's perception of social stimuli and provocation cues in the social context, by one's interpretation of these stimuli, by one's attributions concerning causality and/or responsibility, and by one's evaluation of oneself and the situation. This component represents a significant area for intervention with aggressive adolescents as their perceptions and attitudes serve to prompt most

behavioral responses to provocation. Research on the social and cognitive processing in aggressive youth indicates that distorted interpretations, attributional biases, and deficiencies in problem solving can all influence the selection of aggressive behavior responses. Furthermore, cognitive processing patterns are likely to become more rigid over time, and as such the maladaptive aggressive behaviors prompted by dysfunctional cognitions will be maintained.

* Corresponding author.

Introduction *Acne vulgaris* is a common skin disease that affects the majority of adolescents. The physical changes of acne may have negative effects on the psychological structure of adolescents such as anxiety and depression. Alexithymia has been suggested to be an important symptom in psychodermatological patients.

Objective Our study aims to access depression in adolescents with *A. vulgaris* and to evaluate its relationship with alexithymia.

Methods This is a descriptive cross-sectional study regarding 50 adolescents followed in the outpatient dermatology unit of Hédi Chaker University hospital in Sfax (Tunisia). To assess depression, we used a psychometric tool: Beck Depression Inventory (BDI). The Toronto Alexithymia Scale (TAS-20) was used to evaluate alexithymia. The severity of acne was evaluated with the Global Acne Evaluation (GEA) Scale.

Results The mean age of adolescents was 15 years 9 months. Almost all of adolescents was female (82%), and live in urban area. The severity of *A. vulgaris* was mild in 50%, moderate in 32% and severe in 18%.

The prevalence of depression was 48%. Twenty-four percent of them have a major depression. Forty-six percent of patients scored positive for alexithymia.

The occurrence of depression was significantly associated to alexithymia ($P=0.003$).

Conclusion This study showed a positive correlation between alexithymia and depression.

These results can be useful in treatment based on processing of emotional information and regulation of emotions.

* Corresponding author.

Introduction The developments of familiar therapy allows a systemic (collaborative) approach centered in what functions best in the system, integrating action plans which presupposes a family appreciation concept as a transformer system.

Objectives/aims Presentation of a family clinical case (X family) in which one of the members is diagnosed with “elective mutism”, this being labelled as a “a family problem” which led to familiar therapy.

Methods In the therapeutic process we use a number of resources centered in family strengths as strategies directed to the solution and system change. We incorporate an innovating strategy, which we call “differentiated spectularity”, trying to make something different based on therapy concepts centered on solutions. The presentation of exceptions and the use of scales allowed us to monitor the change process.

Results The strategy materialization, where family members in their family environment saw the film of their latest session in a favourable context for the enlargement of their own vision as a family, allowed change expansion amplifying its complexity. The family members perceive themselves as having a moderate cohesion level, increasing the levels of adaptability, which places the X family in a “balanced” class. The family member with a diagnosis of elective mutism, after six months of family therapy, showed changes in withdrawal, anxiety and shyness behaviour.

Conclusions Sharing family members different versions allows us to tell the story over and over again. The questioning emerging from the pro-active mirror effect is the core element of the change registered with incidence in the emotional and behaviour domains.

* Corresponding author.

Introduction This study aimed to investigate the therapeutic effect of a combination of magnesium, calcium and zinc as a complementary treatment in a population of the children with ADHD in Zahedan.

Material and method In this clinical trial, 40 patients with ADHD aged 6 to 12. The simple convenience sampling was done and the patients were randomly divided into two groups of receiving methylphenidate plus magnesium + zinc + calcium, and methylphenidate plus placebo.

Results The mean severities of the symptoms in the group treated with methylphenidate plus the supplements were $40/4 \pm 2/4$ before the treatment, and $19/5 \pm 6/1$ after 8 weeks of treatment ($P < 0.001$).

Conclusion This study shows that zinc, magnesium and calcium supplement is useful in the treatment of ADHD and can be used to treat patients.

Keywords Methylphenidate; Attention deficit hyperactivity disorder; Zinc; Magnesium; Calcium

Low salivary secretory IgA levels correlate with hyperreactivity in children with autism

M.T. Sindelar^{1,*}, N.E. Furland²

¹ Provincial Southwestern University, Faculty of Local and Regional Development, Bahía Blanca, Argentina

² CONICET-UNS, INIBIBB, Bahía Blanca, Argentina

* Corresponding author.

Introduction Autism is a neurodevelopmental disorder characterized by deficits in communication and social skills as well as stereotypical behaviors. There are multiple lines of evidence, suggesting that the immune system is involved in autism. Since secretory IgA (sIgA) is the predominant antibody isotype in saliva and a marker of mucosal immunity, the aim of the study was to assess if the severity of clinical and behavioral parameters of autistic children was associated with low levels of sIgA in saliva.

Objectives To assess possible associations between salivary levels of sIgA and the severity of behavioral outcomes related to autism. In addition, were studied sIgA in saliva of children with autism and the frequency of respiratory tract infections diagnosed in the first 3 years of life.

Methods Saliva samples were obtained from 3–10 years old autistic children and age-matched typically developing Caucasian children from Patagonia, Argentina.

Results Autistic children with reduced levels of salivary sIgA had a higher incidence of respiratory diseases compared to controls. The reduction in sIgA levels inversely correlated with the severity of the behavioral disorders. The patients with the most severe impairment in autism-related behaviors had the lowest levels of sIgA in the cohort studied.

Conclusions These findings suggest that sIgA could be an early non-invasive indicator of the dysregulation of the immune system in some children with autism. Clearly, the characterization of immunological parameters has important implications for detection of subgroups of children with ASD, and should be considered when designing therapeutic strategies to treat behavioral impairments of ASD.

⁶ Université Lumière Lyon 2, centre Max-Weber, Bron, France

* Corresponding author.

Over the last decade, the frequency of emergency room (ER) visits for pediatric psychiatric disorders has increased in the most western countries. Although data available in France is scarce, a similar trend was observed concerning violent or runaway youth. There is no medical consensus on the status and care management of

disruptive behavior (DB) in children and adolescents in ER. Seclusion and physical restraint are often requested to treat violence. With a blur lawful framework for minors, such coercive measures raise ethical issues while contradicting the idea of the patients' autonomy and well-being. Moreover, consulting in the ER for such situations could lead to an inappropriate use of the healthcare system, a poor assessment of associated psychiatric disorders or co-morbidities and an underestimation of suicide risk. Thus, the ER visit for a disruptive child or adolescent is characterized by its uncertainty. It represents a situation of heterogeneity in care management as well as a stake of social exclusion and of dangerous behavior.

The study aims to:

- analyze these uncertainties by presenting a multidisciplinary and integrative research methodology through combining clinical evidence and social sciences comprehension;

- to implement a cohort to describe children and adolescents admitted to the ER for DB (aggressiveness, violence, fugue or theft), their care management and their social and clinical outcome;

- to pool these clinical data with an ethnographic fieldwork focused on DB as a “trouble” experienced by various professionals in the ER. We will focus our presentation on these methodological considerations.

³ University of Udine, Dependency Department S.S.3, Trieste, Italy

* Corresponding author.

Introduction A collaboration between the Child and Adolescent Unit 2 (Badof-2) and Community Mental Health 2 (CMHC-2) started several years ago in order to have a joint take in charge of under 25 people presenting needs to either one of the services. A major focus has been put, in this period, on early psychotic onset.

Objectives The impact of schizophrenia and other psychotic disorders on daily life has been very well studied in clinical populations and in general ones, leaving some gaps on which are more heavily involved in the resulting disability. In this study, we have used the HoNOS scale, in the Italian validated version, in order to evaluate the single items.

Methods We have enrolled all the under-30 people taken in charge by the two aforementioned services in the period 2013–2016 with a ICD-10 F20–F29 diagnosis, dividing them in two subgroups ('13–'14 and '15–'16) in order to find if there was an impact of the prolonged time of take in charge. A HoNOS evaluation has been submitted to all the 21 people found.

Results HoNOS scores of the first subgroup are generally lower than the ones of the second subgroup (median: 6 vs. 16.5). Self-harmness, cognitive disorders and post-psychotic depression have a heavier impact in daily life than the classic positive and negative symptomatology. Focusing on psychosocial recovery programs, this area has been partly marginally affected.

Conclusions The two subgroups show different HoNOS scores, with lower ones in the '13–'14 group. More studies on general population and covariates should be conducted.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Association of adolescent symptoms of depression and anxiety with daily smoking and nicotine dependence in a sample of Tunisian teenagers

L. Ghanmi^{1,*}, S. Elleuch¹, M. Daoud¹, K. Zitoun¹, L. Zouari², M. Maalej²

¹ Regional Hospital of Gabes, Psychiatry, Gabes, Tunisia

² University Hospital Hedi Chaker, Psychiatry "C", Sfax, Tunisia

* Corresponding author.

Aims To examine the association of adolescent depression and anxiety symptoms with daily smoking and nicotine dependence in Tunisians teenagers.

Design A cross-sectional study including teenagers ($n = 162$) from two colleges located in Gabes (south of Tunisia) and used a self-administered anonymous questionnaire. Adolescent depression and anxiety symptoms were assessed using the Hospital Anxiety and Depression scale translated and validated in Tunisia. adolescent tobacco use was defined as: daily use (6 or 7 days per week) and the loss of autonomy over tobacco use was evaluated with the Hooked on Nicotine Checklist (HONC).

Findings The prevalence of smoking was 61.7%. It was 92% for boys and 8% for girls. In our sample, 30.7% of teenagers used manufactured cigarettes and chicha; 93.8% of daily smokers had already lost control of their smoking. Their average score the HONC was 5.5 (gap deviation 2.4). Of these, 61.3% had a score greater than or equal to 5. Rates of anxiety and depression were respectively 43% and 20%. Nicotine-dependent adolescents were significantly more anxious than non-dependent: 68.3% vs. 48.7% ($P = 0.04$). We do not note significant differences between depressed teenagers and adolescents without depression, regarding nicotine dependence.

Conclusions Smoking is frequent among teenagers in Gabes. Adolescent smokers with anxiety symptoms are at increased risk for nicotine dependence. These results incite to pursue work that takes account of the specific diagnosis and treatment of tobacco dependence among adolescents, especially when psychiatric comorbidity makes smoking cessation more difficult.

Efficacy of romantic and sexual psycho-educational training for adolescent with high-functioning autism spectrum disorder: A pilot study

G. Giovagnoli^{1,*}, G. Mossolani², E. Napoli¹, M. Pontillo¹, S. Vicari¹, L. Mazzone¹

¹ Children Hospital Bambino Gesù, Child Neuropsychiatry, Roma, Italy

² Istituto ReTe, Child Neuropsychiatry, Rome, Italy

* Corresponding author.

Introduction Romantic and sexual functioning in individuals with autism spectrum disorder (ASD) are understudied. Recent findings evidenced that adolescents and adults with present romantic and sexual behaviors comparable with their neurotypical peers. However, it is worth to note that dysfunctional and inappropriate romantic and sexual behaviors are often described in this population.

Objectives To investigate efficacy of a psycho-educational training in a small group of adolescent with high-functioning ASD (HFA, $QI > 70$).

Methods Six adolescents (all males, range age 14–16 years) have been evaluated before (T0) and after (T1) a 10-session sexual and

romantic psycho-educational structured group training, of 90' each session. Clinical evaluation included parent-report questionnaires, as SBS for sexual behaviors and CBCL for behavioral problems, and a self-report questionnaire for sexual behaviors, called SESAMO. Moreover, autistic symptoms were investigated with ADOS-2 at T0.

Results Preliminary analysis revealed a statistically significant differences between T0 and T1 in sexual education ($P = 0.02$) and frequency of dysfunctional sexual behaviors ($P = 0.02$) of SBS and in sexual expectations about the partner in SESAMO ($P = 0.04$). No differences were found in CBCL.

Conclusion Preliminary results showed an improvement of romantic and sexual functioning in adolescent boys with HFA, as reported by either parents and adolescents, after participating to a structured psycho-educational training. More sexual education and information, less inappropriate sexual behaviors and more-appropriate expectations about potential partner were reported at the end of the training. These results should be confirmed in studies including larger ASD and control sample.

Attention deficit hyperactivity disorder (ADHD) and borderline personality disorder (BPD) – intersections systematic review

C. Gomes Cano^{1,*}, S. Pires¹, A.C. Serrano²

¹ Hospital Dona Estefania, Woman, Child and Adolescent Department, Lisboa, Portugal

² Hospital Garcia de Orta, Child and Adolescent Psychiatry Unit, Pediatric Department, Almada, Portugal

* Corresponding author.

Given the well-known overlap of symptoms and diagnosis criteria between attention deficit and hyperactivity disorder (ADHD) and borderline personality disorder (BPD), recent studies have been made in this mental health research field. It is frequently observed that adults with a BPD diagnosis show a history of childhood ADHD symptoms, as well as a diagnosis for both diseases as adults. Even though many hypotheses have been presented, the nature of the relation between these two conditions is yet to be established. Thus, the authors consider the revision of the existing studies concerning how ADHD and BPD are related to be pertinent.

PUBMED was used as a research source, with the search terms attention deficit and hyperactivity disorder and borderline personality disorder. Thirteen studies showing different possibilities and association mechanisms between ADHD and BPD were eligible for revision. All the studies have shown a statistical association between both diseases.

The data mostly support the hypotheses that the two perturbations correspond to the same disease in different stages of evolution; that both are different diseases sharing a common etymological basis; that both perturbations are synergic, mutually powering each other while in comorbidity or that childhood ADHD may be a precursor to BPD during adolescence/adulthood.

The necessity for more studies becomes evident, namely about the influence of the precocious treatment for ADHD and the development of BPD in the future and other potential factors that may be involved in this association.

¹ U.G.C. Salud Mental Almeria, UHSM Torrecardenas, Almeria, Spain

² U.G.C. Salud Mental Almeria, Almeria, Spain

³ Almeria, Spain

* Corresponding author.

Introduction There is a higher incidence of borderline personality disorder (BPD) in families and offspring of people with the disorder, suggesting that both genetic and environmental factors are vulnerable to the condition that is passed from generation to generation.

Objectives Identify the parenting strategies used by these mothers as potential targets for psychological intervention.

Method Literature review of the scientific literature.

Results The literature shows that mothers with BPD often have very characteristic parenting practices and that they are conditioned by what is inherent to BPD – oscillations between a search for excessive control of the other person for fear of abandonment and neglect behaviors, attachment insecure or disorganized. They are between extremes of over-involvement and lack of involvement with the child, that is, mothers who show themselves in some cold, avoidant and rejecting moments and in others that are excessively demanding, invasive and over-involved with the child, consistently denoting a pattern. Of relationship that goes from one end to the other.

Conclusions Attachment-based interventions work through corrective experiences in the therapeutic relationship, work on their attachment style, giving the mother an opportunity to reflect on her own childhood experiences with her caregivers and how they led her to have an insecure or disorganized attachment, while being encouraged to connect these reflections with your current experiences with your child.

Introduction Autistic children could not organize their social life direction and understanding and interpreting other sensation and only achieve so many information by looking others and instinct for creating the best space for achieving success.

Objective The present study was designed to evaluate the efficacy of a multi-dimensional training program, using a combination of TICH and ABA on improving the behavior of autistic children in the city of Karaj.

Method The population in this study was all autistic students in a boys exceptional children school in city of Karaj. All participants ($n = 16$) were randomly assigned in two groups, experimental group ($n = 8$), and control group ($n = 8$). This research was carried out experimentally, and multi-dimensional training program was carried out on experimental group in the context of 12 training session for 2 months and two-hour sessions per week. During this time, the

control group did not receive any training. In order to collect data the Autism Diagnostic Inventory that was proven its validity and reliability has been used.

The collected data were analyzed with co-variance method.

Result The results showed that the multi-dimensional training program had significant influence on social and verbal communication skills and the reduction of stereotyped behaviors in autistic children.

Conclusion Therefore, we can plan a multi-dimensional approach as a comprehensive training program for this group of children and used it weekly as an independent course in autistic children academic schedule.

¹ University of Oslo, Norwegian Center for Addiction Research, Oslo, Norway

² Norwegian Institute of Public Health, Mental Health, Oslo, Norway

³ Sykehuset Innlandet, Norwegian National Advisory Unit on Concurrent Substance Abuse and Mental Health Disorders, Hamar, Norway

* Corresponding author.

Introduction Sleep problems are common in infancy. Some infants are prescribed sleep-inducing drugs even if not approved for the age group. Poor sleep as toddler is a risk factor for development of behavioral problems in childhood. It is unknown if this is true also for attention deficit and hyperactivity disorder (ADHD).

Objectives To evaluate two sources of information on toddler drug use (mother-reported questionnaire-data and prescription database for hypnotic drugs for children aged 0–18 months) and see if these predict receiving a later diagnosis of ADHD.

Aims Are sleeping problems as measured by the use of hypnotics in toddlers a risk factor for ADHD?

Methods Prescription database information data was collected for 47,413 children participating in the Norwegian Mother and Child Cohort, where mothers report on toddler drug use. These two datasets were used as predictors of diagnoses of ADHD as seen in the Norwegian Patients Registry in a 7-year follow up period.

Results Agreement between mother-reported drug use and hypnotics use as measured was less than 50% for all hypnotics (min 19% and max 48%). The two datasets will be further used to investigate the relationship between toddler drug use and a later childhood diagnosis of ADHD.

Conclusions Considering the low to moderate agreement between mother-reported survey data and data from prescription databases it is of value to use both data sources in a study looking at the predictive value of sleeping problems and hypnotics use in toddlers on later development of ADHD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Sluggish cognitive tempo symptoms and psychosocial well-being in adolescents – an epidemiological study in the Northern Finland Birth Cohort 1986

T. Hurtig*, J. Veijola

University of Oulu, Department of Psychiatry, Oulu, Finland

* Corresponding author.

Introduction The investigation of sluggish cognitive tempo (SCT) concept has renewed interest in recent years. Apart from previous studies linking SCT items to ADHD, current research now shows further evidence for the relationship between SCT items and impairment in several domains. Despite it is not a clinical entity, SCT items are often seen in clinical child and adolescent psychiatric populations and, thus, further investigation of these symptoms is clearly needed both in clinical and in community samples.

Objectives Our aim was to investigate the relations between SCT items and psychiatric symptoms, as well as psychosocial and academic functioning in a large general population sample of adolescents.

Methods Fifteen-year old adolescents from the Northern Finland Birth Cohort 1986 ($n = 9432$) completed a postal questionnaire on their health and well-being with a participation rate of 80%. The questionnaire included the Youth Self Report (YSR) which has the following SCT items: I feel confused or in a fog, I daydream a lot, and, I don't have much energy, as well as items constructing the subscales depressed/anxious, withdrawn, somatic complains, social problems, thought problems, attention problems, rule-breaking behavior, and aggressive behavior.

Preliminary results Around 8% of adolescents rated themselves above the 90% cut-off in the sum score of SCT items. They also reported more symptoms in all YSR subscales, lower grade marks in academic field, less friends, and lower life satisfaction than adolescents scoring below the 90% cut-off.

Conclusion SCT may relate to various psychiatric problems and reduced psychosocial well-being.

Disclosure of interest The authors have not supplied their declaration of competing interest.

² "Iuliu Hatieganu" University of Medicine and Pharmacy Cluj-Napoca, Neuroscience Department, Psychiatry and Child and Adolescent Psychiatry Compartment, Cluj-Napoca, Romania

* Corresponding author.

Introduction The clinical practice and available literature attest the presence of affective symptoms in psychosis and affective disorders with psychotic elements, allowing their conceptualization as entities of the same nosologic spectrum.

Objective The description of a clinical picture that is part of the aforementioned pathology, installed under a treatment that has indication in the spectrum, which leads to supporting different pathophysiological mechanisms of those pathologies.

Aim Presentation of an atypical onset of a manic episode in adolescence.

Method At the age of 14, a male adolescent had an acute psychotic episode, in complete remission after three months of treatment with risperidone. The antipsychotic treatment continued for seven months, when the adolescent had a decompensation consisting in a manic episode.

Results Considering the mode of onset of the manic episode, we have assumed a lack of compliance with the antipsychotic medication. The mother denies this possibility. We have continued the treatment with risperidone, which had no effect over the manic clinical picture, and we added valproic acid, failing to alleviate the symptoms. The clinical picture improved, with complete remission, under treatment with aripiprazole and valproic acid. After a month in which he refused to take the medication, the patient had another decompensation in the form of a manic episode with psychotic symptoms. This time we have decided to start long-acting injectable antipsychotic medication.

Conclusion Through this case study, the authors wish to bring into notice the surprises that the clinical practice still offers and the necessity to research the underlining pathophysiological aspects of the disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Determining the relation between the internet addiction in Turkish secondary school students and the perceived family support

I. Işık^{1,*}, G. Ergün²

¹ Yeditepe University, Health Sciences Faculty, Nursing Department, Istanbul, Turkey

² Mehmet Akif Ersoy University, Health Vocational High School, Emergency and Disaster Management Department, Burdur, Turkey

* Corresponding author.

Objectives The purpose of this study is to determine the relation between the internet addiction levels of secondary school students and the perceived family support.

Methods The study was conducted in the cross-sectional and descriptive design, and the data were collected from 3391 students who were studying at 5th and 7th grades at 23 secondary schools in the city of Burdur and its central villages. The Personal Information Form, the Internet Addiction Scale, and the Social Support Received from the Family Scale were used to collect the data. The data were collected between the dates 15.11.2013 and 15.01.2014. After the necessary explanations were made to the students, the informed

consent form were sent to their parents/legal guardians, and the students who returned these forms were included in the study. The numbers, percentages, average values, and standard deviation, which are among the descriptive statistical methods, were used in evaluating the data. The Pearson correlation and regression analysis were applied between the continuous variables of the study.

Results It was observed in the study that 4.6% of the students had internet addiction at pathological level. The factors that influenced the internet addiction were determined as the social support received from the family, being male, low school success, weekly allowance being high, studying at senior grades, and going online frequently.

Conclusions When the study results are analyzed it is observed that the internet addiction in secondary school students in our country is at a rate that has to be taken seriously.

The screening of the risk of autism spectrum disorders in children aged 16–24 months in Russia, 2015

M. Ivanov^{1,*}, N. Simashkova¹, G. Kozlovskaya¹, E. Makushkin²

¹ Federal State Budgetary Scientific Institution “Mental Health Research Center”, Department of Child Psychiatry, Moscow, Russia

² Federal State Budgetary Institution “Federal Medical Research Center of Psychiatry and Narcology of V.P. Serbsky” of the Russian Ministry of Health of the Russian Federation, Administration, Moscow, Russia

* Corresponding author.

Introduction Improving the mental health diagnosis in young children is the high-priority problem in reducing the rate of child disability due to mental illnesses. In 2015, the Ministry of Healthcare (Russia) introduced the pilot project – the total screening of the paediatric population at an early age, detecting autism spectrum disorders (ASD) risk group.

Objectives To determine the broad range of mental disorders: from minor borderline states (states of risk) to serious mental disorders, with an emphasis on determination of ASD in children aged 16–24 months in general population.

Methods The survey was conducted by the total screening in primary health care institutions (in the three largest regions of Russia: Volgograd, Novosibirsk, Chelyabinsk regions). The screening tool: checklist for parents aimed at detection of risk of occurrence of ASD in early children, for screening in general population.

Results and conclusions During 2015, 34,770 parents of children aged 16–24 were questioned. Of these 4102 children or 11.8% (118:1000) formed the risk group in ASD. By the risk group in ASD predisposition (diathesis) is understood, that does not correspond fully to the clinical criteria of illness. This state of predisposition may last for several years and pass either to illness or to health.

The part of the children of the risk group in ASD were consulted by psychiatrist on a voluntary basis (2774 cases). Fifteen children (0.4:1000) were diagnosed with prominent clinical disorders in ICD-10 (F84). This prevalence rate cannot be extrapolated on the general population of the children at the considered age.

Disclosure of interest The authors have not supplied their declaration of competing interest.

U. Jain

SMS Medical College, Psychiatry, Jaipur, India

Background Disruptive mood dysregulation disorders (DMDD) is new to DSM-5 and represents children with rage episodes. Medical treatment is critical but few randomized trials. DMDD may be a replacement for the diagnosis of Bipolar Disorder noted in DSM-IV with a heavy use of atypical neuroleptics. DMDD reflects a more moderate treatment of these symptoms.

Method Telepsychiatry referrals 6–9 year old children randomized into $n = 12 =$ group A (11 males/1 female), $n = 13 =$ group B (11 males/2 females). ANOVA not significant (NS) in age and gender. Group A received guanfacine (GUA) titrated to weight between 3–4 mg. Both groups received behavior support. Group B did not receive medications. Analysis by *t*-test comparison.

Results Group A showed significant improvement in frequency but not in intensity of rage episodes ($P < 0.05$). Major side effects include sedation and gastric irritation. Dropouts from original sample of 22 per group were based on inability to titrate, cost of drug, inability to swallow pills, worsening of symptoms with addition of an atypical neuroleptic.

Conclusion GUA is a possible treatment for DMDD but there are limitations requiring further study. Group B did show improvement reflecting the utility of behavioral strategies (future studies require control groups) but GUA may provide a useful alternative to neuroleptics. Cardiovascular issues were not a problem and were assessed. Future studies are warranted.

Telepsychiatry: The new reality of psychiatry in the future

U. Jain

SMS Medical College, Psychiatry, Jaipur, India

Background Do we need to work from offices in psychiatry? The clinical interface has been debated particularly in child and adolescent psychiatry with continued beliefs related to the differences in therapeutic alliance when compared to face-to-face practice. That literature clearly shows that telepsychiatry is equal in its therapeutic effects. But not much has been written about the other advantages of telepsychiatry, which may be intuitive but needs to be documented.

Methodology The University of Toronto Telepsychiatry Program is the largest in the world with over 60 psychiatrists and 1400 sites. This is an anecdotal review of 25 years of practice using this medium outlining the advantages (ADV) and disadvantages (DADV) to this medium.

Results ADV: convenience from home, complete access to hospital files, physician safety during sessions, able to see multiple sites and include multisystem professionals including schools, cost effective (when compared to outreach psychiatry), simplicity of connection with minimal interference. DADV: novelty to client, quality of video to pick up very subtle nonverbal information, technical support required, capital cost to set up, mental health biases to technology.

Conclusion This technology is evolving. It is essential physicians understand the issues whether it be privacy, cost, utility and clinical application. The long-term impact will likely affect future practice and allow resource sensitive care to outlying areas with the ability

to impact a country's mental health significantly. Health economic data is required for future research.

Yes we can – Positive CAMHS

P. Jansen

Yes We Can Youth Clinic, International Relations, Eindhoven, The Netherlands

Yes We Can Youth Clinics has fundamentally innovated (mental) health care for children and adolescents just by taking a different approach: the force of Positive Health!

The WHO definition of Health, adopted in 1948 and since then never amended, has become obsolete: "Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity."

A new, more positive definition ought to replace the obsolete.

"The ability to adapt and self-manage physical, mental and social well-being challenges."

Different approach WHO.

Health care is to be claimed unlimitedly, making sure you get better, free from symptoms, against any price, something you undergo and releases you from the responsibility to self-manage and recover.

YES WE CAN.

Care appealing to personal strength and possibilities. Care that also demands commitment, not a lack thereof. Care that apart from physical/mental functioning also deals with a spiritual dimension within a personal context. Care that deals with purpose (life goals) for both the patient and the caretaker.

Conclusion Yes We Can and Positive Health has been very successful:

- perfect climate for recovery: e.g. role models, positive group dynamics, expert experience, no coercion or compulsion, structured healthy program;
- focus on strength hand abilities, coping skills, learn what is important, moral, values;
- system oriented: family therapy is mandatory;
- after-care (helping back to school/work);
- be Aware: old fellows help with prevention by visiting various schools.

Illustration Vision of Yes We Can and life story of a fellow.

Teenagers with addictive behaviour: Characteristics of the addiction and the psychiatric comorbidities

J. Jihene^{1,*}, M. Olfa¹, B.H. Ahmed², Z. Haifa¹

¹ Razi Hospital, the Outpatient Service of the Hospital Razi, Mannouba, Tunisia

² Lausanne University Hospital, Psychiatry, Lausanne, Switzerland

* Corresponding author.

Introduction Addiction at a young age constitute a problem of public health. Adolescence is a period at risk for the addicting conducts.

Objectives To establish the characteristics of the addiction and the psychiatric comorbidities.

Methods We led a retrospective descriptive study which concerned 62 teenagers, having addicting conducts, followed in the outpatient clinic of the hospital Razi between January, 2013 and December, 2014.

Results Tobacco is the most consumed product with 90,3% of users, followed by the alcohol (59.7%).

Fifty percent consumed the cannabis.

Benzodiazepin, Trihexyphenidyl chlorhydrate, buprenorphin with high dosage and the organic solvents were raised respectively to about 14.5%, 22.6%, 12.9% and 14.5% of the patients.

The average age of initiation for tobacco was 12 years.

The most frequent motive for consultation was behaviour disorders (37.1%).

Among our patients, 43.5% had psychiatric family history, 11.3% had undergone sexual abuse during their childhood, 17.7% had histories of suicide attempts.

The found diagnoses were the dependence in a substance (25.8%), followed by the major depressive episode (14.5%), the adjustment disorder with depressed mood (11.3%) and the bipolar disorder (8.1%).

Seventeen percent of them had personality traits who would evoke the borderline personality and 11.3% antisocial personality.

Conclusion It is essential to diagnose and to take care of the teenagers having addicting conducts, as early as possible, to avoid transition to a chronic state in the adulthood.

6-months follow up of lisdexanfetamine in adolescent with attention deficit hyperactivity disorder comorbid with severe conduct disorder

S. Otero Cuesta¹, M. Juncal Ruiz^{2,*}, M.J. Gómez Cancio³, M. De las Heras³

¹ Hospital Universitario Marqués de Valdecilla, Child and Adolescent Psychiatry Unit, Santander, Spain

² Hospital Universitario Marqués de Valdecilla, Psychiatry, Santander, Spain

³ Centro Terapeutico de Menores CAEM Valle de Cayon, Psychology, Argomilla Cantabria, Spain

* Corresponding author.

Introduction Adolescents with conduct disorders (CD) often associate symptoms of executive dysfunction and developmental history of attention deficit hyperactivity disorder (ADHD). There is high-quality evidence that psychostimulants have a moderate-to-large effect on conduct problems in youth with ADHD. Lisdexanfetamine (LXD) reduces impulsivity and others ADHD symptoms, has better daylong coverage and less abuse potential than others stimulants.

Aims To evaluate the efficacy of lisdexanfetamine associated to psychological and family interventions in these multi-problem cases.

Method This work presents for discussion the preliminary measures of the effectiveness and security of LXD (range between 50–70 mg, during 6 months), prescribed to seven boys, ages 15 to 17 with ADHD comorbid with severe conduct disorders. All of them were living in a Young Offender Centre, received intensive psychological and psycho-educational treatment during 6 months before and during the use of LXD. Structured clinical assessment, ADHD and Conduct Disorder Scales were performed before the onset and followed 3 and 6 months.

Results Measures of ADHD, and CD symptoms improved at 3 and 6 months comparing to basal measures. Secondary effects were well tolerated and all patients showed a good adherence to treatment except for one of them who was drop out because of increase of anxiety.

Conclusions Evidence indicates that LXD can be beneficial and well tolerate for impulsive and aggressive behaviours in teenagers

with ADHD and severe CD. Limitations are the small number of cases and those related to the controlled observation method used.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The psychological profile and the counter attitudes of encopretic children's mothers: A Tunisian study

W. Kammoun¹, A. Walha¹, I. Hadjkacem^{1,*}, K. Baccouche¹, H. Chaari², H. Ayadi¹, Y. Moalla¹, F. Ghrabi¹

¹ Hédi Chaker University Hospital, Child and Adolescent Psychiatry, Sfax, Tunisia

² Faculty of Medicine, Faculty of Medicine, Sfax, Tunisia

* Corresponding author.

Introduction Persistent encopresis is part of a fairly specific pathologic complex including personality, and familial factors. To a very large extent, interest in encopresis issues has revolved around the mother–child relationship.

Objectives In this study, we aimed to assess the psychological profile and the counter attitudes of encopretic children's mothers.

Methods We led a retrospective and descriptive study carrying on 91 medical records of children with encopresis, followed in the outpatient child psychiatry department of the Hédi Chaker university hospital of Sfax over a period of seven years, going from January 1st, 2000 till December 31st, 2006.

Results In our study, emotional deprivation was noted in 62.2% of cases. Besides, repeated separations from mothers were noted in 26.4% of cases with 2.2% cases of prolonged separations. Our study also revealed that 19.8% of mothers have obsessive personality traits while 14% have rather anxious traits. Furthermore, 6.6% of encopretic children's mothers were found to have anxiety-depressive spectrum disorders according to the DSM-IV-TR. Mothers' intolerance towards encopresis was estimated at 53.3%. This intolerance was mainly reflected in physical punishment, depreciation, blame and humiliation. Toilet training was rigid in more than half of cases (62.2%).

Conclusion Childhood encopresis can be viewed as a result of a maternal-child conflict. In fact, the mother–child relationship appears to be directly involved in the genesis of encopresis. Nevertheless, the role of the own child neurodevelopmental state in response to the family system should not be ignored.

The synergistic relationship between perceived autonomy and environmental factors in adolescents with prosocial behaviour

W. Kammoun^{1,*}, N. Charfi², J. Ben Thabet², M. Mâalej Bouali², N. Zouari², L. Zouari², M. Mâalej²

¹ Hédi Chaker University Hospital, Child and Adolescent Psychiatry, Sfax, Tunisia

² Hédi Chaker University Hospital, Psychiatry, Sfax, Tunisia

* Corresponding author.

Introduction Perceived autonomy (PA) can be considered as the key mediating variable in promoting intrinsic motivation. Therefore, an environment that encourages autonomy increases intrinsic motivation and leads to continuance intention.

Objectives The main purpose of this study was to assess the social conditions which give rise to autonomous forms of motivation.

Methods We led a transversal study, over four months, from June until September 2016. It included 90 adolescents aged 14–20 years and members of voluntary association in Sfax (Tunisia). PA was assessed using the “perceived autonomy in life domains” (PALD) for the life spheres of leisure, interpersonal relationships, school, and general domains.

Results The average age of participants was 16 (14 to 20 years). The sample was female-dominated (53%). All participants were secondary school pupils. Almost 70% were from a high socioeconomic level and over 60% had parents' high level of education.

The mean scores of PA ranged from 117 (SD = 4.5) in general domain to 15 (SD = 4.5) in school domain.

There was a significant correlation between PA and parents' level of education ($P=0.01$), parental relationship ($P=0.01$), level of family communication ($P=0.00$), giving compliments ($P=0.01$) and rights in decision-making ($P=0.05$). The other factors that significantly enhance PA were having a good network of friends ($P=0.01$) and having sports and extracurricular activities ($P=0.03$).

Conclusion The present findings provide additional support for the synergistic relationship between family dynamics and family relationship perceptions and PA, and emphasize the role of parents to encourage autonomy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Social and family characteristics of children with stuttering in Tunisia

K. Baccouche¹, A. Walha¹, I. Hadjkacem^{1,*}, W. Kammoun¹, I. Hariz², H. Ayadi¹, Y. Moalla¹, F. Ghrabi¹

¹ Hédi Chaker University Hospital, Child and Adolescent Psychiatry, Sfax, Tunisia

² Faculty of Medicine, Sfax, Tunisia

* Corresponding author.

Introduction Stuttering constitutes for children a psychological and social disability, in which the environmental context plays an important role in the installation, stabilization and aggravation or attenuation.

Objective Our study aims to describe the socio-familial characteristics of children with stuttering.

Patients and methods This is a descriptive and analytical-retrospective study carried out on 80 children with stuttering and had been followed-up in the child psychiatry department of UMC Hédi Chaker Sfax (Tunisia) for more than 3 years (January 2012 to 31 December 2013).

Results In our study, the prevalence of stuttering in child psychiatry consultation department of Sfax is 4%. Most of the patients were either the youngest (36.25% of cases) or seniors (35% of cases). Personal history of speech disorder had been reported in 8 children (10% of cases). Family history of speech disorder was reported in 33.75% of cases. These disorders had been kind of stuttering in 60.66% of cases, speech delay in 18.52% of cases and sound speech disorder in 7.41% of cases.

The parent–child relationship is marked by a parental rigidity in 18.6% of cases. The existence of triggering factor was noted in 37.5% of cases: traumatic situation (30% of cases), the birth of a younger sibling (22% case).

Conclusion The emergence and evolution of stuttering depend on predisposing, precipitating and chronicising factors. Identifying these factors and adopting a favorable parental attitude contribute to the fight against stuttering in children and, at least, avoid aggravation and chronicity of this disorder.

EV0128

The identifying of depression' risk in students with impaired hearing and vision

I. Kupriyanova

Mental Health Research Institute SB RAMSci, Department of Border States, Tomsk, Russia

Introduction The depressive states in adolescents have their specificity: they are often poorly understood by the children themselves as reduced mood and can be expressed in the growth of aggressive behaviour, stubbornness, oppositional behavior, care. Even the pre-clinical level of depression can have a significant negative impact on the lives of adolescents.

Materials One hundred and seventy-three visually and 139 hearing impaired students of correctional boarding schools, 7–18 years old.

Methods Children's Depression Inventory (CDI) M. Kovacs, statistical (nonparametric test Mann–Whitney).

Results At 20.8% the increased and at 3.1% the high risk of depression was identified. For students with visual impairments often were characterized by significantly higher scores on a scale of "anhedonia" and "incompetence". The girls revealed significantly higher scores for total scale depression, the scale "negative mood", "interpersonal problems" and "negative self-esteem".

A comparative analysis of data, obtained by different researchers was held. There were no literature sources, which would have provided data about the level of depression of children with sensory impairments.

Conclusions Children with sensory impairments have a greater risk of developing depression in comparison with pupils of general education schools. Therefore, a screening of children in this category on the level of depression should be obligatory in addition to clinical examination. The detected data must be taken into account in psychotherapeutic and preventive measures.

Behavioral problems in Silver–Russell syndrome – Case report

K. Karher*, I. Banda

General Hospital Sombor, Department of Psychiatry, Sombor, Serbia

* Corresponding author.

Objectives The aim of this study is to present two cases of Silver–Russell Syndrome patients with behavioural problems. The male is diagnosed with ADHD, and the female shows antisocial behaviour.

Background Russell–Silver syndrome (RSS) is a rare disorder characterized by intrauterine growth retardation and postnatal growth deficiency along with a handful of common physical characteristics and a range of other symptoms.

Methods Clinical observation, tests (EEG, psychological tests – IQ scale, JEPQ, Projective techniques) and interviews with the patients and their parents and foster parents.

Results S.H. (20 years) – is opponent, aggressive, refuses every kind of cooperation with delayed mental development.

V.M. (10 years) – premature baby (born in the sixth month) in a 40 years old mother (second pregnancy); blind on right eye and very low vision on the left eye; lost both of his parents at the age of 1.6 in a car accident; had several operations and is always under some treatments. V.M. had low school performance. The foster parent noticed that he has an attention deficit. Besides, he is very aggressive verbally and physically, has low frustration tolerance, borderline intelligence.

Conclusion According to several studies that claims that patients with Silver–Russell syndrome have behavioural problems and among them, the most common are attention deficit problems; our study improves that hypothesis. Both of our patients have attention deficit problems.

EV0130

The neurocognitive development of premature infants at 5 months corrected ageS. Kiselev^{1,*}, O. Lvova², E. Suleimanova²¹ *Ural Federal University, Clinical Psychology, Ekaterinburg, Russia*² *Ural Federal University, Laboratory for Brain and Neurocognitive Development, Ekaterinburg, Russia*

* Corresponding author.

It is known that prematurity is a risk for neurodevelopmental disorders, particularly for ADHD and autism. However, the impact of prematurity on neurocognitive functions in the early stages of development is not investigated thoroughly.

The aim of research was to reveal the differences in neurocognitive development in premature infants and full-term infants at 5 months age.

The participants were 26 premature infants and 26 gender matched healthy full-term infants. The gestational age of preterm infants was between 29 and 35 weeks.

The Bayley Scales of Infant Development were used to evaluate the neurocognitive abilities in infants.

The one-way ANOVA has revealed that premature infants performed significantly ($P \leq 0.05$) more poorly than the full-term infants on cognitive scale, receptive language and gross motor. No significant differences were found between preterm and full-term infants on expressive language and fine motor.

Two-way ANOVA has revealed no significant ($P \leq 0.05$) differences between female premature infants and full-term female infants on gross motor in comparison to male infants.

It was proposed that the prematurity has specific (not global) negative effect on neurocognitive development at 5 months age with gender effect on development of gross motor.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0131

Visual delayed memory in ADHD children

S. Kiselev

Ural Federal University, Clinical Psychology, Ekaterinburg, Russia

It was shown that children with ADHD have deficit in cognitive abilities. Particularly, in our previous research we have revealed that children with ADHD have weakness have deficit in memory for faces and for names in delayed recall condition.

The goal of this research was to examine the hypothesis that children with ADHD have weakness in visual memory in delayed recall condition.

The experimental group included 19 children with ADHD at age 6–7 years. The control group included 19 typically developing children. The children from experimental and control group were matched for IQ, gender and age.

Children from both groups were assessed with visual memory subtest from Luria's neuropsychological assessment battery. This subtest is designed to assess the ability to perform the visual

memory for objects in immediate and delayed conditions. Two-way ANOVA was used to reveal group differences in reproducing the objects in two conditions.

We have not revealed significant differences between children from experimental and control group in the reproducing the objects in immediate condition. However, the interaction of condition type and group was significant ($P \leq 0.05$). ADHD children were less successful in reproducing the objects in delayed condition.

In view of the obtained results, it can be assumed that children with ADHD have specific deficit in memory domain – weakness in delayed memory.

Disclosure of interest The author has not supplied his declaration of competing interest.

Acknowledgements The research was supported by Act 211 Government of the Russian Federation, agreement No. 02.A03.21.0006, by Russian Foundation for Basic Research, grant No. 15-06-06491A.

Child obsessive-compulsive disorder presenting with catatonic-like features: Case presentation

V. Kodra (Resident in Child, Adolescent Psychiatry)^{1,*}, V. Alikaj², B. Allkoja², B. Zenelaj (Resident in Child, Adolescent Psychiatry)¹, D. Sanxhaku (Resident in Child, Adolescent Psychiatry)³

¹ Psychiatry, Durres, Albania

² Psychiatry, Child and Adolescent, Tirana, Albania

³ Psychiatry, Tirana, Albania

* Corresponding author.

Introduction Although catatonia was conceptualized as a subtype of schizophrenia, it is now recognized to occur most commonly in the course of other psychiatric disorders, in drug-induced disorders [1] or neurologic conditions [2]. Catatonia is rarely seen together with OCD and there are a limited number of case reports in the literature [3,4].

Objective We describe the case of a 12 year boy who presented in our clinic with mutism, negativism, immobility, social withdrawn, rigid posture, refusal to eat.

Method We performed a thorough psychiatric diagnostic assessment of the child as well as laboratory tests and MRI of the brain.

Results The child's first symptoms appeared 2 years ago: initially the child became socially withdrawn, spent most of time at his room, and became preoccupied with rituals of hand washing, walking back and forth, preoccupations with food contamination, became aggressive if someone would interrupt what he was doing, stopped going at school, and stopped calling his parents "mother" or "father". Brain MRI showed lateral ventricular asymmetry and suboccipital cyst.

Conclusions The child was put on therapy with lorazepam and sertraline. His obsessive-compulsive symptoms improved, and the apparent catatonic like features resolved and did not return over follow-up.

Discussion Catatonia is not uncommon among children and adolescents, and the relationship between OCD and catatonia is still misunderstood, but it may be an indicator of the severity of the OCD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clinical and psychopathological aspect of electrophysiological abnormalities in adolescents with behavior disorders

I. Leshchyna^{1,*}, T. Mozgova¹, S. Fedorchenko²

¹ Kharkiv National Medical University, Psychiatry, Narcology and Medical Psychology, Kharkiv, Ukraine

² Kharkiv Medical Academy of Postgraduate Education, Neuropathology and Neurosurgery, Kharkiv, Ukraine

* Corresponding author.

Medical and social significance of behavioral disorders in adolescents and their consequences makes the relevance of the study of clinical manifestations and causes the need for early preventive intervention.

Aim Studying the role of neurophysiological disorders in the formation of behavior disorders in adolescents.

Two hundred and two adolescents aged 11–15 years with behavior disorders were observed. The diagnostic methods included electrophysiological, clinical psychopathological and statistical methods. In the structure of behavioral disorders, psychopathological syndromes in adolescents have been identified: psychopathic ($n=106$), asthenoneurotic ($n=50$), asthenoabulic ($n=26$) and anxiety-depressive ($n=20$).

As a result, it was found that high seizure activity commonly observed in adolescents with anxiety-depressive syndrome ($66.67 \pm 10.33\%$); less frequently in adolescents with asthenoneurotic ($40.00 \pm 6.79\%$), psychopathic ($38.71 \pm 4.64\%$), asthenoabulic ($28.57 \pm 8.68\%$) syndromes.

At the same time, diffuse changes with dysregulation of the diencephalic-stem structures were observed in the majority of adolescents with psychopathic ($61.29 \pm 4.64\%$), asthenoneurotic ($60.00 \pm 6.79\%$), asthenoabulic ($57.15 \pm 9.51\%$) syndromes and much less frequently in adolescents with anxiety-depressive symptoms ($33.33 \pm 10.33\%$).

Dystonic rheoencephalography type was observed in a third of adolescents with psychopathic ($35.48 \pm 4.55\%$), asthenoneurotic ($30.00 \pm 6.35\%$) and anxiety-depressive ($33.33 \pm 10.33\%$) syndromes, while the hypertensive rheoencephalography type was prevailed in adolescents with asthenoabulic symptoms ($14.29 \pm 6.73\%$).

Liquor hypertension in adolescents with asthenoneurotic ($15.00 \pm 4.95\%$) and psychopathic ($9.67 \pm 2.81\%$) syndromes was more common.

The statistical analysis indicated that violations of bioelectric properties of the brain with high seizure activity and dysfunction of the low stem structures and disorders of cerebral hemodynamics by dystonic type are risk factors for the formation of behavioral disorders in adolescents.

Detection of neurophysiological disorders in adolescents is an informative diagnostic method of early signs of behavioral disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

The book “I conquered my fears” was created as a result of the clinical experience of the author. It is a therapeutic tale, which is valid as a resource to be used by health workers and parents so as to help children overcome their fears at bedtime.

Because experience is important for an adult so as to better reflect on the theme, the book also includes an appendix to help accordingly.

The adult is invited to express what he/she likes to hear the most and the least, when waking from a sleepless night, and is also invited to dynamically interact with the book, give answers and create hypothesis, with no fear of making mistakes.

The parents, after reading the book, refer a better stress management capacity at critical moments experienced with the children at bedtime.

² *ForAll, Desenvolvimento Pessoal e Bem-Estar, Unipessoal, Lda., Psicologia, Porto, Portugal*

* Corresponding author.

The author has devoted her life to matters relating to communication, whether in business contexts, or as a mediator, trainer and moderator.

The trilogy “Lili, do conflito à Mediação de Conflitos” aims to help create more informed citizens, starting from an early age, namely in terms of the new forms of solving conflicts.

In the first book: “Lili and the conflicts” (“Lili e os Conflitos”), we find the theme of conflicts; how to deal with them; respect for the different other; to put oneself in the place of the other.

In the second book: “Lili and Conflict Meditation” (“Lili e a Mediação de Conflitos”), we find the space created by conflict mediation so the parts in conflict can be heard; the enormous need to listen to the other; the needed empathy so as to know the reality of the other. In the third and final book: “Lili and the Conflict Mediator” (“Lili e o Mediador de Conflitos”), we explain what it is to be a conflict mediator, this “new” profession, distinguishing it from other professions which also use the word “Mediator”.

The author makes presentations of the books and its topics, bringing these issues to debate and making them known to the school environment, both to students and teachers, as well as staff and parents.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A study on adolescent suicide ideation consulting in emergency

M. Moalla^{1,*}, I. Feki¹, R. Sellami¹, A. Ktata², S. Feki¹, J. Masmoudi¹

¹ *Hédi Chaker Hospital, Psychiatry “A”, Sfax, Tunisia*

² *Manzel Bouzayen Hospital, Emergency Department, Sidi Bouzid, Tunisia*

* Corresponding author.

Introduction Suicide is one of the most leading cause of death for teenagers in the world. Suicide ideation is known risk factor for suicide completion. Suicidal adolescents rarely asked for help. The

contact with the health care system is an opportunities to screen for suicidal ideation.

Aims The aim of this study is to examine the prevalence and the risk factors of suicidal ideation among adolescents consulting in emergency.

Methods Our study was a transversal type, descriptive and analytic. It was conducted with 106 adolescents consulting in emergency for somatic complains. Each participant filled out demographic questionnaire and suicidal ideation questionnaire (SIQ). The SIQ is a self-report instrument for suicidal ideation, appropriate for adolescents. The SIQ has 30 items. The respondent is asked to choose from a 7-point continuum (6 = “Almost every day” to 0 = “I never had this thought”) to assess the frequency of that particular thought within the last month. Cut-off score for the SIQ is a sum of 41 and higher, indicating the presence of serious suicidal ideation.

Results Adolescents were aged between 12 and 19 years with an average age 16.34 ± 2.54 years; 47.2% were boys. According to the SIQ, the prevalence of suicide ideation during the last month were 14.2%.

The risk factors for suicidal ideation among Tunisian adolescents were the female gender, middle school level, low family income, parents’ divorce, parental neglect, family conflicts and previous psychiatric disorder.

Conclusion General physicians should regularly screen for suicidal thoughts in their adolescent patients with these characteristics.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Screening for depressive symptoms among adolescent consulting in emergency

M. Moalla^{1,*}, I. Feki¹, R. Sellami¹, A. Ktata², S. Feki¹, J. Masmoudi¹

¹ *Hédi Chaker Hospital, Psychiatry “A”, Sfax, Tunisia*

² *Manzel Bouzayen Hospital, Emergency Department, Sidi Bouzid, Tunisia*

* Corresponding author.

Introduction Amongst adolescents, depression is a common mental health problem. Adolescent depression is associated with distress, functional impairment and difficulties in relationships with peers and family members. Depressive symptoms, even if sub-threshold to meet diagnostic criteria for a depressive disorder, are also risk factors for these difficulties. Adolescents rarely consult for their psychological distress. Emergency departments, which are often used by adolescents in this context, constitute a privileged place to detect this suffering.

Objectives The objective of this study was to estimate the prevalence and correlates of psychological distress among adolescents seen in emergency department.

Methods Our study was a transversal type, descriptive and analytic. It was conducted with 106 adolescents consulting in emergency department. All adolescents completed a sociodemographic data and the Adolescent Depression Rating Scale (ADRS), a screening questionnaire for depression.

Results The study included 106 adolescents. All of them consult for a somatic complain and none of them goes to the emergency department for a psychiatric reason. The mean age was 16.34 ± 2.54 (12→19 years). Sex ratio (σ/φ) = 0.89. The ADRS score was considered normal (score < 4) for 54.7% of the sample ($n = 58$) and 45.3% of adolescents ($n = 48$) had depressive symptoms (score ≥ 4). Depression was significantly correlated to bad school results ($P = 10^{-3}$), tobacco use ($P = 0.014$), personal psychiatric history ($P = 10^{-3}$) and family problems ($P = 10^{-3}$).

Conclusion Depressive symptoms are frequent among adolescents. Their consultations within emergency department provide a potential opportunity for their identification and for signposting to appropriate specialist services.

Retarded sexual maturity and adolescent conflicts

M. Mohammadi

Education Organization, Physics, Tehran, Iran

Most of the educational psychologists believe that co-education can help the young people to have their sexual instincts activated so that they could release their sexual emotions easily during puberty. In contrast, Islamic educational authorities in Iran strongly insist that children arriving elementary schools must be separated and the teachers and textbooks are chosen according to their sexes. Therefore, men are teaching in boys' schools and women in girls' schools. There has been great effort to include men's pictures in boys' textbooks to prevent from the sexual arousal. As there are not enough universities in the country, the university candidates are mixed in their classes and courses. This can bring flame to the ashes of hidden sexuality and involve the students in abnormal behaviours to control or suppress them. The conflict of interaction with the opposite sex in university with that in the family setting or even society has been proved to create depression among the first year students especially those coming from small and closed environments and rural settings. The statistics of referrals to the counselling office in the university show that self-involvement to control sexual instincts have been the great concern of the students. They spend most of their time thinking about their classmates of different sexes. This paper aims to study the psychological and social outcomes of suppressed instincts for young people having entered the university and the effect on marriage.

Keywords Sex; Education; Segregation; Sexual instinct

Autism, psychosis and marfan: The Lujan–Fryns syndrome

G. Montero*, I. Alberdi

Hospital Clínico San Carlos, Servicio de Psiquiatría, Madrid, Spain

* Corresponding author.

Objectives We report the case of a 19-year-old male who was brought to our psychiatry consultation by his family for behavioural disorders and poor school performance of years of evolution.

Results We found ourselves before a tall, thin, childish, suspicious, perplex, inhibited and minimizer patient, so we sent him to our hospital for psychiatric admission, where he showed a flowery delirium of mystic, religious and megalomaniac content; complex visual and auditory hallucinatory phenomena; and where he was diagnosed of acute polymorphic psychotic disorder and autism spectrum disorder with marfanoid habit. Therefore, we suspected a Lujan–Fryns syndrome and requested genetic confirmation. Risperidone was prescribed as solo treatment, with a rapid control of the symptoms.

Conclusions Lujan–Fryns syndrome, first described in 1984, corresponds to a sequence mutation in exon 22 of med12 gene of chromosome X. It is hard to suspect and diagnose before puberty. Those affected have marfanoid habit and also other psychiatric manifestations such as autistic behaviour, mild-moderate mental retardation (there are some reported cases

with normal intelligence), language disorders, emotional instability, aggressiveness, hyperactivity, shyness which can be extreme, obsessive-compulsive disorder, isolation, delusions, visual and auditory hallucinations, and there are cases that describe schizophrenia. Its diagnosis requires adequate physical and psychopathological examination, and it is established with clinical suspicion and genetic confirmation. There are very few cases described and there is little bibliography available about Lujan–Fryns syndrome [1].

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Adolescence has significant effect on parental relationship. Group therapy in transactional analysis method is an effective method for the treatment program.

Aim Therefore, in this study, transactional analysis group therapy to improve the quality of parent–child relationship in adolescent female, were used.

Method The sample was 40 adolescence high school girls were divided randomly into an experimental group and a control group. Both groups responded to measures of parent–child relationships. Eight sessions of one and a half hours, the components of the experimental group was trained in transactional analysis. The results were analyzed using *t*-test.

Findings The results showed significant effect of transactional analysis group therapy on parent–child relationship adolescence, compared with the control group.

Results Transactional analysis in the area of parent–child relationship requires further attention.

Effectiveness of attention-shaping training in reinforcing attention and academic development and self-efficacy for primary school children with attention deficit hyperactive disorder

M. Nazer

Rafsanjan University of Medical Sciences, Psychiatry, Kerman, Iran

Introduction The present research have done with concentration on examining the impact of selected and divided attention-shaping training in reinforcing attention and the academic improvement and self-efficacy of primary school children with attention deficit-hyperactivity disorder.

Method The research method was a quasi-experimental design with per- and post-test and follow-up with control group. Sta-

tistical society contained all of the primary school children with attention deficit-hyperactivity disorder in Rafsanjan City. Forty children with attention deficit-hyperactivity disorder were chosen by the method of random sampling and randomly assigned in control and experimental groups (20 children in experimental group and 20 children in control group). At first in pretest stage used academic self-efficacy questionnaire and the software of selected and divided attention. For measurements of academic improvement were used the scores of a teacher build test mathematic and spelling. Then, experimental group take 8 sessions education of selected and divided attention-shaping Training. The data were analyzed by analysis of variance with repeated measurement test. **Results** Results of this research show that selected and divided attention training improved the amount of divided and selected attention and academical improvement of children <but it's not effective significantly on reaction time and academic self-efficacy of children with attention deficit disorder-hyperactivity. **Conclusion** Attention training can be effective to increase attention and academical achievement in children with ADHD. **Keywords** Attention training; Selected attention; Divided attention; Academic improvement; Academic self-efficacy; Attention deficit hyperactivity disorder **Disclosure of interest** The author has not supplied his declaration of competing interest.

⁵ Hospital General Villarrobledo, USM, Villarrobledo, Spain

⁶ Hospital Nuestra Señora del Perpetuo Socorro, USM, Albacete, Spain

* Corresponding author.

Introduction Actually psychiatrists around the world are treating children and adolescents (despite limited medical indications in this age group) with atypical antipsychotics at increasing rates for a range of psychiatric illnesses (schizophrenia, bipolar disorder, behavioral changes...). Over the last few years, a number of new long-term injectable treatments (ILD) have emerged, the advantages of which are found in adult (adherence, functionality, consistent blood level without daily peaks...) but we do not have enough data in minors.

Objectives Discuss utility of ILD in adolescents.

Methods We expose a case report about a 17-year-old man, when he was a child he was diagnosed with attention deficit disorder and autism spectrum disorder and also he had a story of disrupted behavioural and aggressively. After been hospitalized in our hospital we remake his clinic history and he was diagnosed with schizophrenia. Before the injectable treatment (ABILIFY MAINTENA®) this patient tried various treatments (mood stabilizers, antidepressants...) and many hospitalizations.

Results After the ILD, our patient has good functionality, he is now living with his parents and studying in the high school. He has not needed another hospitalization after the last one.

Conclusions The ILD in adolescents must be a therapeutic option in mental disease, in this group is very difficult the complementation of the treatment, it's frequent the comorbid use of substances, this population are not used to take medications... so every treatment that facility this kind of problems must be a perfect weapon

to improve their mental health and to prevent relapse and hospitalization.

³ CSM Lorca, Adults Mental Care, Lorca, Spain

⁴ CSM Leon, Psychiatry, Leon, Spain

⁵ CSM Soria, Psychiatry, Soria, Spain

* Corresponding author.

Description/clinical case A. is a 10-year-old girl of Moroccan origin appearing in pediatric specialist of A.P repeatedly by unspecific stomachache, nausea and vomiting. After several visits to the same reason for consulting an exploratory interview alone with the patient in that regard that "sometimes when calms nervous scratching the walls and eating them" is performed. The mother says intrafamily difficulties. Information reported by the patient's mother confirms next visit also providing pictures on the wall of your room is returned. Referral to child and adolescent mental health is decided.

Exploration/complementary tests There is no single test for pica. It is carried out systematic blood, biochemical (iron, zinc, lead...) to assess toxic substances and nutritional levels. Abdominal Rx. Both normal.

Diagnosis Pica (F98.3).

Differential diagnosis Ingestion of nutrients can occur in the course of other mental disorders (for example, a pervasive developmental disorder, schizophrenia), mental retardation, in the Kleine-Levin syndrome... In these cases, should only be established an additional diagnosis of pica if the feeding behavior is sufficiently severe to warrant independent clinical attention.

Conclusions Pica disorder has been studied by pediatricians, gynecologists, dermatologists, psychiatrists, psychologists, nutritionists, anthropologists, etc., which has been interpreted as a conduct disorder, food, mental illness, poverty, hunger... but really the cause it is unknown. Although morbidity and mortality is unknown and difficult to study, include poisonings, parasitosis and surgical abdomen as serious complications. Finally, like all other eating disorders, the overall management of this entity requires the coordinated intervention of various professionals.

Description of clinical case Patient 10-year-old pediatrics sent from service due to history of frequent admissions for recurrent abdominal pain. In the bypass request indicate that this is a patient of perfectionistic traits; detect dysfunctional family dynamics highlighting the rivalry in the phratry, and with an equal difficulty in the field. From 2010 to 2016, he has made more than 30 visits to hospital emergency combined intervention of psychiatry and psychology and multidisciplinary service available with a pediatric surgery and pediatrics is performed.

Exploration and complementary tests From 2011 to 2016, it has made 44 blood tests, sonograms 9 full abdomen, abdominal renal scintigraphy without significant findings.

Diagnosis F45.5 pain disorder.

Differential diagnosis Symptoms due to a medical condition. Other symptoms substance-induced mental disorders: non-specific conversion disorder, pain disorder, hypochondriasis, body dysmorphic disorder, somatization disorder, simulation, factitious disorder, medical symptoms. . .

Conclusions Psychosomatic disorders are one of the most common clinical forms of mental disorders in childhood and adolescence expression. Knowing the stages of development and operating characteristics. In clinical practice, mainly in primary care, tend to find an organic cause somatic complaints in children, so prevalence data and/or referral to specialized services vary depending on mental consulted sources is critical to understand the pathogenesis of these disorders.

Morbidity and mortality during adolescence is primarily the result of certain risk behaviors. Today, it is observed that early teens contact form with snuff, alcohol and legal drugs and not many of them have a high intake of these substances. Habits such as those mentioned on many occasions not only maintained during adolescence, but the rest of life extend causing major consequences for public health.

Objectives To know the magnitude and characteristics of the use of legal drugs (alcohol and snuff) and illegal (marijuana, cocaine, heroin, inhalants) in the – adolescent/child – population who come regularly to addictive behavior unit of a rural environment.

Material and methods Descriptive study of a sample of adolescent patients ($n = 30$) who came in the past two years to addictive behavior unit. Data collection of such patients is performed by assessing sociodemographic characteristics (age, sex, population, education level. . .), age of onset and type of use of psychoactive substances, and comorbidity of psychiatric disorders.

Results/conclusions The average age of the adolescent patient is 14.5 years (SD 1.09) with an age of onset in the consumption of toxic 13.6 years (SD 1.03). As for sex, 20% were women. The dropout among adolescents of this sample is 43.3% (SD 1.05). A complete prevalence of marijuana use (100%), and mono-consumers only 10% was observed. Seventy percent of the sample has associated psy-

chiatric disorders and 46.15% in psychiatric family history there; 38.4% up to legal problems are collected.

Non-suicidal self-injury in adolescents: A diagnostic and psychopathological approach. A case presentation

M.D. Ortega Garcia^{1,*}, V. Marti Garnica¹, S. Garcia Marin², C. Martinez Martinez³, R. Gomez Martinez³, P. Blanco del Valle⁴

¹ CSM Cartagena, Child and Adolescent Mental Health Centre, Cartagena, Spain

² CSM Lorca, Psychiatry, Lorca, Spain

³ CSM Leon, Adult Mental Health Centre, Leon, Spain

⁴ Hospital Center Virgen del Miron, Psychiatry, Soria, Spain

* Corresponding author.

Self-injurious behavior is a major public health problem. An increase in the number of self-injuring adolescents has been observed since the mid-1960s.

Description of clinical case C. is a 14 teenager who comes to a mental health center for the first time a year ago for having numerous self-injuries in the forearm. She says that she cannot avoid doing so in moments of anxiety and that, in addition, when she is hurt she calms down. Throughout the interviews, C. relates that after the death of her best friend in a traffic accident she is alone and with episodes of anxiety.

Exploration and complementary tests It is important to analyze the risk factors of self-injurious behaviors in adolescence such as:

- personal characteristic;
- psychiatric disorders;
- family characteristics;
- mass media.

Diagnosis Depressive episode (F32).

Differential diagnosis In general, self-injury is considered as a symptom or characteristic of a specific psychiatric disorder. Stereotyped self-injury is characteristic of processes of cognitive deficit of the level of severe and profound mental retardation. Compulsive self-harm involves symptomatic habits such as severe scratching of the skin or already differentiated psychiatric entities, such as trichotillomania, onicofagia or delusional parasitosis. . . Important psychotic disorder.

Conclusions Following the Task Force's criteria, in relation to probably effective therapies, it can be concluded that the therapy based on mentation for adolescents (MBT-A) is the first effective treatment for the treatment of self-harm in adolescents.

Must we fear antidepressants in adolescents?

S. Paulino*, N. Santos, A.C. Almeida

Hospital Santa Maria, Psychiatry Department, Lisboa, Portugal

* Corresponding author.

Introduction Epidemiological studies have established that teenager's prevalence rates of major depression are significant (10%). The media has given a good deal of attention to the potential risks of antidepressants and their connection to increased suicidality (especially in children and adolescents). These concerns have had a significant impact on both the prescribing of antidepressants and the parental fears about their use. It is interesting to note

that in large groups' studies of adolescents treated with selective serotonin reuptake inhibitors there have been no evidence of increased suicidal risk.

Objective Understand if there is a significant association between antidepressant treatment and suicidality in a 3-months follow-up study of the adolescent's consultation of Centro Hospitalar Lisboa Norte.

Methods Analysis of 81 adolescents with an initial diagnosis of major depression treated with an antidepressant for at least 3 months.

Results After the follow-up period there has been an improvement in sadness in 92.6% of the adolescents, a remission of death thoughts in 98.8% and an absence of suicides attempts. In 61.7%, it was necessary to introduce also an antipsychotic in a low dose and in 12.3% another antidepressant with a hypnotic effect.

Conclusion It is clear that untreated major depression carries significant suffering and disability. Although treatment with antidepressants may take several weeks before clinical improvement appear and depression may worsen in the first days, its therapeutic effect should not be underestimated even if becomes necessary to add another medication in the first days. In evaluating these kinds of concerns, we must always differentiate between media hype and scientific data.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Is bipolar over diagnosed in adolescents?

S. Paulino^{1,*}, N. Santos², A.C. Almeida², J. Gonçalves²

¹ Hospital Santa Maria, Psychiatry Department, Lisboa, Portugal

² Lisboa, Portugal

* Corresponding author.

Introduction Since the mid-1990s, the diagnosis of bipolar disorder has increased significantly: two-fold among adults, four-fold among adolescents and 40-fold among children. Mood instability is a hallmark symptom of many psychiatric disorders but does not imply necessarily a diagnosis of bipolar disorder. Misdiagnosis is not just an academic issue: mood stabilizers have significant adverse effects and expose patients to side effects that range from mild to potentially life-threatening.

Objectives Discuss the potential overestimation of bipolar diagnosis in the adolescent population through a statistical analysis of a sample from the adolescence's consultation of Centro Hospitalar Lisboa Norte.

Methods Analysis of 106 patients taking into account the initial diagnosis and the diagnostic stability over 6 months. Non-systematic review of the literature.

Results From this sample, 39.2% of the adolescents have a diagnosis of unipolar affective disorder, 0.02% of bipolar disorder and 0.1% of disruptive mood disorder. These diagnoses did not change over the follow-up period.

Conclusion It is important to try to understand the reasons of this potential discrepancy (influence of pharmaceutical company marketing, of parents' desire, of doctors' fear) to reduce controversy and confusion and to adjust treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

² University of Genoa, Department of Educational Sciences, Genoa, Italy

* Corresponding author.

Introduction In the last decade, international study attention to the problem of risk of sexual behavior in adolescents has grown. Some research has shown emotion dysregulation to be an important predictors of forbidding outcomes for example alcohol and drugs abuse or risky sexual behavior.

Objectives The aims of this study are analyze emotion dysregulation in adolescents and their belief regarding sex working of adolescents.

Methods The sample is composed by 123 participants (58 male adolescents, and 65 female adolescents, they is 14–15 years). All participants completed a self-report questionnaire, Difficulties in Emotion Regulation Scale. Them, participants responded to questions on prostitution.

Results Frequency analysis showed that 78% of participants believe that prostitution is wrong; 1.4% of adolescents believe that the voluntary prostitution is not wrong; 2.4% believe that prostitution is not wrong if it can economically help their parents; and 4.9% believe that prostitution is wrong only if the customer is an adult. Regarding emotion dysregulation, test t analysis highlights some differences between male and female. The female presents difficulties ($P=0.025$) to strategies respect male adolescents and they manifest a tendency to significative difference in impulse ($P=0.061$) and goals ($P=0.067$).

Conclusions These preliminary results show that females may experience greater difficulties to take functional strategies to regulate emotions and could risk adopting risky sexual behavior such as prostitution.

³ Institute of Public Health, Tirana, Albania

* Corresponding author.

Introduction Autism is a lifelong disability that impairs 3 main areas: communication skills, social interaction and behavioral patterns.

Objectives To investigate the repetitive behavior in autistic children 3–10 years old.

Aims Comparison of repetitive behavior between autistic children with a control group of clinically healthy children matched for age and sex.

Methods Repetitive Behavior Scale (RBS-R) questionnaire was translated, validated and provided to examine children ($n=70$) in each group.

Results Children with autism show significant behavioral problems as compared to healthy children in all subscales and the full

RBS-R. Results of the *t*-test for independent samples indicated a significant difference in mean score for the children with autism of age 3–6 year old ($M=53.1$) and for control group ($M=11.9$), $t=-13.3$, $P<0.01$. Also, the mean score of children with autism of age 7–10 year old ($M=54.9$) is significantly higher, compared to control group ($M=13.7$), $t=-12.2$, $P<0.01$.

Conclusion This comparison provides information on particular forms of repetitive behavior to further our understanding on these important symptoms.

The case of successful treatment of gender identity disorder of childhood

O. Pityk^{1,*}, V. Seliverstova²

¹ Ivano-Frankivsk National Medical University, Department of Psychiatry, Narcology and Medical Psychology, Ivano-Frankivsk, Ukraine

² Ivano-Frankivsk Regional Psychoneurological Hospital 3, Center of Psychological and Psychiatric Help to Children, Ivano-Frankivsk, Ukraine

* Corresponding author.

Gender identity disorder of childhood refers to a rather rare disorders, but according to the literature girls with the disorder in the future may become homosexual or transsexual. The necessary diagnostic criterion for gender identity disorder of childhood is the presence of a constant desire to belong (or the conviction of belonging) to the opposite sex, coupled with a strong denial of the behavior, characteristics and/or clothing specific to the registered sex. Usually the disorder is manifested in the preschool years, but for diagnosing it is necessary that it manifests before the onset of puberty. Both sexes may have a rejection of anatomical structures inherent in his own sex; however, such unusual display is rare.

Patient V. came to the appointment with psychiatrist with parents 3 years ago. During the interview reported that she starts to feel the boy at the age of 9 years. This announcement provoked outrage from parents. With the beginning of the critical days began to position herself in a male person. The patient met all diagnostic criteria for gender identity disorder of childhood. The patient underwent a course of systemic therapy combined with nootropics. Currently, patient name is the name of a female, the patient wears women's clothing, identifies herself as a woman. The patient continues to meet with a psychotherapist, is satisfied with the treatment, thoughts on sex change does not express. Thus, in the case of diagnosis of this disorder can become effective systemic therapy in combination with nootropics.

Access and participation: What factors influence the provision and utilisation of health care services by children with learning disabilities?

A. Rebowska

Tees, Esk & Wear Valley NHS Trust, Newberry Unit, Darlington, United Kingdom

Aims The aim of this literature review is to explore the range of factors that influence the degree of access to health care services by children and young people with learning disabilities.

Background Children with learning disabilities are at increased risk of a wide range of health conditions comparing with their peers.

However, recent reports by UK government as well as independent charities working with children and young people with learning disabilities demonstrated that they are at risk of poor health outcomes as a result of barriers preventing them from accessing most appropriate services.

Methods Comprehensive searches were conducted in six databases. Articles were also obtained through review of references, a search of the grey literature, and contacting experts in the field. The inclusion criteria were for studies evaluating access to healthcare services, identification and communication of health needs, organisational aspects impacting on access and utilisation, staff attitudes where they impacted on access, barriers, discrimination in patients with intellectual disabilities age 0–18. The literature search identified a sample of 36 papers. The marked heterogeneity of studies excluded conducting a meta-analysis.

Results Barriers to access included problems with identification of healthcare needs by carers and healthcare professionals, communication difficulties, the inadequacy of facilities, geographical and physical barriers, organisational factors such as inflexible appointment times, attitudes and poor knowledge base of healthcare staff.

Conclusion The factors identified can serve as a guide for managers and clinicians aiming to improve access to their healthcare services for children and young people with intellectual disabilities.

Body image, food behavior and models esthetic in university students

A.M. Romero Otalvaro*, M. Munoz-Argel, C. Aguilar-Aruachan, G. Padilla-Vargas Gianina

Universidad Pontificia Bolivariana, Psicología, Montería, Colombia

* Corresponding author.

A growing host is currently evident in young people all about sports culture where interest in body image and a strong cult of the body whose main purpose in many cases prevails is to achieve aesthetic purposes based body models of society, which may be related to an increase in risk eating behaviors and habits of excessive exercise. This research aims to examine the possible presence of three variables: eating behavior, aesthetics models and body image in male college gym users and nonusers. The variables were evaluated by applying Inventory eating disorder EDI 2, which measures the presence of symptoms associated with eating disorders. The Adonis complex Questionnaire which is used to assess the degree of concern about physical appearance and The Questionnaire Body Influences of Aesthetic Model CIMEC-40 which evaluates the internalization of cultural aesthetic ideals. The sample consists of 50 subjects, aged 18 and 24 years, students from the one University of the city of Montería – Colombia.

The results indicate that the user group show greater trend scales obsession with thinness and social insecurity than non-users, like greater influence of verbal messages regarding the cultural aesthetic models, however none of the groups expresses serious or pathological concern about body image.

Background The concept of mental toughness has gained increasing importance among non-elite athletes for its psychological importance and explanatory power for a broad range of health-related behaviors. On the flip side, no study has focused so far on the psychological origins of mental toughness. Therefore, the aims of the present study were three-fold: to explore, to what extent psychological profiles of preschoolers at the age of five years predicted mental toughness scores and sleep disturbances at the age of 14 years, and to explore possible gender differences.

Method Nine years after their first assessment at the age of five years (preschoolers), a total of 77 adolescents (mean age: 14.35 years; SD = 1.22; 42% females) took part in the present follow-up study. At baseline, both parents and teachers completed the Strengths and Difficulties Questionnaire (SDQ), covering internalizing and externalizing problems, hyperactivity, negative peer relationships, and prosocial behavior. At follow-up, participants completed a booklet of questionnaires covering socio-demographic data, mental toughness, and sleep disturbances.

Results Preschoolers with high prosocial behavior and low internalizing and externalizing problems, as rated by parents and teachers, at the age of 14 years self-reported higher mental toughness and lower sleep disturbances. At the age of 14 years, and relative to their male counterparts, female participants reported lower MT scores and higher sleep disturbances.

Conclusions The pattern of results suggests that mental toughness traits during adolescence have their origins during pre-school years.

Psychopathological approach of unsafe games among teenagers: A case report

A. Ben Hamouda, S. Bourgou, S. Ben Rejeb, M. Hamza, B.N. Saguem*, F. Charfi, A. Belhadj
Mongi Slim Hospital, Child and Adolescent Psychiatry, La Marsa, Tunisia

* Corresponding author.

Introduction Voluntary asphyxiation by practicing unsafe games such as choking, hanging, strangulation or other means of inducing hypoxia/anoxia is not uncommon among adolescents and can lead

to unintended death but it stills not very well-known so underestimated by parents and underdiagnosed by health professionals.

Objectives Study of clinical, psychological and psychopathological features in adolescent practicing unsafe games through a case report and a literature review.

Methods We will present the case of a 14-year-old boy followed up in the Child and Adolescent Psychiatry Department of Mongi Slim Hospital (La Marsa, Tunisia) for behavioral disorders and recurrent syncope. This case report will be supported by a literature review.

Case report S.B., 14-year-old boy, unique child of two divorced parents, with precarious family socio-economic conditions, no apparent medical problems and no known history of drug or alcohol abuse, suicidal ideation or suicide attempts, consulted first time in the department for behavioral disorders. The diagnostic of dysthymia was made. Seven months later, he was hospitalized in the medical intensive care unit for postictal coma. All medical investigations were normal. In the following, S.B. revealed that he used to practice voluntary asphyxiation by compressing the two carotids using his fingers until loss of consciousness. The diagnosis of paraphilia (DSM-5) was established.

Conclusions Early recognition of such cases and awareness of psychological and psychopathological motivations might prevent serious complications and lethal outcome for these “unsafe-young-players”.

EPS Hédi Chaker, Child and Adolescent Department, Sfax, Tunisia

* Corresponding author.

Objective To identify correlates that might constitute risk factors for problematic video game use (PVU) among urban Tunisian secondary school students.

Methods This multivariate cross-sectional study was carried out on 587 secondary school students, aged 14 to 20 years. They were randomly selected from seven secondary schools in the urban area of Sfax. The self-administered Fisher's nine-item questionnaire was used in this survey. To identify an associated problematic internet use video game addiction, Young's eight-item questionnaire was used. A self-administered, anonymous questionnaire covered socio-demographic, individual and family data.

Results The prevalence of PVU was 14.01%. In multivariate logistic regression analysis, we found that the individual risk factors for problematic video game use were anxiety symptoms ($P = 0.034$) and an associated problematic Internet use ($P < 0.001$). Playing sport was a protective factor ($P = 0.011$). The poor relationships within the family ($P = 0.001$), the lack of parental supervision of time spent on playing video game ($P < 0.001$) and mother profession as mid-to upper level manager ($P = 0.002$), predicted PVU.

Conclusion The identification of risk factors can help to determine individuals at high risk, and alert mental health providers to be careful to screen these patients for PVU. Total avoidance of the Internet is unrealistic and inadvisable; but a sensibilisation outreach for youth, their families and health professionals may help to limit the onset of PVU among young people.

Aim The aim of our study was to investigate and compare the quality of life of parents of children with ADHD and parents of children within psychiatric troubles.

Methods We conducted a cross sectional and comparative study, on 20 families of children with ADHD, followed in child and adolescent psychiatry department of Sfax, Tunisia, and 20 control families. We used the Short Form Health Survey (SF 36) translated and validated in Arabic to evaluate the quality of life of the parents of the two groups.

Results The average age of the patients of our survey was 9 years 8 months with a predominance of boys. We objectified a significant difference between the overall scores of the quality of life of parents of children with ADHD and the control sample. A highly significant difference was noted in the following areas: mental health, bodily pain and social functioning. The difference was significant in vitality score. The difference was not significant in 4 scores: general health, physical functioning, role physical, and role emotional.

Conclusion Families with a child with ADHD have many challenges which impact certainly in their quality of life. As a child and adolescent's psychiatrics, we should be aware of these consequences in order to help the parents to improve their quality of life.

EV0158

Developing and implementing digital-assisted parent training intervention for disruptive behavior in primary health care

A. Sourander*, T. Ristkari

Turku University, Child Psychiatry, Turku, Finland

* Corresponding author.

Background According to many epidemiological studies early prevention of mental health problems is essential in childhood. The objectives are:

- to determine whether a digital-assisted intervention using whole-population screening that targets the most symptomatic 4-year-old children is effective at 12 months after the start of treatment;
- to describe the Finnish Strongest Families intervention model in primary health care.

Methods The target population was children with high level of DBD symptoms screened from the population of 4-year olds attending annual child health clinic check-ups. The RCT study was conducted in southwest-Finland between 2011 and 2013. In the control group, participants ($n = 232$) were given access to a parent training website and a telephone call from a coach. Participants ($n = 232$) in the intervention group received internet and telephone delivered the Finnish Strongest Families program.

Results During the 12-months follow-up results of the intervention showed the behavioural problems of the four-year-old children reduced significantly in the families who participated in the 11-week program compared to the control group. So far, this evidence-based intervention has been implemented in 13 municipalities in Finland and the nationwide implementing process is in progress.

Conclusions Training parents online and over the telephone significantly decreases preschool children's disruptive behavior. Therefore, it is important to provide low threshold, digitally delivered, family oriented promotion, prevention and early intervention programs in the primary care. More studies are needed to evaluate the long-term effects and cost-effectiveness of digital interventions in preventive mental health care.

Communication in ASD – parents as partners for improving language development

I. Sun*, F. Fernandes, P. Pereira, J. Balestro

University of São Paulo, FMUSP, São Paulo, Brazil

* Corresponding author.

The increase in the prevalence of autism spectrum disorder (ASD) has important consequences to the health and educational systems. The need for specialized care that can improve the chances for a good prognosis must be considered in the research about intervention proposals. Parents can be very important participants in this process. Several intervention programs include the participation of parents but there is relatively little information in the literature about the results of these proposals. This poster will present the results of three different intervention programs with the participation of parents in three different regions of Brazil. In Rio de Janeiro, the parents were instructed about everyday attitudes and interactive management in six monthly group sessions discussing specific issues. In Rio Grande do Sul, specific themes regarding communication awareness and language development were discussed with parents in eight individual sessions conducted once each month. In Sao Paulo, parents were instructed once a week, during ten weeks, about executive functions stimulation. Participants were 18 children and they were all receiving regular speech-language therapy before, during and after the period of instruction to the parents. The results regarding the social-cognitive and communicative performance show a clear effect of the parents' instruction. Each program's results will be discussed individually but the overall results point out to the value of including parents as partners in language and communication intervention processes.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ UKCL, MRC Social, Genetic and Developmental Psychiatry Centre, London, United Kingdom

⁵ Hospital Universitari Vall d'Hebron, Department of Psychiatry, Barcelona, Spain

* Corresponding author.

Attention deficit hyperactivity disorder (ADHD) is one of the most common neurodevelopmental disorder. It is a chronic disease where 50–60% of ADHD cases persist into adult life. ADHD is associated with a range of clinical and psychosocial impairments. In children hyperactivity, impulsivity and inattention are the core

symptoms of ADHD. In adults these core symptom are also present but inattention is more prominent. Correct diagnosis of ADHD remains challenging, especially as several other psychiatric and medical disorders show the similar symptomology.

Objectives The diagnosis of ADHD is clinical based upon a cluster of symptoms and criteria established by guidelines such as the DSM-5. Yet, objective markers are needed to support the clinical ADHD diagnosis in children and adults. Studies suggest that a neurobiological marker (eye vergence i.e. where the eyes move in opposite directions) can detect ADHD in children and adults. The eyes converge during orienting attention, as evidenced by visual event related potentials at parietal locations. This attention related vergence is impaired in ADHD patients.

Methods We review the neurobiology and findings of eye vergence and the relevance of its measurement for the clinical diagnosis of ADHD.

Results Neural circuits underlying eye vergence and attention largely overlap. Using machine learning, eye vergence measurements can classify ADHD in children and adults with high (> 90%) accuracy.

Conclusions Eye vergence is a promising candidate for an objective clinical diagnosis of ADHD.

Objective The need for diagnosis and correct classification of depression among children is dictated by its burdeness with age, high risk of recurrence at further stages of child development and propensity to suicidal behavior.

Materials and methods One hundred and sixty adolescents with ADD were included in our study. The study design comprised: clinicopsychopathological, somatoneurological, psychological and neurohormonal methods.

Results Clustering symptom of anxiety and depression have shown that for children in early puberty is typical more formation of somatic (35.2%), behavioral (21.6%), phobic (21.6%) variants of depression, less-anxiety (13.5%), asthenia (8.1%). For children in puberty – apathetic (30.1%), anxiety (28.9%), dismorfofobic (27.7%), behavioral (13.3%) variants. The proportion of suicidal behavior of depression increases in proportion to age, mainly due to suicidal thoughts, sayings, auto-aggressive behavior. Analysis of the formation conditions of anxiety and depression in children showed a significant correlation of genetic, biological and socio-environmental components.

Symptoms of the minimal brain dysfunction (MBD) at an early ontogeny (prognostic value = +4.8), loaded natal period (PV = +4.2), frequent colds in the medical history (PV = 3.7), signs of cerebro-organic failure (PV = +3.8) and obesity as an endocrine disorder (PV = +2.1), sex and age of the manifestation of the first depressive episode in the early stages ontogenesis in boys aged 7 years (PS = +5.3), in girls aged 9 years (PS = +3.9) have been registered among biological risk factors for the ADD formation. Prognostic

significance of neurohormonal parameters as regards the risk for ADD formation in adolescents is based on a decreased serotonin level in patients with depressive anxiety (PV = +2.8) and a reduced melatonin level, irrespective of the variant of clinical depression (PV = +2.4).

Conclusion Determination of neurobiological and neurohormonal risk markers for the development of the ADD makes it possible to carry out psychoprophylactic measures.

Background and aims The study considers the problem of the anxiety-depressive disorders (ADD) in children with concomitant obesity in the context of the search for effective methods of their correction.

Materials and methods Included 64 children at puberty with the anxiety-depressive disorders, comorbid with obesity. Design comprised: clinicopsychopathological, somatoneurological, psychological monitoring (CDRS-R); the Spielberger, "Me and my illness" and "Man in the Rain" projective drawing tests.

Results The symptoms of emotional and vegetative tension, depression registered in all studied children.

In the developed model of support, the interventions of primary level are aimed on family and closest encirclement of the child (family psychotherapy, psycho-educational programs for children and their parents). Strategies:

- stressful situation in the family (practical, psychological support and education of parents);
- for relief of depressive and vegetative-anxious symptoms (using art therapy, cognitive behavioral therapy);
- for education of patients in the wider context – quality of life, coping, motivation and modification of inappropriate behaviors (modeling of new cognitions).

The technology includes the diagnosis of the psychosomatic core of the disease, areas of neurotic fixation of the child with ADD and obesity, correction of emotional homeostasis and cognitive imbalance by activation of the personality individual resources as a result using cognitive-behavioral and art-dynamic therapy, as well as a "Control of eating behavior" training program, and solving certain situational problems by a child with the disease.

Conclusion Our method makes the tactics of psychotherapeutic and psycho-educational intervention at an early stage of the disease.

Keywords Children; Anxiety-depressive disorder; Art-therapeutic intervention

Pediatric acute onset neuropsychiatric syndrome associated with Epstein–Barr infection in child with Noonan syndrome

G.P. Tisi*, M. Marzolini, G. Biffi

Asst Santi Paolo e Carlo, San Carlo Hospital, Psychiatry, Milan, Italy

* Corresponding author.

Introduction Pediatric acute onset neuropsychiatric syndrome is associated with various infections (i.e. *Streptococcus*, *Mycoplasma pneumoniae*).

Objectives We describe a case of PANS associated with mononucleosis, in a patient with Noonan syndrome.

Aims To report a case of EBV-related PANS.

Methods A 13-year-old patient, diagnosed with Noonan syndrome, was referred to the pediatric unit of our hospital in August 2016 because of aggressive behavior and suicidal ideation. He had no personal or family history of psychiatric disorder. His parents and him denied substance abuse. His symptoms had begun abruptly one month prior to our evaluation, after watching an internet video, and consisted in intrusive thoughts and images associated with mental compulsions. Suicidal thoughts and verbal aggressiveness emerged because he felt overwhelmed by these symptoms.

Results He was initially treated with sertraline 25 mg, and subsequently switched to aripiprazole because of increased anxiety. Throat cultures and anti-streptolysin titer (ASO) were negative, as well as Ig(M) and Ig(G) antibodies for *M. pneumoniae*. Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were also negative. Epstein–Barr virus Ig(M) and Ig(G) were positive. He continued therapy with aripiprazole 10 mg after hospital discharge with partial benefit.

Conclusions Epstein–Barr virus infection has been reported to precede various neuropsychological disorders, but to the best of our knowledge, rare cases of PANS following mononucleosis have been described in literature. In our case, psychopharmacological treatment for OCD symptoms was the only treatment performed and led to a partial remission of symptoms.

Behavioral disorder of adolescents with Prader–Willi SY

M. Tripkovic^{1,*}, S. Knez Kovačić², M. Bogadi¹, I. Bakija³, S. Ropar²

¹ Psychiatric Hospital for Children and Youth, Psychiatric Hospital for Children and Youth, Zagreb, Croatia

² General Hospital Karlovac, General Hospital Karlovac, Karlovac, Croatia

³ Psychiatric Hospital “Sv. Ivan”, Zagreb, Croatia

* Corresponding author.

Introduction The paper discusses the problem of psychiatric treatment of rare diseases and “diagnostic screening” of certain psychic symptoms that affect people with intellectual disabilities. Prader–Willi (PWS) is a genetic syndrome that belongs to a group of rare diseases and is caused by deficiency or loss of function of genes on chromosome 15 inherited from the father. This disease affects both sexes and its main characteristics are: obesity, hyperphagia, mental retardation and hypogonadism. Chronical feeling of insatiable hunger and slow metabolism leads to excessive body weight which is, according to existing data sources and monitoring studies, the primary cause of premature death of patients with PWS. Anxiety, psychomotor agitation, behavioral problems, difficulties with short-term memory, frequent skin injury in the form of wounds and bruises are the symptoms of this disease that hinder

diagnosis and treatment. Research suggests that patients with PWS have unusual reactions to the standard drug dosages, specifically anxiolytics.

Aim We shall present a multidisciplinary approach of pharmacological and psychotherapeutic treatment of a 16-year-old female patient with PWS.

Result This patient responded well to a small dosage of quetiapine, at the same time monitoring other physical parameters. Pharmacotherapy, combined with psychotherapy, along with providing counseling and support for parents resulted in decreased psychomotor restlessness and, subsequently, better control of food intake and prevention of weight gain.

Conclusion This paper has emphasis on the importance of a multidisciplinary approach, as well as experience from clinical practice in the treatment of complex and rare syndrome diseases.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁵ Laboratory of Endocrinology, Imagine Institut, Necker–Enfants–Malades University Hospital, Paris, France

* Corresponding author.

Introduction Although more than 85% of children with DCD are affected by handwriting disorders, their characteristics and underlying mechanisms remain poorly known.

Objectives We aim to better identify the nature of handwriting disorders in subtyping DCD children.

Methods School children aged between 5 to 15 years and exhibited a DCD (according to DSM-5) are eligible for inclusion. They were classified in three subtypes of DCD: ideomotor (IM), visual-spatial and/or constructional (VSC), and mixed (MX). They were assessed with a standardized handwriting evaluation including quality and speed and a clinical observation of motor gestural developmental and temporal-spatial organization of handwriting highlighting six qualitative criteria: irregular handwriting (criterion 1), immaturity of handwriting gesture (criterion 2), excessive pressure of the pen on the paper (criterion 3), neuro-vegetative responses (criterion 4), trembling (criterion 5), slow handwriting velocity (criterion 6). Two groups are established: children with poor handwriting (PH) and children with dysgraphia (DysG).

Results While 89% of children have handwriting disorders, only 20% exhibit dysgraphia. IM DCD is characterized by an immaturity of handwriting gesture and is associated with PH. Dysgraphia appears only in VSC and MX DCD which are characterized by the association of criteria 1, 2, 3, and 4. This association appears to more than 80% in DysG. Slow handwriting velocity is constant between PH and DysG.

Conclusion Immaturity of handwriting gesture is a possible underlying mechanism of poor handwriting. Dysgraphia is associated with specific impairments in spatial organization of letters and in motor control of handwriting gesture.

Self-mutilations – an addictive behavior?

R. Velasco Rodrigues*, J. Mesquita Reis, L. Queiroga
Hospital Dona Estefânia, Child and Adolescent Psychiatry, Lisbon,
Portugal

* Corresponding author.

Introduction Self-mutilations are defined as an intentional behaviour that involves direct aggression to the person's body, without aware suicide intention. The Diagnostic and Statistical Manual of Mental Disorders IV (DSM-IV) included self-mutilation as part of the diagnostic criteria for the other specified disruptive, impulse-control, and conduct disorder or borderline personality disorder. Later, the DSM-5 suggests that this behavior constitutes a separate diagnostic entity. Despite the growing concern regarding the increased incidence of self-mutilation among adolescents, there is still no consensus on the pathogenesis of this behavior. Recent studies have suggested that, in some cases, non-suicidal self-injurious behavior may be understood as an addictive behavior. Based on this hypothesis, several researchers have conducted genetic, neurobiological and clinical studies, to verify the existence of common pathways between these two nosological entities.

Objectives The aim of this study is to conduct a literature review of studies that propose an additive model for self-injurious behavior, discussing its implications in the diagnostic and therapeutic interventions.

Methodology Articles indexed in the Pubmed database were analyzed as well as book and studies published in scientific journals.

Conclusion A better understanding of the pathogenesis of self-mutilation is crucial to our diagnostic and therapeutic interventions. Unfortunately, studies done on this topic in the past were inconclusive. Further clarification, through new studies, is needed in order for us to help adolescents with this behavior in a more effective way.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Face processing in autism spectrum disorder

E. Zaky

Faculty of Medicine, Ain Shams University, Pediatrics, Cairo, Egypt

Background Autism spectrum disorder (ASD) is a lifelong neurodevelopmental disorder that is characterized by impaired social and communicative abilities as well as restricted, repetitive, stereotyped pattern of behaviors, interests, and activities. Significant difficulties in social interactions in autistics are manifested by impairment in eye-to-eye contact, social reciprocity, and response to emotional cues.

Objective Highlighting the neurological basis of normal face processing and its abnormalities in ASD with percussions on the management plan of autistic children.

Summary Human face processing that was proved to be compromised in autistic individuals is pivotal for proper social interactions. Such simple spontaneous perceptual task in normal children is carried out by face processing areas of the brain; fusiform gyrus, superior temporal sulcus, and amygdala. Behavioral, electrophysiological, and neuroimaging studies showed evidences of dysfunction of such areas in autistics who often focus on face periphery and cannot interpret that it tells something about a person's state of mind. Very early targeted intervention can stimulate face processing areas of the brain during the early developmental phases of social brain circuitry which in turn will help autistics to pay attention to faces and learn to understand emotional expressions.

Conclusion Eventually, prevention or at least significant amelioration of severity and symptomatology spectrum of autism might be possible.

Depression episode in a patient with ataxic syndrome (case report)

B. Zenelaj, T. Jupe*, V. Alikaj, B. Allkoja, V. Kodra
University Hospital Centre "Mother Theresa", Psychiatry, Tirana,
Albania

* Corresponding author.

Introduction The etiologic diagnosis of ataxic syndrome is a challenge itself, requiring a complete history, physical examination, and sometimes neuroimaging, as well as extensive laboratory evaluation but despite that in many cases, the etiology remains uncertain. But in this case report, we are focused on a complication due to this syndrome, depression episode in a patient suffering from an yet unknown etiology of ataxic syndrome.

Case presentation An 18.5 years old Albanian female visits for the first time the child and adolescent psychiatry clinic suffering from insomnia for at least 3 months, had difficulties in taking care of her personal hygiene, did not communicate to anyone, loss of appetite, spent 2–3 hours crying without reason and depressive humor. She also manifested tremor and gait abnormalities, which according to her medical history a year ago, in Italy she was diagnosed with ataxic syndrome, but the etiology is not yet specified. BECK Depression Inventory at the first presentation scored 47 points. The girl was hospitalized and treated in our clinic.

Conclusion Patient suffering from ataxic syndrome have many neurologic complication with the passing of the years, but there has been little information or focus on the psychiatric ones and in the literature is described a syndrome called cerebellar cognitive affective syndrome with similar symptoms. In this case, we describe a patient with life-threatening situation due to her mental health condition and by treating the depression we noticed that the neurologic symptoms improved as well.

Moscow, Russia

² Mental Health Research Center of RAMS, Child Psychiatry, Moscow,
Russia

* Corresponding author.

Introduction Autism spectrum disorder and early onset schizophrenia have many similar symptoms, however, these are different disorders. It is important to identify the main similarities/differences in the structure of cognitive impairment to define further assistance these children correctly. We distinguished two options for cognitive defect (total and partial) in children with schizophrenia.

Aims Comparison of cognitive functions at children with autism spectrum disorder and early onset schizophrenia.

Objectives Two groups with autism spectrum disorder (ASD1 – 22 patients of MHRC mean age 8.9; ASD2 – 27 pupils of special school mean age 7.4). Two groups with early onset schizophrenia

(F20.8 – 16 patients of MHRC mean age 10,2; F21 – 18 patients of MHRC mean age 10.0).

Methods Battery of pathopsychological tests for assessing cognitive functions (memory, attention, thinking), test figures of Leeper for visual perception. Z-scales were used for estimation of cognitive deficit or defect.

Results Patients demonstrate variety of cognitive functioning. Normal cognitive functioning: ASD1* – 22%, F20.8 – 18%, F21* – 50% (* – $P \leq 0.05$); partial cognitive defect: ASD1 – 27%, F20.8 – 18%, F21 – 22%; total cognitive defect: ASD1** – 50%, F20.8 – 64%, F21** – 27% (** – $P \leq 0.01$). ASD1 and F20 were the worst in thinking. Children ASD1 and ASD2 demonstrate similar success in recognizing Leeper's figures.

Conclusions There are some common features of cognitive development in children with severe forms of ASD and early onset schizophrenia, first of all in thinking.

No significant differences obtained between severe – mild forms of autistic disorders in visual perception (ASD1 and ASD2).

Disclosure of interest The authors have not supplied their declaration of competing interest.

Complicated grief: Is there a place in psychiatry?

S.L. Azevedo Pinto*, J. Soares, A. Silva, R. Curreal
Hospital de S. João, Clínica de Psiquiatria e Saúde Mental, Porto, Portugal

* Corresponding author.

Introduction Grief is as normal reactive to a significant personal loss. It is characterized by affective, cognitive, behavioural and physiological symptoms. The grieving process is usually divided in five different stages, but in most cases presents a benign course, with decreased suffering and better adaptation to the new context. However, when high levels of emotional suffering or disability persist over a long time period, it becomes a case of complicated grief (CG), which should be adequately addressed.

Objectives To review the characteristics of CG, the evidence that supports it as an individual pathological entity, and its place in current classification systems.

Methods We performed a bibliographic search in Pubmed and PsychInfo, of articles written in English, Portuguese and Spanish, containing the key words: grief, bereavement, psychiatry, classification.

Results The main issue regarding grief is the degree to which it is reasonable to interfere with a usually benign process. Since DSM-III bereavement has been referred to as an adaptive reaction to an important loss, which should not be diagnosed as major depressive disorder or adjustment disorder. However, DSM-5 has stated persistent complex bereavement disorder as an independent entity. In fact, CG fulfils the general criteria of every psychiatric syndrome, namely regarding specific diagnosis criteria, differential diagnosis from depressive disorders and post-traumatic stress disorder, and improvement with adequate treatment.

Conclusion It is important to correctly approach CG, since it presents with characteristic diagnosis features and much improvement may be achieved once adequate treatment is provided.

Bipolar spectrum – A helpful concept?

P. Cabral Barata*, J.C. Melo, T. Maia
Hospital Prof. Doutor Fernando Fonseca, Serviço de Psiquiatria, Amadora, Portugal

* Corresponding author.

Introduction Many patients seen in clinical practice have a mood disorder not well described by the existing diagnostic categories. Formally, they would be called “not otherwise specified” but this creates a huge single category for many patients that belies the richness and complexity of their symptoms.

Objectives Review the existing information regarding the bipolar spectrum concept and reflect about its importance and utility.

Methods Nonsystematic review of the literature – scientific publications from Pubmed and Psychiatry Textbooks.

Results The “bipolar spectrum disorder”, designating those patients who fall in the middle of the mood spectrum between the classic unipolar and type I bipolar extremes, would represent recurrent severe depression, but with a family history of bipolar disorder or antidepressant-induced mania or a number of other features of bipolarity in addition to depressive symptoms, course, or treatment response. The presence of hyperthymic or cyclothymic mood temperaments has also been suggested as part of this bipolar spectrum concept. Several arguments can be found supporting the existence of this spectrum. A validated bipolar spectrum concept will allow a decrease in the diagnostic underestimation of bipolar disease and a more differentiated investigation and treatment model. Bipolar spectrum concepts will help identify those patients to whom antidepressants are not the best therapeutic approach, in relation to mood stabilizers and/or neuroleptics.

Discussion The bipolar spectrum concept has considerable supporting evidence and utility, theoretical as well as practical. Its development and diagnostic acceptance shall allow new discriminated investigation and better patient outcomes.

The profile of female crack users undergoing treatment on psychosocial care center for alcohol and others drugs in Brazil

C.M. Carvalho*, T.V. Cardoso Vernaglia, N. Senju Suzuki, D. de Assis Correa Sória

Universidade Federal do Estado do Rio de Janeiro, Alfredo Pinto School of Nursing, Rio de Janeiro, Brazil

* Corresponding author.

Background The prevalence of crack cocaine on Brazil reveal an increase since 2009 and represents a public health problem.

Aims To describe and study the socio-demographic profile of female crack users undergoing treatment in psychosocial care center for alcohol and others drugs (CAPS AD).

Methods This is a qualitative, ethnographic study of 9 female crack users that was conducted from February until September 2015 at CAPS AD in Brazil. This study is part of a research entitled “The daily life of female crack users: public service access”.

Results These women are young, have children that most of them are separated and have at least primary school. All of them have a long time using crack and different attempts of abstinence. They access different public health programs.

Conclusion The results show the vulnerable profile of female crack users. These findings indicate the need specific public intervention in order to improve social and health conditions.

Introduction Constituting 2% of the population, PWDID are a vulnerable group with a higher prevalence of mental disorders than the general population. ICD diagnostic criteria often rely on adequate cognitive functioning and hence diagnosis of mental disorders in PWDID can be difficult, consequently leading to inequity of treatment, prognosis and stigma. Our study critically analysed the available evidence base and explored the feasibility of applying modified diagnostic criteria within the context of cumulative iterative iteration. We present the outcome using diagnosis of DID and anxiety disorder as examples.

Aims Address current shortcomings in ICD classification regarding PWDID by contributing effectively to the WHO ICD-11 consultation process in collaboration with international stakeholders.

Objectives Facilitate accessibility of ICD-11 criteria for diagnosis of mental disorders capable of engendering robust evidence based epidemiological data and healthcare in PWDID.

Methods We evaluated current evidence via a systematic literature search utilising PRISMA guidelines and developed pragmatic guidelines to adapt ICD diagnostic criteria in PWDID. A brief screener [Glasgow Level of Ability and Development Scale (GLADs)] for detecting DID was also studied internationally within the context of clinical utility ($n = 136$).

Results The evidence base relating to mental disorders in PWDID is poor, significantly hampered by difficulties in applicability of diagnostic criteria. The GLADs appears to be a promising screening tool with good clinical utility for detecting disorders of intellectual development (DID) particularly where resources are scarce.

Conclusions Pragmatic modifications to ICD-11 diagnostic criteria and the GLADs tool facilitates its clinical utility for PWDID and contributes significantly to enhancing research based evidence, and, ultimately their health access and well-being.

* Corresponding author.

Introduction The main feature of body dysmorphic disorder (BDD) is impairing preoccupation with a physical defect that appears slight to others. Previously, its delusional and nondelusional variants were sorted in two separate categories, but owing to new data suggesting that there are more similarities than differences between them, DSM-5 now classifies both as levels of insight of the same disorder.

Objectives To enunciate the similarities and differences between the two variants of BDD.

Aims To better understand the features and comorbidity of BDD, so as to improve its management and treatment.

Methods Taking DSM-5 and DSM-IV-TR as a reference, we have made a bibliographic search in MEDLINE (PubMed), reviewing articles no older than 5 years that fit into the following keywords: body dysmorphic disorder, delusions, comorbidity, DSM-IV, DSM-5.

Results Both the delusional and nondelusional form presented many similarities in different validators, which include family and personal history, pathophysiology, core symptoms, comorbidity, course and response to pharmacotherapy.

Conclusions The new classification of delusional and nondelusional forms of BDD as levels of insight of the same disorder, which places them closer to the obsessive-compulsive spectrum than to the psychotic one, not only improves treatment options, but also reinforces the theory that delusions are not exclusive of psychotic disorders, setting a precedent for the understanding and classification of other disorders with delusional/nondelusional symptoms.

Underestimation of autism spectrum disorders according to DSM-5 criteria: A pilot study

R. Ferrara^{1,*}, M. Esposito²

¹ École doctorale de Lausanne, Department of Biology and Medicine, Roma, Italy

² Università "Sapienza" Roma, Medicina sociale, Roma, Italy

* Corresponding author.

Introduction Recent studies on autism concern the number of individuals diagnosed with pervasive developmental disorder (PDD) according to DSM-IV-TR who may no longer qualify for diagnoses under the new DSM-5 autism spectrum disorder (ASD). ASD is diagnosed using the impairments in two dimensions: – the social and communication dimension;

– the restricted and repetitive interests and behaviors (RRIB) dimension whereas PDD is diagnosed using impairments in three dimensions.

All the studies indicate between 50 and 75% of individuals will maintain diagnoses.

Objectives The aim of the study is to quantify how many individuals with previous PDD diagnoses under DSM-IV-TR criteria would maintain a diagnosis of ASD under DSM-5 criteria.

Methods Our sample consists of 23 cases (21 males, 2 female) related to the treatment Centre “Una breccia nel muro” of Rome and Salerno. All the cases previous received a PDD diagnose according to DSM-IV TR criteria. The mean age of cases was 7.7 years. All the cases were diagnosed by our team according to DSM-5 criteria, clinicians also used to make diagnoses: the Autism Diagnostic Observation Schedule-2, the Autism Diagnostic Interview-Revised.

Results Eighty-seven percent of cases with PDD were classified as ASD using DSM-5 criteria. Thirteen percent of cases, that previous received an Asperger diagnose, did not meet the ASD criteria (Fig. 1).

Conclusions DSM-5 criteria may easily exclude cases with high functioning from ASD because they tend to be atypical for ASD according to this study.

Fig. 1 Autism spectrum disorder according to DSM-5.

Pattern of online technology and its impact on productivity at workplace

H. Gupta

Role of online technology and social networking site at workplace, ACAMHE&NS – CCRAS, Bangalore, India

Background Internet use has affected the pattern of working style at the workplace. Recent years have seen an increased use of online activities (especially pornography/gaming) at the workplace. It has been shown to affect productivity at the workplace. There is a dearth of literature from the Indian context in this area.

Aim This study was conducted to explore the pattern of pornography use and gaming at the workplace and its dysfunctions.

Setting and design The present study was a cross-sectional prospective study.

Materials and methods The objective of the study was to assess the pattern of pornography use at the workplace. Five hundred employees having experience of internet use for more than a year of various government/private sector organizations in Bengaluru were assessed using background data sheet, DSM-5 criteria, internet addiction test and pornography addiction screening instrument. Users who were unwilling to participate were excluded from the study.

Results Seven to 9% reported preference for Internet to work, meals, personal hygiene, sleep, and interaction with family members and effects on productivity. Three to 4% have excessive use of pornography and game.

Conclusions The present study has implications for evolving psychoeducational modules for the promotion of healthy use of technology.

Mental Health Europe’s “beyond the bio-medical paradigm task force” issues on ICD-10

P. Kinderman^{1,*}, P. Pini², S. Wooley³

¹ *University of Liverpool, Psychology, Health and Society, Liverpool, United Kingdom*

² *Mental Health Europe, Beyond the Biomedical Paradigm Taskforce, Brussels, Belgium*

³ *Mental Health Europe, Expert by Experience & Beyond the Biomedical Paradigm Taskforce, Brussels, Belgium*

* *Corresponding author.*

Introduction Recent developments in psychiatric diagnosis risk downgrading psychological and social aspects of personal recovery and marginalise the individual needs and aspirations of people, considered in their local context. The publication of the fifth edition of the Diagnostic and Statistical Manual for Mental Health Disorders (DSM-5) by the American Psychiatric Association (APA) prompted MHE to establish the Beyond the Biomedical Paradigm Task Force (BBPtf) to investigate, debate and report on these issues.

Objectives Mental Health Europe (MHE) – along with others both within and outside mainstream psychiatry – has noted with concern the increasing dominance of a biological approach to mental health problems. We see a risk of diagnoses being misused when they become part of a complex managerial health system responding mainly to the economic and issues of safety or social control. This kind of misuse could breach the principles of the UN CRPD. MHE welcomes the role of the WHO in coordinating internationally appropriate classification systems. However, we want to ensure that systems based on biomedical, economic and managerial issues are balanced with systems based on knowledge of personal experiences, life stories and direct relationships, which have proven outcomes and which respect human rights and dignity.

Aims This workshop will explore the complex philosophical issues associated with psychiatric diagnosis and, in particular, the ICD-10 revision process.

Disclosure of interest I am President of the British Psychological Society and a member of both Mental Health Europe’s “Beyond the Bio-Medical Paradigm Task Force” and the Council for Evidence Based Psychiatry. I am currently in receipt of funding from the National Institute for Health Research (NIHR) and the Economic and Social Research Council (ESRC), and I have previously received funding from a variety of sources.

³ Hospital Universitario Marqués de Valdecilla, General Medicine, Santander, Spain

* Corresponding author.

Introduction Paraphrenia is a poorly defined process whose uncertain origins date back to the German psychiatry mid-nineteenth century. Paraphrenia would be a subtype of schizophrenia characterized by a more benign clinical course in terms of volitional and emotional involvement. Certain types of serious sensorceptive distortions and paranoid symptoms are characteristics of this clinical variant. Despite its diverse presentation, its chronic development and its presence in the daily lives of the patient, the overall functionality is not deeply affected.

Objectives To discuss the validity of this and other clinical processes based on classical clinical descriptions for diagnostic approach of our current patients, in contrast to the common use simplified concept (forgetting in ICD-10 or disappeared in American manuals).

Materials and methods Clinical case a middle-aged woman diagnosed with longstanding paranoid schizophrenia who suffered from a highly systemized delusional and hallucinatory syndrome with chronic evolution after a first relapse due to abandonment of treatment, but keeping high functional performance even during phases of partial remission.

Conclusions Schizophrenia presents multiple symptomatic and prognostic paths. Classical authors named these different subtypes. Revisiting these subtypes could be useful as a complementary tool for predicting clinical outcome based on their descriptions, especially in the absence of reliable material instruments.

A new syndrome? The sport identification addiction and the case of Italian football ultra-fanatical support

M. Lanzaro

ASL BN 1, Department of Psychiatry, Ottaviano, Italy

The new DSM-5 has a number of changes to addictions and substance-related disorders. Internet Gaming for instance is a "Condition for Further Study". This means that it is not an "official" disorder in the DSM, but one on which the American Psychiatric Association request additional research.

The DSM diagnostic criteria for addictions to the X-subject generally include:

- repetitive use of X, that leads to significant issues with functioning;
- preoccupation or obsession with X;
- craving/withdrawal symptoms when not dealing with X;
- the person has tried to stop or curb X, but has failed to do so;
- the person has had a loss of interest in other life activities, such as hobbies;
- a person has had continued overuse of X even with the knowledge of how much they impact a person's life;
- the person uses X to relieve anxiety related to other issues;
- the person has lost or put at risk and opportunity or relationship because of X.

I suggest that some sport fans may:

- meet the above mentioned criteria;
- be subject to over-identification with "their team performances", superstitious conditioning and loss of self-consciousness that may lead to a full blown addictive syndrome, along with comorbidity with pathological gambling.

This seems particularly true in Italy, for example, as far as the phenomenon of ultra football supporters is concerned.

I argue that further research might be needed to explore the psycho-social consequences of obsessive sport addiction and how this may impact on a person's overall functioning.

Depression across DSM and ICD editions: Psychiatric nosology's 'Black Dog'

R. Leite*, P. Macedo, J. Borges, T. Santos

Baixo Vouga Hospital Centre, Department of Psychiatry and Mental Health, Aveiro, Portugal

* Corresponding author.

Introduction The diagnosis of depressive disorders has suffered important modifications throughout DSM and ICD editions. The history of those modifications is an important subject to fully understand the current diagnostic criteria and classification, with milestones often set not by scientific or theoretical data but rather by political decision and conflicting interests.

Objective The authors propose a review of how the concept of major depression has evolved along the several DSM and ICD editions.

Methods The results were obtained searching literature included on the platforms PubMed, Google Scholar, PsycINFO and Psychology and Behavioral Sciences Collection.

Results The current diagnostic entity lacks validity and utility and that is an obstacle to both scientific research and clinical practice.

Conclusion The authors also discuss alternative models which may contribute to a paradigm shift more suitable to clinical reality and to provide a useful framework for all levels of research.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The aim of this study is the approach to mental illness and specifically in serious mood disorders, long-term treatments that improve adherence as continuous treatments ensure compliance are needed, they minimize the risk of relapse and readmission and therefore increase the chances to have a good fit and social, relational and even occupational functioning. We analyzed a sample of 42 male diagnosed with schizophrenia, schizoaffective disorder, chronic delusional disorder that starts treatment with paliperidone palmitate in outpatients. It is analyzed the dose of paliperidone palmitate employed for stabilization and family satisfaction at the time of stabilization is analyzed in the study. Our results are that the mean dose of paliperidone palmitate is 138 mg. The patient diagnosed with schizophrenia are 47.6% and the average dose is 132.5 mg. Chronic delusional disorder is 2.3% and the mean dose 50 mg. Other comorbidity mood disorders are 21.4% and the mean dose is 183 mg. Other disorders (F70, F72. . .) are 28.5% and mean dose 133 mg. The average family satisfaction (minimum 1 up to 5) is 4, with the high-

est score among patients diagnosed with F20. Schizophrenia. To conclude, long lasting injectable achieves important adherence and high percentage of antipsychotic monotherapy, thus reducing the side effects although our sample 4.7% which has occurred removed therefore.

Adherence to treatment program in mental health rehabilitation service

V. Martí Garnica^{1,*}, M.D. Ortega García², M.C. García Pérez², C. Sánchez Carreño²

¹ Servicio Murciano de Salud, San Andrés Community Mental Health Center in Murcia, Murcia, Spain

² CSM San Andrés, Psychiatry, Murcia, Spain

* Corresponding author.

Aims After several years of research to improve the action of antipsychotic medication and to reduce its side effects, we have realized the importance of an accurate intake of antipsychotic medication and because of it we started up a program in our Mental Health Rehabilitation Service. Therefore, we can affirm that outpatients behavior influence their intake medication and also the efficiency of the drug prescription. The main consequence of inadequate treatment compliance is an increase in relapses and hospital admission.

The aim of this program is to improve adherence to pharmacological treatment, to promote the quality of life for a better social integration, to know the use of prescribed medication, to know the health resources of the network to acquire the medication and to acquire skills for greater autonomy in the management and management of medication.

Method We analyzed a sample of 13 outpatient diagnosed with severe mental disorder that started up into our Program "Adherence to treatment" and their stabilization (less relapses and less admissions) in two years' time.

Results One of the patients have completed the aims of the program and he is living on his own, nine of them continue the program without relapses or admissions, one dropped out the program because of relapse and another one have also completed the program but he died because of somatic disease.

Conclusions The experience of this program in group format is positive, since patients acquire skills, knowledge and strategies in their own treatment in line with the recovery model in psychosocial rehabilitation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Hospital Reina Sofía, Psychiatry, Murcia, Spain

⁴ CSM Lorca, Psychiatry, Murcia, Spain

* Corresponding author.

Aim Assess the profile of side effects on sample of outpatients treated with long-lasting injection paliperidone LLIP.

Method Study of a population of 67 patients, 25 people are female and 42 are male. In female sample, more than 52% are diagnosed of Schizophrenia and the majority of female do not refer side effects (88%) and only a little percentage of 12 refer side effects such as amenorrhea (F20), stiffness (F20) and relapse (F25). In male sample, more than 54.7% are diagnosed of Schizophrenia and the majority of male do not refer side effects (80%) and only a little percentage of 20 refer side effects (F70) such fear of injection and sexual dysfunction (F21).

Results and conclusions In our sample, the number of women diagnosed with schizophrenia have a greater number of side effects respects to men with the same diagnosis. However, it would be important to increase the sample size of women to conduct a comparative study men/women to assess research in this field.

Ganser's syndrome: A nosographic approach

M. Moalla*, R. Sellami, I. Feki, S. Hentati, J. Masmoudi
CHU Hédi Chaker, Psychiatry "A", Sfax, Tunisia

* Corresponding author.

Introduction Ganser described a peculiar hysterical state, called Ganser's syndrome. This syndrome raises many etiological and psychopathological unresolved issues.

Objectives This article proposes to present the place of the Ganser's syndrome in the current nosographic framework through the analysis of a clinical case and a literature review.

Observation A 28-year-old man was admitted for fugue and memory loss. This symptomatology evolves since three days after an emotional conflict.

He complained from headache. He showed incoherent speech with approximate responses, lability, anxiety, auditory hallucinations, unstructured mild delusional ideation, cognitive difficulties, altered sleep-wake rhythm and anorexia.

Memory gaps were observed with difficulties in abstract thinking. Symptoms totally regressed after one week under anxiolytic treatment.

Comments Ganser's syndrome was evoked in the presence of suggestive symptoms: presence of a stressor factor, cardinal symptoms (approximate answers), associated symptoms (hallucinations + confusion + somatoform symptoms) and rapid restitution. Ganser considered this syndrome as a special case of crepuscular state, belonging to hysteria. Ganser's syndrome was included in DSM-III but located in factitious disorders against Ganser's position. In DSM-IV, it was positioned in unspecified dissociative disorders. In DSM-5, its place was reduced to a few words in the end of the introduction of dissociative disorders, and was no longer used as dissociative disorder.

Conclusion Although Ganser's syndrome is not part of current diagnostic criteria for dissociative disorders, clinical descriptions of Ganser remain of clinical interest by nosographic questions they have raised, in particular the link between simulation, psychiatric disorder and non psychiatric disorder.

Psychotic and obsessive symptoms: A case report

L. Montes Reula*, A. Portilla Fernández, H. Saiz García
Biomedical Research Center CIB, Psychiatric, Pamplona, Spain

* Corresponding author.

A 28-year-old patient who began three months of symptoms of low mood, apathy and anhedonia. The patient in this last month had accepted a job but the first day had left by “feeling incapable”. He asked for specialized help. He was diagnosed with severe depressive episode and antidepressant treatment. Some weeks of patient treatment did not improve. He began to voice greater feelings of hopelessness and ideas of active death secondary to his process. He was admitted a partial hospitalization for further control and evaluation. In his evolution, visual hallucinations and a mild delusional ideation of unstructured surveillance and injury were observed. The patient verbalized with little repercussion these sensor-perceptive alterations. Neuroleptic treatment was given but we could not manage high doses because of poor tolerance and side effects of treatment. The symptomatology did not improve and the patient’s anguish increased. In the moments of greater distress, the patient performed superficial cuts on his forearms that he criticized. During the following months, symptoms of an obsessive type were observed, which had already pre-entered but had been reactivated. He began to perform rituals of verification with important repercussion.

Discussion In the scientific literature the relationship between psychosis and obsession has been studied on many occasions, without reaching firm conclusions. In 2004, Poyurovsky postulated the possible diagnosis of a subgroup called “schizo-obsessive” that included both disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Safety and efficacy of sildenafil citrate in treating erectile dysfunction in patients with combat-related post-traumatic stress disorder: A double-blind, randomized and placebo-controlled study

M.R. Safarinejad

Clinical Center for Urological Disease Diagnosis and Private Clinic Specialized in Urological and Andrological Genetics, Urology, P.O. Box 19395-1849, Tehran, Iran

To evaluate the safety and efficacy of sildenafil citrate for treating erectile dysfunction (ED) in patients with combat related post-traumatic stress disorder (PTSD).

Patients and methods In all, 266 combat-exposed war veterans with ED (aged 37–59 years) were recruited. They met the Diagnostic and Statistical Manual of Mental Disorders-IV criteria for PTSD according to the Structured Clinical Interview for Patients, Investigator Version. The patients were also evaluated with the Clinician-Administered PTSD Scale, both to establish the diagnosis of PTSD and to measure symptom severity. Only patients with psychogenic ED were included in the study. The patients were randomly divided into a group of 133 who received 100 mg of on-demand sildenafil 0.75–2 h before sexual stimulation, and 133 who received placebo. Patients were asked to use ≥ 16 doses or attempts at home.

Results Sildenafil did not produce significantly and substantially greater improvement than placebo in each of the primary and secondary outcome measures ($P=0.08$). A normal EF domain score (≥ 26) at endpoint was reported by 13 (9.8%), and 11 (8.3%) of patients on the sildenafil and placebo regimens, respectively ($P=0.09$). Patients treated with sildenafil had no statistically significantly greater improvement in the five sexual function domains of the IIEF questionnaire than those treated with placebo ($P=0.08$). The incidences of treatment-emergent adverse events were significantly greater in the sildenafil arm than in the placebo group ($P=0.01$).

Conclusions Sildenafil is no better than placebo in treating PTSD-emergent ED.

Resilience and risk, mental health and well-being: How do these concepts relate?

F. Schultze-Lutter*, S. Ochsenbein, S.J. Schmidt
University of Bern, University Hospital of Child and Adolescent Psychiatry and Psychotherapy, Bern 60, Switzerland

* Corresponding author.

Introduction Resilience and well-being have become commonplace and increasingly used terms in a wide range of scientific as well as mental health political contexts.

Objectives There is much confusion about the relationship of the two constructs: while some use well-being as a proxy measure of resilience, others treat one concept as a component of the other or see interchangeably one as the prerequisite of the other.

Aims To study the definition of these two concepts in relation to each other.

Methods Literature review.

Results Both ‘resilience’ as well as ‘well-being’, have so far defied universal definition and common understanding of their respective measurement. Part of the confusion around these two concepts is the overlap in their components, in particular with regard to resilience and psychological well-being, and the lack of research on these concepts both by themselves, in relation to each other and in relation to other concepts like mental health, risk or protective (or promotive) factors.

Conclusion Our critical and comparative inspection of both concepts highlights the need for more conceptual cross-sectional as well as longitudinal studies:

- to uncover the composition of these constructs and to reach agreement on their definition and measurement;
- to detect their potential neurobiological underpinnings;
- to reveal how they relate to each other;
- to determine the potential role of developmental and cultural peculiarities.

Thus, the use of the terms resilience and well-being should always be accompanied by a brief explanation of their respective meanings and theoretical framework.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0188

Translational inhibitors as potential therapeutic tool of human neuroblastoma through mitochondrial gene expression

S. Hina

International Center for Chemical and Biological Sciences, University of Karach, Dr. Panjwani Centre for Molecular Medicine and Drug Research, Karachi, Pakistan

Neuroblastoma is a solid neuroendocrine tumour and most common type of cancer of infancy. It is a complex heterogeneous disease and many factors such as molecular, cellular and genetic features are involved in its development. Mitochondria play a pivotal role in neuronal cell survival or death. Neurons are highly reliant on aerobic oxidative phosphorylation (OXPHOS) for their energy needs. Defective activities of mitochondrial complexes I, II, III and IV have been identified in many neurological and neurodegenerative

diseases. Human mitochondria with its own genetic material meet the needs required for the assembly of subunits of the oxidative phosphorylation (OXPHOS) complexes. A number of translational inhibitors are known that could potentially effect translation of mitochondrial protein synthesis. Among these puromycin, homoharringtonine and cyclohexamide were selected for the present study. The effect of these translational inhibitors on mitochondrial gene expression for the treatment of neuroblastoma are not well established. Therefore, in this study, we have investigated the effects of these translational inhibitors on the expression of human mitochondrial gene expression in SH-SY5Y neuroblastoma cells.

We observed a significant effect on the level of mitochondrial transcripts upon exposure to these translation inhibitors in SH-SY5Y cells, however, the effects on expression of mitochondrial proteins were minimal. This suggests that translational inhibitors might not directly affect the abundance of mitochondrial proteins. Translational inhibitors induce significant effect on mitochondrial gene expression that can be lead to the new-targeted therapy for treating neuroblastoma.

Behavioral disorders in emergencies. Differential diagnosis and treatment

S.M. Bañón González^{1,*}, N. Ogando Portilla¹,
 M.G. García Jiménez¹, R. Álvarez García¹, F. García Sánchez²

¹ Hospital Universitario Rey Juan Carlos, Psychiatry, Madrid, Spain

² Hospital Universitario de Móstoles, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction The clinical case has been submitted because it presents a number of difficulties in diagnosis. After seven psychiatric hospitalizations, it does not present a definitive diagnosis, poor prognosis and multiple relapses.

Objectives Both analyze clinical, psychopathological and epidemiological characteristics of behavioral disorders in relation to a clinical case and review causes, incidence, prevalence, diagnostic, therapeutic tools and the importance of an appropriate differential diagnosis to reach a correct therapeutic approach.

Methods Review of the impact literature for the last five years concerning behavioral disorders: prevalence, incidence, pathogenesis and its relationship with psychiatric disorders encoded in DSM-V.

Results It is evident that the patient has behavioral disorders and psychotic symptoms in the context of cocaine intoxication. Although sometimes the dose of cocaine has been very small and probably not justifies in all cases a toxic psychosis, it is true that withdrawal periods have been short; therefore difficult to assess. Also mania-like symptoms have been discussed because the patient has an increased activity, dysphoric mood, anxiety and decreased need for sleep.

Conclusions Response to treatment and hyperactivity, impulsivity and inattention characteristics make us consider the diagnosis of adult Attention Deficit Hyperactivity Disorder (ADHD). ADHD in adults and adolescents have significant comorbidity with substance abuse, particularly cocaine, amphetamines and psychostimulants, also alcohol, tobacco and cannabis, and with other psychiatric disorders: oppositional defiant, personality (especially cluster B: antisocial, etc), anxiety (generalized anxiety, phobias, panic..), affective or eating disorders.

The connection between drugs of abuse and personality disorders

Y. Barylnik*, J. Abrosimova, S. Pakhomova, D. Samoylova, E. Kolesnichenko, A. Antonova, E. Bachilo, M. Deeva, N. Filippova, S. Sizov, A. Paraschenko
 Saratov State Medical University, Department of Psychiatry, Narcology, Psychotherapy and Clinical Psychology, Saratov, Russia
 * Corresponding author.

Introduction Patients who are suffering from different type of drugs have special individual and psychological problems. These changes are important for regulation and to control their behaviour.
Objectives To study the psychological characteristics and personal resources of the patients who are suffering from abuse of drugs.

Methods Fifty patients were studied, 63.3% men and 36.7% women and in the ages of 18–21 years. Following psychodiagnostic methods are used: Kettel's sixteen personality factor test, Leonhard-Shmishek's personality test, scale of reactive and personal anxiety Spielberger-Hanin.

Results Amount those patients were suffering from different type of drugs: synthetic cannabinoids-66.7%, 20% were dependent on synthetic cathinone and 13.3% were dependent on opiates (heroin). According to Leonhard-Shmishek's scales, the most often of personality disorders were dysthymic type, hyperthymic type and explosive type. According to Kettel's scale were indicated the leading individually-psychological properties in more than half of the subjects is the development of abstract thinking, free thinking, impulsiveness, lack of confidence to the authorities, the high emotional tension, emotional instability and irresponsibility. An analysis of global factors indicative of the severity indices of extraversion. According to Spielberger-Hanin's scale, 80% of patients with substance abuse had mild level of situational and personal anxiety, which can be identified as an important psychotherapeutic resource.

Conclusions According to scales, the most often of personality disorders were dysthymic type, hyperthymic type and explosive type. Eighty percent of patients with drug abuse had mild level of situational and personal anxiety. This feature is main of predictor as an important psychotherapeutic resource.

Bipolar disorder and substance use disorders in a Tunisian sample

S. Ben Mustapha*, W. Homri, R. Labbane

Razi Hospital, service de psychiatrie C, Mannouba, Tunisia

* Corresponding author.

Aims Describe the sociodemographic and clinical profile of patients suffering from bipolar disorder and substance use disorders comorbidity and assess the consequences of this comorbidity on prognosis and evolution of bipolar disorder.

Methods A case-control study, 100 euthymic patients treated for bipolar disorder, recruited in the department of psychiatry C of Razi hospital. Two groups of 50 patients were individualized by the presence or not of substance use disorders comorbidity. The two groups were compared for sociodemographic, clinical, therapeutic and historical characteristics.

Results Compared to bipolar patients without addictive comorbidity, those with this comorbidity had the following characteristics: we found more male, less family cohesion, more domestic violence, more criminal records, more time spent abroad, more personality disorders especially antisocial and borderline, fewer triggers of bipolar illness, more mood episodes, more psychotic features, higher impulsivity BIS-10 score, an increased need to put in a neuroleptic long term treatment, poor adherence to treatment, lower response to treatment, lower score of global assessment of functioning (GAF), more rapid cycles, shorter period of remission, longer duration of the last mood episode, poor socio-professional integration and poor quality of intervals between mood episodes.

Conclusions It seems important to insist on the identification and the treatment of bipolar disorder or substance use disorders when one of them is diagnosed. This needs to set up urgently facilities and care structures for patients with substance use disorders and to create more addiction consultations.

EV0192

Bipolar disorder and co-occurring cannabis use disorders

S. Ben Mustapha*, W. Homri, L. Jouini, R. Labbane

Razi Hospital, service de psychiatrie C, Mannouba, Tunisia

* Corresponding author.

Aims Assess the prevalence of cannabis use disorders (CUD) in patients with bipolar disorder, describe the demographic and clinical profile socio bipolar patients with comorbid addictive and assess the implications of this comorbidity on prognosis and evolution of bipolar disorder.

Methods A case-control study, 100 euthymic patients treated for bipolar disorder, recruited in the department of psychiatry C of Razi hospital. Two groups were individualized by the presence or not of cannabis use disorders comorbidity. The two groups were compared for sociodemographic, clinical, therapeutic and historical characteristics.

Results The prevalence of CUD was 27.53% ($n = 19$) in our sample. Comparing bipolar patients according to the presence or absence of CUD, we found the following results with patients with CUD comorbidity: younger, mostly male, a disturbed family dynamic, low educational level, poor socio-economic conditions, more time abroad history, more suicide attempts in history, more criminal record, more psychiatric family history, an earlier onset of the disease, a longer duration of undiagnosed bipolar disorder, more personality disorder, more frequent presence of a triggering factor for bipolar disorder, more psychotic features during mood episodes, more need of antipsychotic long-term treatment.

Conclusions The frequency of CUD in BD is higher than the prevalence in the general population and CUD is a factor in the evolution and prognosis of bipolar disorder and promotes the development of mood disorders in predisposed patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0193

Comparison of insight in bipolar disorder with and without co-morbid substance use disorders

S. Ben Mustapha*, W. Homri, L. Jouini, R. Labbane

Razi Hospital, service de psychiatrie C, Mannouba, Tunisia

* Corresponding author.

Aims Compare the level of insight in bipolar disorder (BD) with and without substance use disorders (SUD).

Methods Case-control study during a period of six months from July 2015 to December 2015. One hundred euthymic patients with BD (type I, II or unspecified) were recruited in the department of psychiatry C Razi Hospital, during their follow-up. Two groups were individualized by the presence or not of SUD co-morbidity. We evaluated and compared insight with Birchwood IS scale (with its three sub-scales).

Results The mean age was 40.6 years (± 16.4). The sex ratio was 2. Sixty-six percent of patients were diagnosed with bipolar disorder type 1 and type 2 bipolar disorder remains.

There is no statistically significant difference between bipolar with and without SUD in terms of quality of insight.

As for the subscales, bipolar patients with comorbid SUD had lower scores of awareness of any symptoms, whereas there was no significant difference regarding the awareness of illness and the need for treatment between the two populations.

Conclusions Co-morbid SUD can affect the quality of insight in individuals with BD. Patients with this co-morbidity should be targeted for intensive psycho-educational measures and psychotherapeutic interventions focused on the improvement of insight.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0194

Attempted suicide in people with co-occurring bipolar and substance use disorders

S. Ben Mustapha*, W. Homri, L. Jouini, R. Labbane

Razi Hospital, service de psychiatrie C, Mannouba, Tunisia

* Corresponding author.

Aims Study the impact of SUD co-morbidity on suicide risk in patients with BD.

Methods Case-control study during a period of six months from July 2015 to December 2015. One hundred euthymic patients with BD (type I, II or unspecified) were recruited in the department of psychiatry C Razi Hospital, during their follow-up. Two groups were individualized by the presence or not of a SUD co-morbidity.

Results The average age of patients with SUD was 44.02 years that of the patients without SUD was 44.12 years.

The sex ratio of patients with SUD was 5.25 and that of patients without SUD were 0.61.

Twenty-six percent of patients with SUD comorbidity had a history of suicide attempts. Fourteen percent of patients without SUD had a history of suicide attempts.

The association between SUD and history of suicide attempts was not significant ($P = 0.134$).

The average suicide attempts were 3.08 for patients with addictive behaviors and 2.00 for patients without SUD.

The association between SUD and the number of suicide attempts was not significant ($P=0.375$).

The means of suicide attempts used were drugs in 12% of cases, 3% of cases by phlebotomy, 3% of cases by hanging, 3% of cases by immolation, 2% of cases of organophosphate ingestion, 3% of cases by defenestration, 3% of cases by the precipitation front of a vehicle and 1% of cases by drowning.

Conclusions Co-morbid SUD in individuals with BD is significantly associated with suicide attempts. Individuals with this co-morbidity should be targeted for intensive suicide prevention efforts.

Intellectual developmental disorders, autism, and schizophrenia spectrum: New boundaries in the neurodevelopmental perspective

M. Bertelli^{1,*}, L. Salvador-Carulla², R. Keller³, E. Bradley⁴

¹ Fondazione San Sebastiano, CREA Research and Clinical Centre, Florence, Italy

² Faculty of Health Sciences, University of Sydney, Brain & Mind Centre, Centre for Disability Research and Policy, Sydney, Australia

³ Local Health Unit ASL 2, Adult Autism Spectrum Disorder Center, Turin, Italy

⁴ University of Toronto, Department of Psychiatry, Toronto-Ontario, Canada

* Corresponding author.

Background and aim Recent evidences of clinical overlap, familial co-aggregation, and shared genetic alterations support a neurodevelopmental deviation to represent a probable common vulnerability factor not only for the psychiatric disorders included in the meta-structure of neurodevelopmental disorders, but also for other major psychiatric disorders, including schizophrenia.

The present paper reviews the literature to identify (1) positive and negative implications of the increasing enlargement of the group of neurodevelopmental disorders and (2) most useful clinical aspect for re-defining diagnostic boundaries between syndromic groups. **Methods** The search purpose was reached through a systematic mapping of literature.

Results The last years' trend to increasingly enlarge the number of psychiatric features comprised in the autism spectrum should be better evaluated for potential negative impact on research and clinical resources for those autistic syndromes more reliable with Kanner's descriptions or associated with lower personal functioning profiles and different level of ID.

Crucial clinical aspects for the differentiation resulted to be age of onset, interest towards others, main positive symptoms, and anatomical anomalies of the central nervous system.

Conclusions While on one hand the neurodevelopmental perspective might contribute to a better understanding of the multifactorial aetiopathogenetic mechanisms underlying many psychiatric disorders and provide new intervention strategies, on the other hand it might determine a premature abandonment of the traditional nosology and the appearance of very broad spectrum conditions covering all the range of current psychopathology.

EV0196

One-year changes in psychiatric disorders following bariatric surgery

E. Bianciardi^{1,*}, D.L. Giorgio¹, N. Cinzia¹, G. Flavia¹, G. Paolo², S. Alberto¹

¹ University of Rome Tor Vergata, Systems Medicine, Rome, Italy

² University of Rome Tor vergata, Department of experimental medicine and surgery, Rome, Italy

* Corresponding author.

Introduction Psychiatric disorders in obese patients range from 20% to 60%, with a lifetime prevalence as high as 70%. Bariatric surgery (BS) is an effective therapy for long-term weight control and ameliorates comorbidities. After BS, psychiatric outcomes are still a matter of controversy. Moreover, while psychosocial pre-surgical evaluation is mandatory, post-operatively psychiatric follow-up programs are lacking. Aim of this prospective study was to examine changes in psychiatric symptoms and weight over 1 year of follow-up among a population of individuals submitted to BS.

Methods One hundred forty eight participants were enrolled, 98 women and 50 men; mean age was 46 (SD = 10.7), and mean BMI was 46 (SD = 7.7). Clinical interview and self-report instruments were administered before and one year after BS. Depressive symptoms were measured using Beck Depression Inventory (BDI), Binge Eating Disorder was measured using Binge Eating Scale (BES).

Results One year after surgery 86% of patients achieved a percentage excess weight loss (%EWL) $\geq 40\%$. Rate of psychiatric comorbidities declined from 41% at pre-surgery to 12% at 1 year post-surgery, $P=0.01$. BDI mean score declined from 12 to 8, $P>0.000$. After BS, binge eating, depressive symptoms, and age were independent and significant predictors of %EWL ($F_{6,523} = 79.599$, $P < 0.0001$, $adjR^2 = 0.471$).

Conclusions We reported an improvement of psychiatric symptoms through 1 year after BS. Post surgical binge eating disorder and depression were associated with less weight loss after surgery, adding to the literature suggesting that psychiatric disorder after surgery, unlike pre-surgery, are related to suboptimal weight loss.

EV0197

Improving dual diagnosis care in acute psychiatric inpatient settings through education

K. Bonnie

Providence Health Care/Yale University, Psychiatry, Langley, Canada

* Corresponding author.

Background Patients with co-existing substance use and mental disorder (dual diagnosis) have complex and challenging care needs. Acute psychiatric care settings play a vital role in providing services for patients with dual diagnosis as they often do not voluntarily seek treatment. This is significant in that recent data reveals that 57% of the psychiatric inpatients at an inner city hospital in Vancouver, Canada are characterized as dual diagnosis.

Purpose To develop an educational module which will equip nurses/practitioners with the skills and knowledge required to deliver evidence-based dual diagnosis care in acute psychiatric settings.

Methods A survey of 74 nurses working in acute psychiatric settings was completed to identify their learning needs and challenges. This was followed by a comprehensive review of evidence from literature to identify competencies, knowledge and skills needed to deliver dual diagnosis care. Content for the educational module was then validated by a panel of leading international experts on dual diagnosis. Two focus groups of acute psychiatric nurses were then

conducted to discuss content. An 8 hour educational session was then developed and piloted using the content that was reviewed and validated.

Results Thirteen content areas were identified and validated by experts. Evaluations from participants of the educational session suggest improved knowledge, skills and competencies in dual diagnosis care.

Conclusions This project translates evidence into practice, contributes to the body of knowledge on dual diagnosis care and improves practitioners' confidence and competency in delivering evidence-based care which also will improve patient care outcomes and experiences.

EV0198

QTc Interval in psychiatric inpatients: A retrospective study

N. Brondino*, L. Fusar-Poli, M. Rocchetti, M. Besozzi, A. Mori, F. Fasoli, P. Politi

University of Pavia, Department of Brain and Behavioral Sciences, Pavia, Italy

* Corresponding author.

Introduction Several psychotropic medications (i.e. antipsychotics, antidepressants) have been recently associated with QTc prolongation. Despite literature data report only mild prolongation of QTc following the use of antidepressants or typical antipsychotics, post-marketing studies have clearly evidenced an increased risk of QTc prolongation and potentially lethal arrhythmias (i.e. torsade de pointes) in psychiatric patients.

Objectives We aimed to evaluate the prevalence of prolonged QTc and to identify potential predictors influencing QTc in a psychiatric inpatient population.

Methods Medical records of 200 patients admitted to our psychiatric ward between 2007 and 2012 were retrospectively reviewed.

Results Prevalence of prolonged QTc at admission was very low (0.1%). No significant differences in QTc interval were observed between patients taking or not antipsychotics ($P=0.66$), mood stabilizers ($P=0.36$), or antidepressants ($P=0.07$). A statistically significant difference was observed between patients on depot formulation and patients who were taking oral antipsychotic ($P=0.02$). However, the pharmaceutical class of the medications appeared not significant.

Conclusions We observed a very low rate of QTc prolongation in psychiatric inpatients at admission. Surprisingly we did not find a significant effect of specific medications; however, in our sample intramuscular formulation was associated with lower QTc interval.

Attention deficiency hyperactivity disorder and Internet addiction comorbidity: A case report

Ö.Ç. Cenker^{1,*}, A.C. Ercan², D. Sarikaya Varlik¹, T. Uyar³

¹ Kackar State Hospital, Psychiatry, Rize, Turkey

² Recep Tayyip Erdogan, University Faculty of Medicine, Psychiatry, Rize, Turkey

³ Kackar State Hospital, Neurology, Rize, Turkey

* Corresponding author.

Introduction Internet addiction is a serious problem especially for children and adolescents. It is described by an individual's inability to control the Internet, which causes distress and functional

impairment. Internet addiction symptoms can be Internet surfing, computer gaming, chatting and gambling by using Internet. Previous studies regarding Internet addiction can interfere with some psychiatric disorders; such as bipolar disorder, depression, anxiety or attention deficiency disorder (ADHD). Some researchers emphasized that psychiatric disorders and Internet addiction can be seen together and excessive use of the Internet has been associated with attention deficit hyperactivity disorder.

Case 19 years old male patient discussed in this paper who was admitted to our psychiatric service for the first time in his life, complaining about uncontrollable use of internet. He spent time more than 10 hours/day. His family finally opposed and took his computer from him, just before he got depressive symptoms. We diagnosed him ADHD by using psychometric tests and psychiatric evaluations. After medical therapy and psychotherapy, we discussed changes his psychiatric situations and symptoms.

Discussion This case emphasized possible relationship between Internet addiction and symptoms of ADHD.

EV0200

Cancer incidence in young and middle-aged people with schizophrenia: Nationwide cohort study in Taiwan, 2000–2010

L.Y. Chen

Taipei City Psychiatric Center, Taipei City Hospital, Addiction Department, Taipei, Taiwan, ROC

Aims The relationship between cancer and schizophrenia requires re-examination. We investigated the cancer risk among young and middle-aged patients with schizophrenia.

Methods Records of newly admitted patients with schizophrenia ($n=32,731$) from January 2000 through December 2008 were retrieved from the Psychiatric Inpatient Medical Claims database in Taiwan, and the first psychiatric admission of each patient during the same period was defined as the baseline. Five hundred and fourteen incident cancer cases were identified and standardized incidence ratios (SIRs) were calculated to compare the risk of cancer between those with schizophrenia and the general population. Stratified analyses of cancer incidences were performed by gender, site of cancers, and duration since baseline.

Results The incidence of cancer for all sites was slightly higher than that of the general population for the period (SIR=1.15 [95% CI 1.06–1.26], $P=0.01$). Men had a significantly higher incidence of colorectal cancer (SIR=1.48 [95% CI 1.06–2.06], $P=0.019$). Women had a higher incidence of breast cancer (SIR=1.47 [95% CI 1.22–1.78], $P<.001$). Intriguingly, the risk for colorectal cancer was more pronounced 5 years after the first psychiatric admission rather than earlier (SIR=1.94 [1.36–2.75], $P<.001$), and so was the risk for breast cancer (SIR=1.85 [1.38–2.48], $P<.001$). The cancer incidence was higher in schizophrenic patients contradicting the belief that schizophrenia was protective of cancers.

Conclusions Men and women with schizophrenia were more vulnerable to certain types of cancers, which indicate the need for gender-specific cancer screening programs.

The very special way of eating for a man with a very short bowel syndrome and an ileostomy

I. Christodoulou*, F. Tsiompanou, N. Peitsidis, G. Dounias, I. Tsakiridis, V. Kelesidou, A. Paraskevas
G. Papanikolaou General Hospital, B'surgical Department, Thessaloniki, Greece
* Corresponding author.

Aim of this study is to present the extraordinary case of a 45-year-old man with very short bowel syndrome and ileostomy, who is currently engaged in a long hospitalization module of life because of the constant need for parenteral nutrition which he has developed due to Crohn's disease treatments. Case presentation: A Russian young man, with low education, a borderline intellectual functioning and a low socio-economic status, was operated numerous times due to breakouts of Crohn's disease. For the last year, he stays mostly in the hospital. Practically he needs constant intravenous parenteral nutrition due to his very short bowel syndrome, otherwise he cannot live outside the hospital. The patient was advised by his surgeon to eat any kind of food but had the limitation to drink not more than 500 ml of water per day, (the rest of water was taken IV). During the first months, the patient seemed willing to do anything needed, but when he started to get tired, he started to drink more than 2 litres of water per day, ignoring his doctor's advice. One of his main problems was that he was able to see that eggs, meat and other food he was eating were very soon appearing in the ileostomy bag and this led him to think that he would die soon. Neither the patient himself nor his wife and relatives asked for help from supervisory bodies of the National Health System and are not at all aware of his need for transplantation.

EV0202

The interesting case of a woman who gets eating satisfaction through a gastrostomy tube

I. Christodoulou*, F. Tsiompanou, N. Peitsidis, G. Dounias, I. Tsakiridis, V. Kelesidou
G. Papanikolaou General Hospital, B'surgical Department, Thessaloniki, Greece
* Corresponding author.

Aim of this study is to show how people are getting accustomed to alternative ways of eating in cases of illness and eating disability. Case report presentation: A 60-year-old woman was admitted in the Intensive Care Unit due to an acute upper airway obstruction. The woman was tracheostomized before entering the ICU and presented a large goiter and thus she was operated two days later and a thyroidectomy was executed. Post-operatively, it was diagnosed that a tracheo-esophageal fistula was present and the patient was obliged to live with a gastrostomy for months. During the first attempts for eating via a nasogastric tube at first and later via a gastrostomy, she had various problems with enteric nutrition, most prominent of which was osmotic diarrhea. The patient asked soon to stop eating enteral nutrition and preferred to eat food of her choice according to her appetite. She insisted that she was able to receive eating satisfaction, even by eating through a gastrostomy, because her bowels gave to her a positive feedback with the form of abdominal comfort after lunches. She said that the only food that would not harm her was real food and she chose food on her own with the help of her sister. This woman never presented any kind of psychiatric disorder in the past, neither she lost her courage inside hospital, although she was forced to live with a tracheostomy and a gastrostomy for more than 6 months.

Psychogenic headache and analysis of 65 cases with craniocervical junction malformation operated

S.C. Vasconcelos^{1,*}, M.M.A. Holanda², C.I.E. Melo², T.S. Silva², S.A. Araújo-Neto², E.J. Silva Neto³

¹ Federal University of Paraíba UFPB, Public Health Nursing, João Pessoa, Brazil

² Federal University of Paraíba UFPB, Department of internal medicine, João Pessoa, Brazil

³ Federal University of Paraíba UFPB, Department of anatomy, João Pessoa, Brazil

* Corresponding author.

Introduction Craniocervical junction (CCJ) malformations are common pathologies in Northeast of Brazil, predominating Basilar Invagination (BI) and Chiari Malformation (CM), sometimes associated to syringomyelia (SM).

Aims Analyse the headache pattern in cases with CCJ malformation operated.

Methods Retrospective study of 65 cases with CCJ malformation, operated between 1994 and 2015, with analysis of headache pattern.

Results Of 65 cases operated, 29 patients (44.6%) had BI and CM, 26 (40%) had BI, CM and SM, 2, only CM and 1, CM and SM. Of all patients, 39 (49.2%) presented headache and 43 (66.1%), nuchal pain. Among those who presented BI and CM, 12 (41.4%) presented headache and nuchal pain association. Of 26 with BI, CM and SM associated, 11 (42.3%) presented headache and nuchal pain association. We notice yet the presence of brachycephaly in 44 cases (67.7%) and brevis collis in 42 (64.6%). Headache, nuchal pain, brachycephaly and brevis collis were all present in 9 patients (31%) of BI and MC group, and in 8 (30.8%) of IB, CM and SM group.

Conclusions Several denominations referred to psychogenic headache: muscle contraction headache, stress headache and, finally, tension headache, well defined in the classification of International Headache Society (IHS) with clear diagnosis criteria. Bilateral location, predominantly occipital, is an important differential diagnosis with holocranial headache or occipital secondary to craniocervical malformations, and when associated to brachycephaly and brevis collis, should be carefully investigated. Diagnostic failure in symptomatic or neurological deficit patients can sequelae due to chronic compression of structures adjacent to CCJ.

Delusional hyperthyroidism-A case report

M. Cotter^{1,*}, S. Domingues², I. Amado³, R. Massano³

¹ Centro Hospitalar Médio Tejo, Psiquiatria, Guimaráes, Portugal

² Centro Hospitalar Médio Tejo, Psiquiatria, Leiria, Portugal

³ Centro Hospitalar Médio Tejo, Psiquiatria, Coimbra, Portugal

* Corresponding author.

Introduction Disorders of endocrine function are among the most common etiology of psychiatric illness.

The link between psychosis and hyperthyroidism is still poorly understood. We report an unusual presentation of hyperthyroidism as a psychotic state. Careful history, physical examination, and laboratory investigation, including thyroid function tests, should be

part of the assessment of patients with any unexplained acute psychosis to detect this potentially curable disease. In this way, this article analyzes the psychiatric, physical and laboratory findings associated with hyperthyroidism and treatment.

Objectives To report a case of psychosis in a patient with endocrine disease.

Methods Clinical records. Research on PubMed and Medscape using the Mesh Terms “hyperthyroidism”, “psychosis” and “thyroid and psychiatric manifestations”.

Results We present the case of a male patient, previously followed on our ambulatory psychiatric service for drug-induced psychosis. He was hospitalized due to psychotic symptoms, without substance abuse. Inpatient evaluation diagnosed hyperthyroidism. The patient did not present any somatic changes, except for psychosis. The patient was effectively treated with antipsychotics. He was referred to further evaluation and started antithyroid therapy.

Conclusions Thyroid disease should be considered in the differential diagnosis of a broad spectrum of psychiatric symptoms. Psychosis is a rare complication of hyperthyroidism, ranging between 1–20%. The typical psychosis is reported to simulate manic-depressive psychosis. This association reinforces the need of a careful clinical evaluation in patients presenting with psychosis. Such psychiatric symptoms remit successfully with concomitant administration of antipsychotics and normalization of thyroid levels.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Alcohol use and bipolar disorder comorbidity: Synthesis and perspectives

A. Dahdouh^{1,*}, B. Semaoune², A. Tremey³, L. Samalin³, V. Flaudias³, I. De Chazeron³, P.M. Llorca³, G. Brousse³

¹ University of Oran, Departement of Psychiatry, Oran, Algeria

² University of Algiers, Departement of Psychiatry, Algiers, Algeria

³ University Hospital of Clermont Ferrand, Departement of psychiatry, Clermont Ferrand, France

* Corresponding author.

Objective Alcohol use disorders and bipolar disorder commonly co-occur and both are associated with more pejorative outcomes, thus constituting a major public health problem. We undertook this synthetic review to provide an update on this issue in order to clarify the nature of the relationship between the two disorders, improve clinical outcomes, prevent complications and therefore optimize management of patients.

Methods We conducted an electronic search by keywords in databases MEDLINE, EMBASE, PsychINFO, published in English and French from January 1985 to December 2015.

Results The AUD prevalence is important among BD patients in whom the effects of alcohol are more severe. However, in terms of screening, it appears that the comorbidity is not systematically sought. The concept of co-occurrence finds its clinical interest in the development of specific screening and therapeutic strategies. To date, there are only few recommendations about the management of dual diagnosis and the majority of them support “integrated” approaches.

Conclusions Recommendations should emphasize this strong co-occurrence and promote systematic screening and offered integrated cares.

² Habib Bourguiba Hospital, Neurology, Sfax, Tunisia

* Corresponding author.

Introduction Epilepsy is a chronic disease defined as a brain disorder, characterized by a predisposition to present seizures, generating cognitive, psychological, and social consequences.

Objective To determine the prevalence of psychiatric comorbid disorders in patients with epilepsy (PWEs) and its associated factors.

Methods We conducted a cross-sectional study involving 30 PWEs who were treated in the neurology department of Habib Bourguiba Hospital in Sfax, Tunisia. We used the Mini International Neuropsychiatric Interview for the diagnosis of Axis I psychiatric disorders.

Results The half of patients had psychiatric comorbidities: 4 had major depressive disorder (MDD), 2 had MDD with generalized anxiety disorder, 4 had MDD with social phobia, 1 had bipolar disorder type I, 1 had panic disorder, 1 had agoraphobia and 2 had generalized anxiety disorder.

Twenty-five PWEs had seizure-onset below 30 years old and among them, 40% had psychiatric comorbidities. Among patients who had seizure-onset above 30 years old, none had psychiatric comorbidities. Psychiatric comorbidities were found in 71.5% of patients with seizure frequency >2 per year. Psychiatric comorbidities were more common in patients with generalized seizures compared to whom with partial seizures (53% versus 45%). It was also more common in patients treated with polytherapy compared to whom with monotherapy (64% versus 37.5%).

Conclusion The prevalence of psychiatric comorbidities is relatively high among PWEs. The most frequent diagnoses found were mood and anxiety disorders. It is very important to identify them and treat them to enhance seizure control.

Cancer, depression symptoms and quality of life: The role of creativity

L. Delpech^{1,*}, F. Sordes², J.L. Sudres³

¹ CERPPS/LORDAT, Psychopathology, Toulouse, France

² CERPPS, Psychologie de la santé, Toulouse, France

³ CERPPS, Psychopathologie, Toulouse, France

* Corresponding author.

The diagnosis of cancer is associated with the occurrence of psychopathological symptoms, which cause even more difficulties to patients. Scientific research demonstrates that creativity could help increase the general population's quality of life and regulate their negative emotions, but only a few studies are available on the link between creativity and the regulation of patients' respective experience. This study aims at (1) measuring the impact of creativity on the patient's level of depression and quality of life and (2) evaluating the psychopathological profile of the creative person. Thirty-five subjects undergoing chemotherapy treatment (age: 61 + 11) took part in this study. The experimental protocol is composed of creativity, depression and QoL tests. The results show that creativity is negatively correlated with depression level and positively with QoL ($r = -.45$; $P = <.05$ and $r = .54$; $P = <.01$ respectively). The linear regressions show that creativity is a variable, which predicts a high QoL ($F = 13.83$; $P = .001$). Also, 29.5% of the QoL variability is explained by creativity. A cluster analysis sorted out three different groups:

very creative persons (VCP); mildly creative persons (MCP); slightly creative persons (SCP). VCPs have a significantly lower level of depression and have a better QoL compared to SCPs. MCPs have a level of depression between the other groups and a similar level of QoL than VCPs. These results suggest that creativity could have a noticeable influence on how patients experience their cancer. Further studies on this phenomenon will be necessary for creativity to be taken into account for psychological follow-up in oncology.

Temporal tumor as a cause of bipolar-like disorder?

S. Domingues^{1,*}, M. Cotter², I. Amado³, R. Massano⁴

¹ Centro Hospitalar do Médio Tejo, Hospital de Tomar, Psiquiatria, Leiria, Portugal

² Centro Hospitalar do Médio Tejo, Hospital de Tomar, Psiquiatria, Guimarães, Portugal

³ Centro Hospitalar do Médio Tejo, Hospital de Tomar, Psiquiatria, Coimbra, Portugal

⁴ Centro Hospitalar do Médio Tejo, Hospital de Tomar, Psiquiatria, Tomar, Portugal

* Corresponding author.

Introduction The relationship between brain tumours, temporal epilepsy and psychiatric symptoms are historically known.

Objectives To report a case of mania in a patient with previous diagnosis of bipolar disorder, temporal tumour and temporal epilepsy.

Methods Clinical records. Research on PubMed, using “lateral temporal epilepsy” or “brain tumour” and “mania”.

Results A 52 years old man was conducted to the emergency department by the police. He was found with psychomotor agitation at the Sanctuary of Fátima. He was apparently hyperthimic with flight of ideas. He had a history of epilepsy and temporal tumour and two previous manic episodes. It was assumed as a manic episode.

During inpatient evaluation, patient had memory for the occurrence. He described a sudden onset on the day before, after drinking wine. He described delirant atmosphere, persecutory and mystic delusional beliefs “this is the third secret of Fátima being revealed”, followed by ecstasy and psychomotor agitation. Remission was obtained in one week on psychotropics. MRI documented the lesion. Electroencephalography performed one month later revealed “slow waves.”

Conclusions Organic causes should be excluded before consider a psychiatric disorder. The hypothesis of epilepsy-related psychosis or mania and other effects of a temporal tumour should be considered in etiology. However, co morbidity with bipolar disorder cannot be excluded.

Misophonia and affective disorders: The relationship and clinical perspective

M. Erfanian^{1,*}, J. Jo Brout², A. Keshavarz³

¹ Maastricht University, Faculty of Psychology and Neuroscience, Maastricht, The Netherlands

² International Misophonia Research Network, Sensory Processing Disorder, New York, USA

³ Azad University, Psychology, Torbat-e-Jam, Iran

* Corresponding author.

Misophonia is characterized by aversive reactivity to repetitive and pattern based auditory stimuli [1]. Misophonic sufferers demonstrate autonomic nervous system arousal, accompanied by heightened emotional distress. Sufferers describe extreme irritation, anger, and aggressive urge with physiological reactions including hypertonia, diaphoresis and tachycardia [2]. Some studies have found comorbidity with psychiatric disorders. However, most of these studies used small samples and few experimental methodologies [3]. This study identifies the possible relationship between misophonia and affective disorders, and any difference between the severity of misophonia in male and female patients. Fifty misophonic patients (female = 25, mean age = 46.28) were evaluated with Amsterdam Misophonia Scale (A-MISO-S) for the diagnosis of misophonia and with the M.I.N.I International Neuropsychiatric Interview for the diagnosis of affective disorders. Among $n=50$ misophonic patients, we found major depression (MDD) = 11, melancholic depression = 5, dysthymia = 11, suicidality = 10, manic = 3, panic disorder = 8, agoraphobia =, social phobia =, obsessive compulsive disorder (OCD) = 14, post-traumatic stress disorder (PTSD) = 15. Misophonia was associated with MDD ($U=76, P=.001$), suicidality ($U=67, P=.001$), OCD ($U=115, P=.002$) and PTSD ($U=142.5, P=.008$). There was an indication of a significant difference between men and women in severity of misophonia ($U=160.5, P=.002$). The presence of these varying affective disorders suggests that the sufferers are at high risk for affective disorders. Investigation of the co-morbidity will assist researchers to better understand the nature of the symptoms and how they may be interacting.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Therapeutic patient education: A solution to the treatment of obesity and metabolic syndrome in psychiatry

A. Bailly, L. Fau, C. Lourieux, N. Gramaje, A. Mechain, A. Arnaud, F. Pillot-meunier*

Centre Hospitalier Le Vinatier, Pole Up Mopha, Bron, France

* Corresponding author.

Introduction/objectives Obesity and overweight are major public health issues. Obesity is a risk factor associated with many non-communicable diseases such as diabetes, certain types of cancers, musculoskeletal disorders and cardiovascular, dermatological or gastroenterological diseases. Patients with severe psychiatric disorders have a higher risk of developing overweight or obesity than the general population. The risk of obesity in schizophrenics patients can be multiplied by a factor ranging from 2.8 to 3.5. Patients suffering from mood disorder have slightly lower risk of obesity, however we still consider a factor ranging from 1.2 to 1.5. This significant weight gain can be partly explained by medication.

Methods The hospital centre Le Vinatier, in France, has developed a therapeutic patient education program in helping patients to self-manage their preventable disease. In order to tackle the multifaceted nature of obesity, the program used the expertise of many different professionals: general practitioners, dieticians, dentists, physical adapted education teachers, pharmacists, nurses and so on. This programme is provided for patients suffering from obesity or an overweight complicated by diabetes, or/and metabolic syndrome, and/or history of cardiovascular diseases or/and a failure of a dietary monitoring. The program includes individual care and collective workshops in nutrition, oral health, body image, adapted physical education, and roundtable.

Results/conclusions A retrospective study has already shown that this therapeutic patient education program, like others before, presented better results than dietary consultations. A prospective study is currently being carried out to validate these results in the long term and to demonstrate the benefit associated to this program.

Prevalence of depression among patients with tuberculosis at Perundurair TB hospital, Tamilnadu–depression, a comorbidity of TB

D.L. Francis

Tamil Nadu Dr MGR Medical University, Public Health, Chennai, India

* Corresponding author.

Introduction Tuberculosis is one of India's major public health problems. According to WHO estimates, India has the world's largest tuberculosis epidemic. Many research studies have shown the effects and concerns revolving around TDR-TB especially in India, where social and economic positions are still in progression. **Materials and methods** Seventeen questionnaires were administered to the consented participants regarding the demographic data and awareness, also Hospital Anxiety and Depression Scale (HADS) was recorded to analyse the level of depression. The average age was 32.3 years (STD = 12.7), and the age range was from 13 years to 71 years. The data collected was analysed with SPSS 19.

Results The patients who were in the intensive phase had a considerably higher depression rate (42%) than the patients who were in the continuous phase (22%). However, the variations were not enough for the statistical significance. The patients with TB only (35%) showed a higher depression rate than the patients with TB/HIV (28%).

Conclusion According to this study, it can be found that the prevalence of depression was lower for patients who were old, female, college educated, married, and earned the highest, compared with their counterparts. Most of these findings might agree with a general perception that social and financial stabilities would provide a less likelihood of being depressed.

Prevalence and predictors of metabolic syndrome in a sample of Italian psychiatric inpatients

L. Fusar-Poli*, N. Brondino, M. Rocchetti, M. Ballerio, M. Vercesi, F. Grasso, P. Politi

University of Pavia, Department of Brain and Behavioral Sciences, Pavia, Italy

* Corresponding author.

Introduction Psychiatric population is characterized by a higher prevalence of cardiovascular events compared to general population. This difference might be due, in part, to the metabolic adverse effects of psychotropic agents, and, in part, to common risk factors such as smoking, sedentary lifestyle and unhealthy diet. Another potential risk factor is represented by the presence of metabolic syndrome (MetS).

Objectives We aimed to evaluate the prevalence of MetS and to identify the baseline predictors for the longitudinal development of MetS in a sample of Italian psychiatric inpatients.

Methods Medical records of 343 patients admitted to our psychiatric ward between 2007 and 2012 were retrospectively reviewed. **Results** Prevalence of MetS was 21.5%. MetS appeared directly associated with age and number of medication assumed. ROC curves showed HDL as the best predictor of metabolic syndrome in our sample.

Conclusions Our results confirm previous data on the association between metabolic syndrome and exposure to complex polytherapy. Additionally, our findings support the notion of psychiatric patients as an at-risk group for metabolic abnormalities, which should be carefully monitored.

Introduction Pathological gambling, as behavioural addiction, is always related with psychosocial important problems. In this case, everything is even more difficult due to grave mental disease associated, Paranoid Schizophrenia. Man, 26 years old, single. He was diagnosed of psychotic disease at the beginning due to his grave addiction to THC and others stimulant drugs. His outpatient treatment was complicated and he needed to be hospitalised once (being diagnosed of Schizophrenia). After that, he improved till he got a standardised job. He was able to have his medical treatment (Aripiprazol 15 mgs per day and Biperidene 4 mgs per day) although he kept his isolation. Then, the patient could talk about his pathological gambling. He suffered from slot machine addiction, and he also suffered from depression symptoms closely related to family and economic problems due to pathological gambling. This patient was in contemplation state and he accepted to start with antidepressant (Mirtazapine 15 mgs per day) and psychological treatment. We agreed to make a record of his gambling uses (with regular self-reports). His salary would be administered by his parents and he only could take a little money every week. The treatment was useful; it increased the capacity of economic self-management and the recovery of depression disease related.

Conclusions In our opinion, he used gambling as filling a need for activity, and as a way of connecting with society/world. These findings suggest the need for improved prevention and treatment efforts related to problem/pathological gambling in individuals with psychotic disorders.

* *Corresponding author.*

Since Dual Disorders expression was used for the first time, the old dilemma between categorical and dimensional grew again as a main issue because many authors wondered about its utility. The question was how far we can speak about two different entities, because doing so we are assuming comorbidity instead of a complex syndrome, with different clinical presentations (i.e. Talking about fever and cough instead of pneumonia). Child and adolescence psychiatry uses developmental psychiatry as a very useful tool to understand patients. Syndromes are seen as dynamic as patients. At the same time that patients grow their clinical presentations, evolves new symptoms or signs. We have reviewed retrospectively a group of twenty patients that were named as dual disorders, with different substance abuse but a common path in their childhood; all of them were diagnosed of ADHD and Conduct Disorder. We chose them because of the differences that DSM, ICD and main researchers have about this group, which some consider better described as a Disocial hiperkinetic disorder (ICD) than a ADHD with a conduct disorder associated (DSM), comorbidity again. We agreed with ICD opinion and will discuss how in some way we are somehow as those blind people describing different parts of the same elephant when we talk sometimes about dual. Truth is that opposite dual view or its syndromic treatment developmental psychiatry has all the time underlined the role of reward circuits/executive functions as epigenetic issues, both modulated by gene and environment.

¹ *University of Trieste, Mental Health Department, Trieste, Italy*

² *University of Udine, Mental Health Department, Trieste, Italy*

³ *University of Udine-Italy, Dependency Department, Trieste, Italy*

* *Corresponding author.*

Introduction The factitious disorder is characterized by simulation or exaggeration by the subject of his/her physical or psychological symptoms to take a sick role. This disorder may be associated with a real disease, used to simulate other symptoms and receive treatment. Our case is represented by a 49-year-old man, affected by Arnold Chiari Malformation Type I (ACM-I), a structural defect in the cerebellum with extension of the cerebellar tonsils into the foramen magnum, without involving the brain stem. The patient had three surgical operations involving the complete resolution of the disease. However, the subject reported a worsening of all symptoms, with the outcome of a severe self-limitation, with admission to a residential care and taken over by the multidisciplinary equipe of the district. Symptoms, which mainly consisted in pain, motor functional impairment, headaches, slurred speech were not evaluated due to the ACM-I. This diagnosis was confirmed when there was the complete resolution of the symptoms in a date pointed by the patient.

Methods To make an appropriate differential diagnosis, in addition to the neurological examination, the subject had psychiatric interviews and completed an MMPI evaluation.

Results Neurological examinations revealed no residual outcome of the ACM-I. At MMPI there were not significant peaks. Regarding to the attitude towards this test and its validity, it appears an obvious attempt to lie from the patient, which tries to present himself in a favourable unrealistically way.

Conclusion This case shows that appropriate diagnosis can help health services in a better management of their resources in such situations.

Does comorbid depression and alcoholic dependence influence cognition in Bulgarian women?

V. Giannouli^{1,*}, D. Ivanova²

¹ *Aristotle University of Thessaloniki, School of Medicine, Drama, Greece*

² *South-West University "Neofit Rilski", Department of Psychology, Blagoevgrad, Bulgaria*

* *Corresponding author.*

Introduction Previous research on the impact of alcohol intake on human behavior and cognition has revealed the detrimental effects of alcohol dependence. Especially in women, depression is often associated with the initiation of alcohol abuse that provokes new episodes of depression and this cycle tends to chronify.

Objective Although the co-occurrence of depression and alcoholism is well documented, there is still scarce data on the cognition of depressed alcohol-dependent women. The aim of the present study is to examine the cognitive function in women who demonstrate both depression and alcohol dependence.

Method A group of fifty-three Bulgarian women with a formal diagnosis of alcohol dependence (Mage = 43.89, SDage = 9.48; level of education: all with high school education) and varying levels of depressive symptomatology were examined at the Municipal Council on Drug Addiction Blagoevgrad. Information were collected from personal history taking (anamnesis), self-reports and the Lesch Alcoholism Typology-Questionnaire (LAT online program). The women were grouped according to their age (27–45 and 46–71).

Results Results indicated that there is a significant influence of depression ($P = .032$), a slightly above the statistical significance level non-influence of age ($P = .056$), and an interaction of the influence of depression*age ($P = .048$) on self-reported cognitive performance.

Conclusions The present research suggests that future researchers should further clarify in a more systematic way the factors that influence cognition in this special population with comorbid depression and alcoholic dependence.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The relationship between personality disorders and substance abuse disorders

S. Goretta^{1,*}, M.D.C. Sánchez Sánchez², P. Lucas Borja², G. Bautista Rivera², M. Rodríguez Lara²

¹ *U.G.C Salud Mental Almería, UHSM Torrecardenas, Almería, Spain*

² *Almería, Spain*

* *Corresponding author.*

Introduction A frequently observed fact in clinical practice is the relationship between Substance Abuse Disorders and Personality Disorders (PD). Epidemiological investigations have found that diagnoses of PD seem to increase vulnerability to other pathologies, including substance abuse and addiction, and it is possible to speak of comorbidity or dual pathology.

Objective To describe the comorbidity between PD and substance abuse disorders.

Methods Systematic review of the literature on the subject. The databases consulted were Dialnet, Pubmed and Cochrane.

Results The various studies allow estimating that between 65% and 90% of subjects treated for substance abuse or dependence have at least one concomitant PT. Studies show a higher prevalence of Cluster C for alcohol consumption and Histrionic, Narcissistic, Boundary and Antisocial Disorders (Cluster B) for illegal drugs, mainly cocaine. Cluster B is the one that the literature has most related to substance use. It is also the group in which there is a greater predominance of impulsivity, which would be worth remembering its role as a vulnerability factor for addictions.

Conclusions What the research has shown is that a good deal of the problems that accompany substance use come from dysfunctional patterns of behavior that are maintained over time with high stability and can justify, in part, both the persistence of the addictive behavior as the difficulty of handling the patients who present them. At present, although the high comorbidity between TP and substance use is sufficiently documented, many questions still remain to be solved.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Treatment difficulties in the pathology of the frontal lobe

A. Isac^{1,*}, B. Cristina¹, L. Viorel²

¹ Children's Emergency Hospital, Child and Adolescent Psychiatry, Cluj-Napoca, Romania

² "Iuliu Hatieganu" University of Medicine and Pharmacy Cluj-Napoca, Neuroscience Department- Psychiatry and Child and Adolescent Psychiatry Compartment, Cluj-Napoca, Romania

* Corresponding author.

Frontal lobe lesions may present as mood disorders, with apathy, emotional flattening and indifference towards the environment, referred to as "pseudodepression". A 14-year-old adolescent is transferred from a pediatric ward for frontal headaches, sleepiness, apathy, food refusal, irritability and marked weight loss (BMI = 14 kg/sqm). The patient has a history of Socialized Conduct Disorder, with extremely low compliance towards treatment. When admitted he is cooperating partially, has an influenced general state and refuses to drink liquids. He is sad, impulsive, with low frustration tolerance, negativist, oppositionist, with voluntary urine emissions and marked sleepiness. There are clinical signs of dehydration and an intermittent convergent strabismus in the left eye. Laboratory tests show an inflammatory syndrome, nitrate retention, dyselectrolytemia. Neurologically: exaggerated tendon reflexes, frust bipyramidal syndrome, slight ptosis of the left eye; electroencephalogram–slow activity (lesion?) in left deviations. A consult with the Infectious Disease unit renders a diagnosis of headache syndrome and frontal sinusitis. The MRI is suggestive for a left frontal infectious expansive process (abscess) and massive maxillary–ethmoidal–frontal sinusitis. Combined parenteral antibiotics and pathogenetic treatment are initiated and the patient undergoes neurosurgery with the evacuation of the tumor. A cystic formation of 6/5/1, 5 cm, containing an opalescent yellow liquid is found at the histopathological exam. Streptococcus spp. is identified by the bacteriological exam. The evolution is good under treatment, with a slight accentuation of the behavioural symptoms. This case illustrates the importance of correct differential diagnosis, the psychiatric diagnosis being one of exclusion.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychiatric comorbidities in temporal lobe epilepsy: A case study

L. Jouini*, U. Ouali, R. Zaouche, R. Jomli, Y. Zgueb, F. Nacef
Razi hospital, "A" psychiatry department, Tunis, Tunisia

* Corresponding author.

Introduction Psychiatric disorders frequently occur in patients with temporal lobe epilepsy (TLE) (70%). This combination further reduces the quality of life of patients as diagnosis is difficult and therapeutic opportunities are often missed.

Objectives The aim of this case study is to show the possible association between TLE and psychiatric semiology and its therapeutic implications.

Methods Presentation of the clinical case of Mr BH who experienced psychosis like symptoms, was finally diagnosed with TLE and put under anti-epileptic drugs.

Results Mr BH, aged 22, with no family or personal history, was admitted for aggressive behavior, self-harm, pyromania, and depression. Three years prior to onset of psychiatric symptoms, he reports episodes of pulsatile–left–temporal headache followed by hypertonic movements of the neck. Symptoms were intermittently followed by total amnesia or impaired consciousness. The patient explained symptoms by an inner presence that he called "his twin" and to whom he attributed those behaviors contrary to his will. The discovery of bilateral hippocampal atrophy in magnetic resonance imaging with a normal electroencephalography suggested the diagnosis of TLE with post-ictal psychotic disorders. Patient was put initially on diazepam and olanzapine with partial improvement. Association of valproate led to progressive but then complete disappearance of symptoms and so confirmed our diagnosis.

Conclusions It is often difficult to attach psychiatric symptoms to epilepsy. The diagnosis should be done on a set of clinical, radiological and electrical arguments.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clinical features of PTSD in patients with TBI

O. Khaustova^{1,*}, O. Smashna²

¹ Bogomolets national medical university, psychosomatic medicine and psychotherapy, Kiev, Ukraine

² SHEI Ternopil state medical university named after I. Ya.

Gorbachevskyy MHC of Ukraine, psychiatry, Ternopil, Ukraine

* Corresponding author.

Objective Modern scientific researches about interaction between TBI and PTSD are characterized by few amounts and contradiction of conclusions.

Method Twenty-eight persons with TBI were examined by means of questionnaires and structured clinical interviews. 17 patients were suffering from PTSD. We compared clinical features in patients with isolated TBI and group with both disorders.

Results Four groups of symptoms were analyzed–sleep, emotions, cognition and personality features. Disorders of sleep were presented with violation of REM cycle, nightmares, hyperexcitation, increase watchfulness during the sleep. Emotional disorders were expressed as lability without external irritations; an excessive emotional reaction is on small events, agitation, irritability, inadequacy of emotional reactions and apathy (loss of desire to think, to feel, and/or to operate). Cognitive disorders included deceleration of psychomotor reactions, difficulties of searching of words in communication, problems of switching of attention, rigidity, difficulties in planning, decision of multistage tasks, violation of operative memory, executive dysfunction. Features of personality disorders were loss of initiation and self-control, decline of spontaneity, sur-

plus attention is to the details, inadequacy of self-appraisal, feeling of inferiority, an increase necessity is for control and lordship over other, aggression (socially inadequate behavior, episodes of anger). **Conclusions** Psychopathological features presented in patients with comorbidity of PTSD and TBI are not specific and can be within the framework of other psychogenic, exogenous, organic, posttraumatic or neurological disorders and diseases. PTSD can combine with other psychical and somatic disorders that caused chronological and pathogenetical comorbidity in patients with both states.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Influence of depression on the quality of life after stroke

E. Kostadinova^{1,*}, A. Anita²

¹ Clinical hospital Shtip, Psychiatry, Shtip, FYR Macedonia

² University clinic of neurology- Skopje- Macedonia, intensive care, Skopje, FYR Macedonia

* Corresponding author.

Aim Approximately 30–60% of the stroke survivors suffers from depression. This, together with the physical changes after stroke may lead to a decline in their quality of life (QOL). The aim of this paper was to analyse the incidence of post-stroke depression, associated risk factors and its influence on the QOL.

Material and methods We carried out a prospective study on stroke patients during a period of 6 months. We excluded patients with dysphasia and aphasia. For each patient, we collected socio-demographic characteristics as well as clinical and therapeutic data. We used the Hamilton Depression Scale to screen for anxiety and depression, the SF-36 scale to assess the quality of life and modified Rankin scale (mRS) to measure the degree of disability.

Results We included 155 men and 143 women with stroke, with mean age of 58.15 years. Out of 298 analysed patients, depression was present in 147 (49.3%). Associated risk factors were hypertension, female gender and severity of stroke ($P < 0.05$). The mean score of the SF-36 was 52.18. Impaired QOL was found in 221 (74.1%) and mRS > 3 was found in 169 (57.1%) of the patients. Impaired mental component of QOL significantly correlated with the presence of depression ($P < 0.05$) and anxiety ($P < 0.05$). The severe degree of disability had a significant negative impact on all areas of QOL.

Conclusion Important effect after stroke is occurrence of depression which affects the QOL and functional outcome. All stroke patients should be evaluated for depression through regular interviews with them and their families or caregivers. Adequate antidepressant treatment should be given, in order to improve the QOL and physical rehabilitation.

* Corresponding author.

Introduction Extended brief interventions (EBIs) are effective in targeting alcohol misuse in the general population. However, little is known on the effects of EBI in adults with intellectual (also known as learning disabilities).

Objectives In this feasibility trial we compared EBI with usual care for alcohol misuse in adults with mild to moderate intellectual disability (ID).

Methods The study took place in three community ID services in England. Participants aged 18–65 years with reported alcohol problems, a score > 8 on the alcohol use disorder identification test (AUDIT), and IQ < 70 ($\pm 5\%$ CI) were recruited and were randomly allocated to either EBI (5 weekly sessions and 1 follow-up at 8 weeks) and usual care or usual care alone. Research assessments took place at baseline, two and three months.

Results Thirty individuals were randomised (15 in each arm). In regard to harmful drinking, at baseline, all the participants exceeded the relevant threshold. At 8 weeks, the proportion of participants with harmful drinking decreased to 60% for both groups, at 12 weeks it was decreased by 66.7% and 46.7% for the intervention and the control group respectively. The unit cost for the delivery of EBI is £ 430.

Conclusions Recruitment to this trial has been proven challenging as prevalence of alcohol misuse in the targeted population was lower than anticipated. EBI may provide an effective low intensity treatment for this population. Participants' and carers' feedback on their experience was overall positive.

* Corresponding author.

Background Attention deficit hyperactivity disorder (ADHD) is a neurodevelopmental disorder characterized by persistent difficulties with attention, increased impulsivity and hyperactivity. Comorbidity is often reported in adults with ADHD with a range of 60–100% of patients having at least one co-morbid condition.

Objective The purpose of this study is to determine the prevalence of ADHD among university students and to investigate some co-occurring symptoms and disorders.

Aims We aimed to raise awareness of adult ADHD and underscore its co-morbidity.

Method 486 undergraduate students at Bezmialem Vakif university in Istanbul filled in the Adult ADHD Self-Report Scale (ASRS), Beck Anxiety Scale (Beck-A), Beck Depression Scale (Beck-D) and a purpose-designed structured socio-demographic form.

Results Our results revealed that 6% of participants reported significant ADHD symptoms using 1.5 standard deviation above mean on the ASRS. 67% of students with significant ADHD symptoms had a psychiatric history other than ADHD. History of depression, anxiety and sleep problems were significantly higher in this group ($P < 0.05$). They scored higher on Beck-A and Beck-D ($P < 0.05$). Students with significant ADHD symptoms reported more night eating, binge eating behaviours and more headache ($P < 0.05$). There was no statistically significant difference in the history of epilepsy, asthma, allergy and diabetes. Family history of psychiatric disorder partic-

ularly ADHD, depression and eating disorder were higher in the ADHD group ($P < 0.05$).

Conclusion Our results demonstrate that ADHD is prevalent among university students with high co-morbidity. Hence people with ADHD need comprehensive and lifelong assessment and management of their symptoms and needs.

Patients with mood disorders and chronic coronary artery disease receiving conservative therapy have a higher risk of death during affective episode

E.V. Lebedeva^{1,*}, E.D. Schastnyy¹, G.G. Simutkin¹, T.N. Sergienko², T.G. Nonka², A.N. Repin²

¹ Mental health research institute- Tomsk national research medical center- Russian academy of sciences, affective states department, Tomsk, Russia

² cardiology research institute- Tomsk national research medical center- Russian academy of sciences, department of rehabilitation of patients with cardiovascular diseases, Tomsk, Russia

* Corresponding author.

The contribution of comorbid with coronary artery disease (CAD) mood disorders (MD) into total mortality is contradictory.

Objective To study frequency and time until death due to general causes in groups of patients with comorbid MD, and without them as well as interrelationship of these indicators with comorbid MD and therapy with antidepressants.

Methods Inpatients with chronic CAD ($n=333$) under conservative therapy were investigated (31% females ($n=103$), 69% males ($n=230$), mean age 61.8 ± 9.8 years). Team of cardiologists and psychiatrists followed up patients for 7 years (2008–2014). Survival frequency was evaluated by method of life tables.

Results Among patients under conservative therapy of CAD the death frequency due to general causes did not differ significantly in presence ($n=80$) and absence of MD ($n=253$) and was 18.8% and 16.6%, respectively. Correlation of deaths with hypomanic and mixed episodes was revealed ($r_s=0.3$). The groups differed according to function of immediate risks: patients with MD were at high risk of death during the year after detection of affective symptoms, and in group without MD it increased over the time of observation ($P=0.0000$).

Duration of antidepressant therapy was 5.5 ± 0.5 months. Among patients receiving antidepressants ($n=20$), during therapy and after one month after discontinuation there were not deaths. Difference of function of immediate risks in these subgroups was not significant ($P=0.09$).

Conclusions Patients with affective disorders and chronic CAD under conservative therapy are at high risk of death within affective episode and therapy with antidepressants did not influence change of risk of death.

Tobacco treatment of indigent patients alcoholics rehabilitation in the Association Rauxa

M.L. Marín Puig, Dra. ML. Marín, D. Rodríguez, JM. Calvo, M.J. Acero

Associació Rauxa, directora medica, Barcelona, Spain

* Corresponding author.

Introduction Smoking is the leading preventable cause of morbidity and mortality in the world and the leading cause of death in alcoholics. The prevalence of smoking among alcohol addicts is very high as among homeless people. Both groups have a higher risk of smoking-related illnesses. It seems that quitting smoking increases the rate of alcohol abstinence. It is therefore crucial to perform treatment of tobacco dependence among this population.

Material and method Population: homeless alcoholic patients in treatment at the Association Rauxa with dependence criteria DSM-IV-TR and DSM-V, male, over 18 years. Anamnesis, examination, analysis, chest X-ray, addictive history is practiced. Patients are encouraged to start smoking treatment. Once the decision is made. Tests: motivation, Fagerstrom, fasting weight; weekly and random monitoring of CO in exhaled air. Treatment with decreasing nicotine patches. Weekly smoking therapies. Withdrawal symptoms and relapse, timely or complete, if it occurs, are evaluated. Treatment ends in one year without relapse.

Results $n=237$ (2006: $n=19$; 2007: $n=26$; 2008: $n=24$; 2009: $n=33$; 2010: $n=31$; 2011: $n=25$; 2012: $n=33$; 2013: $n=25$ y 2014: $n=21$)

Get high on2006:10/19 (53%); 2007:14/26(54%); 2008:13/24 (54%); 2009:9/33 (27%); 2010:6/31 (19%); 2011:2/25 (8%); 2012:8/33(24%); 2013:9/25 (36%); 2014:11/21 (52%). In 9 years, 82/237 (35%) finishes treatment without relapse.

Discussion A percentage of 35% is obtained discharge. Different parameters-relapse are correlated to see predictors of relapse. No correlation is found statistically significant.

Through the analysis of a case report to analyse the importance of the interdisciplinary approach in people suffering from severe mental disorders for management of an outpatient.

The diagnosis was clear, I wanted to rule out organic pathology was added due to the irregularity in the outpatient monitoring and control (F20. Paranoid schizophrenia)

Community intervention with people suffering from severe mental disorders has some peculiarities. The “in vivo” treatment requires the establishment of the frame, in a space that is constantly changing. It consists of the setting-up of a new working area. Social and community intervention is inter-institutional; include movement between different institutions (health, socio-economic and community). In this new changeable and dynamic, “working area”, the professional is of professional is essential using clinical strategies and social and community coordinating. It is important to highlight the role of community treatment for severe mental disorder. Thus developing social skills is as necessary and also combats social stigma and prejudice to achieve a social integration in community.

Substance Use Disorders (SUD) and Attention Deficit Hyperactive Disorder (ADHD) are frequent conditions in out drug treatment centers. There are evidences about the high prevalence of ADHD in SUD patients (20%) compared with just ADHD in general population (1–7.3%). Both disorders and psychiatric comorbidity are important in the diagnosis proceeding. The objective of this study is search the difference in psychiatric comorbidity conditions between patients with ADHD and Cocaine SUD and ADHD and Cannabis SUD. ADHD was present in 158 patients of a total sample in which 46.8% used cocaine, 17.1% cannabis and 36.1% used both. Mood disorders were 26.8% in cocaine users, 21.7% in cannabis and 18.9% in both. Anxiety disorders were 20.3% in cocaine users, 37.5 in cannabis and 13% in both users. Primary psychotic disorders were 2.9% in cocaine users, none in cannabis and 11.1% in both drug users. Personality disorders by cluster were, Cluster A: 11.3% in cocaine group, 36% in cannabis group and 24.5 in cannabis and cocaine group. Cluster B: 33.8% in cocaine group, 44% in cannabis group and 51.9% in cannabis and cocaine group. Cluster C: 9.9% in cocaine group, 28% in cannabis group and 19.2% in cannabis and cocaine group. There could be common pathways of neuronal damage related to psychiatric comorbidity depending of used drug, the differences in comorbidity found in this study could explain a little part of it. It is important to manage SUD-ADHD and other psychiatric comorbidity in order to improve the outcomes of these patients.

Introduction Women with bipolar disorder are more prone to psychiatric co-morbidity as anxiety, substance use disorders, eating

disorders and borderline personality disorder. Nevertheless, substance abuse disorders as co-morbidity in bipolarity are higher in males than females.

Objectives To describe differential characteristics of patients admitted to a psychiatric unit referring to gender in a group of patients with bipolar disorder co-morbid with substances disorders (dually diagnosed patients).

Methods Sociodemographic, clinical and administrative data of all patients diagnosed with bipolar admitted to a dual diagnosis during a 3-year period were collected. The psychiatric diagnosis was made according to DSM-IV-R criteria.

Results From the whole sample ($n=66$), males (84.8%) were prevalent. Mean age were 37.71 ± 11.7 and mean length of admission was 24.94 ± 17.9 days. Cannabis (34.8%) and cocaine (33.3%) were the most frequent SUD diagnosis and main reasons for admittance were conduct disorder (33.3%) and mania (25.8%).

Women showed higher length of admission, higher severity scores at admission and greater reduction in severity scores along hospitalisation. No other clinical or sociodemographic differences were found comparing both groups of patients (Tables 1–4).

Conclusions Women affected by dual bipolar disorder showed higher severity scores at admission but achieved better remission rates during hospitalisation.

Table 1 Demographic characteristics of both groups.

		Women (n=10; 15%)	Male (n=56; 85%)	P value
Age, years	Mean (SD)	34.5 (18.4)	38.3 (11.8)	0.35

GERD is associated with the outcome of MDD treatment

K. Matić^{1,*}, I. Šimunović Filipčić², Ž. Bajić³, I. Filipčić¹

¹ Psychiatric hospital Sveti Ivan, psychiatric hospital Sveti Ivan, Zagreb, Croatia

² University hospital center Zagreb, department of psychological medicine, Zagreb, Croatia

³ Biometrika healthcare research, Zagreb, Croatia

* Corresponding author.

Introduction Gastroesophageal reflux disease (GERD) is more prevalent among patients with major depressive disorder (MDD) than in general population, and vice versa. Bidirectional association of GERD and MDD is well documented. Although protective effect for gastric symptoms has been indicated for several antidepressants like trazodone, citalopram, fluoxetine, mirtazapine or fluvoxamine, these findings are sometimes contradictory. Similar may be claimed for antidepressant effect of some proton pump inhibitors. We decided to examine the association of GERD with the long-term efficacy of MDD treatment.

Objective To examine the association of GERD and efficacy of MDD treatment.

Methods This nested cross-sectional study was done during 2016 at Psychiatric hospital Sveti Ivan, Zagreb, Croatia on the sample of 1008 psychiatric patients. Key outcome was the number of psychiatric rehospitalizations since the first diagnosis of MDD. Predictor was patient-self-declared diagnosis of GERD. Covariates controlled by multivariate analysis of covariance were sex, age, duration of MDD in years, education, marital status, number of household members, work status, clinical global impression scale-severity of MDD at diagnosis, treatment with tricyclic antidepressants (TCA), selective serotonin reuptake inhibitors (SSRI),

serotonin-norepinephrine reuptake inhibitors (SNRI), noradrenergic and specific serotonergic (NaSSA) and antipsychotics.

Results MDD patients with GERD had significantly larger number of psychiatric rehospitalizations (mean=5.4 (SD 6.82)) than MDD patients with no GERD (mean=3.1 (SD 4.45)). After adjustment for all covariates, GERD significantly moderated the efficacy of treatment of MDD ($P=0.048$; $\eta^2=0.05$) (Figure 1).

Conclusion To treat MDD effectively we should treat GERD as well.

Figure 1 Number of psychiatric rehospitalizations in patients with MDD and GERD; error bars represent 95% confidence intervals ($n=1008$).

* Corresponding author.

Introduction Personality disorder (PD) with an associated diagnostic of major depressive disorder (MDD) is a common occurrence, being considered a factor of treatment resistant depression. In this study, we compare two groups of patients' one group having Major Depressive Episode (MDD) and the other with MDD and PD as comorbidity.

Methods This is an observational study of all patients admitted with diagnosis of MDD during one month period in an acute psychiatric hospital. Data collection is made using patients files. During one month period a total number of 105 MDD cases were recorded (group A-75 cases with MDD and group B-30 patients with PD and MDD). The diagnosis was recorded in files by a specialist psychiatrist. Data is analyzed using SPSS v.20.

Results A significant difference is found when comparing age groups, mean age for group A being 60 years and for group B 35 years ($P=0.05$). Regarding suicide attempts a higher prevalence is found in Group B (Group A 6.7%, Group B 20%) although with statistical relevance ($P=0.04$). Study limitation: small sample size of group B does not allow analysis on different type of personality

disorders, length of hospitalisation could be biased by the requirements of assurance company.

Conclusions The risk of admission is higher at younger age in patients with MDD associated with PD than in MDD alone. The risk of suicide attempts is significantly higher in group of MDD associated with PD.

Cancer and serious mental illness: A qualitative exploration–findings

J. Millman*, K. Galway, O. Santin, J. Reid

Queen's university Belfast, school of nursing and midwifery, Belfast, United Kingdom

* Corresponding author.

Introduction Serious mental illness (SMI) is associated with poorer cancer outcomes. Reasons for such inequalities are unclear; those with this comorbidity receive fewer specialist interventions and die earlier than the general population. Further exploratory work is required.

Objectives Exploring the experience of SMI and cancer from the perspective of those affected by this comorbidity and those caring for them professionally or informally.

Methods Semi-structured interviews were conducted with 'key patients' living with SMI who had received a cancer diagnosis ($n=7$), significant others who had supported key patients ($n=4$) and healthcare professionals who had worked with at least one KP ($n=17$). A panel of patients and professionals ratified interview guides. Interviews were analysed thematically.

Results Mental health professionals were more confident in their knowledge of the needs of this population than oncology professionals, but were challenged by working with patients with major physical health needs. Key patients' mental health appeared to remain stable after cancer diagnosis, and they expressed altruism towards others with comorbid cancer and SMI. Significant others and healthcare professionals were more likely to critique systemic aspects of care than were key patients.

Conclusions Professionals feel challenged when working outside of their usual job role. Training needs include mental illness awareness in an oncology setting. Improved coordination and communication is required, encompassing significant others as well as professional groups. SMI may protect against the psychological impact of cancer. Key patients were keen to provide advice and support to others in similar situations. Further research is needed into these areas.

VTE and physical health assessment upon admission to acute functional and organic psychiatric in-patient wards: An audit

N. Mistry^{1,*}, G. Sikka²

¹ Macclesfield District general hospital, psychiatry, Manchester, United Kingdom

² Pennine Care, psychiatry, Manchester, United Kingdom

* Corresponding author.

Introduction Venous thromboembolism (VTE) is a condition that causes a blood clot to form within the venous blood system. If this blood clot forms in the peripheral venous system it can cause symptoms such as calf pain and swelling. If this clot becomes dislodged,

it may travel through the vessels into the pulmonary artery which can have much more severe consequences.

Objectives There has been a great deal of effort in recent years to increase the percentage of in-patients receiving a VTE assessment; and for those patients to receive appropriate VTE prophylaxis. VTE is a significant cause of inpatient deaths. This audit aims to compare current working practice to local standards and identify learning points.

Methods VTE and physical health assessment data was collected by checking electronic admission summaries from three acute psychiatric in-patient wards on a random date in 2016. The local pathway for the management of physical health and wellbeing states that the VTE assessment and Physical Health Assessment should be completed within 6 hours of admission. NICE guidelines also state that all patients should be assessed on admission, with a standard of 100%.

Results 60% of patients had a VTE assessment and 54% of patients had a physical health assessment done within 6 hours of admission.

Conclusions This audit shows that the necessary standards are not met. Importance of these assessments has been communicated during induction programmes for all staff.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Aspects of the psychological consequences of cannabis use

L. Montes Reula*, A. Portilla Fernández, H. Saiz García

Biomedical research center CIB, psychiatric, Pamplona, Spain

* Corresponding author.

Cannabis is seen among general population as an "anti-depressive drug". Many papers have been published in the field of investigation about the relationship between cannabis use and affective disorders. We pretend to find the aspect of the psychological consequences of cannabis use.

Methods Using Pubmed and PsychInfo, we conducted a narrative review of the literature on cannabis and psychiatric comorbidity using the keywords cannabis, psychosis, mood, depression, mania, bipolar, and anxiety.

Results There is substantial evidence of an association between cannabis use and psychosis. A few reports suggest an association with bipolar disorder while the association with depression and anxiety disorders is mixed.

Conclusions The present review confirms earlier findings of an association between cannabis use and a lower age at onset. Data shows that cannabis use, beginning in the adolescence and with a frequency higher than once a week, correlates with the development in adult age of affective symptoms and/or disorder, mainly in bipolar disorder, with a moderate relation with Depressive spectrum. Even more, some authors hypothesize that cannabis may play a role in the development of the disorder, that to say, affective disorder would not appear in the absence of cannabis use. The current findings suggest that recent cannabis use is associated with a more severe course of illness in the early phase of BD I. Recent cannabis use was also associated with more lifetime suicide attempts.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Pancreatic carcinoma (PC) belongs to the most aggressive tumours worldwide, with a five year survival of 7%. Mostly, diagnosis is made in late stages, as by now no early detection method is available. Symptoms of depression occur frequently before diagnosis of PC. PC and depression are both known to go along with changes in the kynurenine-pathway.

Objectives This study aimed to examine the kynurenine pathway (Figure 1) and evaluate a possible depression in newly diagnosed PC patients in comparison to healthy controls (HC).

Methods 26 PC patients and 26 age and sex matched HC participated in this study. We investigated serum-levels of kynurenine, kynurenic-acid, quinolinic-acid and tryptophan. To diagnose features of depression SKID-II and BDI were used.

Results None of the participants fulfilled criteria of a depressive episode. Regarding BDI-scores, 2 PC-patients showed features of mild depression. PC patients showed significantly lower tryptophan-levels ($P=0.05$) and significantly increased quinolinic-acid levels ($P=0.01$) compared to HC. Quinolinic-acid levels were correlated with BDI ($r=0.23$, $P=0.02$).

Conclusions Our study results imply IDO-activation and kynurenine-pathway activation by showing decreased tryptophan and high quinolinic-acid levels in our PC patients compared to HC. Larger studies are needed to gather further insight in the kynurenine pathway in PC.

² The Arctic university of Northern Norway- clinical medicine, telemedicine and e-health, Tromsø, Norway

* Corresponding author.

Introduction Mental illness are among the most prevalent causes of death [1]. Larger population based studies are needed in order to control the high mortality rates for psychiatric patients [2].

Objective To examine the relationship between psychiatric disease and somatic illness.

Method Data from health-related databases and registries are cross-matched by social security number for all psychiatric patients in North-Norway for 2008–2016/2017. $n = 4000-6000$.

(Table 1)

Mortality is considered multifactorial, and risk factors may appear as both direct and indirect causes. A high number of demographic, somatic, psychiatric and service related variables allow the study to control for interactions and confounding associations by multivariate analyses.

Results/planned papers – 1 A case-register study of the comorbidity of mental and somatic disorders in North Norway: Research protocol.

– 2 Increased mortality in psychiatric patients: A case-registry study.

- 3 Comorbidity of cancer and psychiatric illness: Findings from North Norway.
- 4 Cardiovascular disease is prevalent among people suffering from depression and anxiety.
- 5 The importance of the use of antipsychotic medication for physical health.
- 6 Coercion and general health among psychiatric patients. The importance in continuity of care.
- 7 Substance-use among psychiatric patients. Implications for general health and care pathways.
- 8 Psychiatric patients use of general practitioner medical treatment.

Table 1 An overview of the information that will be retrieved from the registries.

Source	Personal information and medical records
Norwegian Health Economics Administration (HELFO) – KUHR	Date and time of treatment elective/acute, diagnoses (ICPC-2), procedure codes, institution or GP which assumes responsibility upon discharge, time of treatment termination
The Norwegian Patient Registry (NPR)	Diagnoses (ICD-10, all chapters), functioning level, medical procedures, date of referral, treatment priority, treating doctor or institution, level of care, date and time of treatment, elective/acute, referring institution or doctor, institution or doctor which assumes responsibility upon discharge, time of treatment termination
The Cause of Death Registry	Time and cause of death
Statistics Norway – socio-economic registries	Sex, age, marital status, municipality, working affiliation (employed/unemployed/disability pension etc)
Cancer registry of Norway	Diagnoses and treatment variables
Norwegian Prescription Database	Consumption, type and dosage of generic drugs / psycho-pharmacology
Norwegian cardiovascular Disease Registry	Diagnoses and treatment variables

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychopathological consequences of introducing psychopharmacological treatment in patients with ADHD with comorbid drug use. A preliminary study

L.A. Núñez Domínguez^{1,*}, O. Arbo Ruiz², L. Barrado Los Arcos³

¹ Centro médico, psychiatry, Pamplona, Spain

² Centro de Día Zuria, psychiatry, Pamplona, Spain

³ Mental health net, psychiatry, Pamplona, Spain

* Corresponding author.

Introduction There exists a high prevalence of SUD among patients suffering ADHD and the consequences of this comorbidity are that ADHD and SUD may exacerbate the outcome of SUD and vice versa. The presence of both disorders increases the risk of chronicity and the level and/or the number of symptoms. The main objective is to evaluate how the introduction of treatment correlates with a better control of symptoms.

Material and methods We select a group of patients with both diagnosis treated in a Mental Health Day Center in Pamplona, Spain. We employ several scales to evaluate the sample: SCL-90, SF-36, Weiss Scale and a Scale of Satisfaction, in three times: at the beginning, one month and three months. We employ urinalysis to detect level and number of substances.

Results The sample is comprised by 12 patients, main age of 42.6 years. 8 patients are cocaine addicts. The majority received Atomoxetine (main dosage 36.0 mg)

Our data shows an important decrease in the score of Neurotics groups of symptoms and Hostility. We observe a decrease in score of items correlated with physical health and an increase in emotional aspects of daily life.

Eight patients get abstinence and the punctuation of craving decrease from 21 to 5.2.

The level of satisfaction with treatment was very high.

Conclusions The psychopharmacological treatment of patients diagnosed of ADHD with comorbid SUD implies a great improvement in the symptomatology and quality of life of the patients, with a low level of craving.

* Corresponding author.

Introduction Methanol poisoning is uncommon but potentially lethal. The way of poisoning is usually oral. However, in a small number of cases, inhaled methanol poisoning was described. Most of these occurred among patients suffering a disorder by use of this substance. This type of poisoning has an insidious presentation, that complicates its diagnosis. This poisoning may be lethal. It may produce a chronic and severe affectation of the central nervous system in those who survive to the poisoning. After diagnosis, it is compulsory to act quickly, and it often requires advanced vital support and hemodialysis.

Objectives Educate the Mental Health professionals about a type of disorder by consumption increasingly more frequent in some cities across Europe. This is a high fatality related poisoning that emergency and general psychiatrists should know as it is increasingly common in Europe.

Methods We present the case of a 20-year-old patient, treated at the emergency department of our hospital in context of methanol inhalation. The patient regularly attended to our Dual Pathology outpatient unit due to a severe inhalant use disorder. Several stays at the intensive care unit had been recorded and he already presented with severe optic nerve affectation.

Discussion In recent years there has been an increase in inhalant abuse in Europe, which is still underestimated by our poor knowledge about its potential toxicity.

Conclusion Inhaled methanol poisoning occurs with a typical presentation, and may appear after suicide trial or overdose. Mental health professional should become aware of its potential lethality to approach properly to these patients.

¹ Hospital Universitario de Álava, psychiatry, Vitoria, Spain

² H. U. Marqués de Valdecilla, psychiatry, Santander, Spain

³ H. Zamudio, psychiatry, Zamudio, Spain

* Corresponding author.

Introduction Several studies point to the importance that the complex formed by GABA and the benzodiazepine receptor play for cerebral dopaminergic transmission and, hence, to the pathophysiology of psychotic symptoms. The decrease in GABA neurotransmission or the hypofunction of the system in the hippocampus, cortex and other limbic prefrontal or subcortical regions has consequences as emotional dysregulation, cognitive impairment and development of positive psychotic symptoms.

Objectives We intended to show an additional practical example to the limited literature available based on a case linking the emergence of psychotic symptoms due to acute benzodiazepine withdrawal.

Methods We present the case of a 21 year old man who was sent to the emergency room of our hospital after an episode of aggressiveness on the street. The patient showed a psychotic schizophrenic syndrome with significant emotional and behavioural impact with aggressive and bizarre movements. In parallel, restlessness, sweating, tremor, increased blood pressure and tachycardia were observed. Symptoms had started abruptly two hours earlier. The patient companion explained that he usually took Alprazolam at an of over 40 mg per day. He had decided to give up this consumption abruptly four days earlier.

Discussion GABAergic deficits cause the imbalance between excitatory and inhibitory neurotransmission that may relate the pathophysiology of psychotic symptoms. The dysfunction of the GABAergic cortical interneurons could affect to the modulating response from the association cortex, which, could also relate with the appearance of these symptoms.

Conclusion This case could relate a decrease in GABAergic transmission with the appearance of psychotic symptoms.

* Corresponding author.

Introduction Psychiatric disorders, particularly mood disorders, have a profound effect on the use of and adherence to highly active antiretroviral therapy (HAART) among patients with human immunodeficiency virus (HIV) infection.

HIV infection and mood disorders have features in common, and each is a significant risk factor for the other.

Objective The objective is to highlight the clinicians on the importance of screening and treating affective disorders among patients with HIV infection.

Methods Two cases of HIV infected patients with comorbid mood disorder and torpid evolutions by poor adherence to treatment are reported.

A brief literature review on this subject is done.

Results Major depression has been shown to alter the function of killer lymphocytes in HIV-infected patients and may be associated with the progression of HIV disease.

HIV-positive patients with mental disorders are less likely to receive and adherence to antiretroviral therapy.

First case-report: a man 52 years old, HIV-positive since 1985 with a comorbid bipolar disorder, with recurrent depressions and poor adherence to both treatment with a rapidly exitus laetalis.

Second case-report: man 45 years old, HIV-positive since 1992 with a comorbid depressive disorder, non-adhered to both therapy and HIV-associated dementia.

Conclusions Depressive disorders are common in HIV infection. Antiretroviral regimens for HIV-infected patients require strict adherence. Untreated depression has been associated with medication nonadherence. Understanding the contribution of depression and its subsequent treatment on antiretroviral therapy adherence might direct clinicians toward earlier identification and more aggressive treatment among this population.

Introduction Although psychoactive substance use disorders (PSUD) belong to the domain of mental health, their management varies greatly among European countries. Furthermore, both the role of psychiatrists and trainees in the treatment of PSUD is not the same for each European country.

Aims Among the context of the European Federation of Psychiatric Trainees (EFPT), the PSUD Working Group has developed a survey that has been spread out between the 15th of August 2015 and 15th of October 2016, at the aim of gathering information about the training in PSUD in Europe, both from Child and Adolescent, and General Adult Psychiatric (CAP and GAP) trainees.

Objectives The survey investigated, at European level, the organisation of the PSUD training, trainees satisfaction, attitudes towards people who use psychoactive substances, management of pharmacologic and involvement in common clinical situations.

Methods A 70-items questionnaire regarding the aforementioned objectives was developed, and shared through an online data-collecting system among European CAP and GAP trainees, with 40 trainees per country filling the survey in at least 25 countries. One national coordinator per country facilitated the delivering of the survey.

Results A total of 1250 surveys were filled from more than 25 European countries.

Conclusions Data from the survey will be promptly analysed. The survey will be the first to explore European psychiatric trainees attitudes and practices about PSUD. Findings from this independent survey may serve in understanding the needs of trainees in the field of substance misuse psychiatry.

Hepatic comorbidity in psychiatry. A case report

G. Pardo de Santayana^{1,*}, R. Landera¹, M. Juncal¹, O. Porta¹, L. Sánchez¹, M. Gómez², N. Núñez²

¹ Hospital universitario Marques De Valdecilla, psychiatry, Santander, Spain

² Hospital universitario Alava-sede Santiago- Vitoria-gasteiz, psychiatry, Vitoria, Spain

* Corresponding author.

Introduction Comorbidity between mental and physical illnesses is very common and their possible interactions must always be taken into account. Hepatic disorders in particular, can affect the blood levels of antipsychotic drugs altering their effects on patients. Therefore, it is very important to assess in each case which treatment might be the most beneficial for the patient to avoid iatrogenic complications.

Aim To review articles in Pub-Med and UpToDate about the possible iatrogenic complications that can arise using antipsychotic drugs in patients with hepatic disorders.

Methods We describe the case of a 52-year-old male with Schizophrenia who was diagnosed of HCV infection ten years ago, for which he rejected any kind of treatment due to delirious ideation. In the past he was treated with oral Paliperidone with good tolerance, which he discontinued because of poor insight and stopped attending Psychiatric consultation. In April 2016 the patient was hospitalised suspecting a hepatocellular carcinoma.

Results During hospitalization he began treatment with long-acting injectable formulation of Paliperidone Palmitate that improved his insight. The patient agreed to perform the necessary tests to verify the suspected diagnosis, which was sadly confirmed. He achieved psychopathological stability, but unfortunately the patient died 6 months later because of his hepatocellular carcinoma.

Conclusions Paliperidone is a good therapeutic option in patients with hepatic disorders because it is not metabolised by the liver. It also has a depot formulation that improves adherence in patients with low insight, reducing the danger of future psychotic decompensation and improving the long-term prognosis.

Cases where pituitary tumor is presented first with psychiatric signs are very rare

Dr. Taulant Pengili*, M.S.Dr. Anila Hashorva, Dr. Ina Prifti, Dr. Marsida Lici, Dr. Enida Balani

University Hospital Center Mother Theresa, Psychiatry, Tirana, Albania

* Corresponding author.

Objective To describe a rare case of Acromegaly presenting as psychotic disorder without neurological signs, in a 19 years old boy.

Method Single case report.

Results We describe the case of a 19 years old boy, that was taller than his peers and had started to grow his hands. He suddenly presented with an acute psychotic episode. He presented with persecutory delusions, perceptual abnormalities, disorganization and marked fluctuation in his behavior, he showed marked emotional lability, fluctuations in orientation and psychotic symptoms in the form of grandiosity, persecutory delusions and delusional misidentifications. At times, he was seen talking to himself, although he denied hearing any voices. There was no impairment of consciousness. His mood was irritable. An urgent CT and subsequent MRI scan revealed a pituitary macro adenoma, extending into the cavernous sinus. The initial diagnosis of prolactinoma was revised to acromegaly. His symptoms responded to combination of olanzapine and valproic acid, followed by trans sphenoid resection of the adenoma.

Conclusions This case highlights the need for investigation, especially of neuroimaging, in atypical presentations of psychosis, which may be first manifestation of rare disorders like acromegaly. Despite a lack of information regarding the path physiology, this particular case emphasizes the importance of ruling out an organic cause for atypical presentation of psychosis.

Comorbidity between obsessive-compulsive disorder and attention deficit/hyperactivity disorder

J. Perestrelo*, A. Samico, G. Lapa

Centro hospitalar Vila Nova Gaia/Espinho, psychiatry and mental health, Porto, Portugal

* Corresponding author.

Introduction The comorbidity between obsessive-compulsive disorder (OCD) and attention deficit/hyperactivity disorder (ADHD) has been discussed for a couple of decades. Reported co-occurrence rates are highly inconsistent in the literature.

Objective To review phenomenological and theoretical issues concerning concomitant OCD-ADHD.

Aims Phenomenological and theoretical issues regarding OCD-ADHD comorbidity are reviewed.

Results Although numerous studies suggest an OCD-ADHD comorbidity, thus far etiological (i.e., genetic) background has

been provided only for a pediatric comorbidity. High rates of co-occurrence may be mediated by the existence of tic disorders, and evidence of impaired neuronal maturational processes in OCD pediatric population may lead to probably transitory phenotypical expressions that look like ADHD symptomatology. Thus, it is possible that ADHD-like symptoms resulting from OCD-specific symptomatology may be misdiagnosed as ADHD. This may explain the lower co-occurrence rates reported in adolescents and adults.

Conclusion OCD and ADHD are very different disorders in terms of pathophysiology, phenomenology, and treatment strategies. Several methodological concerns have been identified in our review. Future studies on OCD-ADHD comorbidity should try to mitigate these biases.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Other ways for the treatment of alcohol dependence: A patient treated with nalmefene

O. Porta Olivares^{1,*}, M. Juncal Ruiz¹, M. Gómez Revuelta², G. Pardo de Santayana Jenaro¹, L. Sánchez Blanco¹, R. Landera Rodríguez¹, A.B. Pérez Santos³, F. Arnaiz de Las Revillas Almajano³

¹ Hospital universitario Marqués de Valdecilla, general psychiatry, Santander, Spain

² Hospital universitario de Álava, general psychiatry, Vitoria-Gasteiz, Spain

³ Hospital universitario Marqués de Valdecilla, general medicine, Santander, Spain

* Corresponding author.

Introduction Alcohol dependence belongs to one of the major risk factors to health worldwide. Alcohol consumption is a significant factor for mortality in the world: 6.3% in men and 1.1% in women. The alcohol use disorder is also very common: 5.4% in men, 1.5% in women. Despite its high frequency and severity of this disorder, only 8% of all alcohol dependents are treated once.

Aims An interesting treatment option is geared toward reducing alcohol intake. Some patients in treatment for alcohol use disorder prefer an initial target of reducing consumption. Nalmefene, an antagonist naltrexone associated with opioid receptors, has been authorized in the European Union to help alcohol-dependent patients reduce their consumption. Antagonists' opiate receptors are associated with reduced reward in relation to alcohol consumption, thus helping patients in reducing energy consumption.

Methods A man of 39 years old, with a diagnosis of alcohol use disorder and depressive disorder and poor outcome despite different types of treatment (as aversive agents) was treated with nalmefene.

Results After a few months, nalmefene had a beneficial effect on the patient, with a significant reduction in the number of days of excessive alcohol consumption and total consumption in the sixth month. In addition, treatment was well tolerated, with no observed secondary effects.

Conclusions Nalmefene appears to be effective and safe in reducing heavy drinking. Drugs such as nalmefene have demonstrated efficacy in association with a biopsychosocial approach to help patients achieve their personal objectives for this disorder.

Rehabilitation program: Results of a clinic in Lisbon

H. Prata-Ribeiro^{1,*}, S. Hanneman², C. Ana²

¹ Centro hospitalar Psiquiátrico de Lisboa, serviço de psiquiatria geral e transcultural, Coimbra, Portugal

² Centro hospitalar psiquiátrico de Lisboa, Serviço de reabilitação, Lisboa, Portugal

* Corresponding author.

Introduction Modern psychiatry includes within its purposes to reintegrate patients into society. Our work's goal is to evaluate in terms of outcome, the current status of patients that underwent the rehabilitation program in a clinic in Centro Hospitalar Psiquiátrico de Lisboa, in Lisbon.

Methods The methods consisted of retrospective evaluation of the sample of patients that successfully completed the rehabilitation program between 2012 and 2015. Gender, age, provenience, previous and current socio-economic situations were taken into account.

Discussion Twelve patients concluded the program in the timeframe studied: 64 % males and 36 % between the ages of 36 and 40 and more than half were in homelessness situations. They progressed in increasing levels of autonomy and by the program's end, ten were dismissed and two were still waiting for housing. Ten of the patients are now living with their families or have been integrated in social housing program. Two await conditions to leave the hospital.

Conclusion The program had a positive impact on the life of all patients that have engaged in it. Only two remain waiting social housing responses. Although the results are satisfactory, the number of patients admitted must improve in coming years.

EV0246

From alcohol to delusional jealousy

M. Rodríguez^{1,*}, Y. Rojas², P. Ortega¹, S. Goretti¹

¹ Centre hospitalier Torrecárdenas, psychiatry, Almería, Spain

² H. De Poniente, psychiatry, Almería, Spain

* Corresponding author.

Purpose With this clinical case we want to show an example of diagnosis and treatment of a frequent psychiatric comorbidity in alcohol dependence: delusional jealousy.

Methods We analyzed a clinical case of a 52-year-old man who has a voluntary drug intake promoted by a delusional jealousy to his wife in a context of chronic alcohol consumption. A bibliographic search is made about the comorbidity of delusional jealousy in alcoholism.

Results A 52 year-old man is brought to the hospital after to have a voluntary drug intake. He has not got medical history of mental health. As personal antecedents, the harmful alcohol consumption of the last 6 years in which he is unemployed is highlighted. After the clinical interview with the patient and with direct relatives (woman and daughter), we have the suspicion that it is a case of cellotopia induced by alcohol, in which the patient has made an autolytic attempt fomented by a delusion of jealousy. In this moment treatment is started. After a few weeks in which the patient starts treatment and leaves alcohol consumption, delusional clinic of jealousy refers progressively.

Conclusions The alcoholic etiology of cellotopia has not been specifically confirmed. However, clinical experience shows this association is extremely frequent. It's a chronic delusional disorder with content of jealousy, providing interpretations and suspicions unfounded. Is added hostility to his partner, with potential risk of heteroagresivity. The most important thing is to assess the

emotional and behavioral resonance of delirium. The treatment consists of indicating abstinence from alcohol and administration of neuroleptics.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0247

A Clinical review about differential diagnosis and comorbidities on premenstrual dysphoric disorder

L. SÁnchez Blanco^{1,*}, M. Juncal Ruíz¹, G. Pardo de Santayana Jenaro¹, R. Landera Rodríguez¹, M. GÁmez Revuelta², O. Porta Olivares¹, N.I. NÁñez Morales²

¹ Hospital universitario Marqu (s de Valdecilla, psychiatry, Santander, Spain

² Hospital universitario de  lava-sede Santiago, psychiatry, Vitoria-Gasteiz, Spain

[ ] Corresponding author.

Introduction Symptoms of premenstrual dysphoric disorder (PMDD) recur during the premenstrual phase of the cycle and disappear to the beginning or after last menstruation. The main symptoms are emotional lability, dysphoria and anxiety.

Objectives To review PMDD for helping in the differential diagnosis between this disease and classical anxiety disorders.

Methods It was made a clinical review about differential diagnosis and comorbidities on PMDD in specialized literature and Pub-Med.

Results PMDD causes significant distress and impairment in social or occupational functioning the first week following menstruation. In relation with differential diagnosis on PMDD, on the one hand, several organic diseases could produce the same symptoms than PMDD: for example gynecological pathology as dysmenorrhea or menopausal transition, endocrinological diseases as hypothyroidism and hyperthyroidism and some hormonal treatment including hormonal contraceptives. In addition, a variety of medical disorders are concomitant pathologies that could be associated with PMDD (eg, migraine; epilepsy, asthma, allergies, systemic exertion intolerance disease, chronic fatigue syndrome; irritable bowel syndrome). These pathologies are exacerbated just before or during menstruation. On the other hand, several psychiatric disorders as bipolar disorder, major depression, dystimia, and anxiety disorders could get worse on the premenstrual phase.

Conclusions In relation with the diagnosis of PMDD, it seems necessary to consider various differential diagnosis such as psychiatric, gynecological and endocrine disorders because of all of them share like symptoms. For this purpose it is very important to make both a good clinical history and a comprehensive physical examination to offer the most accurate diagnosis and treatment.

Adult ADHD diagnosis and binge eating disorder

J. Sevilla Vicente^{1,*}, I. Basurte Villamor², A. Sedano Capdevila¹, M. Migoya Borja¹, R. Navarro J (mez¹, L. Serrano Marugan¹

¹ Fundaci n Jim nez D (az, psychiatry, Madrid, Spain

² hospital universitario Gregorio Marañ n, psychiatry, Madrid, Spain

* Corresponding author.

The association between attention deficit hyperactivity disorder (ADHD) and eating disorders has not been yet clarified. The presence of ADHD was significantly correlated with more severe binge eating, bulimic behaviors, and depressive symptomatology. The

aim of this work is to study the relationship between ADHD subtypes in adults and the risk of food addiction (binge eating disorder). The sample was collected on a specific program for adults with ADHD diagnosis in Madrid (Spain). In total, the sample was 110 patients, and we collected information about socio-demographic factors. All patients met DSM-5 criteria for ADHD in different subtypes. We used the conner's Adult ADHD rating scales and the Barrat impulsiveness scale. Also we used the Shorter Promise Questionnaire. This is a 16 scale self-report instrument to measure an individual's level of addictive tendency.

The 36.4% were at high risk of developing a food addiction. For binge eating disorder (BE), no statistically significant differences were found by gender within patients with ADHD.

Binge eating was significantly related to the impulsivity and emotional liability subscale of the CAARS ($P < 0.05$). The risk of develop BE in ADHD was 4.7 (CI 95% 1.8–12.07). Binge eating was significantly related to the total score on the Barrat scale ($P < 0.05$) Risk of 3,5 (CI 95% 1.5–7.9) and within the subtypes of impulsivity, motor impulsiveness was the one that was significantly related to BE ($P < 0.001$)

There is a clear relationship between impulsiveness symptoms and BE in patients with ADHD. It's important to note that there are no gender differences within ADHA patients to develop a BE disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

From psychiatric to critical care: Patient profile and predictive transfer elements

R. Trabelsi^{1,*}, N. Bram², I. Benromdhan², W. Homri², N. Staali², R. Labbene²

¹ Razi hospital, departement psychiatry F, Mannouba, Tunisia

² Razi hospital, psychiatric department C, La Mannouba, Tunisia

* Corresponding author.

Introduction Patients with mental illness have an increased risk of morbidity and mortality from somatic complications, with a reduction in life expectancy of 15 to 30 years. During hospitalization in a psychiatric setting multiple risk factors can combine and contribute to a severe deterioration in the general condition of patients who may require reanimation.

Aim Describe the profile of patients admitted to Razi who required transfer to an intensive care setting during hospitalization to more precisely determine the predictors of severe somatic decompensation.

Methodology A descriptive retrospective study of patients transferred from the Razi hospital to the emergency medical assistance center (CAMU) during the period between 1 January 2014 and 31 December 2015.

Results The average age of patients was 39.5 years; 64.2% of the patients were men, 60% had a low socio-economic level, 34.7% had a comorbid disease. Forty-one percent (41%) of the patients transferred had been diagnosed with schizophrenia, and 27% had bipolar disorder. Antipsychotics were the most prescribed psychotropic drugs. High doses were used with therapeutic combinations in 85% of the cases. A toxic cause was identified in 58% of cases, including neuroleptic malignant syndrome in 18%. Dehydration and ionic disorders are among the most frequent causes in 27% of cases. Conclusion; Identifying risk factors for deaths in psychiatric hospitals highlights needed changes in psychiatric management strategies taking into account the patient's characteristics as well as the drugs' safety profile.

Generalized anxiety disorder comorbidities: Panic and depressive disorder

M. Turki*, J. Ben Thabet, N. Charfi, M. Mezghanni, M. Maalej Bouali, N. Zouari, L. Zouari, M. Maalej Hedi Chaker university hospital, psychiatry "C" department, Sfax, Tunisia

* Corresponding author.

Introduction It has been well documented that generalized anxiety disorder (GAD) can co-occur with mood disorders and other anxious disorders, particularly panic disorder (PD). These comorbidities can complicate therapeutic management and burden the prognosis.

Aim To highlight the relationship between GAD and panic and depressive disorders.

Methods We conducted a cross-sectional study, among 250 subjects consulting in 6 primary care units in Sfax, Tunisia. These participants, randomly chosen, were asked to answer a questionnaire after their consent. The diagnosis of GAD and PD were assessed by the "Mini International Neuropsychiatric Interview" of the DSM-IV. Depressive symptoms were evaluated using the "Beck Depression Inventory" (BDI).

Results The average age was 39 years. The sex ratio M/F was 1/2. The GAD was diagnosed in 10.8% of participants. The mean IDB score was 3.8. According to this scale, a mild depression was noted in 23.6%, moderate 12% and severe in 2.8% of cases. The GAD was statistically associated with psychiatric histories ($P=0.009$), particularly depression disorder ($P=0.004$) and the history of suicide attempt ($P<0.001$).

The IDB score was significantly higher in participants with GAD ($P<0.001$). Among them, 74% presented moderate to severe depression.

GAD co-occurs with PD in 22.2% of cases. This association was statistically significant ($P<0.001$). Participants presenting GAD- PD comorbidity are at higher risk of developing depression ($P=0.003$).

Conclusion One must always think to screen comorbidities in the presence of either diagnosis, in order to ensure a better management.

Psychiatric hospitals may enhance holistic care by introducing medical and surgical liaison teams

R. Sacco*, C. Micallef, G. Grech, C. Role, S. Mercieca, A. Grech Mount Carmel hospital, psychiatry, Attard, Malta

* Corresponding author.

Introduction Patients with mental health problems (MHP) are known to have more physical co-morbidities compared to the general population.

In Malta, Mount Carmel hospital (MCH) which is the main psychiatric hospital (consisting of both acute and chronic wards), is separate from Mater Dei hospital (MDH) which is the general hospital at which medical and surgical care is provided.

Such a division in healthcare may result in inadequate focus on physical health amongst patients of high demand in this regard. This subsequently puts an increased strain on the general hospital through repeated referrals.

Objectives The purpose of this study is to show that inpatients with MHP have a significant number of co-morbidities and require multiple referrals to a general hospital for medical and surgical attention.

Methods Three hundred and ninety-three inpatients at acute and chronic wards of MCH (during the first week of December 2016) were enrolled in the study.

Treatment charts and iSOFT (healthcare IT software used in Malta) were used to determine patient's diagnosed co-morbidities, number and type of referrals to MDH outpatient clinics (OPC), casualty and admissions at MDH over 1 year.

Results Results of the audit indicate that a significant number of inpatients at MCH have medical co-morbidities and the majority have been referred to MDH for OPC and casualty over the past year.

Conclusions Having medical and surgical liaison teams in psychiatric hospitals may enhance patient care and reduce the pressure exerted on general hospitals.

* Corresponding author.

Introduction Research shows that the prevalence of obesity is greater in individuals with mental disorders than in general population. According to literature, obesity is correlated with intensity of symptoms and suicidality.

Objectives The aim of this study was to determine whether there is a correlation between BMI and severity of symptoms, as well as suicidality and gender. The aim was also to determine whether there is a difference in the severity of symptoms and suicidality among individuals with different diagnoses.

Methods Participants in this study were 37 men and 73 women with diagnosis of psychosis, personality disorder, bipolar affective disorder, unipolar depression and anxiety disorder treated in Psychiatric hospital "Sveti Ivan", Zagreb, Croatia. Sociodemographic data were collected and BMI was calculated. All participants fulfilled the DASS 21 (Depression, Anxiety and Stress Scale by Fernando Gomez) and Suicide Severity Rating Scale (Columbia–Suicide Severity Rating Scale (Center for Suicide Risk Assessment)).

Results There is no significant correlation between BMI and severity of symptoms, as well as between BMI and suicidality. But there are significant differences in the severity of stress ($P=0.005$) and suicidality ($P=0.004$) in individuals with different diagnoses.

Conclusions The results identify that a significant part of individuals with mental disorders are either obese or overweight, but there were no significant differences in relation to suicide and intensity of symptoms depending on the BMI.

Sleep disorders associated with interferon in chronic viral hepatitis C

C. Aarab*, A. Bout, R. Aalouane, I. Rammouz
 Psychiatrist hospital Ibn Alhassan, psychiatry, FEZ, Morocco
 * Corresponding author.

Chronic infection with hepatitis C is a public health problem in Morocco and in the world. The objective of the work screens for sleep problems during the disease and its management to better guide the monitoring and psychiatric interventions.

Methodology Sixty-eight patients followed for hepatitis C were recruited. The treatment was based on the combination of pegylated IFNa or standard IFNa and ribavirin for 6 to 12 months. The evaluation was done by a questionnaire containing demographic information, medical and psychiatric history, substance use. Sleep assessment was made by Pittsburgh Sleep Quality Index, and measuring the quality of life by SF36. The assessment before starting treatment and at 1 month and 4 months. Statistical analysis by SPSS 21 software read.

Results Fifty-six patients were able to complete the monitoring. 36 women to 20 men. The average age is 59.1 years old (standard deviation 9.88). A quarter of patients still gainfully employed. 64.3% of participants live in couple. Seventy-six point eight percent of patients live in the city. Seven per cent consume tobacco and single patient use cannabis occasionally. Sleep disorders increased from 37.5% before the start of the treatment to 55.4% after its start. While 44.5% have kept a sleep disturbed to 4 months. At first, the quality of life had more impaired scores on psychological than physical scores. The overall score declined significantly way after initiation of treatment (0.04). A larger decline on the psychological component (0.000) while the physical score did not significantly decrease.

CL is a subspecialty in psychiatry and provides a variety of consultation services including diagnosis, therapeutic and teaching efforts of a psychiatrist in none psychiatric units or hospitals.

Objectives This is a retrospective descriptive study that evaluated the consultation liaison (CL) psychiatry services in Imam Khomeini hospital, during two recent years.

Methods The information has been obtained from reviews of medical profiles of patients who attended the hospital.

Results A total of 681 patients (365 patients were male) received CL services during the study period. The most prevalent diagnosis groups were mood disorder (37.91%), delirium (13.6%) and anxiety (12.64%). Our study revealed that cardiovascular unit, infectious disease unit and general surgery units frequently requested for consultations among all hospital wards. Pediatrics unit had the lowest request rate for psychiatric consultation.

Conclusion CL is on the rise in general hospitals, specifically in internal medicine and surgery units which alarm us to pay more attention to preventive strategies focused on the most referred problems including mood disorders, delirium and anxiety disorders in patients who attended general hospitals.

Low frequency of request for liaison psychiatry: A difficulty in the early detection of mental disorders by medical assistants?

M. Aguiar Machado*, J. Gonçalves Oliveira, E. Oliveira Cunha, E. Vieira de Melo, E. Oliva-Costa
 Universidade Federal de Sergipe, departamento de medicina, Aracaju-SE, Brazil

* Corresponding author.

Introduction The liaison psychiatry (LP) is a feature used by the psychiatrist in order to improve the management of patients with mental suffering and/or mental disorder admitted to general hospital.

Objectives To characterize the epidemiological profile of hospitalized patients at the university hospital of the federal university of Sergipe (HU-UFS) submitted to LP.

Methods retrospective and observational study, through analysis of medical records of patients admitted in the wards of clinical medicine and surgery from the HU-UFS, in the period from January to December 2015, submitted to LP. The information collected fed a specific questionnaire developed by the authors, intended for research of socio-demographic data and clinical profile.

Results the frequency of request for LP was of 3.5%, with the majority of applications was performed by clinical medicine (71.2%), while the surgical clinic was responsible for 28.8%. The main reason for the request of LP was the presence of depressive symptoms (49.1%). There was a predominance of females (52.5%) and the mean age was 45.9 ± 14.6 years.

Conclusions The frequency of request for LP was very low, suggesting a difficulty in the early detection of mental disorders by physicians. This finding points to an underreporting of cases, since the prevalence of depressive symptoms in hospitalized patients is over 50% in this institution.

³ Mental health research institute–Tomsk national research medical center- Russian academy of sciences, department of psychoneuroimmunology and neurobiology, Tomsk, Russia

* Corresponding author.

Present days are characterized by increased level of various psychosomatic disorders among different populations in economically developing countries. Moreover every mental disease contains somatic symptoms and these symptoms may interfere in whole picture, change the diagnostic schedule. In case of mild disorders patient's reaction to somatic disease was mostly hysterical: exaggeration of pathological sensations, suggestibility and self-suggestibility. Whole picture of the neurosis was very colourful, dynamical, with instable pathological manifestations, intention to draw one's attention.

Transition to long-term variant of dynamics mental disorder was accompanied by concentration on the smallest somatic sensations, seeking benefit from a disease state, "flight into the illness", nosophilia. We identified prominent increase of hypochondriac symptoms in the group of patients with long course of dissociative disorders (33.4%) as compared with the group of acute and sub-acute course of the disorder (11.4%).

In patients with long course of dissociative disorders we observed accumulation of somatic pathology, in most cases one patient suffered from different somatic diseases. Increasing of rate of hypertension (31.33%) and different dishormonal disorders (37.5%) was the most prominent.

In psychological "portrait" of the patients with psychosomatic disorders we identified the great number of combinations of pathocharacterologic traits, creating the patient's "facade", complicating interactions and compliance with physicians and psychiatrists.

Interactions between features of mental disorders and somatic disorders, psychological stress appear to us to be rather close. Presence of the somatic process leads to chronification of the neuroses, "flight into the illness", decrease of dependence of clinical dynamics on psychogenesis.

Irreversible silent

Z. Azvee

Beaumont hospital, Liaison psychiatry, Dublin, Ireland

Objectives Lithium is a well-known substance used in treatment of mood disorders. It has a narrow therapeutic index with recognised adverse effects on renal and thyroid function. Clinical guidelines published by the national institute for health and clinical excellence in the United Kingdom (NICE) recommend renal and thyroid function checks before lithium is prescribed, as well as ongoing monitoring of renal function, thyroid function and serum lithium levels. Lithium-induced drug toxicity is frequently seen in clinical practice. While the ongoing monitoring serves to monitor reversible side effects of Lithium provided its discontinued, rarely patients develop a persistent neurological side effect known as a syndrome of irreversible lithium-effectuated neurotoxicity (SILENT).

Method This is a case report on a patient where the patient developed SILENT syndrome after being treated with Lithium, long term for bipolar disorder.

Results This case supports the biological mechanism of SILENT syndrome. It also caused a huge implication in the patient's care.

Conclusions As clinicians, we are well aware of following treatment guidelines for Lithium. This case report was written to raise awareness regarding a "SILENT" albeit significantly debilitating syndrome of Lithium use.

The sofa is better than Freud

G. Buffardi

UOSM 13, ASL Caserta, Aversa, Italy

When it comes to the therapeutic dialog between doctor and patient, psychiatrist or psychotherapist and user, there are several factors that are taken into consideration, though some of these aren't of a specific psychological model, they fulfill an important role both in the management of the relationship itself as well as in the care.

Their importance in the therapeutic relationship is such that a doctor or a therapist cannot simply manage them by "common sense", or follow his own propensity for dialogue: he must know them well and he needs a training on their own management with the same precision that is needed for the specific psychological model training.

Contrary to widespread belief we think that education on non-specific factors has to be desirable and that the ability to manage them can be implemented both by a deeper understanding as well as by dedicated training tools.

Suspension of judgement: A tool for non-invasive therapeutic relationship

G. Buffardi

UOSM 13, ASL Caserta, Aversa, Italy

* Corresponding author.

We often refer to our ability to perceive the other mind as a gift of our experience that helps us in our work. But to use this insight as a guidance counselor in the treatment process is sometimes a harbinger of relational mistakes that affect the success of the treatment.

The specialist, psychiatrist or psychotherapist (but also other aid professionals), has to learn the process of the suspension of judgement "epochè", described in Jaspers' psychopathology.

To foster learning of "epochè" we developed some exercises that help the young therapist in training. We believe they are also particularly useful for the training of students who are undergoing specialized training to become psychiatrists.

Neurosyphilis presenting with affective psychosis and Parkinsonism: A case report

H.S. Butt*, C.W.P. Hopkins

Prospect Park hospital- Berkshire NHS trust, Rose ward, Reading, United Kingdom

* Corresponding author.

Introduction A 38-year-old gentleman was admitted to an inpatient psychiatric unit with a first episode of fluctuating affective psychosis. He initially presented as manic although subsequently evolved a severe depressive episode, with prominent bizarre, affect-incongruent delusions throughout this period. Upon admission, anisocoria was evident, although this was attributed to a past head injury. Over the course of his admission he developed emergent Parkinsonism, initially ascribed to prescription of aripiprazole. Given his anisocoria and worsening Parkinsonism, further investigation was undertaken. While his MRI brain scan was unremarkable, his serum and CSF specimens tested positive for

Treponema pallidum serology, and he was diagnosed with neurosyphilis. He was treated with a single dose of intramuscular penicillin, but experienced marked deterioration of neurological symptoms (paraparesis and truncal ataxia) and was transferred to the general hospital for an extended 14 day course of intravenous penicillin. Following this extended course of antibiotic therapy, resolution of neurological symptoms was seen, but no sustained improvement in residual psychotic symptoms has been seen.

Conclusions This case demonstrates the potential neuropsychiatric consequences of neurosyphilis, and serves as a reminder of its potential to imitate other psychiatric presentations. This gentleman, and many like him, continue to experience severe and enduring psychopathology despite penicillin treatment when cases are detected late. Given the potential consequences of this, we would advocate assertive screening for syphilis in patients admitted to psychiatric units.

EV0261

Liaison psychiatry–characterization of inpatients with psychiatric pathology in the infectiology service

T. Carvalho

Hospitais da universidade de Coimbra, psychiatry, Coimbra, Portugal

Introduction The interface of the Liaison Psychiatry with Infectiology is fundamental for the continuous and specialized support of these patients. Prevalent psychiatric records are known in the HIV infection, such as anxiety, depression and abuse and/or addiction to substances. There are also different neuropsychiatric situations associated with this infection owing, namely, to the HIV direct action on the central nervous system, to the adverse effect of the antiretroviral therapy and to the resurgence of existing prior pathology.

Objective The author intends to characterize the population evaluated in the Liaison psychiatry in the Coimbra university hospital with respect to inpatients of the Infectiology Service in a central hospital in order to optimize resources and better adjust interventions made.

Methods and results The quantitative retrospective study was carried out between May 2015 and May 2016, with a duration of one year, in the infectiology service of the Coimbra university hospital. Observation and evaluation of the inpatient of the infectiology service having in view the sample characterization in relation to demographic data, nature of the request, antiretroviral therapy, psychiatric diagnosis, type of intervention and follow-up. The quantitative data were subject to statistical analysis.

Conclusion The prevalence of the psychiatric disorders associated with HIV infection is high and with great emotional impact and implications in the personal, sexual, occupational and social life of the individual. The diagnosis and treatment of the psychiatric comorbidity is determinant in the patients' evolution, both in reducing suffering associated with experience of HIV infection and in its implications.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

From 'Big 4' to 'Big 5': A review and epidemiological study on the relationship between psychiatric disorders and World Health Organization preventable diseases

G. Chartier¹, D. Cawthorpe^{2,*}

¹ The university of British Columbia, psychiatry, Vancouver, Canada

² University of Calgary, psychiatry, Calgary, Canada

* Corresponding author.

Introduction Chronic diseases, such as heart disease, stroke, chronic respiratory diseases and diabetes, are by far the leading causes of mortality in the world, representing 60% of all deaths. However, chronic disease rarely exists in isolation. Nevertheless, study of chronic disease rarely takes into account comorbidity and virtually none examine their occurrence in populations.

Objectives and aims To review the association between psychiatric disorders and other medical comorbidities.

To study the association between psychiatric diseases and medical comorbidities on a population-scale.

To reconsider our approach to medical comorbidities.

Methods Using an informatics approach, a dataset containing physician billing data for 764 731 (46% male) individuals spanning sixteen fiscal years (1994–2009) in Calgary, Alberta, Canada was compiled permitting examination of the relationship between Physical Disorders and Mental Disorders, based on the International Classification of Diseases (ICD).

Results All major classes of ICD physical disorders had odd ratios with confidence intervals above the value of 1.0. Ranging from 1.47 (Injury poisoning) to Circulatory systems (3.82). More precisely, when a psychiatric disorder is present, the likelihood to develop one of the four preventable diseases is significantly increased: Stroke (4.27), Hypertension (3.34), Diabetes (2.66) and COPD (2.43).

Conclusion We postulate that psychiatric disorder should be included in the classification of preventable chronic diseases that have a profound impact on society. Developing a consistent and standardized approach to describe these features of disease has the potential to dramatically shift the format of both clinical practice and medical education.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A rare type primary central nervous system lymphoma with primarily psychiatric diagnosis- a case report

U. Cikrikcili^{1,*}, B. Saydam¹, M. Aktan²

¹ Istanbul university, psychiatry, Istanbul, Turkey

² Istanbul university, hematology, Istanbul, Turkey

* Corresponding author.

Primary central nervous system lymphoma (PCNSL) is a high-grade malignant B-cell non-Hodgkin neoplasm that is an infrequent variant of all intracranial neoplasms (1%) and all lymphomas (< 1%) PCNSL is documented mainly in immunocompromised patient groups, although it may also be diagnosed in immunocompetent patients. It affects mainly the eyes, supratentorial areas, or the spinal cord. The lesions are typically localized in frontal lobes, corpus callosum and basal ganglia. Additionally, lesions might rarely be detected at infratentorial areas and in medulla spinalis. Even though a wide spectrum of treatment options are available, such as chemotherapy, radiotherapy, or surgery; response rates are low and prognosis is poor in spite of appropriate treatment.

The case we reported here is 57-year-old male presented with symptoms of aggressivity, impulsivity, depressive mood and personality changes. Histopathological diagnosis was CD5 positive diffuse large B cell lymphoma, which is very rare in high-grade lymphomas. There were no neurological signs related to CNS tumor and the clinical manifestations responded very well to chemotherapy consisting of high dose methotrexate, vincristine and procarbazine. The significance of such neuropsychiatric symptoms in the course of treatment for PCNSL has been previously documented as well. These behavioral and emotional symptoms might manifest

themselves based on where the neoplasm is localized. Therefore, psychiatrists should be more aware of the uncommon manifestation of the disorder as reported in this case. Consultation for differential diagnosis might also be necessary in such cases.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Experimental intervention program in psychosomatic pathology

A. Coutinho*, D. Silva, I. Carvalho, R. Ribeiro Silva, L. Ribeiro
Centro hospitalar de Vila Nova de Gaia e Espinho/E.P.E, psychiatry
and mental health department, V.N. De Gaia, Portugal

* Corresponding author.

Introduction The work of Bion, developing the psychoanalytic theories of Freud and Klein on the origins of anxiety in childhood, includes the hypothesis of a protomental system as a matrix in the human organism in which physical and mental are at first undifferentiated. He defends that the continuing experience by the infant of parental containment of its anxieties, through a process of projection and introjection, develops its capacity for thinking about frustration rather than evading it. This conception was extended to psychosomatic illness, by the hypothesis that, without this experience, frustration may lead to basic assumption mentality and psychosomatic illness rather than emotions and thought.

Objectives This work aims to describe an experimental technique of group psychotherapy, inspired in Bion's principles combined with relaxation techniques, in the context of psychosomatic diseases.

Aims The authors pretend to identify improvement in clinical symptomatology, quality of life, identification and expression of emotions, in the group submitted to this method, compared to controls.

Methods It was performed a weekly group psychotherapeutic session and a weekly relaxation session (using Jacobson's method), along two months. The patients were randomly selected and submitted to psychological evaluation with scales and questionnaires, in the beginning and at the end of the study.

Results At the time of submission of this work, the results of the intervention were in analysis.

Conclusions This paper describes an experimental method of psychotherapeutic intervention in the field of psychosomatic disease, using a transdisciplinary perspective.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Attention, vigilance and visuospatial function in hospitalized elderly medical patients—relationship to delirium syndromal status and motor subtype profile

C. Daly
Department of psychiatry, St. Lukes hospital, Kilkenny, Ireland

* Corresponding author.

Objective The early and efficacious detection of neurocognitive disorders poses a key diagnostic challenge. We examined how nine bedside cognitive tests perform across the spectrum of delirium and motor subtypes.

Methods The performance on a battery of nine bedside cognitive tests were compared in elderly medical inpatients with DSM-IV delirium, subsyndromal delirium, and no neurocognitive disorder and in different motor subtypes of patients with delirium.

Results One hundred and ninety-eight patients (mean age 79.14 ± 8.26) were assessed with no delirium ($n=43$), subsyndromal delirium ($n=45$), and full syndromal delirium ($n=110$). The ability to meaningfully engage with the tests varied from 59% for vigilance B test to 85% for Spatial Span forward test and was found to be least in the full syndromal delirium group. The no delirium group was distinguished from the delirium groups for all the tests and from the full syndromal delirium group for the vigilance B test and global visuospatial function test. The subsyndromal delirium group differed from the full syndromal delirium group in respect of global visuospatial function test, spatial span backwards and vigilance A tests. Patients with full syndromal delirium were best identified using the interlocking pentagons test and clock drawing test. The ability to engage with testing was higher for those in the no subtype group.

Conclusions Simple bedside tests of attention, vigilance, and visuospatial ability are useful to help to distinguish neurocognitive disorders namely subsyndromal delirium from other presentations.

⁴ University of Groningen- University Medical Center Groningen, Department of Old Age Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction Borderline personality disorder (BPD) is characterized by pervasive instability in moods, impulsivity, intense and unstable or disturbed interpersonal relationships and self-image, and often self-destructive behaviour. BPD seems to be more common in patients suffering from migraine. However, typical migraine characteristics in this population remain partly unknown.

Objectives & aims To present the specific clinical characteristics of migraine patients with BPD and to assess their response to migraine treatment.

Methods We examined 10 patients with migraine and previously diagnosed with BPD (group 1), 10 patients with migraine and no history of BPD (group 2), and 10 patients with migraine and no history of BPD matched to group 1 for age, gender, and frequency of headache. Migraine was treated in group 1 and 3 and pharmacological treatment outcome was assessed after 6 months.

Results The group of migraine patients with coexisting PBD was associated with female gender, increased prevalence of medication overuse headache, higher rates of self-reported depression, increased migraine-related disability, and a decreased response to pharmacological migraine treatment.

Conclusion Patients with migraine and previously diagnosed BPD can be regarded as a distinct population. They are more suffering from depressive symptoms, more disabled by their migraine, are more resistant to pharmacological treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Misdiagnosis of loin pain hematuria syndrome as a somatization disorderL. De Jonge^{1,*}, S. Petrykiv², J. Fennema³, M. Arts⁴¹ Leonardo scientific research institute, geriatric psychiatry, Bergen op Zoom, The Netherlands² University of Groningen–university medical center Groningen, department of clinical pharmacy and pharmacology, Groningen, The Netherlands³ GGZ Friesland, geriatric psychiatry, Leeuwarden, The Netherlands⁴ University of Groningen–university medical center Groningen, department of old age psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction Loin pain hematuria syndrome (LPHS) is a rare kidney disease with a prevalence of ~0.012%. Its clinical features include periods of severe uni- or bilateral loin pain, accompanied by (microscopic) hematuria. It is often misdiagnosed as a psychiatric condition, particularly under the heading of a somatization disorder.

Objectives We describe the case of a patient who developed depressive symptoms after decades of suffering from severe intermittent bilateral loin pain.

Aims To report a case-study, describing LPHS as a cause of severe chronic pain and persistent depressive symptoms.

Methods A case-study is presented and discussed, followed by a literature review.

Results A 55-year-old female was referred to a psychiatrist for her depressive symptoms and persistent periods of severe unilateral or bilateral loin pain and intermittent hematuria for over 25 years. There she was diagnosed with a depression and somatization disorder. She received amitriptyline for many years, without any effect. Finally, the patient opted for a second opinion in an academic hospital in Belgium where it was quickly discovered. After surgery, including renal denervation and kidney autotransplantation, her somatic problems and depressive mood disappeared.

Conclusions The awareness of LPHS is still very limited in medicine. This may lead to incorrect diagnoses, including psychiatric disorders such as somatization disorder. More awareness could lead to earlier diagnosis and prevent the consequences of severe debilitating pain.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Lithium toxicity after bariatric surgeryL. De Jonge^{1,*}, S. Petrykiv², J. Fennema³, M. Arts⁴¹ Leonardo scientific research institute, geriatric psychiatry, Bergen op Zoom, The Netherlands² University of Groningen–university medical center Groningen, department of clinical pharmacy and pharmacology, Groningen, The Netherlands³ GGZ Friesland, geriatric psychiatry, Leeuwarden, The Netherlands⁴ University of Groningen–university medical center Groningen, department of old age psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction Bariatric surgery is globally increasingly being applied in patients with morbid obesity to achieve permanent weight reduction. More than fifty percent of these patients have a psychiatric disorder in their history and over thirty percent take psychotropic medication. The prevalence of bipolar disorder in patients who undergo bariatric surgery is around four percent, and most of them are treated with lithium.

Objectives & aims To report and discuss the effect of bariatric surgery on changes in lithium absorption.

Methods We present all published case studies and literature review on lithium toxicity after bariatric surgery.

Results To date; only two case-reports were published with dramatic changes in lithium level after vertical sleeve gastrectomy and Roux-en-Y bariatric surgery. Within a period of two to five weeks, the patients were presented to the emergency department with signs of dehydration and acute kidney failure.

Conclusion Clinicians should be aware of dramatic and possibly even life-threatening pharmacokinetic changes in drug absorption that may occur after bariatric surgery. Careful monitoring and even reduction of lithium dosage before and after surgery could potentially prevent serious complications.

Depression in people with multiple sclerosisF. Ellouze^{1,*}, W. Bouali¹, B. Hidouri², S. Younes¹, M. Nasr¹¹ CHU Tahar Sfar, Psychiatry, Mahdia, Tunisia² CHU Tahar Sfar, neurology, Mahdia, Tunisia

* Corresponding author.

Introduction Depression is the most common syndrome associated with Multiple Sclerosis (MS) with a high prevalence during a lifetime.

Objectives To assess the prevalence of depression in patients treated in neurology for MS.

Methods We performed a retrospective study on 17 patients diagnosed with MS and confirmed with the criteria of Mac Donalds 2010 with a follow-up in the neurology department of the EPS Mahdia for a period of nine years (2006–2014), then addressed to a psychiatric consultation for depression.

Results In total 17 patients were hospitalised in the neurology department during the study. Ages ranged from 20 to 39 years with an average of 33 years. The average course of the disorder is 5 years. We objectified a female predominance with 82%, a professional activity was found in 76% of patients. The comorbidities found are mainly hypertension, diabetes and asthma, respectively in 11%, 5% and 5%. Depression was clinically confirmed in 9 patients, that to say, 52% of our sample addressed in the psychiatric consultation, whose 6 received an antidepressant (fluoxetine) and 3 received paroxetine. An anxiolytic was given to the half of these patients.

Conclusion The association between MS and depression would, therefore, be neither fortuitous nor only related to non-specific factors of any chronic disease. Specifying the relative share of these explanatory factors is probably one of the challenges for future researches in this area.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ “Victor Babes” university of medicine and pharmacy Timisoara, discipline of Child Care and Neonatology, Timisoara, Romania

⁴ “Victor Babes” university of medicine and pharmacy Timisoara, Internal Medicine III, Timisoara, Romania

* Corresponding author.

Introduction In 2015, the worldwide point prevalence for diabetes mellitus was 8.8%. Type D personality was found as being more prevalent in type 2 diabetes than in the general population. **Objectives** We aimed to reveal the frequency of type D personality and to analyze the impact of type D personality on both quality of life and angiopathic complications, in patients with type 2 diabetes from our region.

Methods A cross-sectional research was performed on 79 out-patients that were monitored for diabetes mellitus at Timisoara diabetes, nutrition and metabolic diseases clinic. Type D personality was assessed with the DS-14 scale. Quality of life was quantified by using the Q-LES-Q-SF scale (Quality of Life Enjoyment and Satisfaction Questionnaire-Short Form). The angiopathic complications were abstracted from medical records.

Results Type D personality was present in 38 subjects with diabetes mellitus (48.10%). Compared to those without type D personality, patients with type D personality and diabetes had significant lower mean scores for the following domains of the Q-LES-Q-SF scale: social relationships ($P < 0.001$), daily life function ($P = 0.027$), sexual activity ($P = 0.005$), to get around physically ($P < 0.001$), work or hobbies ($P = 0.008$) and raw score ($P = 0.003$). Type D personality did not make any difference regarding micro and macroangiopathic complications of type 2 diabetes patients.

Conclusions Type D personality, a highly frequent entity, did not make the difference with respect to diabetic complications; however, it may interfere significantly with several facets of the quality of life of these patients. These results should be taken into account for an interdisciplinary approach to these patients.

³ Hedi chaker hospital, epidemiology, Sfax, Tunisia

* Corresponding author.

Introduction Obstructive sleep apnea syndrome (OSAS) is a highly widespread sleep-related breathing disorder that leads to serious impairment in quality of life (QOL).

Objectives We aimed to assess QOL in patients with OSAS and to investigate its relationship with illness representations.

Methods We performed an analytical cross-sectional study of 87 recently diagnosed OSAS patients. Apnea hypopnea index (AHI) was determined by an overnight polysomnography. Excessive daytime sleepiness (EDS) was assessed by the Epworth Sleepiness Scale (ESS). QOL was assessed by the 36-item short form health survey (SF-36). Illness representations were measured by the Brief Illness Perceptions Questionnaire (B-IPQ); High scores reveal a more threatening perception of the illness.

Results Mean age of the participants was 55.7 years (SD = 11.6). According to the AHI, 70.1% of the patients had severe OSAS, and

16.1% had moderate OSAS. The mean score of the SF-36 was 40.2 (SD = 18.7). Overall QOL was impaired in 87.7% of the patients. There was a considerable decrease in both mental and physical QOL. EDS was associated with impairment in mental QOL. Illness representations were negatively correlated with overall QOL ($r = -0.45$; $P < 0.01$). No relationship was found between QOL and illness severity.

Conclusion The present study provides evidence that OSAS has serious influence on QOL of patients, which could be mediated by negative illness perception. So it is extremely important to know how OSAS sufferers perceive their illness to better understand their coping behavior and to improve their adherence to treatment and their QOL.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Impact of coping strategies on emotional status in patients with obstructive sleep apnea syndrome

I. Gassara¹, J. Ben Thabet^{1,*}, S. Msaad², K. Medhaffar¹, S. Omri¹, M. Maalej¹, N. Charfi¹, N. Zouari¹, S. Yaich³, L. Zouari¹, S. Kammoun², M. Maalej¹

¹ Hedi chaker hospital, psychiatry, Sfax, Tunisia

² Hedi chaker hospital, pneumology, Sfax, Tunisia

³ Hedi chaker hospital, epidemiology, Sfax, Tunisia

* Corresponding author.

Introduction Obstructive sleep apnea syndrome (OSAS) is a common sleep disorder, which leads to higher morbidity, and mortality and can result in various psychological problems, such as depression.

Objectives The purpose of this study was to assess the severity of depression and to examine its relationships with coping strategies in OSAS patients.

Methods We performed an analytical cross-sectional study of 87 recently diagnosed OSAS patients. Apnea hypopnea index (AHI) was determined by an overnight polysomnography. Depressive symptoms were evaluated by the hospital anxiety and depression scale (HADS). Coping strategies were assessed by the brief cope.

Results Subjects included 38 men and 49 women averaging 55.7 years of age (SD = 11.6) with a mean body mass index (BMI) of 33.8 kg m⁻². According to the AHI, 70.1% of the patients had severe OSAS, and 16.1% had moderate OSAS. Depressive symptoms were found in 44.8% of all patients. Emotional coping was used by 72.4%, while problem-focused coping was used by 28.7% of the patients. The score of depression on HADS (HADS-D) showed positive correlation with BMI ($r = 0.48$; $P \leq 0.001$). No significant association was found between HADS-D and AHI. Depressive symptoms were associated with more emotional coping ($P = 0.03$) and with less problem-focused coping ($P = 0.002$).

Conclusion Our findings suggest that depression is highly prevalent among patients with OSAS, and that coping style seems to have a significant influence on emotional status in these patients. Further research should explore the possibilities of intervening on this factor, aiming to lessen depressive symptoms in OSAS patients.

EV0273

Neuropsychiatric manifestations in patients with HIV treated with antiretroviral drugs versus untreated

V. Gonçalves^{1,*}, A. Ribeiro¹, L. Ferreira¹, P. Cintra²¹ Santarém hospital, department of psychiatry and mental health Santarém hospital, Santarém, Portugal² Cascais hospital, department of psychiatry and mental health of Cascais hospital, Cascais, Portugal

* Corresponding author.

Introduction Untreated patients for H.I.V can present various types of neuropsychiatric syndromes (NPS): subclinical cognitive symptoms, behavioral changes, agitation, personality changes, dementia complex associated with H.I.V and delirium, depressive disorder, bipolar affective disorder or manic episode. However, it is controversial whether antiretroviral induce NPS, or on the contrary, when there are patients will evolve into an AIDS stage for therapeutic resistance or noncompliance.

Aims Describe qualitatively and quantify the epidemiological point of the main subclinical and NPS symptoms in patients untreated and treated with antiretroviral drugs and their frequencies. Propose pharmacological treatments for each of the specified conditions.

Methods Search in PubMed with the words “Neuropsychiatric and antiretroviral therapy” by applying the limits: full and free texts, past 10 years, Human, English language and adults; research liaison psychiatry textbooks.

Results Results yielded 381 articles with the criteria selecting 102, the most relevant for the purposes of work. They chose four most relevant chapters in the literature.

Conclusions The most effective treatment of NPS in unmedicated patients is to start antiretroviral therapy; only if it does not improve them should be introduced psychiatric drugs as if they were functional. 50% of treated with efavirenz patients will develop NPS in the early days with gradual decrease. The dropout rate associated with these adverse events varies from 2.6–16%. Treatment of these NPS a challenge by the existence of numerous drug interactions, it is essential to know to deal with these entities to improve the quality of life of people with this chronic disease.

Sun lupus and energy. Systemic lupus erythematosus presenting as mania

M.J. Gordillo Montaño^{1,*}, S. Ramos Perdigues¹, M.A. Artacho Rodriguez², S. Latorre¹, C. Merino del Villar¹, C. Caballero Roy¹, S.V. Boned Torres¹, M. de Amuedo Rincon¹, P. Torres Llorens¹, M. Segura Valencia¹¹ Hospital Can Misses, psychiatry, Eivissa, Spain² Hospital Can Misses, medicine, Eivissa, Spain

* Corresponding author.

Introduction Systemic lupus erythematosus is a chronic disease that can give neuropsychiatric episodes and systemic manifestations. About 57% of patients with SLE have neuropsychiatric manifestations in the course of their illness, however an initial presentation with neuropsychiatric clinic is rare.

Objective Describe how patients receiving corticosteroids as part of their treatment can develop mental disorders but not only them.

Method It will raise grounds with a case: 20-year-old woman recently diagnosed with SLE because of arthritis in his ankle. Treatment was initiated with prednisone 10 mg and chloroquine 200 MG. After 20 days the patient comes to the emergency after episode of turmoil at home with major affective clinical manifold. Presenting fever. The presence of fever downloads the possibil-

ity of a psychosis chloroquine or corticosteroids to be a small dose. Treatment was initiated with high doses of prednisone and immunosuppressants. In addition to associating specific anticonvulsant and antipsychotic drugs at usual doses for a manic episode.

Results Treatment of psychosis in SLE is essentially empirical, and depends on the etiology. It usually responds to the use of high doses of corticosteroids combined with immunosuppressive drugs. Psychosis induced by corticosteroids requires lowering them. It is valid concomitant use of antipsychotics.

Conclusions The presence of psychotic symptoms in a patient with systemic lupus erythematosus forces to distinguish between various etiological possibilities.

Corticosteroids may cause a variety of psychiatric symptoms. And yet, in patients with SLE these syndromes are not always attributable to the use of corticosteroids.

Confusion between symptom and disease. Parkinson vs meningioma

M.J. Gordillo Montaño^{1,*}, S. Ramos Perdigues¹, C. Merino del Villar¹, C. Caballero Roy¹, S. Latorre¹, M. Guisado Rico¹, A. Bravo Romero¹, S.V. Boned Torres¹, M. de Amuedo Rincon¹

Hospital Can Misses, psychiatry, Eivissa, Spain

* Corresponding author.

Introduction Parkinson's disease is caused by decreased dopaminergic neurons of the substantia nigra. Psychosis occurs between 20 and 40% of patients with Parkinson's disease. Dopaminergic drugs act as aggravating or precipitating factor. Before the introduction of levodopa patients had described visual hallucinations but the frequency was below 5%.

Objective Illustrated importance of treatment, reassessment after its introduction and refractoriness to answer; as well as the importance of a differential diagnosis at the onset of psychotic symptoms later in life.

Method Clinical case: female patient 75 years tracking Neurology by parkinsonism in relation to possible early Parkinson disease. She was prescribed rasagiline treatment. Begins to present visual and auditory hallucinations, delusional self-referential and injury. She had no previous psychiatric history. She went on several occasions to the emergency room, where the anti-Parkinson treatment is decreased to the withdrawal point and scheduled antipsychotics did not answer. Doses of antipsychotics are increased despite which symptoms persist and even increase psychotic symptoms. In this situation it is agreed to extend the study. Subsequently an NMR of the skull where the image is suggestive of a right occipital meningioma appears.

Results/conclusions With the emergence of psychotic symptoms later in life it will be important to ask a broad differential diagnosis, since in a large number of cases will be secondary to somatic or to drug therapies.

Parkinsonism can be a symptom of occipital meningioma, presenting in the psychotic clinic. Refractoriness, on one hand to the suspension of treatment for Parkinson's disease, such as poor response to antipsychotics, did extend the study, which ultimately gave us the diagnosis.

Role of online technology and social networking site at workplace

H. Gupta

Role of online technology and social networking site at workplace, ACAMHE&NS-CCRAS, Bangalore, India

Background Internet use has affected the pattern of working style at the workplace. Recent years have seen an increased use of online activities (especially pornography/gaming) at the workplace. It has been shown to affect productivity at the workplace. There is a dearth of literature from the Indian context in this area.

Aim This study was conducted to explore the pattern of pornography use & gaming at the workplace and its dysfunctions. Setting and design: The present study was a cross-sectional prospective study

Materials and methods The objective of the study was to assess the pattern of pornography use at the workplace. Five hundred employees having experience of Internet use for more than a year of various government/private sector organizations in Bengaluru were assessed using background data sheet, DSM V criteria, Internet addiction test & pornography addiction screening instrument. Users who were unwilling to participate were excluded from the study.

Results Seven to nine percent reported preference for Internet to work, meals, personal hygiene, sleep, and interaction with family members and effects on productivity. Three to four percent have excessive use of pornography & game.

Conclusions The present study has implications for evolving psychoeducational modules for the promotion of healthy use of technology.

Psychiatric morbidity managed by liaison psychiatry in a Tunisian populationN. Charfi¹, K. Hajbi^{2,*}, M. Maâlej Bouali¹, L. Zouari¹, N. Zouari¹, J. Ben Thabeb¹, M. Maâlej¹¹ CHU Hedi Chaker Sfax–Tunisia, psychiatry “C”, sfax, Tunisia² CHU Hedi Chaker Sfax–Tunisia, psychiatry, sfax, Tunisia

* Corresponding author.

Introduction The epidemiology of the association between mental disorders and medical illnesses is the subject of many research studies, mainly due to the worse prognosis associated with this comorbidity.

Objectives To investigate the psychiatric morbidity associated with somatic diseases in liaison psychiatry outpatients and to identify factors associated with this morbidity.

Methods A descriptive and analytical cross-sectional study was conducted. It took place at the psychiatry outpatient unit at CHU Hedi Chaker of Sfax in Tunisia. We collected 110 files of patients having a medical and/or surgical condition, addressed for the first time in 2014, as part of liaison psychiatry.

Results Major depressive disorder (MDD) and adjustment disorder (AD) with anxious and/or depressive mood were the most common diagnoses in liaison psychiatry (respectively 53 cases and 28 cases).

MDD has been diagnosed mainly during the course of three somatic illnesses: cancer, sciatica and hypertension, with respective rates of 90%, 85.7% and 60%.

The onset of a MDD during the evolution of a somatic disease was significantly more common in female patients ($P=0.04$) and those living in couple family ($P=0.005$).

Conclusion Among all psychiatric disorders, depression and AD were the most frequently associated disorders with somatic diseases. This comorbidity may be explained by the physiological and psychological impact of certain somatic diseases, the iatrogenic effect of certain treatments, or the involvement of a biological, psychological or environmental common factor for both conditions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Treating out of the box: A psychiatry for all!L. Jouini^{1,*}, W. Homri¹, A. Mrabet², R. Zaouche³, R. Labbane¹, B. Meddeb⁴, E. Gouider⁴¹ Razi hospital, “C” Psychiatry department, Tunis, Tunisia² Faculty of medicine of Tunis, preventive medicine department, Tunis, Tunisia³ Razi hospital, psychiatry outpatient Unit, Tunis, Tunisia⁴ Aziza Othmana hospital, center of Hemophilia, Tunis, Tunisia

* Corresponding author.

Introduction Psychiatrists used to focus on some chronic illness such as schizophrenia and bipolar disorder. However, non-psychiatric chronic illness also need psychiatric follow-up. Indeed, the reciprocal impact of chronic illness and depression is becoming increasingly clear. There is evidence that living with a chronic illness can increase the risk for depression and that depression can impair the quality of life (QoL).

Objectives We aim to assess the prevalence of depression in a chronic disease such as hemophilia and to evaluate the patients' QoL.

Methods Thirty-seven adults from the hemophilia treatment center were screened for depression using the Hamilton Scale for Depression. QoL was assessed using the norm based scores of the SF-36. When the group's score was below 47, the quality of life was below the average.

Results The average age of our population was 26.5 years. 46% were married, 27% achieved a superior level of education and 30% were jobless. Good social and professional integration were reported in 70% and 76% respectively. 77% of our sample had depressive symptoms which were mild (30%), moderate (24%) or severe (13%). The physical and mental Component Scores (PCS and MCS) of the SF-36 scored 46.48 and 43.45 respectively. PCS and MCS were significantly lower in patients with depressive symptoms ($P=0.002/P=0.048$). However, depressive symptoms and SF-36 scores did not differ according to education level, marital and professional status.

Conclusions Psychiatrists should be aware of the psychological impact of general chronic illness. Psychiatric consultations must be implemented in every general hospital.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychopathological features of mental disorders in IDPsO. Khaustova^{1,*}, N. Kovalenko²¹ Bogomolets National Medical University, Psychosomatic medicine and Psychotherapy, Kiev, Ukraine² URISFPDA, psychosomatic medicine, Kiev, Ukraine

* Corresponding author.

Objectives Violation of mental health is common in forced migrants. Lack of positive motivation to move and physical impossibility of further stay at home, mental trauma caused by the history and causes of migration; difficulties in adapting to new location

determine the formation of specific experience IDPs. The most common are psychogenic depression, anxiety and somatoform disorders.

Methods We had observed 60 IDPs aged 18 to 80 years: medical history, current complaints and mental state.

Results We allocated 3 groups: persons of retirement age with severe chronic physical illness or disability on physical illness (1 group); persons with disabilities to mental disease (group 2) and persons without chronic diseases or disability (relatively healthy, caring for the sick) (group 3). Group 1 patients have anxiety (51.4%) and depression (42.8%) syndromes; 25.7% of subjects showed suicidal thoughts and intentions; 25.7% have some PTSD symptoms, including avoidance, overexcited, emotional numbness, pointing to adjustment disorder. In group 2 patients, changes were not found in mental state. Despite traumatic events delusional story does not change, recurrence and relapse rating was stable. In some cases, patients begin to abuse alcohol. In 3 group 31.3% persons experienced depression, 25%-anxiety symptoms, combined with a severe somatic symptoms; 12.5% showed suicidal thoughts; in 18.7% were diagnosed adjustment disorders. So among IDPs the individuals with severe medical conditions are most vulnerable population in the formation of stress-related and neurotic disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychological distress following spinal cord injury

R. Kinson*, J. Tan, D. Hussain, P.S. Looi, L. Tan
TISH, Psychological Medicine, Singapore

* Corresponding author.

Introduction There is limited data on psychological burden following spinal cord injury (SCI) in Singapore.

Aims (1) To describe the prevalence of depression and anxiety at admission for inpatient rehabilitation and (2) describe the baseline characteristics that predict the development of anxiety or depression in patients following SCI.

Methodology We retrospectively reviewed medical records of SCI patients at admission from 01-06-2013 to 31-12-2015. The Hospital Anxiety and Depression Scale (HADS), ASIA score and demographics were collated.

Results A total of 157 subjects were included, 62.4% ($n=98$) were male with a mean age of 56.7 years. 43.4% ($n=68$) had a traumatic SCI with 73.9% ($n=116$) having had spinal surgery. The average length of stay was 46.6 days with most discharged to their own homes. Ten subjects screened positive for anxiety (6.4%) and 16 for depression (10.2%). 13.4% ($n=21$) screened positive for anxiety and/or depression. Two third ($n=95$) had injuries at the cervical level and 14% ($n=22$) scored ASIA A/B. 45.9% ($n=72$) was referred to the psychologist. A significantly higher proportion of subjects ($P<0.05$) who screened positive had a past psychiatric history, were prescribed antidepressants at admission and during rehabilitation. Significant differences were noted in primary caregiver (nursing home vs. others) following discharge when comparing those that screened positive vs. negative however there were no significant differences between baseline demographics, neurological level and ASIA score.

Conclusion Psychological burden following SCI is significant. Standardized screening and psychological support is warranted with special attention to those with a past psychiatric history.

Delirium: “The out of the track” of physicians

M. Mangas^{1,*}, G. Alcobia Santos², Y. Martins¹, A. Matos Pires¹

¹ Hospital José Joaquim Fernandes, Mental Health and Psychiatric Service, Beja, Portugal

² Hospital do Espírito Santo de Évora, Internal Medicine Service, Évora, Portugal

* Corresponding author.

Introduction Delirium is an acute clinical syndrome with diverse and multi-factorial etiologies. It has high prevalence in hospitalized patients and it is associated with serious adverse outcomes, increasing morbidity and mortality. Delirium requires a differential diagnosis with a wide range of mental disorders.

Aim To evaluate cases referred to liaison psychiatry in Hospital José Joaquim Fernandes, in regard to the frequency, cause and misdiagnoses of delirium.

Methods A retrospective analysis of liaison psychiatric referral from January to August 2016.

Results The overall referral consisted of a total of 111 cases. Delirium was the second most frequent referral (21.6%), after depression. Half of patients had an advanced age (71–90 years). A total of 44.8% of patients with delirium were misdiagnosed and the referral causes were “depression”, “dementia”, “aggressive behavior”, “agitation” and “schizophrenic psychosis”. The majority of patients were referred by internal medicine. The most frequent underlying conditions were: postoperative (27.6%), respiratory diseases (24.1%) and sepsis (17.2%).

Discussion/conclusion Delirium is one of the most frequent diagnoses in liaison psychiatry. This study supports the statement that delirium is often not recognized and that is misdiagnosed as a primary psychiatric illness, mainly, dementia or mood disorder. Although delirium is classified in ICD-10 as a psychiatric diagnosis and clinically manifests with a wide range of neuropsychiatric abnormalities, it is secondary to a medical/surgical disorder that requires urgent approach by the respective specialty.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Postictal psychosis – A complex challenge

M. Marinho^{1,*}, J. Marques², M. Bragança¹

¹ São João Hospital Centre, Clinic of Psychiatry and Mental Health, Porto, Portugal

² Local Healthcare Unit of Matosinhos, Clinic of Psychiatry, Matosinhos, Portugal

* Corresponding author.

Introduction Patients with epilepsy have 6–12 times higher risk of suffering from psychosis, with a prevalence of about 7–8%, and the coexistence of these two conditions is associated with increased morbidity and mortality. The psychosis of epilepsy is generally split into two groups: interictal psychoses and postictal psychosis (PIP), and the latter has been estimated to represent 25% of all types. However, many of these episodes remain under-recognized and/or are often misdiagnosed.

Objectives To provide an overview of PIP.

Methods Literature review based on PubMed/Medline, using the keywords “epilepsy” and “psychosis”.

Results PIP has been recognized since the 19th century, when Esquirol described postictal “fury”. Although its etiology and pathogenesis remain poorly understood, several risk factors and etiopathogenic mechanisms have been suggested and analysed. An essential step in PIP management is its accurate and early diagnosis. Generally, before the onset of PIP there is a lucid period of one

to six days after the seizure(s). PIP frequently has a polymorphic presentation, tends to be affect-laden and symptoms often fluctuate. It is of limited duration and frequently responds very rapidly to low doses of benzodiazepines and antipsychotics. However, the propensity of the antipsychotics to provoke seizures and the risk of pharmacokinetic interaction with anti-epileptics are important considerations. Recurrence rates range 25% to 50%.

Conclusions Given the negative impact of PIP in morbidity and mortality among these patients, it is crucial that neurologists and psychiatrists are able to adequately recognize and treat this clinical condition.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Through the analysis of a case report to analyze the importance of the coordination between primary care and mental health service for a better management of an outpatient. It is known that primary care is the gateway to the patient in the health system. Therefore, the role of physicians headers is essential for diagnosis, for the start of drug treatment and referral to specialized care. It is known that one of every four patients have mental health problems. To meet the standards of primary care, physicians should ensure personalized assistance, integrated, continuous and permanent. Therefore, in relation to the accessibility of patients, it is essential to establish the diagnosis as soon as possible and initiate appropriate treatment to alleviate the symptoms of this type of psychiatric disorders and should track patients and their caregivers. For all this, it is essential that there is proper coordination between primary and specialty care in mental health. The interdisciplinary approach in these situations can assist the patient and family from a holistic perspective. This approach strengthens and reinforces the subsequent treatment, not only care but also evolutionary. Thus arises the interdisciplinary work as an opportunity to access the new and complex this social situation.

Introduction According to international scientific literature, and as summarized in the guidelines of the International Society of

Hypertension, lowering of blood pressure can prevent cardiovascular accidents. Some studies suggest that hypertension, anxiety, and depression might be inversely correlated.

Objective To investigate whether blood pressure is associated with anxiety and depression.

Methods Cross-sectional design. Male and female primary care patients were enrolled, aged 40–80. Criteria of exclusion adopted: use of antidepressants or antipsychotics; previous major cardiovascular event; psychosis or major depression; Type 1-DM; pregnancy and hereditary disease associated to obesity. Anxiety and depression symptoms were assessed using HADS. Waist circumference, hip circumference, blood pressure, HDL, triglycerides, blood sugar, hypertension, albumin concentrations and serum iron were also assessed.

Results Of the 210 subjects, 84 were men (40%), mean age was 60.88 (SD ± 10.88). Hypertension was found to correlate significantly to anxiety (OR = 0.38; 95% CI = 0.17–0.84), older age (OR = 3.96; 95% CI = 1.88–8.32), cigarette smoking (OR = 0.35; 95% CI = 0.13–0.94), high Body Mass Index (OR = 2.50; 95% CI = 1.24–5.01), Waist-hip ratio (OR = 0.09; 95% CI = 0.02–0.46) and the Index of comorbidity (OR = 16.93; 95% CI = 3.71–77.29).

Conclusions An inverse association was found between anxiety and hypertension, suggesting the need to clinically manage these two dimensions in a coordinated way. Other findings are well known and already included in prevention campaigns. Further research is needed, also to better understand and explain the causative pathways of this correlation.

Impact of classification systems (DSM-5, DSM-IV, CAM and DRS-R98) on outcomes of delirium

G. McCarthy^{1,*}, D. Meagher², D. Adamis¹

¹ NUI Galway and HSE West, Sligo Leitrim Mental Health Service, Sligo, Ireland

² University of Limerick, Psychiatry, Limerick, Ireland

* Corresponding author.

Introduction Previous studies showed different classification systems lead to different case identification and rates of delirium. No one has previously investigated the influence of different classification systems on the outcomes of delirium.

Aims and objectives To determine the influence of DSM-5 criteria vs. DSM-IV on delirium outcomes (mortality, length of stay, institutionalisation) including DSM-III and DSM-IIR criteria, using CAM and DRS-R98 as proxies.

Methodology Prospective, longitudinal, observational study of elderly patients 70+ admitted to acute medical wards in Sligo University Hospital. Participants were assessed within 3 days of admission using DSM-5, and DSM-IV criteria, DRS-R98, and CAM scales.

Results Two hundred patients [mean age 81.1 ± 6.5; 50% female]. Rates (prevalence and incidence) of delirium for each diagnostic method were: 20.5% (n = 41) for DSM-5; 22.5% (n = 45) for DSM-IV; 18.5% (n = 37) for DRS-R98 and 22.5% (n = 45) for CAM. The odds ratio (OR) for mortality (each diagnostic method respectively) were: 3.37, 3.11, 2.42, 2.96. Breslow-Day test on homogeneity of OR was not significant $\chi^2 = 0.43$, df: 3, $P = 0.93$. Those identified with delirium using the DSM-IV, DRS-R98 and CAM had significantly longer hospital length of stay (los) compared to those without delirium but not with those identified by DSM-5 criteria. Re-institutionalisation, those identified with delirium using DSM-5, DSM-IV and CAM did not have significant differences in discharge destination compared to those without delirium, those identified

with delirium using DRS-R98 were more likely discharged to an institution ($z = 2.12$, $P = 0.03$)

Conclusion Assuming a direct association between delirium and examined outcomes (mortality, loss and discharge destination) different classification systems for delirium identify populations with different outcomes.

* Corresponding author.

Introduction Diagnosis and treatment of patients with craniofacial anomalies such as cleft lip and palate and skeletal malocclusions present a challenge to public health. Dentofacial abnormalities may be associated with depressive and anxiety disorders and poor quality of life.

The aim of this screening study was to evaluate and to compare the rates of anxiety and depression in cleft patients and non-cleft patients with skeletal malocclusions.

Methods The study used psychometric method-HADS and State Trait Anxiety Inventory were used. The first group consisted of cleft patients, the second group consisted of non-cleft patients with skeletal Class II, Class III and anterior open bite malocclusions; the third group was control.

Results Study sample consists of 42 patients (33 females; 24 ± 7.2 years). In the 1st group, anxiety symptoms were detected in 34.7%; depression symptoms - in 17.2% of patients, high rates of reactive anxiety were registered in 35.8%. In the 2nd group, anxiety symptoms were detected in 29.6% of patients; depression symptoms - in 13.1% of patients, high rates of reactive anxiety were registered in 34.2%. In the 3rd group anxiety (18.7%) and depression (8.3%) symptoms and high rates of reactive anxiety (17.7%) were registered significantly less often than in 1st and 2nd groups ($P < 0.005$, $P < 0.001$ and $P < 0.001$ respectively).

Conclusions Our data suggest that cleft-patients and non-cleft patients with skeletal malocclusions have statistically significant higher rates of anxiety and depression than controls and require orthodontic-surgical treatment that should be organized with the assistance of psychiatrist.

Causeless appearance discontentment in patients of plastic surgeons and cosmetologists: Risk factors and patterns of dynamics

V. Medvedev*, V. Frolova

PFUR University, Chair of Psychiatry, Psychotherapy and Psychosomatic Pathology, Moscow, Russia

* Corresponding author.

Introduction Though phenomenon of dysmorphic disorder has been studied extensively clinical dynamical characteristics of this disorder are still being investigated.

Aim of this study was to evaluate patterns of dynamics and risk factors of body dysmorphic disorder in patients of plastic surgeons and cosmetologists.

Methods We included adult patients of Maxillofacial Surgery and Cosmetology departments of Moscow State University of Medicine and Dentistry (from January 2010 to May 2016) with unconfirmed “facial deformity” diagnosed with dysmorphic disorder (F45.2 and F22.88 according to ICD-10). The study used clinical psychopathological method with follow-up period 1–3 years. Data from clinical psychopathological assessment were processed using correlation analysis and non-linear regression analysis by means of logistic regression method.

Results Study sample consisted of 103 patients (78.6% female; mean age 33.4 ± 4.7 years). Statistically significant chronobiological (age, hormone fluctuations, genesial cycle) and psychosocial (financial changes, forced separation, bereavement, loss of job, reduction of social activity, conflict situation, sexual dysfunction, violation of law, diagnosing of somatic disease) risk factors for dysmorphia in different life periods have been established. Strong correlations were found between dysmorphic disorder heterogenic clinical picture (overvalued–33%, affective–24.3%, hypochondric–23.3%, obsessive-compulsive–10.7%, delusional–8.7%) and patterns of dynamics (phasic–41.7%, recurrent–33%, chronic–25.3%). Our data suggest that dysmorphia manifests in any age group and in 74.7% cases is not continuous.

Conclusion Our findings allow to conduct focused diagnostic search, prophylactic psychotherapeutic interventions and early psychopharmacological treatment in individuals with identified risk factors for dysmorphic disorder.

Behavioral manifestations post hemispherectomy due to Sturge–Weber syndrome—A case of success

J. Melim*, A. Batista, A. Tarelho, R. Araújo, S. Fonseca

Centro Hospitalar de Leiria, Psychiatry, Leiria, Portugal

* Corresponding author.

Introduction Sturge-Weber syndrome or encephalotrigeminal angiomatosis is an uncommon neurocutaneous syndrome that manifests with vascular malformations involving the brain, eye and skin; Severe cases present with refractory seizures, sometimes requiring major surgery such as hemispherectomy. Most of the times, some degree of mental retardation and behavioral problems are associated, requiring use of psychotropic medication and other contention strategies. This report describes the case of a 19-year-old boy who was submitted to a left hemispherectomy by the age of one, and was still able to successfully complete basic education. He started presenting severe behavioral problems, with aggressive outbursts, by the beginning of adulthood, having been committed to psychiatry ward. By the age of 22, the patient finds himself calm and functional considering his limitations, with no need for hospital admission for 2 years.

Objectives/aims To describe a clinical case whilst reviewing literature concerning this matter.

Methods Case report with complete clinical history and medical data. Non-systematic review of PubMed database under the terms “Sturge-Weber disease”, “Hemisferectomy”, “behavioral disorder due to organic causes”, “post hemisferectomy out-comes”.

Results/discussion Although presenting with severe arteriovenous malformation, refractory epilepsy and left hemispherectomy, the patient was able to conclude basic instruction; He has lived with his family until the age of 19, when he started displaying disruptive behaviour; after 3 hospital admissions and perfecting

psychotropic drugs treatment, the patient was admitted to an institution for rare diseases patients. Since then he has experienced a calm and functional life, with trained professionals who can offer the non-pharmacological approaches he needs.

³ University of Coimbra, University Medical Services, Coimbra, Portugal

* Corresponding author.

Introduction University students represent a specific population with concerns, burdens and worries that differ from other age and occupation groups. Students' experiences are often exciting and empowering, yet facing multiple stressors that may trigger various forms of psychopathology. Our psychiatry department created a specific liaison service for university students in order to provide an easy and quick access to this medical speciality, included at the Multidisciplinary University Medical Services.

Aims To characterize a sample of college student users of our Psychiatry Liaison Unit regarding socio-demographic and clinic variables.

Methods Socio-demographic and clinic characterization was undertaken in all students observed during sixteen months (1st April 2015–30th July 2016).

Results Fifty-three outpatients were observed: 35 females (66%) and 18 males (34%), aged between 18 and 39 years old (average: 23.94; median: 23). The majority was Portuguese and lived originally in urban areas. A total of 75.3% were displaced and 60% lived with colleagues while 84.9% attended an undergraduate degree, and 38% studied at faculty of Science and Technology. Clinically, 79.2% were referenced by the University Medical Services, and adjustment disorders (ICD-10 F43.2) were the most frequent diagnosis. Relatively to suicidal behaviors and self-harm, 5.7% did self-cutting, 49.1% took an antidepressant combined with another psychotropic drugs, and 81.1% maintained cognitive-behavioral interventions.

Conclusions The typical university students' psychiatry outpatient was of female gender, in an undergraduate degree, displaced and living without their family. The most frequent diagnosis was adjustment disorder, and about a quarter were successfully discharged. Multidisciplinary University Medical Services located near to students can easily refer patients to Psychiatry Liaison Units, allowing diagnosis and intervention at early stages of mental disease.

In research, based on the systematic approach of evaluating results of complex clinical-psychopathological, psychodiagnostic investigation myocardial infarction and cerebral stroke patients the clinical structure features, regularities in the formation, development and course of somatogenic depression and associated disorders on these patients was determined. At patients with cardiac infarction in acute period the pain syndrome is the main one, leads to severe psycho-emotional disorders. Against the background of cognitive function preservation phobic, anxiety and depressive symptoms prevail, their intensity depends on the severity of pain. Subsequently, the primary psycho-emotional constituent element disappeared and anxiety-depressive disorders developed along with hypo and anozognostical type of personal condition perception. At cerebral stroke, patient's disorders of level of consciousness were primary with cognitive and asthenic disturbances with subsequent formation of psycho-emotional disorders, anxiety and depressive disorders with hypochondrical elements on the basis of persistent cognitive impairments.

Multiphasic personality inventory on pneumo- or hemo-thorax: Retrospective cross-sectional analysis of military candidate in Korea

B. Nam^{1,*}, M.C. Ahn¹, T. Kim²

¹ Konkuk university, psychiatry, Chungju, Republic of Korea

² Gongju National Hospital, Psychiatry, Gongju, Republic of Korea

* Corresponding author.

Objectives The aim of this study was to identify association between pneumo- or hemo-thorax and psychological distress using the Military Personality Inventory (MPI).

Methods A retrospective cross-sectional study was conducted with 19-yr-old examinees who were admitted to the Military Manpower Administration in Korea from February 2009 to January 2010. A total number of 1955 young men were enrolled in this study. The normal volunteer group ($n=1561$) comprise individuals who did not have pneumo- or hemo-thorax. The pneumo- or hemo-thorax group ($n=394$) included individuals with pneumo- or hemo-thorax. This group was divided into two subgroups, group A (treated with conservative care or chest tube insertion, $n=341$) and group B (treated with wedge resection, $n=53$).

Results We compared each of three groups (Control group, Group A, Group B) using the analysis of covariant (ANCOVA). The somatization subscale score of the neurosis category was significantly higher for group A ($P<0.001$) and showed higher tendency for Group B than the control group ($P=0.073$). The other categories (validity scale; anxiety, depression, and personality disorder subscales for neurosis scale; and psychopath scale) showed no significant difference in the MPI among Group A, Group B and Control group.

Conclusion Conservative care or chest tube insertion group had higher somatization symptoms than control group. Wedge resection group had higher somatization tendency than control group. Individuals with pneumo- or hemo-thorax history may be concerned about their body shape or their general condition. Therefore, supportive intervention and psychiatric education may be needed for them to relieve somatic distress.

³ University of Leeds, School of Psychology, Leeds, United Kingdom

⁴ HELP University, Department of Psychology, Kuala Lumpur, Malaysia

* Corresponding author.

Introduction Although psychological distress is highly prevalent, palliative cancer patients are mostly too lethargic to undergo many sessions of the conventional psychotherapy.

Objectives The study aims to develop a brief, quick and easy to administer psychological intervention for rapid reduction of distress in palliative care patients.

Methods In phase I, an expert panel of multidisciplinary team was formed. The theory of mindfulness-based intervention was simplified into a 5-minute mindful breathing technique that can be learnt and practiced by palliative care patients.

In phase II, the efficacy of 5-minute mindful breathing was investigated in a pilot test that comprised of nine palliative cancer patients and eleven care takers.

In Phase III, the efficacy of 5-minute mindful breathing was further examined in a non-blinded, randomized controlled trial (RCT) that included 60 cancer patients under palliative care. Apart from perceived distress, physiological measures were assessed.

Results The effect of 5-minute mindful breathing in rapidly reducing distress among palliative care patients was confirmed in both the pilot test (Tan et al., 2015) and RCT (Ng et al., 2016). The finding was further supported by the significant physiological changes associated with distress reduction such as decreased breathing rate, blood pressure, pulse rate, galvanic skin and

increased skin surface temperature (Ng et al., 2016) with the 5-minute mindful breathing.

Conclusion The 5-minute mindful breathing is a quick and easy to administer intervention that is useful for reducing acute suffering or distress in palliative care patients.

When seizures are non-epileptic

J. Nogueira^{1,*}, R. Taylor²

¹ Centro Hospitalar de Setúbal, Psiquiatria e Saúde Mental Unidade de Internamento de Doentes Agudos, Setúbal, Portugal

² Royal London Hospital, Liaison Psychiatry, London, United Kingdom

* Corresponding author.

Introduction Non-epileptic seizures (NES) are a diverse group of disorders, whose paroxysmal events can be mistaken for epilepsy, although they are caused by a mental or psychogenic process rather than a neurological cause.

Objectives/methods We present a case of a 45-year-old female patient with history of generalized seizures prior to Meningioma resection in August 2015, referred to the Liaison Psychiatry outpatient follow up clinic at the Royal London Hospital after has gone several times to emergency department complaining about flush and hot sensation that proceeded to corners of mouth turning down, teeth chattering, shaking of left arm and torso at first and then legs. During the episodes, she was awake with no consciousness loss. Her mood was low, with clinical evidence of depression and she had very high levels of health anxiety.

Discussion A diagnosis of non-epileptic attacks was made in the sequence of those episodes. A holistic and multidisciplinary approach was made, including pharmacotherapy, cognitive-behavioral therapy and domiciliary support. The clinical response was good regarding both mood, anxiety levels and NES.

Conclusions Approximately 25% of patients who have a previous diagnosis of epilepsy and are not responding to drug therapy are found to be misdiagnosed and it is common that epileptic patients have both epileptic and non-epileptic seizures. Although distinguishing epileptic and non-epileptic seizures is not easy, there are some clinical clues that the physicians should look for, like age of onset, time of the day that episodes occur and presence or absence of postictal confusion.

Prevalence of depressive symptoms among inpatients at the university hospital of Sergipe, Brazil

J. Oliveira^{*}, M. Machado, E. Cunha, K.M. Mansilla, E. Vieira Melo, E. Oliva-costa

Federal University of Sergipe, Medicine Department, Aracaju, Brazil

* Corresponding author.

Introduction Depressive Symptoms (DS) generate a public and economic health problem, with decreasing productivity, labour market withdrawal and increased demand for health services. Studies show that in hospitalized patients, DS rates are higher than in the general population, in medical practice, however, they are under diagnosed or under-treated. Consultation Liaison Psychiatry (LP) can prevent aggravation of the psychic symptoms by early identification of them and by integration of psychiatry with the other medical specialties.

Objectives To estimate the prevalence of DS and associated factors in inpatients and the frequency of consultation LP.

Methods A cross-sectional study was carried out in March 2016, with 87 patients hospitalized in the clinical and surgical wards at the University Hospital (Sergipe/BR), through two instruments: (1) Structured Questionnaire prepared by the authors, (2) Beck Depression Inventory (BDI). Data analysis through descriptive and analytical statistics with final step of logistic regression.

Results The prevalence of DS were 54%, of which 24% correspond to moderate and severe symptoms, and only 3.4% of the patients had a LP. In Logistic Regression, the only factor associated with DS was the reason for hospitalization. Clinical causes (87.2%) were 9.24 times more likely to develop DS than surgical causes.

Conclusions Results suggest a high prevalence of inpatients with some psychic symptom. Physicians did not detect these symptoms and, therefore, LP request was low. These data reinforce the importance of LP for early identification of DS that should be stimulated during medical training.

⁴ *Bakırköy Research and Training Hospital for Psychiatry, Neurology and Neurosurgery, Psychiatry, Istanbul, Turkey*

* Corresponding author.

Aim Although current standard treatment for migraine headache is medication, high levels of psychological comorbidity has led to migraine influencing by cognitive, emotional and environmental factors, as well as biological. Viewing migraine in a biopsychosocial framework introduces the possible utilisation of psychological treatment options, such as cognitive behavioural therapy (CBT). The aim of this study was to evaluate the efficacy of CBT for chronic migraine.

Methodology Thirty-five participants diagnosed as chronic migraine were recruited from Headache Clinic. According to inclusion criteria 14 participants, underwent bi-weekly lasting 30 minutes CBT sessions for 6 months, were administered Hamilton Anxiety Scale, Hamilton Depression Scale, Visual Analog Scale (VAS) and the Migraine Disability Assessment Scale (MIDAS) before and after CBT.

Findings Nine of the participants were female and 5 male. Mean age of group was 34.35 ± 8.17 . Duration of illness was 13.07 ± 7.18 and 12 of participants had the history of a psychiatric illness whose diagnoses were depression (7), anxiety disorder (4) and post-traumatic stress disorder (1). Nine of the patients had prophylactic migraine treatment. There were statistically significant difference in Hamilton Depression scores between before CBT (29.07 ± 7.74) and after CBT (14.21 ± 7.7); in Hamilton Anxiety scores before CBT (26.8 ± 11.7) and after CBT (11.7 ± 2.6); in VAS scores before CBT (8.07 ± 0.91) and after CBT (3.71 ± 1.32); in frequency of migraine attacks between before CBT (10.85 ± 3.50 day) and after CBT (4.92 ± 2.70 day) and in MIDAS before CBT (55.5 ± 20.4) and after CBT (20.12 ± 16.6) ($P < 0.05$).

Conclusion CBT might reduce the severity of symptoms in migraine patients especially with the comorbidity of psychiatric illness.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Report of clinical case: Catatonic symptoms as a result of cerebral venous sinus thrombosis

P. Ortega Orihuela^{1,*}, A.L. Pérez Morenilla², C. Hernández González²

¹ *Psychiatry Trainee, Unidad de Hospitalización de Salud Mental de Puerto Real, Chiclana, Spain*

² *Hospital Universitario Puerto Real, Psychiatry, Puerto Real, Spain*

* Corresponding author.

Clinical case We present the case of an 18-year-old woman attending the emergency room due to behavioral disorders that appeared 24 hours ago. The clinic was of restlessness, uninhibited behavior, stereotyped movements, global insomnia, semimutism and negativism. Initially she was diagnosed with catatonia, and was admitted to the Mental Health Hospitalization Unit. There were no previous psychopathological antecedents, although relatives reported that she had several stressors. During admission, she had a partial response to benzodiazepine treatment, and a loss of strength in the left upper limb was evidenced, and venous sinus thrombosis was diagnosed. With the anticoagulant treatment, the psychiatric symptomatology presented was markedly improved.

Medical examination Normal vital signs, afebrile. Absence of focal neurological signs. Stereotyped movements, oral-buccal dyskinesia. Negativism, disinhibition and oppositional behaviour. Supplementary tests with results within the normal range. Cranial MRI: Upper, transverse and sigmoid right sagittal sinus thrombosis.

Conclusions Numerous cases of thrombosis have been documented as a result of a catatonic state, mainly due to the immobilization and the risk involved. However, in this case, sudden onset of psychiatric symptoms, absence of psychiatric antecedents, and excellent response to anticoagulant therapy, leads us to conclude that catatonic symptoms could be considered as a consequence of cerebral edema caused by thrombosis. The presentation of catatonia as the sole cause of a somatic disorder is not common, but would be stimulated by certain factors, such as excessive stress and personality disorders, documented as vulnerability factors for such symptoms.

³ *"Victor Babes" University of Medicine and Pharmacy, Biostatistics and Medical Informatics, Timisoara, Romania*

* Corresponding author.

Introduction COPD (chronic obstructive pulmonary disease) is a chronic illness associated with psychological distress. Self-esteem and the associated comorbidities, like depression and anxiety, can influence its evolution.

Objectives To analyze how predominant coping styles associated with different levels of self-esteem and mental status in patients with COPD.

Aims To demonstrate that different types of coping-styles have an impact on self-esteem, depression and anxiety.

Methods To a lot consisting of 28 subjects with COPD, was applied the COPE scale to assess the style of coping, to rate anxiety and depression The Hospital Anxiety and Depression Scale (HADS) and for self-esteem the Rosenberg Self-Esteem Scale. According to their higher coping sub-scale score, they were classified to one dominant coping type as follows: patients with problem-focused coping type ($n=9$), emotion-focused coping ($n=10$), social support-focused coping ($n=6$), respectively avoiding coping type ($n=3$).

Results Patients with dominant problem-focused coping had the most elevated self-esteem compared to patients with social-focused coping (22.0 vs. 16.2; $P=0.039$), the depression score was the highest in patients with dominant avoidance-type coping and the lowest in patients with dominant problem-focused coping (11.0 vs. 5.6; $P=0.042$) respectively anxiety, was the highest in patients with dominant social-focused coping and the lowest in patients with dominant emotion-focused coping (11.6 vs. 5.0; $P=0.006$).

Conclusions In patients with COPD, problem-focused and emotion-focused copings are adaptive, while avoidance and emotion-focused copings are maladaptive on self-esteem and mental status. Such as, the coping represents a psychological dimension with an impact on the evolution of the disease, and the patients with COPD should be assessed and addressed multidisciplinary.

The role of alexithymia in non-psychotic mental disorders' development in patients with primary hypothyroidism

O. Pityk^{1,*}, M. Pityk², I. Kuzhda³

¹ Ivano-Frankivsk National Medical University, Department of Psychiatry, Narcology and Medical Psychology, Ivano-Frankivsk, Ukraine

² Ivano-Frankivsk National Medical University, Department of Neurology, Ivano-Frankivsk, Ukraine

³ Ivano-Frankivsk Regional Children Hospital, Department of Ophthalmology, Ivano-Frankivsk, Ukraine

* Corresponding author.

In the formation of non-psychotic psychiatric disorders in patients with thyroid pathologies are important neurohumoral mechanisms, and one reason is psychosomatic relationships. The modern concept of relationships includes alexithymia model. The situation of chronic physical illness is regarded by many authors as one that provokes a crisis of mental development (and in fact, identity crisis) and therefore is a traumatic situation, that is a risk factor for the development of mental disorder. The aim of the study was to investigate the alexithymia level in patients with primary hypothyroidism. We used Toronto Alexithymia scale proposed by Taylor G. 50 patients with hypofunction of the thyroid gland were investigated. In a study of 42 patients (84%) had a rate alexithymia more than 74 points, 12% of patients were classified as areas of uncertainty and only 4% of patients according to the method proved non-alexithymic. It was found that patients with an uncertain alexithymia level had difficulties in describing their inner feelings, did not give much attention to the absence of well-being in the emotional sphere, believed that painful symptoms of mental health problems are caused by only thyroid pathologies, even during sighting surveys ignored the presence of emotional stress and conflict experiences that showed a reduced capacity for understanding and expressing their own feelings, low emotional resonance. Thus, psychotherapeutic and psycho-corrective work with such patients should take into consideration alexithymia radical in the personal structure of such patients.

Cognition, disability and quality of life of patients with chronic migraine

M. Pompili^{1,*}, V. Corigliano¹, E. Denise¹, M. Migliorati¹, P. Martelletti², P. Girardi¹

¹ Sapienza University of Rome, Department of Neurosciences, Mental Health and Sensory Organs, Rome, Italy

² Sapienza University of Rome, Department of Clinical and Molecular Medicine, Rome, Italy

* Corresponding author.

Introduction Chronic migraine is commonly regarded as one of the most disabling headache conditions. Although there has been some research indicating the severe impact of this chronic headache, there is little comprehensive evidence of its impact on quality of life, disability and cognitive function.

Objectives The aims of this cross-sectional study were to investigate cognition, disability and quality of life in patients with chronic migraine compared to healthy control subjects.

Methods Participants were a convenience sample of 58 adult outpatients admitted to Headache Centre of the Sant'Andrea Hospital in Rome (Italy). Inclusion criteria were a diagnosis of chronic migraine (illness duration >5 years). Fifty-eight age-matched healthy subjects were recruited as controls. Participants were administered the Mini Mental State Examination, the Italian Perceived Disability Scale (IPDQ), the 12-item Short Form Health Survey (SF-12) to assess physical and mental health, and the neurocognitive task Visual Perspective Taking (VPT), as a measure of social cognition.

Results Patients with chronic migraine showed higher perceived disability and poorer well-being compared with healthy controls. No differences were found in global cognitive function and in the performance of the neurocognitive task.

Conclusions Addressing the burden associated with subjective state of disability and well-being in migraineurs is important because of its association with a worse prognosis and a worse response to treatment. Findings did not confirm the hypothesis that migraineurs are more impaired in social cognition. Further studies are needed to assess different cognitive dimensions in migraineurs, including various measures of social cognition, to better understand neurocognitive profile of this patients' population.

Ethical predicaments in decisional capacity evaluations

H. Raai^{1,*}, A. Mateoc²

¹ Bronx Lebanon Hospital Center, Department of Psychiatry and Behavioral Sciences, New York, USA

² Bronx Lebanon Hospital Center, Department of Psychosomatic Medicine, New York, USA

* Corresponding author.

Introduction Facing a growing number of capacity evaluation requests in the general hospital, physicians increasingly encounter ethical issues and dilemmas that drive them to seek unnecessary psychiatric consultations. This practice raises the expectation that the consultant psychiatrist would be, somehow, the ethicist on board whose role is to bring the most moral solution to their predicament.

Aims Literature review and discussion about ethical questions facing decisional capacity evaluation.

Methods Clinical and literature reviews.

Results (Case report) This poster presents the case of 92-year-old woman who lives alone with no family support who was brought to the emergency room due to a fall. Consequently, she was diagnosed with small cell lung carcinoma. Instead of the proposed short term rehab to receive radiotherapy, the patient insisted that she be discharged to her home. The psychosomatic team was consulted to evaluate the patient's capacity to make a decision regarding this form of treatment. The psychiatrist who evaluated the patient felt that she lacks capacity. However, palliative care felt strongly that patient's capacity should not be challenged, arguing that she has been living independently, doing well, and is agreeing to treatment.

Conclusion We will review the most updated guidelines on how to perform a capacity evaluation, how these guidelines are incorporated in residency curriculums, and whether residents from various specialties are being trained on evaluating decisional capacity. We will also explore optimal ways to educate primary care physicians on how to evaluate decisional capacity and when to seek psychiatrists' expertise for these evaluations.

Polydipsia and intermittent hyponatremia

S. Ramos-Perdigues*, M.J. Gordillo, C. Caballero, S. Latorre, S.V. Boned, G. Miriam, P. Torres, M. De Almuedo, M.T. Sanchez, E. Contreras, E. Gomez, E. Sanchez, M. Segura, C. Torres, G. Gemma, M. Tur, A. Fernandez, C. Merino

Psychiatry Unit, Can Misses Hospital, Psychiatry, Ibiza, Spain

* Corresponding author.

Introduction Hyponatraemia occurs in 4% of schizophrenic patients. Dilutional hyponatraemia, due to inappropriate retention of water and excretion of sodium, occurs with different psychotropic medications and could lead to hippocampal dysfunction. This complication is usually asymptomatic but can cause severe problems, as lethargy and confusion, difficult to diagnose in mentally ill patients.

Objectives To describe a case of a patient with psychotropic polytherapy, admitted three times due to hyponatremia and the pharmacological changes that improved his condition.

Aims To broadcast the intermittent hyponatraemia and polydipsia (PIP), a not rare condition, suffered by treated schizophrenic patients and discuss its physiopathology and treatment through a case report.

Methods A 56-year schizophrenic male was admitted for presenting disorganized behavior, agitation, auditory hallucinations, disorientation, ataxia, vomits and urinary retention. He was on clomipramine, haloperidol and clonazepam (recently added), quetiapine, fluphenazine and clonazepam. After water restriction his symptoms improved and he was discharged. Twenty-five days later, he was readmitted for presenting the same symptoms and after water restriction, he was discharged. Five days later, he was again admitted and transferred to the psychiatric ward.

Results Haloperidol, fluphenazine and clomipramine were replaced by clozapine. These changes lead him to normalize the hypoosmolality and reduce his water-voracity. Endocrinology team did not label this episode of SIADH due to its borderline blood and urine parameters.

Conclusions Hyponatremia is frequent in schizophrenic patients and may have severe consequences. Therefore, a prompt recognition and treatment is warranted.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clozapine induced diarrhea

S. Ramos-Perdigues*, M.J. Gordillo, C. Caballero, S. Latorre, S.V. Boned, M.T. Sanchez, P. Torres, M. Guisado, E. Contreras, M. De Almuedo, E. Esmeralda, E. Sanchez, M. Segura, A. Fernandez, C. Torres, G. Herrero, M. Tur, C. Merino

Psychiatry Unit, Can Misses Hospital, Psychiatry, Ibiza, Spain

* Corresponding author.

Introduction Clozapine (CZP) is the only antipsychotic approved for resistant schizophrenia 1. Due to its side effects, CZP is not the first therapeutic option in a psychotic episode. Its anticholinergic effects often cause constipation, however, diarrhea have also been described in literature.

Objectives We describe a patient with two episodes of severe diarrhea after clozapine initiation, which lead to CZP discontinuation.

Aims Discuss about the differential diagnosis of diarrhea in CZP patients and the needing of a further studies for clarify the more appropriate management in CZP induced diarrhea.

Methods We present a case report of a 46 years man diagnosed with schizoaffective disorder who presented two episodes of severe diarrhea with fever, which forced his transfer to internal medicine and UCI after CZP initiation.

Results At the first episode analytical, radiological and histological findings led to Crohn's disease diagnosis, which required budesonide and mesalazine treatment. In the second episode, the digestive team concluded that the episode was due to clozapine toxicity despite the controversial findings (clostridium toxin and Crohn's compatible biopsies)

Conclusions Diarrhea caused by CZP has been controversial in the literature. However due to the severity of digestive episodes and the paucity of alternative treatments further studies for a better understanding of its physiopathology are warranted.

The unnoticed interictal dysphoric disorder

S. Ramos-Perdigues^{1,*}, E. Bailés², A. Mané³, L. Pintor⁴

¹ Psychiatry Unit, Can Misses Hospital, Psychiatry, Ibiza, Spain

² Univeristy Pompeu Fabra, Psychology, Barcelona, Spain

³ Institute of Neuropsychiatry and Addictions, Psychiatry, Barcelona, Spain

⁴ Epilepsy Unit, Hospital Clinic of Barcelona, Psychiatry, Barcelona, Spain

* Corresponding author.

Introduction Psychiatric morbidity in refractory epilepsy is frequent and has a negative influence on quality of life. Treatment-refractory epileptic patients are at higher risk of developing psychiatric disturbances. The interictal dysphoric disorder (IDD) has been described as a pleomorphic pattern of symptoms claimed to be typical of patients with epilepsy. It is characterized by 3/8 symptoms: depressive mood, anergia, pain, insomnia, fear, anxiety, irritability, and euphoric mood.

Objectives To provide evidence that psychiatric morbidity is high in refractory epilepsy and to describe associations to IDD.

Aims The present study aims to show that there are typical psychiatric conditions in epilepsy that can be unnoticed.

Methods We cross-sectional analyzed the psychopathologic outcomes of patients with refractory epilepsy. The assessments methods included SCID for DSM-IV and clinical interview for epileptic specific psychiatric conditions.

Results The sample consists of 153 patients, with a mean age of 37. A total of 42.5% were males. One or more Axis I diagnoses

was seen in 38% of the patients. The most common condition was IDD (27.1%), followed by affective and anxiety disorders (22 and 15.3% respectively). Considering patients with IDD, we found differences in locus ($P=0.001$) (present in 34.3% of non-established locus, 8.6% of extra-temporal locus and 57.1% of temporal locus) but not with hemisphere, sex, type of crises, treatment. We neither found correlation with age, number of crisis or number of treatments.

Conclusions Psychiatric co-morbidities as IDD do not appear in the DSM-IV but are prevalent and could be related with temporal locus.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Anxiety disorders and Cardiovascular (CV) diseases, among the most common disorders in Western World, are often comorbid. A chronic systemic inflammatory state might be a shared underlining pathophysiological mechanism.

Aims To investigate the association between anxiety symptoms, CV risks factors and inflammatory markers in an outpatient sample.

Methods Cross-sectional study. Inclusion criteria: outpatients aged ≥ 40 years, attending colonoscopy after positive faecal occult blood test, negative medical history for cancer. Collected data: blood pressure, glycaemia, lipid profile, waist circumference, BMI, PCR (C Reactive Protein), LPS (bacterial Lipopolysaccharide). Psychometric tests: HADS, TCI, IMSA, SF36. Statistical analysis performed with STATA13.

Results Fifty four patients enrolled (27 males, 27 females). Sixteen patients (30.19%) were positive for anxiety symptoms. Thirty-three patients (61.11%) had hypertension, 14 (25.93%) hyperglycaemia and 64.81% were overweight, with frank obesity ($BMI \geq 30$) in 11 subjects (20.37%). Anxiety symptoms were associated with low hematic HDL values ($OR=0.01$; $P=0.01$) and high concentration of triglycerides ($OR=0.023$; $P=0.02$) at the multiple regression model. At the univariate logistic analysis, anxiety was associated with LPS ($OR=1.06$; $P=0.04$).

Conclusions Further evidence over the epidemiological link between common mental disorders and CV diseases was collected, with possible hints on pathophysiology and causative mechanisms related to inflammation. The importance of screening for anxiety and depression in medical populations is confirmed. Suggestions on future availability of screening tools based on inflammatory-related indicators should be the focus of future research.

⁵ Università degli Studi di Modena e Reggio Emilia, Dipartimento di Medicina Diagnostica- Clinica e di Sanità Pubblica, sezione di Psichiatria, Modena, Italy

* Corresponding author.

Introduction Inflammatory state of the large bowel is a key factor for the development of colorectal cancer (CRC). It has multifactorial aetiology, including psychological determinants. Physical activity may have a protective function against CRC via anti-inflammatory properties; on the contrary, personality traits correlate with an unhealthy and dangerous lifestyle.

Objective To measure the association between personality traits, lifestyle and colonoscopy outcome.

Methods Cross sectional study. Patients undergoing colonoscopy aged 40 or more, with a negative history for cancer or inflammatory bowel disease, were enrolled. Data collected: colonoscopy outcome, smoke, alcohol, physical activity, presence/absence of Metabolic Syndrome, personality traits assessed by the Temperament & Character Inventory (TCI).

Results In a sample of 53 subjects (females = 24, 45.3%), the mean age was 60.66 ± 9.08 . At least one adenoma was found to 23 patients (43.3%). Twenty patients were smokers (37.74%), 36 (67.92%) drank alcohol at least weekly; approximately 60% reported regular physical activity. At the multivariate regression, the outcome was associated to: TCI Self Transcendence domain (ST) ($OR=1.36$, $P=0.04$) and physical activity ($OR=0.14$, $P=0.03$).

Conclusion People with ST's characteristic personality traits and sedentary life style are more likely to have precancerous colorectal lesions. This confirms the protective role of physical activity, and suggests to further explore the role of personality in cancerogenesis.

Psychiatry intervention in cerebellar cognitive affective disorder: Case report

O.E. Rodriguez

Gold Coast Hospital, Mental health, Broadbeach, Australia

Background/objectives Cerebellar cognitive affective syndrome (CCAS) is a condition that arises from cerebellar lesions. CCAS can easily be overlooked by medical teams; therefore a bibliographic

review will facilitate the understanding of symptoms in order to effectively diagnose and provide a holistic early treatment approach.

Methods A case report of a 72-year-old woman with bilateral cerebellar lesions with high pre-morbid function presented with classic symptoms of CCAS. Multidisciplinary workup included medical, psychiatric, neuropsychological assessment (R-BANS (Form 1), Digit Span, Verbal fluency tests, the Hayling Test, the Delis-Kaplan Executive Function System) as well as other investigations (neuroimaging and blood tests) were conducted on the patient to confirm CCAS and exclude other differential diagnoses.

Results The results from the medical assessments conducted showed symptoms of cerebellar dysfunction. A psychiatry and neuropsychological review revealed aggression, irritability, disinhibition, deterioration in cognitive function and personality changes. A multidisciplinary team was formed to rehabilitate the patient however patient was non-compliant with therapy. The patient was prescribed Seroquel 50 XR and she responded well to the medication.

Conclusion This case review illustrates the challenges associated with engaging a CCAS patient in rehabilitation activities due to cognitive and mood disorders. The use of psychotropic medications can be an effective method in improving cognition and mood disorders in CCAS patients. Early psychiatry and psychological intervention can significantly improve the overall outcome of a patient diagnosed with CCAS.

Neuropsychiatric and behavioural manifestation in a rare lysosomal storage disorder (Fabry's Disease): A case study

A case study

D. Roy

The Prince Charles Hospital Metro North Health Services, Acute Care Team, Departement of Psychiatry, Chermshire, Australia

* Corresponding author.

Introduction Case presentation of a young woman Ms. SH, with neuropsychiatric presentation in a rare Lysosomal Storage Disorder (Fabry's disease).

Case report A 19-year-old female with Fabry's disease (FD) presented initially with symptoms of obsessions of dirt and contamination and compulsions of washing and also with overvalued persecutory ideas of being followed. Since the age of 14, she had suffered from various psychiatric symptoms increasing in frequency and intensity. Routine examinations including cognitive testing, electroencephalography and structural magnetic resonance imaging revealed no pathological findings. During the course of a year, her OC symptoms improved significantly with the use of Fluoxetine 40 mg mane. However, she then became more depressed and psychotic (despite continuing on Fluoxetine). Addition of Risperidone (gradually increased to 2 mg nocte) led to attenuation of her symptoms and she recovered completely over a course of another 6 months.

Discussion Mental and behavioural symptoms in Fabry Disease symptoms usually begin during late childhood or adolescence but may not become apparent until the second or third decade of life. Early symptoms include episodes of severe burning pain in the hands and feet and skin lesions. The psychiatric manifestations can be varied, e.g. the index patient, initially presented with what appeared like an Obsessive Compulsive disorder but later as a depressive illness (Muller et al., 2006) with psychotic symptoms.

Conclusions To showcase mental and behavioural symptoms associated with a rare disorder like Fabry's disorder and treatment options may be helpful.

* Corresponding author.

Background There are few studies specifically investigating the acute treatment procedures of patients with schizophrenia in the context of Consultation-liaison psychiatry (CLP).

Purpose Describe the main clinical features of the referrals of patients with schizophrenia, attended by a general hospital CLP service.

Methods Longitudinal observational and descriptive study, assessing adult inpatients with schizophrenia (DSM-IV-TR criteria) admitted to non-psychiatric units of Hospital Clínic of Barcelona (Spain), who were consecutively referred to our CLP service over a 10-year period (from January 1, 2005, through December 31, 2014).

Results During that period, 9.808 psychiatric consultations were requested. 163 of them (1.8%) concerned patients with schizophrenia. These groups of patients were aged 50.9 ± 15.3 years and 65% were male. A 25.9% of patients had history of suicide attempts and 45.6% presented current psychosocial stressors.

Characteristics of referrals Referral sources according to medical specialties are shown in [Table 1](#).

The major medical conditions for referral according to ICD-10 categories were: external causes of morbidity (21.5%), infectious diseases (13.5%) and diseases of the digestive system (10.4%).

The two most frequent reasons for referral were the assessment of psychopharmacological treatment and/or psychopathological state examination (62%) and suicidal risk/attempt assessment (8.6%).

Conclusions In our sample, only a 1.8% of all patients for whom psychiatric consultation was requested had a diagnosis of schizophrenia. The most common profile of them was: male, 50 years old, coming from general medicine department due external causes of morbidity and referred to the CLP service because of psychiatric state and/or medication review.

Table 1 Referral source (n = 163).

Specialty	Number	%	Number/year
General Medicine	42	25.9	4.2
Surgery	13	8	1.3

A case report of mansonellosis with neuropsychiatric symptoms

R. Sánchez González^{1,*}, D. Maia Asseiceiro², R. Torres Miravet³

¹ Institut de Neuropsiquiatria i Addiccions. Parc de Salut Mar, department of Psychiatry, Barcelona, Spain

² Hospital Dos de Maig - CAP La Pau, Family and community medicine, Barcelona, Spain

³ Hospital Obispo Polanco, department of Psychiatry, Teruel, Spain

* Corresponding author.

Introduction According to the WHO, tropical diseases affect 1/5 of the world population, being increasingly frequent in Europe. Most of these diseases produce mainly physical symptoms, but the appearance of accompanying neuropsychiatric symptoms are not uncommon.

Objective To present a clinical case of mansonellosis with neuropsychiatric symptoms.

Clinical case Twenty-two-year-old man from Equatorial Guinea, resident in the European Union for 3 years without psychiatric history. His medical history included recurrent malaria, syphilis treated with penicillin and he was HBsAg carrier.

He presented with a 10 month history of headache, pruritus, retrograde amnesia, episodes of anxiety and persecutory delusions. Previously he had gone to the emergency room several times. Cranial CT scan showed no abnormalities. Anxiolytic treatment with benzodiazepines was started, with partial response of the symptoms.

The blood tests revealed a WBC count of $62 \times 10^9/L$ leukocytes with 11% eosinophils, IgE 5242 IU/mL and IgG 1740 mg/dL. Given the suspicion of filarial infection, a thick blood film was done, the result being positive for *mansonella perstans*. He was administered treatment with albendazole 400 mg/12 h for 10 days and ivermectin in single dose. One month after start of treatment the patient was asymptomatic with complete resolution of the neuropsychiatric symptoms and correction of eosinophilia.

Results The patient's origin, his medical history and the typical symptoms of parasitosis should raise the suspicion of an infectious origin of the neuropsychiatric symptoms.

Conclusions The patients from tropical regions with neurological and/or psychiatric symptoms should undergo comprehensive diagnostic workup to rule out an infectious disease as a possible cause.

Describing the assistance, the basis for improvement

E.J. Pérez Sánchez*, J.M. Ginés Miranda, V. Chavarría Romero, J. Moreno, A. Palma, L. Alba Pale, J. Leon, A. Bulbena, V. Perez Institut de Neuropsiquiatria i Addiccions, Psychiatry, Barcelona, Spain
* Corresponding author.

Introduction Consultation-liaison (CL) psychiatry is a branch of psychiatry that study and treat mental health of patients with other medical or surgical conditions. The assistance between hospitals and health services is heterogeneous.

Aims and objectives For this reason, the objective of our research is to define the clinical characteristics from our CL service and check out the quality relationship with the applicant service, for improving future assistance.

Methods We made a descriptive analysis of clinical variables from the patients who received assistance during 2 months by the CL service from the hospital del Mar, Barcelona. We got the frequencies and we used the Chi² test for the comparison between variables: Diagnosis, appearance in the report and treatment in the report.

Results Total of the sample: 42 patients, 61.9% women. Mean age: 55.1 years. Psychiatric diagnosis was present before the assistance on 57.1% of the patients. The most frequent diagnosis was Adjustment Disorder (47.6%) and more than one diagnosis was made in the 14.3%. Near the half of the patients required only primary care assistance after the discharge from the hospital. In the 68.3% of the reports appeared information about CL assistance and the indicated treatment didn't appear in all the reports. Statistically significant differences weren't found in the comparisons.

Conclusions Adjustment Disorder is supposed to be the most common psychiatric diagnosis in our CL psychiatry service, as we found in the reviewed literature. The results reveal that relationships between services can be improved. More studies must be done for completing information in this issue.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

HIV-associated neurocognitive disorders (HAND) may include neurological disorders of various severities such as AIDS dementia complex (ADC) also known as HIV dementia and HIV-associated dementia (HAD), HIV encephalopathy, and Mild Neurocognitive Disorder (MND). As it seems HIV-associated neurocognitive disorders are associated with a metabolic encephalopathy induced by HIV infection and fueled by immune activation of macrophages and microglia. Despite of a group, evidences have described presence of cognitive alterations in HIV patients at different stages of HIV infection so far; little is known about the neurocognitive state of patients at very early stages of HIV infection. Here, we explored the neurocognitive profile of a group of cases of HIV patients at very early stages of HIV infection. We have analyzed of three groups of subjects, thus, we have studied a group of patients with early HIV infection, a healthy control group and a group of patients with mild cognitive impairment due to neurodegenerative causes. Our results suggested that cognitive processes are sensitive to very early neu-

ropathological changes in HIV infection. Noteworthy, our results also showed that neurocognitive profile of HIV patients differs from those cognitive alterations in patients with mild cognitive disorders associated to primary neurodegeneration. Together, our results point out that HIV infection generates neural changes even at early stages of infection. Furthermore, our results highlight the importance of a deep neurocognitive exploration at very early stages of HIV infection as this approach allow improve the accompaniment, clinical attachment and interventions.

Consistent with social-cognitive theory (Bandura 1994), adherence problems to treatments and difficulties to acceptance HIV diagnosis are linked with deficits in self-efficacy as well as problems in perceived social norms and behavioral intentions. In this study we have presented the beliefs and narratives of a group of recently diagnosed HIV patients who voluntarily decided not to tell to family or couples about their diagnosis. According to the patients' reports they believe they should not tell about their own physical condition. In a second approach, we have explored empathetic and moral behavior (by using a usual procedure used to keep track those cognitive domains) in this group of HIV patients and we compared that behavior with a group of healthy controls. Results revealed a particular and differential empathic concern, and discomfort sensitivity in HIV patients who no tell in contrast to healthy controls. Together, our results highlight the importance of exploring the reasons, fears, and the empathetic and moral determinants of those patients who not to tell about their diagnosis. Our results open a new door to explore new approaches to accompany patients with recent HIV diagnosis.

Study of vitamin D deficiency in depression patients-is it the reason for high rates of somatic presentation of depression?

D. Sanyal^{1,*}, B. Mukherjee²

¹ KPC Medical College-jadavpur, Psychiatry, Kolkata, India

² Maldah Medical College, Psychiatry, Maldah, India

* Corresponding author.

Introduction Vitamin D receptor (VDR) is widely distributed in the human brain including areas that are assumed to be involved in the pathophysiology of depression. Vitamin D deficiency may cause physical symptoms like pain.

Objectives See if somatic presentation of depression has any correlate with vitamin D deficiency.

Aims To compare prevalence of vitamin D deficiency between depressed and non-depressed subjects and see if somatic presentation of depression has any correlate with vitamin D deficiency.

Methods Sixty diagnosed MDD patients consenting to participate in the study from a large private hospital selected, provided they were non-smoker, 18–65 years, free from chronic illness and not taking anti-depressant control (60 subjects) comprised of close family members of patients. FSC (functional somatic complaints) was assessed using local language version of Bradford Somatic Inventory (BSI), while severity of depression was assessed using HDRS-17. Based on the total score, FSCs are categorized into 3 grades (>40 'high, 26–40 'middle, and 0–25 'low' range).

Results Vitamin D status (deficiency: insufficiency: sufficiency) was 70: 30.0: 0.0% in depressed, which significantly worse compared to control subjects (55%: 25: 20%). Patients with higher BSI scores (i.e. more somatisation) showed non-significantly lower vitamin D level. These results were more prominent for female subjects.

Conclusions Vitamin D deficiency is more common in depression subjects, which might thus need to be looked for and treated. However, no significant link between somatisation and vitamin D deficiency could be established.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction In the context of the importance of psychotherapy in mental health care the aim of our study is to highlight the importance of supervision as an integral part thereof.

Aim We analyze the relationship between the assessment of the quality of supervision and the perceived self-efficacy of the psychotherapist as one of the antecedents of decision-making in the psychotherapeutic process. This framework is applied to an empirical study that focuses on psychotherapist's perception of clinical supervision in relationship to professional self-efficacy in the therapeutic process.

Methods The study was operationalized using the Manchester clinical supervision scale (MCSS), containing a demographic questionnaire, counselor self-efficacy scale–modified version. One hundred and twenty-five psychotherapists with supervisory experience participated in the research, including 67 trainees and 58 graduates of psychotherapy training.

Results The results show a positive relationship between effective supervision and self-efficacy ($r=0.363$; $\text{sig}=0.000$; $n=125$). The participants who attributed higher ratings to supervision and supervision work alliance also assigned higher scores to perceived self-efficacy—although there is a significant relationship among the participants of psychotherapeutic training ($r=0.444$; $\text{sig}=0.000$; $n=67$), this relation is not significant among the actual graduates. Based on modeling, rapport was discovered to be the most important predictor of supervision effectiveness assessment.

Conclusions The results support the merits of supervision in the education of psychotherapists and the importance of investing resources in its regular implementation.

Keywords Self-efficacy; Supervision; Psychotherapists in trainee; Graduate

Background Morgellon disease is a delusional disorder that leads to the belief that one has parasites or foreign material moving in, or coming out of, the skin. The name was coined in 2002 by Mary Leita; a mother who rejected the medical diagnosis of her son's delusional parasitosis. She revived it from a letter written by a physician in the mid-1600s.

Objective In this case report, we aim to describe the clinical characteristics and manifestation of morgellon disease in 26 years man.

Results and discussion Bulgarian athlete of 26 years stopped to be actively involved with the sport after a severe contusion to the right knee during the race. Had a joint surgery in the Netherlands and of course when that will not be able to compete more professional sports began to use cannabinoids daily. After three months patient went to dermatologist because of skin rashes and intense itching, crawling sensation on and under the skin. The patient reported that pull out threads from his skin. Dermatologist Initiated treatment with antibiotic creams and corticosteroids. The symptoms persist and the patient has consulted a psychiatrist regarding appeared complaints of fatigue, poor concentration and increased anxiety. Psychiatrist based on clinical and medical history was diagnosed morgellon disease. We started treatment with risperidone in increasing doses up to 2 mg/day. After a month the patient has a significant reduction of symptoms.

Conclusion Morgellon disease is a little-known disorder that is often associated with non-specific skin, nerve, and psychiatric symptoms.

* Corresponding author.

Introduction Diabetes mellitus (DM) is associated with chronic complications and comorbidities. Psychopathology and personality changes (PCh) are also found in DM. Some authors suggest organic PCh. The aim of our study was to access DM associated PCh and their relations with DM complications, glycemic control (GC) and family history for DM (FH).

Material and methods We examined 47 patients with DM type 2 (64.65 ± 9.78 years old; 14 males, 33 females; 24 with and 23 without FH, 20 with good, 15 with poor and 12 with very poor GC). All of them underwent somatic and neurological examinations. Blood count and biochemistry, urine analysis, brain computer tomography, electroneurography, electrocardiography and neuropsychological battery were applied. PCh were assessed by Minnesota Multiphasic Personality Inventory.

Results The most frequent PCh were hypochondriasis (Hs, 77%), hysteria (Xy, 74%) and schizoidia (Se; 77%); hypomania was low in 60%; 30% showed low psychasthenia and 49% low psychopatia. High paranoia had 23% and low–15%. Poor GC was associated with cognitive impairment (CI) and high Hs, Xy and Se. Patients with high Hs, Xy and Se showed more frequent diabetic complications (retinopathy, polyneuropathy and nephropathy), comorbidities and CI than those without, even after correction for age, therapy and DM duration. FH was risk factor for PCh.

Conclusions Patients with DM show specific PCh. High scoring on Hs, Xy and Se scales are associated with poor GC, chronic DM complications, co-morbidities and CI. FH is risk factor for PCh.

Emotional expectations reported by hospitalized women in southeastern Brazil before being submitted to mastectomy with immediate breast reconstruction: A clinical-qualitative study

G.L. Almeida¹, R.M.C. Sena¹, V.L.P. Alves¹, C. Cardoso-Filho²,
E.R. Turato^{1,*}

¹ UNICAMP–State University of Campinas, LPCQ–Laboratory of Clinical-Qualitative Research, Campinas, Brazil

² UNICAMP–State University of Campinas, Department of Tocogynecology, Campinas, Brazil

* Corresponding author.

Introduction Breast cancer is a type that more affects female population in the world. Surgical indication, present in most cases, is a mutilating procedure and mentally traumatic for majority of women subjected. Thus, immediate breast reconstruction, which is the choice to rebuild the breast during the mastectomy surgery, is an alternative to reduce discomforts associated with loss of the breast, in addition to being associated potentially with improved emotional and psychosocial quality of life.

Objective To discuss, from psychological viewpoint, the emotional expectations about surgical results of a planned mastectomy with immediate breast reconstruction, reported by women with breast cancer treated in a university hospital in Campinas, state of São Paulo.

Method Qualitative design, particularized in the clinical-qualitative method, adequate to health assistant settings, using the semi-directed interview with open-ended questions in-depth, fully transcribed and after submitted to content clinical-qualitative analysis. Intentional sample closed by criterion of information theoretical saturation with 12 sequential participants.

Results Amongst the emergent categories from free-floating readings, we have chosen the following to presentation:

- The desire of healing above expectations of the aesthetic aspects;
- The perception of the surgical approach predominantly with aesthetic effects;

- The desire of a contra-lateral healthy breast withdrawal, too.

Conclusions Face the proposal of mastectomy with immediate reconstruction, days before the surgery, women reported to be well emotionally organized for the procedure, although in different ways. This occurs probably due to emotional meanings built by many experiences from their psychological histories, as well as from values provided by the socio-cultural environments.

Which are the possibilities of psychiatric liaison-consultation in dentistry? By the way a qualitative study on symbolic meanings reported by dentists on handling of dental-carries

P.A.T. Leme¹, R.A. Bastos¹, S.A.S. Vedovello², E.R. Turato^{1,*}, M.C. Meneghim¹

¹ UNICAMP–State University of Campinas, LPCQ–Laboratory of Clinical-Qualitative Research, Campinas, Brazil

² UNIARARAS, Orthodontic Department, Araras, Brazil

* Corresponding author.

Dental caries is the main oral disease and there is a possible psychological resistance from dentists to change clinical practice towards in sense of health promotion as opposite to invasive mechanical practice. We hypothesized that the discussion of their practice with mental health professionals, highlighting the humanist view in approaching patients, would imply reviewing usually invasive practices.

Objective To understand the psychological meanings attributed by dentists to the treatment of dental caries considering the frequent invasive treatment.

Method Clinical-qualitative method derived from qualitative designs proper to human sciences and applied in assistance settings. Sample composed of all available dentists (ten participants) within an area of basic health units of Piracicaba, São Paulo state. Semi-directed interview with open-ended questions, in-depth, was used. After full transcription of the interviews, qualitative content analysis was carried out, including floating readings to emerge core of meanings with consequent categorization for discussion.

Results Two categories show conflicts in the interpersonal relationship: psychological discomfort due to a perspective of care different from patient and presence of an ideologically vertical relationship. One category showed a successful approach: the patient through openness.

Conclusions There were feelings of impotence in face of difficulties in interpersonal communication. It was possible to observe the influence of bio-power that weakens the possibility of empowering patients. In this way, a mechanical way of practice “saves” professionals from thinking about these human dilemmas. On the other hand, the liaison-consultation psychiatry, at primary care, allows dental professionals to have a personal affective support to rethink approaches on use of technology.

* Corresponding author.

Introduction Sjogren's syndrome (SS) is a common autoimmune disorder that is characterized by chronic inflammation of lachrymal and salivary glands. The well-known clinical manifestations of SS are dry eyes and dry mouth. However, the disease may first present itself with psychiatric symptoms, such as depressed mood, agitation or irritability.

Objectives Our objective is to highlight the importance of systemic examination, including detailed biochemical workup in psychiatric patients with somatic complaints like fatigue and those patients with partial response to treatment.

Methods We present a 35-years-old woman who had depressed mood, obsessions and compulsions, chronic fatigue, generalized muscle and joint pain, balance problems, weight loss, dry mouth and dry eyes for the past few years. Her symptoms would worsen during spring. She was diagnosed with seasonal affective depressive disorder and chronic fatigue and was started on mirtazapine 30 mg/day and venlafaxine 75 mg/day. She was partially responsive to this treatment. The detailed biochemical workup came 1/320 positive for anti-nuclear antibodies (ANA). The oral biopsy showed Sjogren's disease. Gluten sensitivity was found as well.

Results The patient was started on hydroxychloroquine sulfate 400 mg/day in addition to her anti-depressant medication. She was put on a gluten-free diet. She was in full remission in a month and had no depressive attack in spring. Her ANA decreased to 1/80.

Conclusion Psychiatric syndromes may arise from different pathologies of the central nervous system. In patients with recurrent psychiatric syndromes or patients who are partially responsive to conventional treatment approaches further systemic evaluation of the patient is needed.

The psychological signs of the patients who receive treatment in the general clinic

L. Utas Akahn

Bulent Ecevit University, Health College Head of Psychiatry Nursing Department, Zonguldak, Turkey

* Corresponding author.

Background For most of the physical illnesses, behavioral, emotional, cognitive and inter-personal reactions develop. These psychiatric conditions and reactions are actually the adjustment process of the organism.

Objectives Study is conducted in order to identify the psychiatric signs as well as findings of the patients who receive treatment in the general services of hospitals.

Methods The study was carried out with a total of 500 patients who receive treatment in the general service of a hospital of a ministry of health in Turkey between February and May in 2015 by descriptive cross-sectional method. For collecting the data; patient charts, SCL90-Rand general health questionnaire as well as hospital anxiety and depression scale were utilized. Kolmogorov Smirnov Normality test was applied for the average SCL90R and general health. Questionnaire, as a result of the test, it was detected that both scales did not meet the assumption of normality Therefore, Kruskal Wallis test of non-parametric was used.

Results The study showed no significant difference among the lengths of stay in the hospital according to the average SCL90-R and general health questionnaire It was observed that the patients in the cardiology, neurology, and plastic surgery departments had a higher rate of signs of obsessive compulsive disorders; that the patients in the plastic surgery and internal diseases departments had a higher rate of depressive signs; that the patients in the neurology and plastic surgery departments had a higher rate of paranoid ideation; and that the patients in the neurology service had a higher rate of psychoticism.

Conclusions Overall, it has been observed that the patients hospitalized in the neurology and plastic surgery services had more physiological signs compared to those receiving treatment in the other services.

Evaluating quality of sleep in patients with diagnosis of chronic obstructive pulmonary disease

L. Utas Akhan

Bulent Ecevit University, Psychiatry Nursing Department, Zonguldak, Turkey

Background Multicenter study showed that sleep disorders was diagnosed in approximately 40% of patients with chronic obstructive pulmonary disease. COPD is a condition that is most widely investigated regarding its relation with sleep.

Objectives Our study is a complementarily one that is carried out to determine how COPD affects the quality of sleep.

Methods This study enrolled 300 patients with COPD, who receive treatment in an occupational diseases hospital of ministry of health, Turkey, and control group of 100 healthy volunteers. This definitive, cross-section study was conducted between 01.02.2016–31.04.2016. Socio-demographic details form, epworth sleepiness scale and Pittsburgh sleep quality index are used to gather the study data. Any disease that affects sleep structure (Obstructive sleep apnea syndrome, substance abuse, irritable leg syndrome, depression, anxiety disorder, peptic ulcer) and a treatment that can affect sleep patterns (antidepressant, anxiolytic, diuretic) and to work all patients who were planned to receive Hamilton depression and were assessed with anxiety scale and anxiety, depression those who have high points to think of the reins are not included in the study.

Results Score obtained from Pittsburgh sleep quality index–A subjective test - was significantly high in the COPD group. Actigraphic sleep parameters that include ‘actual wake time’, ‘actual wake %’, ‘total activation score’ and ‘fragmentation index’ were significantly high in the COPD group comparing to control group. Among actigraphic sleep parameters, ‘actual sleep time’, ‘actual sleep’ and ‘sleep efficiency’ were significantly lower in the COPD group comparing to control group.

Conclusions The study demonstrates that chronic obstructive pulmonary disease poses negative influence on the quality of sleep and leads to sleep disorders.

Prevalence frequency of disabilities and psychological symptoms in patients diagnosed chronic obstructive pulmonary disease

L. Utas Akhan

Bulent Ecevit University, Psychiatry Department, Zonguldak, Turkey

Background Chronic obstructive pulmonary disease (COPD) is a major cause of morbidity and mortality chronic obstructive pulmonary disease can cause intense psychological distress due to the caused problems that individuals experience in their lives. COPD is among a number of medical disorders associated with a high rate of depression and other psychological problems.

Objectives In this study, it is aimed to evaluate the prevalence of psychological symptoms and disability in patients with chronic obstructive pulmonary disease.

Methods The study includes 100 volunteers as a control group and 200 patients diagnosed with COPD who are being treated

in a hospital for occupational diseases of the Turkish ministry of health. It is performed as definitive-cross-sectional between 12.03.2016–30.04.2016. In gathering the data; socio-demographic Information form, brief disability questionnaire and Beck depression scale and SCL 90 R scale are applied. The mean age of the COPD group is 49.2 ± 3.4 (25–78) and the control group is 45.1 ± 2.4 (27–60).

Results In our study, depression was detected in 56% of cases with chronic obstructive pulmonary disease. Mean brief disability questionnaire score was found 7.28. Mild disability was found in 21%, moderate disability in 38% and severe disability in 29%. Moreover, It was also found that obsessive-compulsive and depressive symptoms were higher in COPD cases in comparison with the healthy group.

Disclosure of interest The author has not supplied his declaration of competing interest.

EV0324

Exploring sources and types of information about Huntington disease received by affected families

M. Vamos^{1,*}, J. Conaghan², T. Lewin³

¹ John Hunter Hospital, Liaison Psychiatry, Newcastle, Australia

² John Hunter Hospital, Social work, Newcastle, Australia

³ University of Newcastle, Faculty of Health, Newcastle, Australia

* Corresponding author.

Introduction While revealing the presence of Huntington Disease (HD) within the family setting has received considerable research interest, the sources of information and the detail of which aspects of the illness are discussed remains unexplored. This study's primary aim was to identify HD information sources, both professional and family, and to describe the types of information received by members of affected families, with the hypothesis that some aspects of the disorder would be more fully addressed than others.

Method Clients drawn from a specialist genetic unit looking after families with HD ($n=46$) were engaged in structured interviews and completed standardized questionnaires, including: the psychological adjustment to genetic information scale (PAGIS); and a current psychological distress measure (K10). Participants obtained HD related information from a mean of 4.76 sources (49.3% professional).

Results As expected, genetic and neurological symptoms were more frequently described (97.7% and 86.4% respectively) than cognitive and psychological/psychiatric (63.6%; 52.3%). Regression analyses were used to identify potential predictors of current distress, adjustment, and information satisfaction. Rated satisfaction with information received was higher among participants with a gene positive family member. Across the PAGIS subscales, there were differential associations with the predictors examined.

Conclusions Given that HD is a multi-faceted condition affecting the entire family, needs would be better addressed if information provided went beyond discussion of genetic and movement disorders, and extended to the cognitive, psychological and behavioral aspects which are strongly associated with quality of life.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Depression and cognitive disorders in Behçet's disease and rheumatoid arthritis patients

D. Veltishchev^{1,*}, T. Lisitsyna², O. Kovalevskaya¹, O. Seravina¹, D. Ishchenko¹

¹ Moscow Research Institute of Psychiatry, Stress Related Disorders, Moscow, Russia

² Nasonova Research Institute of Rheumatology, Systemic Rheumatic Disorders, Moscow, Russia

* Corresponding author.

Background Mental disorders (MD), especially depressive, have high rates in rheumatic disorders (RD)–Behçet's Disease (BD) and Rheumatoid Arthritis (RA). Depressive and cognitive disorders have close pathogenesis interrelations with RD.

Objective To compare the variants of MD in BD and RA-patients. **Methods** Two hundred and twenty-five (100 BD and 125 RA) inpatients were enrolled in the study. In BD patients prevailed men (70%) in RA–women (77%). MD were diagnosed in accordance with the ICD-10 in semi-structured interview. For evaluation of severity and the variants of cognitive disorders psychology and neuropsychological methods were used.

Results MD were diagnosed in the majority of patients (86%), significantly more often ($P < 0.001$) in RA (94%) versus (vs) BD (79%) patients. The depressive disorders dominated (BD–100%, RA–93%). The chronic and recurrent depressive disorders prevailed in both groups : in RA more often than in BD patients (58.4% vs 39.2%, $P = 0.003$). Cognitive disorders of different severity were diagnosed in most patients with BD and RA (73% vs 66.4%, n/s). The mechanical memory (63%) and attention deficit (72%) in BD and impairment of associative memory (90%) and logical thinking (71%) in RA were the most frequent manifestations of cognitive disorders.

Conclusion The results have shown high rates of MD, especially chronic depression and cognitive disorders in BD and RA patients. The necessity of interdisciplinary strategy implementation for the improvement of individualized treatment approaches in RD has been confirmed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Somatic symptoms, drinking, and mental distress among Russian female patients with rheumatoid arthritis: A pilot study

K. Yoshimasu^{1,*}, S. Takemura¹, E. Myasoedova², S. Myasoedova³

¹ Wakayama Medical University, Hygiene, Wakayama, Japan

² Mayo Clinic, Health Science Research, Rochester, USA

³ Ivanovo State Medical Academy, Internal Medicine and Endocrinology, Ivanovo, Russia

* Corresponding author.

Introduction Drinking has been shown to be a protective factor against the risk of rheumatoid arthritis (RA). On the other hand, high prevalence of depressive symptoms has been observed among RA patients.

Objective To evaluate the association between depressive symptoms and somatic factors as well as drinking habits in RA patients.

Methods Drinking habits and physical symptoms in 182 female RA outpatients in Ivanovo, Russia (average [standard deviation] of age, 62.0 [11.7] years), were investigated. Drinking status was classified as current drinkers (alcohol consumption within the previous 12 months) and others. Depressive symptoms were evaluated with MINI, HADS and CES-D questionnaires. Outcomes were (a) presence or history of major depressive disorder, presence of

melancholic major depressive disorder, presence of dysthymia, or 1 point or greater of suicidal risk score in MINI, (b) 8 points or greater in HADS-depression, (c) 8 points or greater in HADS-anxiety, and (d) 16 points or greater in CES-D. Stepwise logistic regression was used to evaluate somatic factors associated with depressive symptoms, with age and drinking status included.

Results Drinking was rather protective against depression, but did not reach statistical significance. Symptomatic parts in the extremities associated with the outcomes were shoulders for MINI, elbows and knees for HADS-depression, shoulders for HADS-anxiety, and hands, elbows and shoulders for CES-D. In the stepwise selection, some symptoms in the extremities were positively associated with the outcomes.

Conclusion Symptoms chiefly in large joints contributed to depressive symptoms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0327

Long-term validation of the SAD PERSONS scale for prediction of repeat self-harm in A&E patients with and without a prior self-harm history

Y. Zakaria*, A. Mitchell

University of Leicester, Psychiatry, Leicester, United Kingdom

* Corresponding author.

Objective Repeated self-harm is difficult to predict particularly in the long-term. Scales that help identify risk of repetition are widely used, and the most popular is the modified SAD PERSONS scale (mSPS). We aimed to clarify the accuracy of the mSPS in first time and non-first time patients presenting with self-harm with an extended follow-up period of observation.

Method We conducted the UK's first long-term prospective risk prediction study of patients to an Accident and Emergency (A&E) department. We followed up 774 patients for a mean period of 7.4 years. At the time of study 429 patients presented with their first episode of self-harm and 345 had a hospital record of past history of self-harm.

Results During 7.4 years of follow-up 54.7% of those who initially presented with self-harm represented with a repeat self-harm episode. Four hundred and twenty-one patients had a mSPS score less than 6 (low risk), 260 had a score between 6 and 8 (moderate risk) and 94 scored 9 or higher usually notated as high risk. The clinical utility of the mSPS was "poor" for predicting future self-harm but at cut-offs ≥ 7 it was "fair" for predicting non-repetition. Of the individual questions in the mSPS, a positive answer to "stated future wishes" was a true positive in 74.0%.

Conclusions We found the mSPS was a relatively poor indicator of future self-harm risk in a long term follow-up of patients who self-harmed regardless of hospital record of previous self-harm history. However, mSPS did have modest value in predicting non-repetition.

Quality of life between two groups of psychiatric patients in Baghdad, Iraq

H. Abdullah

Ibn Rushd Hospital, Child Psychiatry, Baghdad, Iraq

Objectives To assess and compare the subjective rating of quality of life (QOL) in psychiatric patients who attended two psychiatric outpatient clinics in Baghdad city [Al-Rashad psychiatric teaching hospital and Baghdad teaching hospital]. In addition, it also aims at studying the effect of socio-demographic and clinical characteristics on the patients' life qualities.

Method A sample of one hundred patients divided equally into two groups (fifty patient) from each hospital were interviewed and diagnosed in accordance with the DSM-IV diagnostic criteria, for the period (from the 1st of March to the 1st of September 2011). The Arabic modified version of WHOQOL-BREF questionnaire (modified by WHO) was applied on each patient.

Results Data gathered from completed hundred forms showed that 50% of patients from Baghdad teaching hospital responded and scored (fair, acceptable) to describe their satisfaction in overall QOL, while (38%) of patients from Al-Rashad teaching mental hospital scored (bad) and (16%) scored (very bad). There was no significant difference in the four domains of QOL between the two studied groups. The findings were discussed accordingly.

Conclusions This study showed that although the overall satisfaction of the patients' life quality was higher in patients from Baghdad teaching hospital than those of Al-Rashad teaching mental hospital, a non-significant difference in the four domains between the two hospitals was found. The socio-demographic and clinical characteristics were not significantly correlated to the QOL domains except for the educational level, which was significantly correlated, with the physical health domain in patients from Al-Rashad teaching mental hospital.

Public perception of mental illness in Oman: A cross-sectional study

M. Al Alawi^{1,*}, H. Al Sinawi¹, S. AL-Adawi¹, L. Jeyaseelan², S. Murthi³

¹ Sultan Qaboos University Hospital, Behavioral Medicine, Muscat, Oman

² Sultan Qaboos University Hospital, Department of Statistics and Health Information, Muscat, Oman

³ Oman Medical Specialty Board, Department of Studies and Research, Muscat, Oman

* Corresponding author.

Introduction Stigma toward mental illness is an international phenomena and it has negative consequences on the patients and their families. Studies on public attitudes toward people with mental illness (PWMI) in the Arab world initially reported less prevalence of stigma compared to other societies; however, follow up studies showed that stigma was influenced by specific socio-cultural factors.

Aims This study aims to examine public attitudes toward people with mental illness in Oman and the impact of socio-demographic factors.

Methods This is a cross-sectional survey conducted among the general public in Oman. The attitude was measured via the Attitude toward Mental Illness (AMI) questionnaire. Various demographic

factors were examined including age, place of residence, occupation and previous encounter with PWMI. The data were collected using online research methods.

Results A total of 601 subjects participated in this study, (M: 41.4%, F: 58.6%). 48% of the participants were aged 15–30 years while 46% were aged 31–45 years. The majority of the participants were employed and 10% were students. After adjusting for all other variables, subjects aged (15–30years) had less positive attitude compared to those aged (46–60 years) ($P=0.06$). Socio-demographic factors such as gender, occupation and previous contact were correlated with the endorsement of positive attitudes toward PWMI.

Conclusion This study illustrated that public attitudes toward PWMI in Oman is generally sub-optimal. The observed attitudes were strongly influenced by age, gender, occupation and previous exposure to PWMI. Future studies with robust methodology are recommended to scrutinize the present findings.

The impact of shame and cultural beliefs on mental illness and treatment adherence: A case report

A. Albassam*, A. Ameen, V. Chiappetta, A. Hanif, L. Gonzalez

Bronx Lebanon Hospital Center, Psychiatry, Bronx, USA

* Corresponding author.

Introduction Shame, especially when enmeshed in cultural beliefs about mental illness and cultural roles, could be a detrimental factor in psychiatric illness in context of adherence to treatment and continuation of care. Shame is defined as a painful experience which embodies multiple components including: collapse of self esteem, feeling of humiliation, rupture of self continuity, sense of isolation, and feeling of being watched by critical others.

Objective Understanding the psychodynamics of shame, in a particular cultural milieu and its components which could impact psychiatric treatment and care.

Method Here we present a case report of a 41-years-old Arab male patient from Yemen, with a history of paranoid schizophrenia who was admitted to inpatient psychiatric service for bizarre and aggressive behavior.

Results Initially the depth of patient's delusions and psychotic symptoms were not fully appreciated due to the cultural gap between the patient and the treatment team. He was then re-evaluated through the implementation of the cultural formulation interview (CFI) by clinicians from same cultural background. This team was able to elucidate the deep feelings of shame and inadequacy in patient's presentation and provide a culturally tailored treatment plan.

Conclusions Evaluation of psychiatric patients in a different cultural setting where western values do not apply might not be sufficient to assess the breadth of psychotic symptoms especially when an underlying feeling of shame contribute to presenting symptoms. Treatment of those patients with neuroleptics without assessing the cultural dynamics might result in poor adherence to medication and follow up.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Does consanguinity increase the risk of mental illnesses? A population based study

A. Bener

Istanbul University, Biostatistics and Public Health, Istanbul, Turkey

The aim of this study was to assess the impact of consanguinity on risk for mental disorders especially in primary health care- PHC settings. It was decided to ascertain prevalence of common mental disorders and consanguinity. We set out to study the burden of commonest psychiatric disorders among consanguineous marriages at PHC using the WHO Composite International Diagnostic Interview (WHO-CIDI) and examine their symptom patterns and co-morbidity in Qatar. A prospective cross sectional study was carried out over a year between November 2011 to October 2012. A total of 2,000 Qatari subjects aged 18 to 65 years were approached; 1,475 (73.3%) gave consent and participated in this study. Prevalence of psychiatric disorders using the WHO Composite International Diagnostic Interview (CIDI, version 3.0) showed that six most common disorders were major depression disorders (18.3%), any impulse control condition (18.3%), any anxiety disorders (17.2%), any mood disorders (16.9%), followed by separation anxiety disorders (15.2%), personality disorder (14.1%). The mean age \pm SD of the 1,475 subjects interviewed was 39.3 ± 9.8 years. The rate of consanguinity in the present generation was 31.5% [95% CI = 29.1–33.7]. There were statistically significant differences between consanguineous and non-consanguineous with regards to age, educational status, occupation status, household income as well as BMI, cigarette smoking and sheesha smoking. One-fifth of all adults who attended the PHC center 20% had at least one psychiatric diagnosis. The prevalence of the generalized anxiety disorders; social phobia, specific phobia, major depression, and personality disorders were significantly higher in consanguineous marriages than in non-consanguineous.

Risk factors in emotional and personal development of senior preschool children from different social strata (middle-high and middle-low social layers)

N. Burlakova*, P. Davidovich

Lomonosov Moscow State University, Faculty of Psychology- Department of Neuro- and Pathopsychology, Moscow, Russia

* Corresponding author.

Introduction Methodological basis of Vygotsky's scientific school implemented in the study provides possibility to detect risk variants in emotional and personal development of children from different social strata and to explore the mechanisms responsible for pathological development.

Objectives and methods The study included two groups: (1) children from a middle-high social stratum ($n = 31$); (2) children from a middle-low social stratum ($n = 36$). All the children were between ages 5.5–7 years at the moment of research, lived in Moscow and attended extracurricular activities. Following methods were used: objective description of child's development in socio-cultural context; semi-structured interview; long-term overt and covert observations; diagnostics of intellectual, emotional and personal school readiness.

Results Children from the 1st group demonstrate higher level of intelligence; they are more successful in solving unusual tasks. Children from the 2nd group tend to follow instructions given by

teacher. Children from the 1st group unlike those from the 2nd one are characterized by lower level of social competence; they encounter difficulties in establishing contacts and don't perceive hierarchy in adult-child relationship. Mass protection typical for children from the 1st group and hyper-satisfaction of their needs determine decrease of frustration and don't deepen their personal experience providing basis for pathological development. Children from the 2nd group are more inclined to demonstrate alarm reactions, but in general they possess higher level of emotional and personal maturity and social flexibility.

Conclusion Socio-cultural environment has a direct say in potential risk zones of child development.

Parental expectations in families from different social and cultural groups and their influence on emotional and personal development of a child

N. Burlakova*, P. Davidovich

Lomonosov Moscow State University, Faculty of Psychology- Department of Neuro- and Pathopsychology, Moscow, Russia

* Corresponding author.

Introduction The study explores subjective image attributed by parents to their child that was formed under the influence of different socio-cultural conditions and affects communication with a child. Methodological basis of Vygotsky's scientific school was used in the research.

Objectives and methods The study included two groups of families from different social strata: group 1 – middle-high stratum, group 2 – middle-low stratum ($n_1 = 31$, $n_2 = 36$), all the families live in Moscow; the children (5.5–7 years old) attend extracurricular activities. Following methods were used: analysis of social context of child's development; long-term overt and covert observations; analysis of complaints, ambitions and expectations – “a project of future development” of a child imagined by parents followed by reconstruction of their relations that appear to be the basis for the “project”; method of semi-structured interview.

Results First group demonstrates high level of irrelevance in subjective extra-positive image of a child. That poses risk for child's emotional and personal development. Families from different strata tend to demonstrate irrelevance between ambitions and real success of a child. First group tend to overstate, 2nd group – to understate. In some cases parents' mindsets cause emotional peculiarities of the child: individuality and as a result inflated ego, demonstrative behavior accompanied by interest to external attributes. In 2nd group children are mostly anxious and encounter difficulties in demonstration their abilities, but they possess higher level of emotional and personal maturity and social flexibility.

Conclusion Socio-cultural features of the stratum influence parental expectations that form potential risk zones in child development.

Death in the work of Jorge Amado: The function of art in education for death

S. Färber^{1,*}, M. Färber²¹ VIVER Psicologia e Tanatologia, Tanatologia, Cascavel, Brazil² VIVER Psicologia e Tanatologia, Psicologia, Cascavel, Brazil

* Corresponding author.

Introduction Review the work of Jorge Amado in the thanatological hermeneutics makes it come to be apparent the role of art in shaping the popular imagination and its educational purpose, which art cannot do without.

Objective The purpose of this research is to present that, Jorge Amado using various methods causes a semiotic and polysemic reading of life and a hermeneutics review of death, making his literary art an instrument of education for death.

Methods Using the transversal method of bibliography review of the author's work.

Results We noted that in the anthropology of Jorge Amado, death might be the exercise of power, as those legitimated by a theology casuistry, in "Violent Land". However, death can be an element of transformation of the state of life and overcoming the limits of the roles that society has agreed to be played by its subject, paradigm of this counterculture is Livia, widow of Guma in "Sea of Death". In "The Double Death of Quincas Water-Bray" dead and death inset in starring roles, provoking a psychological reflection about death as a complex dimension, able to have their own intentions and itinerary and, assigning the dead freedom and responsibility for his death and die, the author will say: "Everyone take care of your own funeral."

Conclusion Death has the function of unveiling character and affections, and balance all forces presents in the society, and the art is the instrument to that reflection reach the community.

Political and religious violence: What psychiatry can bring to Middle East?

F.D. Gandus

Former Researcher at La Sorbonne University, Philosophy and Human Sciences Research, Kyriat Arba, Israel

Middle East is one of the most violent regions of the world. This phenomenon is most often due to the fact that religious problematic and political challenges are immediately mixed in places where, moreover, the states don't assume their role as expected about structuring their societies, supporting freedom and respect for the individual rights and life-projects of their citizens. This complex configuration makes a lot of populations in Middle East develop discreet but serious mental problems such as schizophrenia with paranoia-tendencies or loss of rationality among other possibilities. The aim of this lecture (if still possible) or poster (if the program of speeches is already closed) is to demonstrate what psychiatry (such as elaborated in the west) could bring to Middle East, as well as the difficulties this discipline will have to face to gain respect and interest over there. A focus will be made about an example of "loss of rationality" and how it leads to a projection of violence against animals and its specific meaning in the context of a conflict.

Disclosure of interest The author has not supplied his declaration of competing interest.

* Corresponding author.

Introduction Transcultural psychiatry is a branch of psychiatry where cultural context for psychiatric symptoms is studied. It emerged as a consequence of migration of diverse ethnic groups and questions whether international diagnosis classifications fit in different cultures.

Objectives The aim of this review is to make professionals aware of the importance of cultural context for the way mental disorders present themselves depending on the patient's origin.

Materials and methods We report the detailed case of a 23-year-old Moroccan woman, attended for the first time by the mental health services when she was 8. Since that moment, she felt herself possessed by a strange being. Auditory hallucinations appeared. It was only when her father or her husband were at home that she felt the "being" was gone. Her husband, as formerly his father, represented a symbol of protection against that evil being and indeed against her mental disorder, which was directly related to her cultural beliefs.

Discussion Every country has a different culture and every migration brings with it a new environment. The way people adapt to it may result in mental illness. We want to discuss if symptoms fit international diagnosis classifications.

Conclusion Psychiatrists should become aware of the limitations of the international classifications when used on different ethnic groups. We should have a cultural approach in order to treat the diverse populations from all around the world.

Keywords Transcultural; Diagnosis.

Quixotic delirium, around the fourth centenary of the publication of the second part of Don Quixote de la Mancha: About a case

G. Hernandez Santillan*, I. Mirapeix Bedia

Hospital Universitario Príncipe de Asturias, Psychiatry, Alcalá de Henares, Spain

* Corresponding author.

Psychosis, understood as a judgment out of reality, is sometimes considered as a defensive mechanism in the face of an overflowing situation. However, beyond the pathological, given its fantastic nature, has also brought its form and content to art in its various manifestations. Thus, we bring up a similar case. A 51-year-old male, who has one brother with schizophrenia; in his childhood and adolescence excelled by an excellent academic performance, even won a national prize of Economy; and very scarce emotional ties outside the family environment. At the age of 23, during his stay in a foreign country after obtaining a scholarship in a world-renowned company, he presented disorganized behavior and thought, disinhibition, delusions of persecution, prejudice and referentiality; then, he was repatriated by his family to enter in a psychiatric center. After, he continued psychiatric monitoring irregularly, with no disease awareness and little therapeutic adherence. In his last decompensation, he shown a megalomaniacal delusion, he defined himself as "a living being, brother of all living beings, who fought to defend peace, justice and the good of mankind". The last year, he had been helping economically the homeless, interceding before the authorities for strangers and needy people; he restored and prayed in temples of different religions. Furthermore, with a significant deterioration in their self-care and family life. In consequence, he required a third forced psychiatric admission. After two months, he received discharge for clinical improvement and treatment with

injectable paliperidone. Eight months later, he continues to be monitored and markedly recovered.

Understanding the cultural concept of “highly sensitive person” among bipolar patients

M. Ioannou*, M. Dellepiane, S. Olsson, S. Steingrimsson
University of Gothenburg - Institute of Medicine, Psykiatri Affektiva,
Gothenburg, Sweden

* Corresponding author.

Introduction The concept of “highly sensitive person” is a cultural concept, which has become popular in western societies including Sweden. A highly sensitive person (HSP) is usually described as having hypersensitivity to external stimuli, different cognitive processing and high emotional reactivity. Although the concept lacks diagnostic validity, psychiatric patients may refer to this concept.

Aims To examine the feasibility of the Cultural Formulation Interview (CFI) and the clinical relevance of cultural concepts of distress among patients with bipolar disorder that report being a HSP.

Methods A case series of three patients with a diagnosis of bipolar disorder that report HSP. The CFI was conducted with all patients and the applicability of the DSM-5 cultural concepts of distress tested.

Results In all three cases, the CFI facilitated the clinical consultation as reported from the patients and in one of the cases also increased the treatment engagement. The HSP-concept could be conceptualized as a cultural syndrome, idiom of distress and as an explanatory model.

Conclusion The CFI and the cultural concepts of distress proved to be useful for understanding the concept of HSP as also they increased the cultural validity of the diagnostic interview. The three cases illustrate the challenges when encountering patients with other cultural references than clinicians. This highlights the necessity to integrate anthropological thinking in our current diagnostic work in order to reduce the “category fallacy” and promote a more person-centered approach in psychiatry.

‘The Good Parent’ and ‘The Other Parent’: Medicalization, othering and social exclusion in Israeli professional discourse regarding learning disorders and difficulties

O. Katchergin
Oranim Academic College, Sociology and Anthropology, Givatayim,
Israel

This lecture seeks to uncover the various textual techniques through which binary representations of ‘parenthood’ are constructed in the framework of clinical professional discourse of Israeli learning-disorders experts. Historically this discourse has constructed two contrasting parenthood representations: ‘parenthood of learning-disordered children’ on the one hand, and ‘parenthood of cultural deprived children’ on the other hand.

The lecture posits the following main questions: Which textual representations of ‘parenthood’ were constructed in the framework of

the aforementioned discourses? Which affinities can be identified between the textual representations and the contextual characteristics of social class, culture, ethnicity and educational capital? And which affinities can be identified between these representations and the explicit or implicit normative messages of ‘blame’, ‘responsibility’ and ‘agency’ embedded in the texts? Discourse analysis was implemented in order to uncover the mutual and contradictory construction processes. The analysis also reveals the stereotypical imputation of ‘normative’ parents with a well-off, well-educated and western origin population, as well as the stereotypical imputation of ‘problematic’ parents with a low class, little educated and eastern origin population. The lecture concludes by situating the texts in the social and historical context of their formulation: The processes of psychocultural othering which operated on low class, little educated and eastern origin parents are interpreted on the historical background of the class and ethnic hierarchical structure of the Israeli society. The conclusion also raises a conjecture regarding a rising new medicalizing ‘othering’ potential, a potential, which was already implicitly embedded in the analyzed historical texts.

* Corresponding author.

Introduction Hikikomori, a form of severe social isolation, once characterized as a Japanese cultural-bond behavior with social and economic consequences, it is now being described in other countries. Its presentation mimics some clinical features of various classified mental diseases, such as prodromal phase of schizophrenia, personality disorders, Internet dependence, social phobia or depression, without fulfilling their defining criteria.

Objectives/method This work aimed to do a brief review of this subject, describing one case that is probably the first ever reported in Portugal, comparing it with similar cases around the world.

Results The patient was a 22-year-old male, taken to psychiatry evaluation after 4 years of social withdrawal, avoiding or blocking any contact even with family members, which resulted in work and school impairment. He spent most of his days locked at his room, investing his time in particular interests and Internet use, only leaving to eat or do his basic hygiene. At that time, he presented no affective or psychotic symptoms and perceived his behavior as egosyntonic. After six appointments with psychotherapeutic approach, he was able to get a job and improved his communication with the others, especially with family.

Discussion/conclusion This case fits most of the reports found on literature, in its presentation and clinical management. Hikikomori is not considered yet a disorder and further documentation of these cases is still needed to define its place in psychiatric nosology.

⁵ Evang, Hospital Elisabeth Herzberge, Department of Psychiatry-Psychotherapy and Psychosomatic, Berlin, Germany

Introduction In Vietnam, as well as in other low and middle-income countries, stigmatization and discrimination of mentally ill patients is highly prevalent.

Objectives It is important to identify determinants of stigmatization in a socio-cultural context as they may reveal anchor points for anti-stigma efforts.

Aims This population based study conducted in urban and rural Hanoi aims to explore whether public perception of prognosis and course of illness concerning people with symptoms indicating schizophrenia have an impact on the desire for social distance, an important factor of stigmatization.

Methods Based on a population survey using unlabelled vignettes for schizophrenia carried out in the greater Hanoi area in 2013, a sum score of the Social Distance Scale was calculated. A regression analysis was carried out to examine the impact perception of prognostic factors on the desire for social distance. The stratification of the sample ($n=455$) was representative in terms of gender, age, urbanity and household size to the Hanoi population according to the 2013 census.

Results Factor analysis revealed three independent factors of prognosis perception:

- 1. lifelong dependency on others;
 - 2. loss of social integration and functioning;
 - 3. positive expectations towards treatment outcome.
- Both negative prognostic ideas (1,2) were significantly correlated with more desire for social distance in schizophrenia.

Conclusion Stronger desire for social distance was observed among people with negative expectations about the prognosis of persons suffering from psychotic symptoms. Thus, our study indicates a link between social acceptance and ability to maintain a social role in the Vietnamese society.

Stories of exceptional survivors who visit aboriginal healers: Cross-cultural lessons for psychiatry

L. Mehl-Madrona

Eastern Maine Medical Center, Family Medicine Residency, Bangor, USA

Introduction Indigenous communities exist within most countries. These communities often have their own informal and invisible (to their mainstream neighbors) systems of health care. We wondered what happened to people who approached traditional community healers for help with mental health problems.

Methods We interviewed 100 people who had received mental health diagnoses from conventional practitioners and then sought traditional community healers for help. We compared them to a matched population from a computer database who did not seek traditional healers. Patients who visited the healers did statistically significantly better than the comparison group. Panels of naïve graduate students evaluated patient interviews and picked themes that consistently emerged. Scenarios were developed to rate patients along these dimensions from “1” to “5”. New panels did the ratings. Comparisons were made between these 2 groups of people, and those who improved with healers had more change from before to after treatment on the dimensions of Present-centeredness; Forgiveness of others; Release of blame, bitterness, and chronic anger; Orientation to process versus outcome; Sense of Humor; Sense of Meaning and Purpose; and Faith and Hope. The patients who worked with the healers had a new and plausible (to the patient, his or her family, and the healers) explanation for why he or she got well, including a story reflecting a belief about how he or she can stay well; supportive community who believes in the person’s cure.

Conclusions The treatment provided by conventional healers produces measurable changes in several parameters associated with improved mental health.

Mental health consequences of bride kidnapping in the Kyrgyz republic

E. Molchanova^{1,*}, T. Galako²

¹ American University in Central Asia, Psychology, Bishkek, Kyrgyzstan

² Kyrgyz State Medical Academy, Psychiatry, Bishkek, Kyrgyzstan

* Corresponding author.

The consequences of gender-based violence (GBV) in the Kyrgyz Republic have often remained outside of both police officers’ and mental health care specialists’ attention. Statistical data on gender-based violence in the Kyrgyz Republic are underestimated, given that the majority of victims prefer not to seek help at all. One of the types of GBV in the Kyrgyz Republic is bride kidnapping, which is still very popular in rural areas of the state. Brides, that were kidnapped, present common behaviors and symptoms, such as an submissiveness, idealization of a husband, numbing, permanent desire to please a mother-in-law and other relatives of higher status in the family. Problems with the urogenital system, such as signs of urethritis and cystitis, vaginal itching, menstrual irregularities are also very common among daughters-in-law who were brutally kidnapped and had been experiencing violence from members of their families. Authors present an algorithm of dealing with the problem, which has been already implemented as a pilot project in one of the regions of the state.

Reflection of local and universal historical time in symptoms of paranoid schizophrenia

E. Molchanova^{1,*}, R. Tsoy², I. Sim³

¹ American University in Central Asia, Psychology, Bishkek, Kyrgyzstan

² Kyrgyz State Medical Academy, Psychiatry, Bishkek, Kyrgyzstan

³ American University in Central Asia, Psychology, Bishkek, Kyrgyzstan

* Corresponding author.

Psychopathological signs reflect general and significant phenomenon, the whole “extract” of a particular historical time, consisting of a bizarre set of events, influential characters twisted in an individual history of a patient. Except detailed “real” clinical picture reflecting socio-political events, authors consider formatting mechanisms of “unreal” content of hallucinatory-delusional symptoms. In such cases, main heroes are mythological characters for example gins or intimidating heroes of modern movies like vampires and zombies. Events in the social sets, such as Facebook and Instagram are also reflected in experiences of patients. Authors focus their attention on a paradox of logical reflection of events in the context of delusional symptoms versus paralogical interpretations. Research is based on clinical cases, and shows up a spectrum of mechanisms of how events are either included or ignored in the forming a content of psychopathological experiences.

Mental health stigma among Oman Medical Speciality Board (OMSB) residents

S. Musharraf^{1,*}, W. Al-Ruzaiqi², S. Al-Adawi³

¹ OMSB, psychiatry, Muscat, Oman

² OMSB, Child health, Muscat, Oman

³ SQUH, Behavioral medicine, Muscat, Oman

* Corresponding author.

Background Arab/Islamic culture such as those in Oman has been prescribed to be part of “collective culture” where family is central to one’s identity. It is not clear how mental illness is perceived among young doctors in Oman in the light of modernization and acculturation.

Aims Explore the socio-cultural teaching impact on attitudes towards mental health problems among Omani physicians.

Method The consenting residents were asked to fill self-reported questionnaire Attitudes towards Mental Health Problems (ATMHP). It measure: external shame (beliefs that others will look down on themselves self if one have mental health problems); internal shame (related to negative self-evaluations); and reflected shame (believing that one can bring shame to their family/community). Socio-demographic information was also sought, including age, gender and previous contact with a person with mental illness.

Results One hundred and seventy residents filled the questionnaire. The response rate was >80%. The majority were female. It showed elevated scores in indices of external shame and reflected shame. However, having a history of mental distress or having contact with a person with mental illness have moderate indices external shame and reflected shame.

Conclusion This study suggests that medical education has little eroded societal teaching among physicians under training in Oman. Thus, their attitude toward mental disorder appears to be expressed in term of external shame and reflected shame, which, in turn, encapsulate cultural patterning of shame and the centrality of family identity in Oman. Such socio-cultural teaching could lay groundwork for further research to mitigate mental illness in Oman.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0346

Performance of cognitive measures and affective ranges in clients marked with spirit possession in Oman

S. Musharraf^{1,*}, Y. Al-Kalbani¹, S. Al-Adawi²

¹ OMSB, psychiatry, Muscat, Oman

² SQUH, Behavioral Medicine, Muscat, Oman

* Corresponding author.

Background There is a dearth of studies that have explored cognitive performance in different grades of spirit possession.

Aim This study was undertaken to investigate two areas: the first was to explore whether there is a difference in demographic characteristics among presently defined grades of spirit possession in Oman: total possession (TP), partial possession (PP) and symbiotic possession (SP) seen in the Omani society. The second was to compare cognitive performance among the different grades of possession. Assessment criteria for these three groups included indices of current nonverbal reasoning ability, attention/concentration and recall, and those measures calling upon executive functioning.

Results In terms of socio-demographic characteristics, being female, having low education and being in a particular age group are strongly associated with participants classified as TP. In contrast, the SP group endorsed more history of trauma. The three groups showed performance variation in current nonverbal reasoning ability, attention/concentration and recall, and executive functioning, with TP appearing to have poorer performance on these measures compared to PP and SP.

Conclusion Previous studies have investigated whether spirit possession is a pathological state or a culture-specific idiom of distress. To our knowledge, this is the first study that has examined performances in cognitive measures among different types of possession. The entrance of possession trance disorder and dissociative trance disorder into the psychiatric nomenclature warrants more studies of this nature.

Psychometric of questionnaire about cultural factors comorbidity of obsessions and major depressive disorders in Iranian samples

G. Nikpour^{1,*}, A. Homayouni²

¹ Department of Psychology, Allameh Tabatabaai University, Tehran, Iran

² Department of Psychology, Bandargaz Branch, Islamic Azad University, Bandargaz, Iran

* Corresponding author.

Background and purpose Cultural signs may be found among people that speak a local dialect or live in a specific region or historical period. These cultural signs could influence psychopathology. The aim of this study was to design and validate a questionnaire that could evaluate the cultural factors causing concurrent obsessions and major depressive disorders in Iran.

Materials and methods To design the questionnaire, 10 psychologists and psychiatrists who were members of academic boards were questioned by an open questionnaire. Then, the answers to the questions were classified and based on exploratory factor analysis the questionnaire containing 11 factors and 79 questions was confirmed. Internal homogeneity was analyzed by Cronbach’s alpha.

Results The results of Cronbach’s alpha for all factors showed that the highest reliability was 0.90 and the lowest was 0.42. In exploratory factor analysis using Varimax rotation 11 factors were extracted that predict 47.3% of the scale variance. 25 factors were extracted of which 14 had less than three items, therefore they

were omitted because of not being able to acquire reliability as sub factors. Accordingly, a questionnaire containing 11 factors and 79 questions was constructed.

Conclusion The findings showed that the instrument could identify the cultural factors that cause concurrent obsession and major depressive disorders in Iran.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Hospital Clínico Universitario, Psychiatry, Valladolid, Spain
* Auteur correspondant.

Objectives Show with a case report how psychiatric pathology may face differential diagnosis problems when sociocultural aspects are involved.

Methods and materials Seventy-three year old man, born in Colombia. During the last two months, he had come many times to the emergency service due to behavioural changes. He does not have previous psychiatric history. His daughter refers that one of the patient's sisters has been diagnosed of "mystical madness". The previous days he abandoned his medical treatment saying that he "gets in touch with his wife and that he wants to meet her". Since his wife's dead, he had presented an excessively adapted behaviour, without grief symptoms. The first hospitalization day he said we wanted to get married with one of his daughters, with a sexual content speech, being able to get emotional when he spoke about his dead wife. Now the patient is under frequent reviews, and it is thought the differential diagnosis of depression with psychotic symptoms, due to the lack of symptoms remission.

Conclusion Whenever we face different psychiatric diagnosis we don't keep in mind some sociocultural factors, which could be masked and raise different doubts. It is important to keep in mind that each country or ethnical have their own cultural habits which are going to deeply influence patient's personality.

The Senegalese accompagnant model in psychiatric care: How hospitalization with a relative may contribute to the therapeutic process

B. Ory^{1,*}, S. Benmansour², B. Pachoud¹
¹ Université Paris-Diderot, UFR d'études psychanalytiques, Paris, France

² Faculté de médecine UCAD, Psychiatrie, Dakar, Senegal

* Corresponding author.

Introduction The accompagnant model was set up at the Fann psychiatric hospital in Dakar in 1971 by prof. H. Collomb. It requires the patient to be hospitalized with a non-patient to accompany him/her at all time during the hospitalization. This model compensates for economic and human deficiencies, and also presents itself as a therapeutic tool in the treatment of mental illnesses.

Objectives The contemporary use of the accompagnant model will be presented and its advantages and disadvantages assessed.

Aims We investigate how the accompagnant model may have a role in the therapeutic process, and to what extent this model (or part of it) could be exported.

Methods A qualitative study of the practice at Fann Psychiatric Hospital has been carried out, based on interviews with patients, professionals and accompanying persons.

Results There is a striking consensus between patients, professionals and the accompanying persons about the advantages of this practice. It facilitates the encounter between professionals and patients, and reduces the risk of living hospitalization as a traumatic experience. The accompanying persons contribute to warrant the respect of human dignity, and to maintain a therapeutic dynamic through their participation in the development of a caring environment and their expectation of a recovery process. They help ensure continuity of care and medication after the hospital stay.

Conclusion The accompagnant model emphasizes the role relatives may play during and after the hospitalization, in ways that could be compared with what is currently expected from family therapeutic education.

Gypsies's beliefs about the evil eye in relation to mental illness

T. Paralikas^{1,*}, S. Kotrotsiou¹, E. Kotrotsiou¹, M. Gouva², C. Hatzoglou³, D. Kavadias⁴

¹ University of Applied Sciences of Thessaly, Nursing-Postgraduate Program in Mental Health-Research Laboratory of Care, Larissa, Greece

³ University of Thessaly, Medicine, Larissa, Greece

⁴ University of Virginia, Anthropology, Charlottesville-Virginia, USA

* Corresponding author.

Introduction The focus of Medical Anthropology is, among other things, the study of medicine as an expression of culture and involves the analysis of healing traditions, both "traditional" and biomedical.

Objectives Greek Gypsies who have their own *habitus*, language, and culture.

Aims The discussion of treatment options that gypsies have or seek in order to address critical life situations outside a biomedical context.

Methods Field research with interviews and observation.

Results Using Geertz's analytic approach of symbolic interpretation, this paper focuses on the mobilization and transformation of religious symbols in the clinical setting: how these "converse" with biomedicine and how they participate in the process of healing. Painful life experiences drive subjects to seek recourse in remedies outside the biomedical system. At the center of these experiences are thought to be attacks from the "evil eye." According to the subjects' worldview, all people are potential victims of the evil eye. A person's glance can provoke the injury, illness, mental illness or even death of another. Consequently, there is a hierarchy of therapeutic choices in which first preference is given to their own means for addressing a situation—only in the case of failure do they turn to specialists.

Conclusions The beliefs of the subjects are strongly influenced by their worldview, a historically inherited model of health and healing that, unlike the biomedical model, expresses a belief that ailments are successfully cured "with God".

Psychotic episode during a travel to Saint-Petersburg. A variation of Stendhal Syndrome

I. Rubio Zavala*, G. Martínez-Ales García, A. De Diego Cornejo, M.P. Sánchez Castro, A. Fraga Domingo, I.I. Louzao Rojas, M. Bravo Ortiz

Hospital Universitario La Paz, Psychiatry, Madrid, Spain

* Auteur correspondant.

Introduction Journeys have been considered life-changing experiences since the first chronicles of humanity. Interest towards the relationship between travels and mental illness started off with the publication, in 1897, of *Les aliénés voyageurs*.

Case report We report the case of a 52-year-old gentleman, married and without children, who works as a couch driver and has no past medical records. During a holiday trip, at his arrival to Saint Petersburg, he first experienced haze and cognitive and memory failures, along with malaise and sweating. The day after, while visiting the Hermitage museum, he underwent forthright auditive hallucinations, diffusion of thought phenomena and harm delusions. After ruling out diagnosable organic causes through CT scan, MRI and blood analyses including immunologic studies, he was put on olanzapine 10 mg/day with total symptomatic remission within 2 weeks.

Discussion Stendhal syndrome, described back in 1899 by Dr. Magherini, refers to anxious, somatic and psychotic symptoms affecting tourists who visit Florence. The celebrated author, himself, experienced intense emotions due to an overdose of beauty at the Italian city. Further clinical pictures related to journeys include Jerusalem Syndrome and Way of Saint James Syndrome. Another entity, Paris Syndrome, differentially affects Japanese visitors, disappointed with the actual experience of visiting the French city.

Conclusion During journeys, people often abandon everyday life in order to open up to unknown sights and feelings. These can eventually, lead to certain sorts of mental illness.

Socio-demographic and cognitive determinants of xenophobia among the GCC citizens

F. Al-Kubaisi, A. Soliman*

Qatar University, Social Sciences Psychology, Doha, Qatar

* Corresponding author.

Introduction Xenophobia has been referred to as a global phenomenon, linked to the globalization process and noted in countries undergoing transition. It comes from the perceived threat of foreigners' impact on the citizens' identity or individual rights. Although the Gulf countries host a large number of migrants from several different cultures and ethnicity, so far no study has examined the conceptualization and pervasiveness of Xenophobia and counter strategies to such phenomenon.

Objectives Exploring Xenophobia in the Gulf context. Exploring socio-demographic and cognitive factors affecting xenophobia.

Aims Validating a measure of Xenophobia in the Gulf cultural context. Examining the gender differences in Xenophobia among the GCC individuals. Studying socio-demographic and cognitive predictors of Xenophobia.

Methods A sample of 513 individuals from the GCC countries completed several measures of socio-demographic and cognitive variables. Likert-type scale of xenophobia was developed and validated on a large sample of Qatari citizens that showed trustworthy indications of validity and reliability and delivered via internet survey.

Results The findings showed that Xenophobia negatively correlated with age, parents' level of education, and varied subject to the type of father's job. The females showed Xenophobia more indications than males. Participants from the six GCC countries showed different levels of Xenophobia indicators. Bad experience with expatriates fully mediated the relationship between the socio-demographic of subjects and the number of Xenophobia indicators. Cognitive factors were also good predictors of Xenophobia across all cultures and gender.

Conclusions Xenophobia in the Gulf region is influenced by several cognitive and socio-demographic factors that is mediated by, but not limited to, negative personal experiences and their cultural backgrounds.

Ethno-cultural predictors, which determine features of cognitive behavioral therapy of persons with PTSD

M. Sulaimanova¹, R. Sulaimanov^{2,*}

¹ Kyrgyz-Slavic University, Medical Psychology- Psychiatry- and Psychotherapy, Bishkek, Kyrgyz Republic

² Osnabrück Universität, Cognitive Science, Osnabrück, Germany

* Corresponding author.

Objective Study of the predictors of ethno-cultural adaptation among male population with PTSD.

Materials and methods We examined 72 males (age: 18–52) with PTSD (F43.1), acquired in interethnic Kyrgyz-Uzbek conflict. In the process of CBT 3 psychotherapeutic groups were formed: 1st (2 homogenous subgroups) included 24 ethnic Kyrgyz, 2nd (2 homogenous subgroups): 24 ethnic Uzbeks, 3rd (2 heterogeneous subgroups): 12 Uzbeks, 12 Kyrgyz.

Methods Semi-formalized interview, standardized scales for evaluating PTSD, anxiety, depression, aggression, loneliness.

Results High levels of aggressiveness among Kyrgyz: 52.4, among Uzbeks: 51.7 ($P < 0.05$), loneliness among Kyrgyz: 38.9, among Uzbeks: 46.2 ($P < 0.05$), anxiety among Kyrgyz: 48.8, among Uzbeks: 52.4 ($P < 0.05$), depression among Kyrgyz: 57.5, among Uzbeks: 61.1 ($P < 0.05$) are mutually conditioning factors. In the CBT process, the values decreased: in 1st group anxiety level to 44.4 ($P < 0.05$), depression: 54.2 ($P < 0.05$); aggressiveness: 48.2 ($P < 0.05$), loneliness: 38.4 ($P < 0.05$); in 2nd: anxiety: 49.4 ($P < 0.05$), depression: 59.8 ($P < 0.05$), aggressiveness: 47.3 ($P < 0.05$), loneliness: 42.4 ($P < 0.05$); in 3rd: anxiety: 41.1 ($P < 0.05$), depression: 52.2 ($P < 0.05$), aggressiveness: 46.5 ($P < 0.05$), loneliness: 35.5 ($P < 0.05$).

Conclusions High levels of aggressiveness and loneliness among the respondents of both ethnic groups are the predictors of PTSD. Emphasized anxiety-phobic (group 1) and anxiety-depressive (group 2) disorders are the activating mechanisms of adaptation processes in micro-society (psychotherapeutic group). Dominating anxiety-phobic disorders (group 1), anxiety-depressive disorders (group 2), and their entanglement with values of aggressiveness and loneliness determine development and stability of clinical-psychopathologic manifestations as dysthymic disorders, which is an indicator for biological treatment. Heterogeneous group, as a result of CBT, has shown activation of psychological adaptation mechanism by the dissociative type, which is one of the mechanisms of ethno-cultural adaptation and requires subsequent research.

Strategies to reduce the stigma toward people with mental disorders in Iran based on stakeholders view: A qualitative study

A. Taghva

Aja university of medical sciences, Faculty of medicine, Tehran, Iran

* Auteur correspondant.

Introduction Stigma effects on the process of mental disorders and many researchers consider it as the most serious risk factor and inhibitor in promoting mental health.

Aims The aim of this study was to explore the strategies to reduce the stigma toward people with mental disorders in Iran.

Methods This qualitative study, using content analysis method, was undertaken from 2013 to 2015. All participants were recruited by purposive sampling method. They were stakeholders of mental health in Iran. Data were collected through 16 individual interviews, 2 focus group interviews and 6 written narratives. The data were collected, coded and analyzed simultaneously.

Results The major themes were: "Emphasis on education and changing attitudes", "Changing the culture", "Promoting services and support coverage", "Role of various organizations and institutions", "Integrated reform of structures and policies to improve the performance of custodians", and "Evidence-based actions".

Conclusion It seems crucial to adopt strategies that lead to reduce the stigma of mental illnesses and increase awareness among people, scholars and service providers in the field of mental health. Additional studies are needed to evaluate the effectiveness of the emerging strategies to reduce stigma.

Spirituality meanings reported by Southeast Brazilian nursing staff at the psychiatric ward of a university general hospital: A clinical-qualitative study

G. Lavorato-Neto, L. Rodrigues, E. Turato*, C.J.G. Campos UNICAMP–State University of Campinas, LPCQ–Laboratory of Clinical-Qualitative Research, Campinas, Brazil

* Corresponding author.

Introduction Despites nursing holistic trends for caring, in psychiatric wards of general hospitals the spiritual dimension remains controversy. Evidence shows spirituality rule in recovering and also alerts about complications associated to mental disorders and spirituality.

Aim To describe spirituality meanings attributed by a psychiatric nursing team and discuss how they apply them on professional cares.

Method Clinical-qualitative design is a particularization of generic qualitative strategies brought from humanities to approach symbolic research questions in clinical settings. A semi-directed interview with open-ended question, in-depth, was carried out with a team of 22 nursing professionals in the psychiatric ward of a general hospital in Southeast Brazil. Data analysis was driven under the Ricoeur understanding of Freudian symbolic meaning, which affirm that a statement reveals multiple meanings overwritten.

Results Spirituality is developed from several sources of restlessness and living together. The function of spirituality is to help fulfill social roles, keep internal balance and to maintain sacred practice attitudes towards life that brings symbolic salvation: help or redemption to hard life times. Nature of mental illness

remains as spiritual stigma and a suspicion contradictorily to spiritual approach caring to patients in inpatients services, which is described, as inappropriate or confusable.

Conclusions Even spirituality meanings are covered by symbolism, which expresses human attitudes to help in life crises they are surrounded by contradictions that situate this dimension in the limit of reason, which approximates carriers and patients causing weirdness. Nursing staff still needs training to deliver holistic care, and spiritual counseling to gain clarity in this issue.

Residential facilities project in Cuba: An original working model

A. Vaccaro^{1,*}, M.J. Brito Broche², M.I. Capote³,C.B. Borrego Calzadilla⁴, C. Mencacci¹¹ Ospedale Fatebenefratelli e Oftalmico, Neuroscienze, Milano, Italy² Jefa de Sección de salud mental, Ministerio de la Salud, La Habana, Cuba³ Vicedirectora del Hospital psiquiatrico de La Habana, Psiquiatria, La Habana, Cuba⁴ Jefa de la Sección de salud Mental, Ministerio de Salud Pública de la República de Cuba, La Habana, Cuba

* Corresponding author.

Psychiatry must have among its main aims to reintegrate in their own environment of life people with psychotic disorders, personality disorders and other serious disorder of the psychic sphere. We must be able to operate in places built ad hoc, that is, where time, space and procedures are marked with certainty and, as much as possible, managed firsthand. The environment must be constructed or modified in such a way as to make it unlikely the failure or discomfort. Patients also need to be strengthened in their ability to integrate in their environment and in the ability to cope with various life events. The goal is to transfer a first group of patients from large psychiatric hospital of La Habana to the territory, specifically in 2–3 already identified communities, to realize the rehabilitation projects that in 3–4 years can bring patients selected at their home or, alternatively, at self-managed apartments. The reference model of rehabilitative interventions is multimodal. The model explains the onset, course, prognosis and social functioning of the major mental disorders as a complex and mutually conditioning relation between biological, environmental and behavioural. The results will be evaluated over the next three years and will be the subject of future publications. A good practice cannot disengage from safe theoretical and methodological references. To show clearly and verifiably their work, operators must be trained before and during all phases of work, a job training, continuing education, which has as its primary objective the descriptive clarity and verifiability of results.

Between creativity and death: Abstract expressionists and alcohol use disorders

O. Vasiliu*, D. Vasile, F. Androne, M. Patrascu, E. Morariu "Dr. Carol Davila" central military hospital, psychiatry, Bucharest, Romania

* Corresponding author.

American Expressionists were a group of American artists who valued free expression of unconscious elements, combining emo-

tional intense expressions with anti-figurative abstract style. Their main place of creative debates was Cedar Tavern in New York City, considered by art critics an important incubator of the Abstract Expressionism. Jackson Pollock, one of the most prominent figures of this movement, suspected of having bipolar disorder, abused alcohol during long periods of his life, for which he even underwent psychotherapy. Unfortunately, he died in a car accident while driving under influence, after decades of innovative work, during which he created a new painting method and produced compositions which are nowadays between the most expensive works of art. Mark Rothko also had periods of heavy drinking, and finally he died by cutting his arms with a razor. He is considered a genius, who created a completely new perspective over painting, and his works are also between the most expensive paintings in the world. Willem de Kooning was affected by alcoholism since his early years, and developed dementia, at least partially induced by abusive drinking. Although affected by neurocognitive disorder, he continued to produce amazingly creative paintings until his final years and in 2016 one of his works obtained the record for the most expensive painting ever sold. Using alcohol as a tool for increasing creativity risks to expose the creator to severe disorders or even death, the subject walking on a narrow line between sublimation of unconscious impulses and tragic resignation before them.

The claim that “thinking positive” betters one’s life has become pervasive in our contemporary culture. Proponents of this style of reasoning, including the head of the positive psychology movement, Martin Seligman, claim their goal is to create a field focused on human well-being and the conditions, strengths and virtues that allow people to thrive, and back their standpoint with a great number of studies.

However, critics of the movement have, first of all, pointed out flaws in some of the concepts and studies backing them, and second, performed experiments of their own which show not only that forced positive thinking doesn’t help, but can sometimes be harmful.

More worrisome than disputes in the therapeutic community is the tendency of mass media and our commodified society to abuse

these approaches, the end result being a whole scope of popular psychology books which promise wealth, happiness and ideal partners to those prepared to “believe”, and the presence of a horde of self-appointed gurus promising easy answers and quick solutions. This is only a symptom of our contemporary postmodern condition, one well phrased by the Slovenian philosopher Žižek - “the commandment of the ruling ideology is ‘enjoy!’”.

From philosophers of negativity (Nietzsche, Schopenhauer) to psychotherapists dealing with automatic negative thoughts, we come to our proposed field of research in the “neuroscience of negativity”, a search for the biological underpinnings of positivity/negativity, focusing primarily on their relation to Cloningers’ dimensions of personality and mood disorders.

Is international affective picture system (IAPS) appropriate for using in Iranian culture, comparing to the original normative rating based on a North American sample

N. Zamani

Tehran university of medical sciences- Tehran- Iran., sports medicine research center- neuroscience institute, Tehran, Iran

Background Previous studies have shown that cultural context has an influence on emotion and cognition. In this study the emotional response to international affective picture system (IAPS) was compared between Iranians and normative ratings of Americans young adults.

Method One hundred and thirty eight Iranian university students (85 women, 48 men) age 18 to 52 (average= 31, SD = 7.76) enrolled in the study. Participants’ emotional response to IAPS images were rated in three dimensions (valence, arousal, dominance) using self-assessment Manikin (SAM) system. Then, valence, arousal, dominance scores were compared to those of 100 American undergraduates (50 females, 50 males) of the same age group, enrolled at Florida university and surveyed by Prof. PJ Lang in 2008.

Result Our results indicate that there is complete correlation between the mean ratings of valence, arousal and dominance between Iranian and American participants. Also the results showed similarities in valence ratings, but arousal ratings especially in female participants were different. The relationship between arousal and valence showed a similar boomerang shaped distribution seen with the North American sample. Iranian sample showed positively offset and negative bias comparable to the American counterparts.

Conclusion The results are promising in the sense that IAPS images can be used in studies within Iranian cultural context. However, arousal values require a modification for their proper application in Iranian cultural context.

⁴ Kuopio University Hospital, Primary Health Care Unit, Kuopio, Finland

⁵ Institute for Molecular Medicine Finland, Metabolomics unit, Helsinki, Finland

* Corresponding author.

Introduction The global arginine bioavailability ratio (GABR) is used to estimate arginine supply. Arginine is precursor to nitric oxide (NO) that has been suggested to play a role in major depressive disorder (MDD). NO also participates in neuronal, inflammatory and cardioprotective functions.

Objectives To compare GABR between:

- D patients and non-depressed controls;
- remitted and non-remitted MDD patients;
- baseline and follow-up within remitted and non-remitted MDD groups.

Aims To investigate the role of NO production in MDD.

Methods The sample comprised 99 MDD patients and 253 non-depressed controls (Beck Depression Inventory scores < 10) aged 20–71 years. Altogether, 78 patients returned for the follow-up; 33 were remitted and 45 non-remitted. GABR was calculated from serum levels of arginine, citrulline and ornithine, which were analysed using ultra-performance liquid chromatography. Differences between the study groups were examined using logistic regression adjusted for age, gender, smoking, alcohol use, physical exercise and glycated haemoglobin. The follow-up regression analyses were adjusted for age, gender and physical exercise.

Results Lowered GABR was associated with belonging to the MDD group (OR 0.13, 95% CI 0.03–0.50). Exclusion of participants using anti-depressants that were associated with measured

metabolites did not change the results. Over the follow-up period, the remitted and non-remitted groups both showed an increase in GABR ($Z = -.53, P < 0.001$ and $Z = -3.00, P = 0.003$, respectively).

Conclusions Decreased GABR may characterise MDD. This could affect neuronal, immunological and cardioprotective functions of NO.

Depression and multiple sclerosis–pathophysiological links: From biology to treatment

S.L. Azevedo Pinto*, R. Coelho, A. Silva

Hospital de S. João, Clínica de Psiquiatria e Saúde Mental, Porto, Portugal

* Corresponding author.

Introduction Depressive disorders (DD) are the second cause of disability worldwide. DD affect predominantly working age individuals, recurring in 75% of cases. DD pathophysiology is intricate and multi-factorial. Several inflammatory diseases have been linked to mood disorders. Amongst these conditions is multiple sclerosis (MS), a chronic inflammatory disease of the central nervous system, characterized by frequent exacerbations and progressive functional loss.

Objective To review the current knowledge on DD and MS as comorbidities and the underlying pathophysiologic mechanisms.

Methods We performed a bibliographic search in PubMed–publications released in the last 5 years, written in English, Portuguese and Spanish, containing the keywords depression, inflammatory disorders, multiple sclerosis.

Results The inflammatory hypothesis of depression provides a strong foundation to explain its close link with multiple sclerosis. The incidence and prevalence of DD is significantly higher in MS, especially in men. Functional imaging studies have shown that depressive symptoms are closely linked to the extension of inflammatory lesions, especially on the frontal and parietal regions, with particular emphasis to those affecting the grey matter. On the one hand, the clinical course and response to treatment of MS may be hindered by DD; on the other hand, the evolution of MS lesions leads to fluctuations in mood, with significant improvement of DD with successful MS treatment, independently of physical improvement.

Conclusions There appears to be a biological link between DD and MS, with a bidirectional interference in the clinical course, prognosis and treatment response. Thus, both conditions must be correctly identified and treated.

Correlation between depression and happiness among Kuwait university students

G. Baqer

Kuwait University, Department of Psychology, Faculty of Social Sciences, Kaifan, Kuwait

Background The Beck Depression Inventory (BDI-II) has become one of the most widely used instruments for evaluating the severity of depressive symptoms in psychiatric patients and in normal populations. The Oxford Happiness Questionnaire (OHQ) has been derived from the Oxford Happiness Inventory (OHI). The OHI follows the design and format of BDI-II, which provided, when reversed, a set of 20 multiple-choice items relevant to subjective well being. Further items were added to cover aspects of happiness and 29 items were retained in the final scale. OHQ was translated into Arabic for the first time in the present study. The aim of the study is to examine the correlation between depression and happiness.

Materials and methods BDI-II (alpha .87) and the Arabic version of OHQ (alpha .92) were completed by a sample of (380) Kuwait university students (180) males and (200) females with mean age of 22.19 ± 2.8 years old. Pearson correlations were calculated.

Results Significant ($P > 0.01$) reverse correlation was found between depression and happiness ($r = -0.54$).

Conclusion Although significant negative relationship existed between BDI-II and OHQ, the coefficient for determination of this correlation shows that nearly only half of depression changes are described and assessed with happiness score! It seems that the two psychometric tools do not completely stand against each other. However, further evaluation of this relationship is needed.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Alternating intravenous racemic ketamine and electroconvulsive therapy in treatment resistant depression: A case report

L. Bartova*, A. Weidenauer, M. Dold, A. Naderi-Heiden, S. Kasper, M. Willeit, N. Praschak-Rieder
Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria

* Corresponding author.

Introduction Treatment resistant depression (TRD) affecting approximately 10–30% of all depressed patients often remains misdiagnosed and undertreated, leading to a higher risk of relapse and suicide. Electroconvulsive therapy (ECT) and sub-anesthetic ketamine have repeatedly shown to be effective in the TRD population. Administering ketamine as an anesthetic component to augment antidepressant efficacy of ECT has been proven inconclusive, while a combination of alternating ECT and ketamine has not been investigated yet.

Case report We present a severely depressed and chronically suicidal female inpatient who failed multiple antidepressant treatment attempts, requiring frequent psychiatric admissions. Since

available conventional as well as non-conventional antidepressant treatment strategies were nearly exhausted, we employed a combination of ECT (bilateral stimulation up to 150%) 2–3 times/week, while intravenous racemic ketamine (up to 75 mg per infusion) was administered on ECT free days 2–3 times/week. Consequently, robust anti-suicidal and antidepressant effects could be observed already during the first treatment week. The temporarily occurring subjective forgetfulness disappeared after the last ECT. Summarizing, we employed 9 ECT treatments and 7 ketamine infusions leading to a stable psychopathological state even after discharge from psychiatric inpatient care. In order to prevent relapse a maintenance-therapy comprising ECT once monthly and 2 ketamine infusions (up to 100 mg per infusion) administered on the day before and after ECT was established.

Conclusions In our patient alternating ECT and intravenous racemic ketamine were proven safe and long-term effective after numerous failed antidepressant trials including ECT and ketamine alone. We may hence encourage clinicians to widen their therapeutic armamentarium in severe TRD.

Relationship between pain-coping strategies, catastrophizing to pain and severity of depression

B. Batinic^{1,*}, J. Nesvanulica², I. Stankovic²

¹ Clinic for Psychiatry Clinical Centre of Serbia, Faculty of Philosophy Department of Psychology, Belgrade, Serbia

² Faculty of Philosophy, Department of Psychology, Belgrade, Serbia

* Corresponding author.

Introduction Studies have shown that somatic pain influences the severity of major depressive disorder (MDD), and could be moderated through pain coping strategies and not catastrophizing to pain.

Objectives The aim of the study was to ascertain the correlation between pain coping strategies, catastrophizing to pain and severity of depression.

Methods The study sample consisted of 82 patients diagnosed with MDD, aged between 18 and 65 years old ($M = 46.21$). Assessment instruments included The Beck Depression Inventory-II (BDI-II), The Brief Pain Inventory-Short Form-BPISF (consisting of two subscales: BPI1-intensity of pain, and BPI2-interference with daily functioning), The Vanderbilt Pain Management Inventory-VPMI (consisting of active-VPMIAC and passive pain coping mechanism subscales-VPMIPC) and The Pain Catastrophizing Scale-PCS (consisting of subscales of rumination, exaggeration and helplessness).

Results The average BDI-II score was 27.21 ($SD = 11.53$); the average score at BPI1 was 2.99 ($SD = 2.83$) and 3.35 ($SD = 3.26$) at BPI2; the average scores on the active coping mechanism subscale was 20.72 ($SD = 4.87$), and on the passive coping mechanism subscale 34.05 ($SD = 7.86$); the average catastrophizing scale score was 28.78 ($SD = 10.72$). Active mechanism of pain coping has shown significant negative correlation with depression ($r = -0.227$, $P > 0.05$) while passive mechanism of pain coping has shown significant positive correlation with depression ($r = 0.269$, $P > 0.05$). Intensity of depression was significantly positively correlated with intensity of catastrophizing to pain ($r = 0.358$, $P > 0.01$) and its derivatives: rumination, exaggeration and helplessness.

Conclusion Interventions focusing on targeting catastrophizing to pain and pain coping mechanisms should be considered in the treatment of patients with MDD with somatic pain.

Validation of the Tunisian version of the patient health questionnaire (PHQ-9)

H. Belhadj^{1,*}, R. Jomli², U. Ouali², Y. Zgueb², F. Nacef²

¹ Military hospital, psychiatry, Tunis, Tunisia

² Razi Hospital, psychiatry, Manouba, Tunisia

* Corresponding author.

Introduction The PHQ-9 has been recommended as the best available screening and case-finding instrument for primary care based on its brevity, and ability to inform the clinicians on both depression severity and diagnostic criteria.

Objective Our study evaluated the reliability and the validity of the Tunisian version of the PHQ-9 in detecting major depression in general population.

Method We undertook a cross-sectional and analytical study. A total of 134 participants, representative of the Tunisian general population, were enrolled. The PHQ-9 was validated against the HAD reference standard. The types of validity determined for the PHQ-9 in this study were: translation validity, internal reliability and criterion validity.

Results Test-Retest reliability was determined by intraclass correlation. This scale is stable over 2 weeks (ICC = 0.97). The Tunisian version of the PHQ-9 was found to have good internal reliability (Cronbach's alpha = 0.84). As for criterion validity of the PHQ-9, the Pearson's correlation coefficient between the PHQ-9 and HAD was 0.94 and the Spearman's correlation coefficient was 0.81. This indicated a positive association of good strength between the two instruments. A cut-off score of 10 or higher on the PHQ-9 had a sensitivity of 86.2 and a specificity of 83.8. The VPP was 0.6 and the VPV was 0.9.

Conclusion The Tunisian version of the PHQ-9 has several potential advantages. It was found to be a valid and reliable casefinding instrument for detecting depression in general population.

* Corresponding author.

Introduction Depression is a major burden for the health-care system worldwide.

Objective To identify prevalence and severity of depression in Tunisian general population and define sociodemographic characteristics of screened positive to depression participants.

Method We undertook a cross-sectional and descriptive study. A total of 134 participants, representative of the Tunisian general population, were enrolled. Age, gender, and educational level were the major criteria for representativeness. Depression was assessed with the Patient Health Questionnaire (PHQ-9).

Results The cut-off score was 10. The prevalence of depression was 13.4%. There were no statistical difference in gender, education and age for the prevalence of depression.

Conclusion The World Health Organization ranks depression as the fourth leading cause of disability worldwide. Thus, the detection of depression and the dissemination of treatment in the general population are very important to reduce the burden of the disease.

Anxiety and depression at the medical students in post-examination

S. Ben Saadi*, O. Moula, J. Oueslati, I. Jelalia, R. Ghachem

Razi Hospital, Department B, Mannouba, Tunisia

* Corresponding author.

Introduction The course of medical studies is a long route asking for a lot of breath. It is enclosed by the national examination for specialisation, which allows to access professional training. This examination requires a diligent preparation over several months in difficult conditions for the most part of the candidates who are in practical training.

Objectives and aims We suggest estimating the degree of anxiety and depression at the candidates in the week following the national examination for specialization of 2016.

Methods We have put online on the pages of the various Tunisian Faculties of Medicine an anonymous questionnaire intended for the candidates who took the national examination for specialization of 2016. We used the scale HAD (Hospital Anxiety and depression scale).

Results We recruited 220 participants. More or less half of the participants declare to be rather often in a good mood, that they take little only of the pleasure in the same things as before, that they laugh and see the highly-rated voucher of things really less than before, that they are made of the concern very often and that they sometimes experience sensations of fear. A third of the participants feel tense or irritated most of the time feel sudden sensations of panic rather often and have the impression to work in slow motion rather often.

Conclusion Taking the national examination of specialization rhymes with stress and anxiety. It leads us to question: is it necessary to assure a psychological coverage during the preparation and upstream of the competition?

Depression, anxiety and stress [DASS21] symptoms in menopausal Arab women: Shedding more light on a complex relationship

A. Bener

Istanbul University, Biostatistics and Public Health, Istanbul, Turkey

Aim The objective was to determine correlation between depression, anxiety and stress in menopausal and post-menopausal women and shedding more light on a complex relationship.

Methods A cross-sectional based on Arabian women at the Primary Health Care (PHC) Centers in Qatar during July 2012 and May 2014 and 1101 women agreed to participate and responded to the study. Depression, anxiety and stress were measured using the Depression Anxiety Stress Scales (DASS-21). Data on body mass index (BMI), clinical and other parameters were used.

Results The mean age and SD of the menopausal age was 49.55 ± 3.12 , and postmenopausal age was 58.08 ± 3.26 ($P < 0.001$). There were statistically significant differences between menopausal stages with regards to age, ethnicity, educational status, occupation status, and place of living. Also, there were statistically significant differences between menopausal stages with regards to BMI, systolic and diastolic blood pressure, vitamin D deficiency, and diseases. Depression and anxiety were more common among postmenopause women. The multivariate regression analyses revealed that age in years, diastolic BP, consanguinity, regular exercise were predictor for depression. Meanwhile, diastolic BP, occupation and physical activity considered the main risk factors for anxiety. Furthermore, age in years, occupation and

sheesha smoking habits were considered as the main risk factors associated with stress.

Conclusion A large number of factors were associated with experiencing menopausal and psychosocial problems and which had negative effects on the quality of life among Arabian women. Depression, anxiety and stress should be considered as an important risk factors for osteoporosis.

⁴ University of Groningen, Department of Pharmacy, Groningen, The Netherlands

* Corresponding author.

Depressive disorders are a great burden for individual patients and society. Blood-based biomarkers are regarded as a feasible option for investigation of depressive disorders. Several potential biomarkers for depression were selected. We studied the following serum markers: cortisol, melatonin, brain-derived neurotrophic factor (BDNF), prolactin, insulin-like growth factor 1 (IGF-1), β -endorphin, orexin A. The patient sample consisted of 78 persons with depressive disorders. Patients were divided into two groups: 46 patients with a first depressive episode and 32 patients with recurrent depressive disorder. Control group consisted of 71 healthy individuals of corresponding age and sex. All markers were measured in serum using MILLIPEX[®] MAP panels (Merck, Darmstadt, Germany) by analyzer MAGPIX (Luminex, USA). Statistical analyses were performed using SPSS software. Results were expressed as median and quartile intervals [Q1–Q3]. There was a significant increase of serum concentrations of cortisol (663.69 [467.5–959.49] nmol/L, $P < 0.001$) and melatonin (66.31 [33.6–132.59] pg/mL, $P = 0.029$) in patients compared with the control group (526.1 [367.24–654.7] nmol/L and 45.11 [27.47–73.47] pg/mL). In addition, correlations were found between potential biomarkers, clinical indicators and treatment response measured by applying the Hamilton Depression rating scale and the Clinical Global Impression rating scales. A significant correlation was found between the concentration of prolactin and high response to pharmacotherapy ($r = -0.267$, $P = 0.029$). Identifying biomarkers that can be used as diagnostics or predictors of treatment response in people with depressive disorders will be an important step towards being able to provide personalized treatment.

Disclosure of interest The work is supported by the project of Russian Foundation of Basic Research N° 14-04-01157a.

¹ Psychiatric University Hospital, Center for Affective- Stress and Sleep Disorders, Basel, Switzerland

² Department of Adult Psychiatry, Psychiatric Services Solothurn, Solothurn, Switzerland

³ Psychiatric Service St. Gallen, Adult Psychiatry, St. Gallen, Switzerland

* Corresponding author.

Introduction Major depressive disorders (MDD) are among the most prevalent psychiatric disorders worldwide. While there is abundant literature showing that an increased cortisol secretion, understood as a proxy of the deteriorated hypothalamus-pituitary-adrenocortical axis activity (HPA AA), and poor cognitive performance are tightly related, less is known as regards to the HPA AA and higher cognitive information processes such as problem solving.

Aims Investigating the association between cortisol secretion and problem solving performance among patients with MDD.

Methods Fifteen inpatients with MDD (HDRS > 24; mean age: 59 years; 80% females) underwent a pharmacologic HPA AA challenge both at baseline and six weeks later to assess the cortisol secretion. They were treated with standard antidepressants at therapeutic dosages. Further, they learned how to solve the Tower-of-Hanoi problem-solving task (ToH-PS-T) and how to apply the problem solving strategy to other tasks (transfer). Testing occurred both at baseline and six weeks later. Outcome variables were symptoms of depression, cortisol secretion and the performance to transfer the acquired ToH-PS-T.

Results Both symptoms of depression and cortisol secretion decreased over time, and transfer performance increased over time. Neither at baseline nor six weeks later, symptoms of depression, transfer performance and cortisol secretion were statistically related.

Conclusions The pattern of results suggests that cortisol secretion as a proxy of physiological stress regulation, symptoms of depression, and higher order cognitive performances seem unrelated. Given that cognitive information processing performance substantially increased regardless from depression and cortisol secretion, problem-solving skills need to be focused separately.

Poststroke depression

D. Brigadeiro^{*}, J. Nunes, T. Ventura Gil, P. Costa
Hospital Sousa Martins, ULS Guarda EPE, Departamento de Psiquiatria e Saúde Mental, Guarda, Portugal

* Corresponding author.

Psychiatric symptoms are the complications most often ignored in patients who suffered a stroke. Depression is the most common psychiatric complication in post-stroke patients with a prevalence of about 20–50% in the first year and with a peak in first six months after the stroke. Depression in turn, constitutes itself a factor of cerebrovascular risk. Despite its high prevalence this disorder remains under diagnosed and under treated. One explanation for this fact is that depressive symptoms are often misinterpreted as consequences of stroke itself. This reality is even more striking in patients with aphasia. Poststroke depression (PSD) results from the interaction between biological, as the location of the stroke, social and psychological factors. The presence of this disorder is associated with deleterious consequences for rehabilitation process. These patients suffer more often from attention deficits, cognitive difficulties, lower response to rehabilitation programs, poor quality of life and increased mortality.

Objectives To review epidemiology, pathogenesis, risk factors, consequences and current recommendations for therapeutic intervention.

Methods Medline/Pubmed database search using the terms post-stroke depression, depression and stroke, depression and cerebral vascular accident, stroke patients, published in the last 16 years.

Conclusion The treatment of PSD has been shown effective in improving the evolution and prognosis of these patients, therefore it is very important early diagnosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Expert consensus guidelines rely on a relevant methodological procedure complementary to based-evidence recommendations. They aim at offering support strategies derived from expert consensus for clinical situations where the levels of evidence are either absent or insufficient. Recommendations for resistant depressive disorders proposed by french association for biological psychiatry and fundamental foundation, were based on responses from 36 highly specialized experts in this field. They were invited to complete a comprehensive questionnaire with 118 issues. The questions raised covered a wide range of aspects from the evaluation of therapeutic resistance and clinical conditions increasing the risk for treatment failure to the adopted therapeutic strategies organized according the effects of previous treatment lines. Specific populations/situations especially including elderly, comorbidities (anxiety disorders, personality disorders and addictions) were also been studied through specific questions. Such recommendations are intended to substantially help the decision and therapeutic choice of clinician implied in the management of resistant depressive disorders in everyday clinical practice. We propose in this communication to compare the results of these recommendations with the various data from the evidence-based guidelines in order to demonstrate their complementarity for the management of resistant depressive disorders.

Electroconvulsive therapy as an effective alternative in depressive disorder

G.M. Chauca Chauca^{1,*}, L. Carrión Expósito¹, P. Alonso Lobato²

¹ UGC-Salud Mental Hospital Infanta Margarita, Cabra, Córdoba, Spain

² UGC-Salud Mental Área Sanitaria Norte, Peñarroya, Córdoba, Spain

* Corresponding author.

Introduction The efficacy of electroconvulsive therapy (ECT) in the treatment of depressive episodes is well established, and so is reflected in the major guides.

Objectives Description of a clinical case of a patient diagnosed with major depressive episode with psychotic symptoms and obsessive compulsive disorder prevalence of compulsive acts that do not respond to drug treatment but to electroconvulsive therapy.

Methods Presentation and review of a case.

Results A 55-year-old woman diagnosed with recurrent depressive disorder with worsening in the last 4 years.

Clinical depressive Sadness, spontaneous crying in the form of access, apathy, isolation and clinofilia desires, complaints mnemonic deficits and complete anhedonia. Obsessional symptoms compulsive as more repetitive behaviors of obsessive ideas, which repeats incessantly despite checking, that does not prepare or calm. The patient has not responded to any pharmacological strategy, despite using full doses and combinations of antidepressant, but euthymics more antipsychotics (sertraline, fluoxetine, reboxetine, venlafaxine, bupropion, lithium, valproic acid, lamotrigine, risperidone, quetiapine, trifluoperazine, clotiapine). For this reason, it was decided to start treatment with ECT, progressively responds in each session, after 8 sessions the patient is euthymic, it has resumed normal activities, no obsessive or psychotic symptoms.

Conclusions It is important to know that it is a safe technique that would save not only an economic cost, if not a personal emotional cost. It is noteworthy that more than 50% of depressed patients who respond to a course of ECT, fall between 6 and 12 months despite receiving adequate pharmacological treatment then so we will have to closely monitor the patient.

Federal University of São Paulo, Psychiatry, Sao Paulo, Brazil

* Corresponding author.

Introduction The non-competitive N-methyl-D-aspartate glutamate receptor antagonist ketamine has been shown to have rapid antidepressant effects in treatment-resistant depression (TRD). However, only a few studies have investigated which clinical characteristics predict a response to ketamine.

Objectives To assess sociodemographic variables and clinical markers that predict response to ketamine in unipolar TRD patients.

Methods Searches of Pubmed, NCBI and Google Scholar were conducted for clinical trials and systematic reviews, through October 2016, using the keywords:

ketamine, N-methyl-D-aspartate receptor antagonist, rapid-acting antidepressant, depression, treatment-resistant depression, clinical predictors.

Results Findings support the following clinical predictors:

– sociodemographic variables: positive family history of alcohol abuse disorder in first-degree relative (increased antidepressant response and fewer depressive symptoms for up to 4 weeks post-infusions), higher BMI (improvement in depression severity at 230 minutes and one day post-infusion), negative history of suicide attempt (greater improvement at day 7);

– infusion-associated events: greater dissociation during infusion (better antidepressant response at 230 minutes and one week post-infusion); rapid response to first infusion (sustained response to subsequent infusions in one-third responders for up to 83 days);

– symptomatology: anxious depression (fewer depression symptoms at day one up to 25 associated with longer time to relapse); neurocognitive performance (lower attention) predicts change in severity of depressive symptoms over six infusions.

Conclusions Findings suggest that specific clinical characteristics are predictors of ketamine response in TRD. Future studies confirming reliable predictors will assist clinicians to implement efficacious and individualized treatment for TRD patients.

Major depressive disorder: Recurrence risk factors

F. Ellouze*, W. Bouali, I. Marrag, A. Chaabouni, R. Ben Soussia, M. Nasr

CHU Tahar Sfar, Psychiatry, Mahdia, Tunisia

* Corresponding author.

Introduction Despite the frequency and the severity of depressive episodes, the major depressive disorder (MDD) is today inadequately diagnosed and treated, and the risk factors for its recurrence are not well elaborated. The objectives of this study were to describe the sociodemographic, clinical evolutionary and therapeutic features of this disorder and to identify the factors involved in the risk of its recurrence.

Methods This is a retrospective, descriptive and analytical study, involving 150 patients with MDD, isolated episode or recurrent major depressive disorder (RMDD) with a follow-up for at least two years. Data collection was performed using two pre-established questionnaires for the MDD isolated episode and for the RMDD respectively with 51 and 92 items. A study of the recurrence period was performed by Kaplan–Meier method. The Cox-test was used to determine the survival curves and to look for the risk factors significantly associated with MDD recurrence.

Results A total of 150 patients was gathered, predominantly female, married and from urban origin. The average age at the beginning of the disorder was 35 years. The recurrence period was 109 months and the factors associated with recurrence were the early age of onset of the disorder, family history of mood disorders, the severity of MDE index, residual symptoms and discontinuation of treatment.

Conclusion The study of factors involved in MDD recurrence is of a particular importance since it allows not only to know the group of patients at risk but also to improve their therapeutic care.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Prevalence and risk factors of postpartum depression among preterm infant mothers

S. Ellouze¹, J. Aloulou¹, A. Ben Thabet², N. Halouani^{1,*}, A. Gargouri², O. Amami¹

¹ Hedi Chaker University Hospital, Psychiatry “B” Department, Sfax, Tunisia

² Hedi Chaker University Hospital, Neonatology Department, Sfax, Tunisia

* Corresponding author.

Introduction The birth of a preterm infant evokes considerable psychological distress in mothers and is associated with an increased risk for postpartum depression.

Objectives The aim of this study was to assess the prevalence of postnatal depression among preterm infant mothers and to identify highlighting associated factors.

Methods We conducted a cross-sectional, descriptive and analytical study, including 97 mothers of premature infants who presented to the outpatient unit of neonatology at the UH Hedi Chaker of Sfax in Tunisia. For each mother, we collected sociodemographic and obstetric data. We used the Edinburgh Postnatal Depression Scale (EPDS) for screening postpartum depression.

Results Average age of mothers was 30.2 years. Average gestational age was 32.82 weeks. Almost all the mothers were married (99%), had a satisfactory couple relationship (93.7%), almost two thirds were multiparous (64.9%), and 77.3% gave birth by caesarean section. Prematurity was unexpected by 56.7% of women. Regarding newborns, digestive problems were noted in 25.8% of cases and sleep disturbances in 20.6% of them. Prevalence of depression in the population studied was 39.2%. It was significantly associated with unexpected prematurity ($P < 0.001$), impaired couple relationship ($P = 0.001$), digestive problems ($P = 0.013$) and sleep disturbances ($P = 0.002$).

Conclusion Mothers of preterm infants seem to be particularly vulnerable to postpartum depression. Systematic screening for depressive symptoms in this obstetric population can help to have an optimal psychological outcomes for mothers and infants during a crucial period of development of mother–infant coregulation.

Childhood trauma: A factor for increased risk of major depression in psoriatic patients

M. Erfanian

Maastricht University, Faculty of Psychology and Neuroscience, Maastricht, The Netherlands

A history of childhood maltreatment (CM) is an important determinant for understanding the development of psychiatric and physical disorders. CM is associated with sensitization of central nervous system (CNS) that leads to dysregulation of the hypothalamic–pituitary–adrenal (HPA) axis [1]. Early life stress is a well-known contributor to major depression [2]. The dysregulation of HPA axis and sympathetic nervous system activity also impact skin. Epidermis shows a high vulnerability to such psychological stressors resulting to increase risk for psoriasis [3]. The current study investigates the association between childhood trauma and major depression, childhood trauma and psoriasis, and also severity of major depression in female and male patients with psoriasis. Sixty-four psoriatic patients (female = 34, mean age = 46.87) were evaluated with the Childhood Trauma Questionnaire (CTQ) for the history of CM and with the MINI International Neuropsychiatric Interview for the diagnosis of major depression. CM was associated with major depression, indexed by a higher CTQ in emotional ($\chi^2(3) = 26.002$, $P < .0005$) and physical abuse scores ($\chi^2(3) = 23.764$, $P < .0005$). CM limited to sexual abuse was associated with higher severity of psoriasis ($\chi^2(3) = 9.81$, $P < .02$). There was no indication of a difference between men and women in severity of major depression ($U = 444$, $P = .304$). Our findings highlight the importance of recognizing psychiatric comorbidity, in particu-

lar major depression, among psoriatic patients. Depressive disorder with the presence of psoriasis may constitute a separate etiology with a greater contribution of early environment.

* Corresponding author.

The aim of the preclinical study was to examine the effects of chronic the effects of chronic cholecalciferol administration (1.0, 2.5 or 5.0 mg/kg/day, s.c., once daily, for 14 days) on depression-like behavior following ovariectomy in rats. Cholecalciferol was administered to the ovariectomized (OVX) rats and OVX rats treated with 17 β -estradiol (17 β -E₂, 0.5 μ g/rat, s.c., once daily, for 14 days). Depression-like behavior was assessed in the forced swimming test (FST) and the spontaneous locomotor activity was assessed using the open field test (OFT). Treatment with cholecalciferol in high dose (5.0 mg/kg/day, s.c.) significantly decreased immobility time of OVX rats in the FST. Co-administration of cholecalciferol in high dose with 17 β -E₂ exerted a markedly synergistic antidepressant-like effect in the OVX rats on the same model of depression-like behavior testing. Cholecalciferol in high dose administered alone or together with 17 β -E₂ significantly enhanced frequency of grooming of the OVX rats in the OFT. Moreover, cholecalciferol in high dose administered alone or together with 17 β -E₂ significantly decreased the elevated corticosterone levels in the blood serum of OVX rats following the FST. These results indicate that cholecalciferol in high dose has a marked antidepressant-like effect in the adult female rats with low levels of estrogen. The data also indicate that the combination of cholecalciferol in high dose and 17 β -E₂ is more effective than 17 β -E₂ alone in OVX rats inducing a more profound antidepressant-like effect in the FST.

Russian Science Foundation (RSF) funded the reported study accordingly to the research project № 16-15-10053.

Does committed action act as a buffer against the impact of shame on depression?

C. Ferreira*, J. Marta-Simões, I.A. Trindade, A.L. Mendes
Faculty of Psychology and Education Sciences University of Coimbra, CINEICC, Cognitive Behavioural Centre for Research and Intervention, Coimbra, Portugal

* Corresponding author.

Committed action is defined as the ability to take action guided by personal life values, i.e., to be persistent in valued behaviours even when such pursuit implicates facing setbacks and experiencing discomfort. This is a key process for acceptance and commitment therapy, and is linked to several positive mental health outcomes. Although current literature has stressed the pervasive impact of shame on psychopathology, especially on depression, data concerning the role of committed action on the impact of shame on depression is considered insufficient. Considering these premises, the current study intended to explore the moderator role of committed action in the relationship between external shame and depressive symptomatology, in an adult sample of 178 participants of both sexes. Path analysis' results showed that shame holds a positive effect on depression ($\beta = 1.19, P < .001$), and that committed action serves as a moderator of the effect of shame on depression ($\beta = -.63, P < .010$). The tested model accounted for 45% of the variance of depression symptoms. A graphical representation allowed to observe that committed action presents a buffer effect for the harmful impact of shame on symptoms of depression. That is, at any level of shame experienced, those individuals who revealed higher levels of committed action showed less depression symptoms. This study has corroborated the powerful effect of external shame on depression symptoms, which was found to be buffered by committed action. The present findings thus highlight the pertinence of identifying personal life values and motivating committed action, particularly in prevention and intervention programs for depression.

* Corresponding author.

Introduction Depression is a common companion of systemic lupus erythematosus that substantially contribute to patient's suffering and a decreased quality of life. The relationship between depressive symptoms and disease immune processes is not well understood.

Objectives To further understand the relationship between lupus and depression, a patient cohort was examined for correlations between clinical presentation, biological parameters and psychosocial evaluation.

Methods Seventy-two lupus patients were screened for depressive symptoms, clinically and psychologically characterized using a battery of instruments, including assessments for depression, anxiety, fatigue, pain and overall health. Scores from these assessments were correlated with lupus clinical profile and biological parameters namely the immune profile.

Results Forty-two percent of the patients had scores indicative of depression using the HADS Depression scale. Strong correlation was found between pain and depression. Moderate correlation was found between several lupus symptoms, such as mouth ulcers, rash, and arthritis, and psychological evaluation. There was low to moderate correlation between complement levels, C-reactive protein and psychological indicators, but no other lab tests correlated well with the psychological tests.

Conclusion The correlation of depressive symptoms, complement and C-reactive protein with depressive symptoms suggests that these may be mediated by disease activity and share pathophysiological mechanisms. The overall weakness of correlations with biological markers demonstrates that more specific tests need to be developed. The study of lupus associated depression may, furthermore clarify the role of immune dysfunction in the pathophysiology of this psychiatric disorder.

Introduction Depression is one of the most common mental illnesses in the elderly and its consequences are severe.

Aims To measure the prevalence of depression in elderly cancer patients and subsequently determine the sociodemographic and clinical factors correlated with this disorder.

Methods We conducted a descriptive and analytical cross-sectional study of patients aged over than 65 years old, suffering from cancer and who had no cognitive impairment, admitted in 2013 in the Oncology and palliative care unit of Gabes regional Hospital (Tunisia). We used a self-rating questionnaire to detect sociodemographics and clinical variables, the Geriatric depression scale (GDS) to assess depressive symptoms, and the Activity of Daily Living to determine the degree of autonomy.

Results At the end of our investigation, we included 60 patients. The prevalence of depression was 48%. Depression was significantly correlated with: marital status (widower subjects were more depressed (74% vs. 34%, $P=0.007$)), less degree of autonomy (80% vs. 38%, $P=0.04$), fatigue (62% vs. 26%, $P=0.007$), pain (59% vs. 26%, $P=0.02$), family psychiatric history (80% vs. 20%, $P=0.02$), family history of death by cancer (72% vs. 38%, $P=0.01$), WHO condition (67% vs. 34%, $P=0.04$) and the presence of co morbidity in particularly diabetes (69% vs. 41%, $P=0.05$).

Conclusion Depression is prevalent in oncogeriatric environments. This could compromise quality of support and care of these patients. Close collaboration between oncologist and psychiatrist is needed to support and relieve these patients.

Depressive symptomatology and language perception in young women

V. Giannouli^{1,*}, N. Syrmos²

¹ Aristotle University of Thessaloniki, School of Medicine, Drama, Greece

² Aristotle University of Thessaloniki, School of Medicine, Thessaloniki, Greece

* Corresponding author.

Introduction Depression may have numerous effects on cognition. A little investigated topic is the perception of the grammatical gender.

Objective The aim of this study is to examine whether there is a different understanding of grammatical gender in Greek-speaking young women with and without depressive symptomatology regarding names of cars that are female or neutral according to the modern Greek language.

Method Two-hundred fourteen women from Greece (Mean age = 19.59, SD age = 3.60, 18 min–50 max) were examined with the ZUNG Self Rating Depression Scale and a language test that comprised of 38 names of car brands, which were characterized in linguistics either as female or neutral. Half of women scored high in the ZUNG Depression scale.

Results Results indicated that overall there are no statistically significant differences between women with or without depression in their gender perception of the words ($P > .005$). In addition to that, there are no statistically significant differences between the names of car brands that are related to large size cars and/or expensive car models.

Conclusions This research suggests that although there is a tendency to consider the existence of depressive symptomatology as detrimental on cognition, this does not seem to hold true for the perception of the gender of the words as examined by linguistics.

Seasonal affective disorder (SAD) and light therapy: State of the science

C. Glod

Merrimack College, Academic Affairs, North Andover, USA

Major depression with a fall/winter seasonal pattern, also known as seasonal affective disorder (SAD), is a recurrent and prevalent disorder. Treatment may include either pharmacological (antidepressant) or non-pharmacological options, most commonly light therapy. Over the years, light therapy has been explored using various delivery methods including light-emitting diode (LED) devices. For over 20 years, cool-white fluorescent sources that yield 10,000 lux of polychromatic white light have been the standard treatment for SAD. Many investigations have confirmed the clinical effectiveness of white light, its overall tolerability, and adverse reactions, such as agitation, insomnia, and headache. Building upon this, more recent studies have compared alternative light sources and different wavelengths of light, such as white, red, green, and blue. If certain wavelengths are more potent and effective, lower intensities of light could reduce side effects and increase tolerability and adherence. Furthermore, studies of the ocular system particularly, intrinsically photosensitive retinal ganglion cells, discovered differences among specific wavelengths of light. While some reports have suggested that 446–477 nm wavelengths of blue light may be the most potent, published clinical trials have revealed mixed results. The purpose of this session is to review the state of the science on light therapy in the treatment of SAD, and suggest recommendations for clinical practice and implications for patients.

Association of activation syndrome with life-time hypomanic symptoms and Ghaemi criteria

O. Gökçen^{1,*}, S. Özer²

¹ Dumlupınar University, psychiatry, kütahya, Turkey

² Hacettepe University Faculty of Medicine Department of Psychiatry, Hacettepe University Faculty of Medicine Department of Psychiatry, Ankara, Turkey

* Corresponding author.

Objective Activation syndrome consists of 10 suicides associated symptoms, which is induced by antidepressant treatment. These are anxiety, agitation, manic episodes, sleep disruption, irritability, hostility, aggressiveness, impulsivity, akathisia and mania/hypomania. This syndrome is reported to be associated with a bipolar disorder diathesis. The aim of this study is to evaluate lifetime hypomanic symptoms with major depressive disorder, who are prescribed antidepressant medication, and to investigate whether there is a relationship between these symptoms and the development of AS.

Methods Sixty consecutive outpatients with the diagnosis of major depressive disorder who were naturalistically given antidepressant treatment were examined prospectively. Patients were assessed three times; at baseline, 2 and 4 weeks later. At baseline visit, clinical characteristics of patients including Ghaemi criteria were assessed, life-time history of hypomanic symptoms were assessed with the Hypomania-Checklist-32. In all three interviews, Barnes Akathisia Rating Scale, Hamilton Rating Scale for Depression, Hamilton Anxiety Rating Scale and Young Mania Rating Scale were applied to detect the symptoms of AS. The patients who present at least one of the 10 symptoms were considered to have AS.

Results Of the 60 patients 25(41.7%) developed AS. The most prevalent symptoms of AS are insomnia (31.7%), anxiety (25%) and irritability (15%). Significant difference was found between patients with and without AS, with regard to HCL-32 test scores. A moderate correlation between the number of AS symptoms and HCL-32 test scores were determined. AS was found to be significantly more frequent in patients with mere hypersomnia and both increased appetite and hypersomnia those without these symptoms.

Disclosure of interest The findings of this study suggest that certain features of BPS might be associated with the development of AS. Antidepressant treatment of depressive illnesses in this spectrum which are misdiagnosed as unipolar may reveal these symptoms that will complicate the current episode and destabilize the longitudinal course. For this reason, clinicians should evaluate the patients who present antidepressant induced symptoms meticulously and be careful not to overlook the characteristics of BPS.

Reduced latency to first antidepressant treatment in Italian patients with a more recent onset of major depressive disorder

B. Grancini*, B. Dell'Osso, L. Cremaschi, F. De Cagna, B. Benatti, G. Camuri, C. Arici, C. Dobrea, L. Oldani, M.C. Palazzo, M. Vismara, A.C. Altamura

Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico-University of Milan, Department of Psychiatry, Milano, Italy

* Corresponding author.

Introduction Major depressive disorder (MDD) is a prevalent burdensome disease, which frequently remains untreated. The duration of untreated illness (DUI) is modifiable parameter and a valid predictor of outcome. Previous investigation in patients with MDD revealed a DUI of different years, while recent reports have documented a reduction of DUI across time, in patients with different psychiatric disorders.

Objectives/aims The present study was aimed to investigate potential differences in terms of DUI and related variables in patients with MDD across time.

Methods An overall sample of 188 patients with MDD was divided in two subgroups on the basis of their epoch of onset (onset before and after year 2000). DUI and other onset-related variables were assessed through a specific questionnaire and compared between the two subgroups.

Results The whole sample showed a mean DUI of approximately 4.5 years, with a lower value in patients with more recent onset compared to the other subgroup (27.1 ± 42.6 vs. 75.8 ± 105.2 months, $P < .05$). Moreover, patients with onset after 2000 reported higher rates of onset-related stressful events and lower ones for benzodiazepines prescription (65% vs. 81%; $P = 0.02$; 47% vs. 30%; $P = 0.02$).

Conclusions The comparison of groups with different epochs of onset showed a significant reduction in terms of DUI and benzodiazepines prescription, and a higher rate of onset-related stressful events in patients with a more recent onset. Reported findings are of epidemiologic and clinical relevance in order to evaluate progress and developments in the diagnostic and therapeutic pathways of MDD in Italian and other countries.

* Corresponding author.

Introduction Various studies showed the efficacy and tolerability of WS[®] 5570 (Hyperiplant[®] Rx, Dr. Willmar Schwabe GmbH & Co. KG) for the treatment of acute mild-to moderate depression. Beneficial effects of WS[®] 5570 have been also shown in patients with moderate-to-severe depression.

Objectives/aims We present a subgroup analysis of a double blind, randomised trial to compare the therapeutic efficacy of WS[®] 5570 with paroxetine in patients suffering from a major depressive episode with moderate symptom intensity. This analysis on moderately depressed patients treated with WS[®] 5570 tries to support the hypothesis that WS[®] 5570 is an effective remedy in patients with major depression and moderate symptom intensity.

Methods Moderate depression was defined by a baseline Hamilton Depression Rating Scale (HAM-D) total score between 22 and 25. Sixty-four patients received, after a single blind placebo run-in phase of 3–7 days, either 3×300 mg/day WS[®] 5570 or 20 mg/day paroxetine for six weeks. The change of the HAM-D total score was used to describe the efficacy of WS[®] 5570 compared with paroxetine in the subgroup of patients with moderate depression.

Results The reduction of the HAM-D total score was significantly more pronounced in patients treated with 3×300 mg/day WS[®] 5570 compared to 20 mg/day paroxetine. After six weeks, responder (87.1%) and remission rates (60.6%) to WS[®] 5570 were significantly higher than to paroxetine (71%/42.4%).

Conclusions After six weeks, patients treated with WS[®] 5570 showed a higher reduction in depression severity score and yielded greater response and remission rates compared with patients treated with paroxetine.

The Association between self-stigma and coping strategies in depressive disorder—a cross-sectional study

M. Holubova^{1,2,*}, J. Prasko¹

¹ University of Palacky Olomouc, Department of Psychiatry, Olomouc, Czech Republic

² Regional Hospital Liberec, Department of Psychiatry, Liberec, Czech Republic

* Corresponding author.

Background Self-stigma is a maladaptive psychosocial phenomenon that may disturb many areas of patient's life. In connection with maladaptive coping strategies should make mental health recovery more difficult. Specific coping strategies may be connected with the self-stigma and also with the severity of the disorder. The objective of the study was to explore the relationship between coping strategies, the severity of the disorder and self-stigma in outpatients with depressive disorder.

Method Eighty-one outpatients, who met ICD-10 criteria for depressive disorders, were enrolled in the cross-sectional study. Data on sociodemographic and clinical variables were recorded. All probands completed standardized measurements: The Stress Coping Style Questionnaire (SVF-78), the Internalized Stigma of Mental Illness Scale (ISMI), and the Clinical Global Impression (CGI).

Results The patients with depression overuse negative coping strategies, especially escape tendency and resignation. Using of positive coping is in average level. Coping strategies are significantly associated with the self-stigma. Negative coping (especially resignation and self-accusation) increase the self-stigma, using of positive coping (primarily underestimation, reaction control, and positive self-instruction) have a positive impact to decreased self-stigma. The level of self-stigma correlated positively with total symptom severity score.

Conclusions The present study revealed the important association between coping strategies and self-stigma in outpatients with depressive disorders. Decreasing the use of negative strategies, and strengthening the use of positive coping may have a positive impact to self-stigma reduction.

* Corresponding author.

Introduction The international guideline for treating depression has been widely used.

Objectives The current study focused on the maintenance treatment section of the third revision of Korean Medication Algorithm for Depressive Disorder (KMAP-DD)

Methods A 44-item questionnaire was used to obtain the consensus of experts regarding pharmacological treatment strategies for depressive disorder. Of the 144 committee members, 79 psychiatrists responded to the survey. Each treatment strategy or treatment option was evaluated with the nine-point scale.

Results Most clinicians answered to maintain both antidepressants (AD) and atypical antipsychotics (AAP) for psychotic depression in remission state. The duration of AD maintenance: from 19.8 weeks to 46.8 weeks for patients in remission of the first episode, from 34.8 weeks to 78.4 weeks for the second depressive episode, and long-term continuation for three or more depressive episodes. Aripiprazole was the most preferred AAP. The preferred doses of AD and AAP in maintenance treatment were about 75% and 50% of those in acute treatment. The maintenance of AAP in the psychotic depression in remission was similar to the AD, although shorter and less.

Conclusions The maintenance strategies of KMAP-DD 2017 were similar to those of KMAP-DD 2012. Most clinicians preferred to maintain AD for substantial duration after achieving remission. The maintenance of AAP was also preferred, but the duration was shorter than AD.

² University of Bristol, School of Social and Community Medicine, Bristol, United Kingdom

³ Bath Spa University, School of Society- Enterprise and Environment, Bath, United Kingdom

⁴ Swansea University Medical School, Farr Institute, Swansea, United Kingdom

* Corresponding author.

Introduction Emerging evidence suggests that sedentary behaviour, specifically time spent taking part in screen-based activities, such as watching television, may be associated with mental health outcomes in young people [1]. However, recent reviews have found limited and conflicting evidence for both anxiety and depression [2].

Objectives The purpose of the study was to explore associations between screen time at age 16 years and anxiety and depression at 18.

Methods Subjects ($n = 1958$) were from the Avon Longitudinal Study of Parents and Children (ALSPAC), a UK-based prospective cohort study. We assessed associations between screen time (measured via questionnaire at 16 years) and anxiety and depression (measured in a clinic at 18 years using the Revised Clinical Interview Schedule) using ordinal logistic regression, before and after

adjustment for covariates (including sex, maternal education, family social class, parental conflict, bullying and maternal depression). **Results** After adjusting for potential confounders, we found no evidence for an association between screen time and anxiety (OR = 1.02; 95% CI 0.95–1.09). There was weak evidence that greater screen time was associated with a small increased risk of depression (OR = 1.05, 95% CI 0.98–1.13).

Conclusions Our results suggest that young people who spend more time on screen-based activities may have a small increased risk of developing depression but not anxiety. Reducing youth screen time may lower the prevalence of depression. The study was limited by screen time being self-reported, a small sample size due to attrition and non-response, and the possibility of residual confounding. Reverse causation cannot be ruled out.

Cross-cultural adaptation, reliability, and validity of the revised Korean version of Ruminative Response Scale

W. Kim

Inje University Seoul Paik Hospital, Psychiatry, Seoul, Republic of Korea

Objective Rumination is a negative coping strategy defined as repetitive and passive focusing on negative feelings such as depression. The Ruminative Response Scale (RRS) is a widely used instrument to measure rumination, but there is continuing argument about the construct validity of the RRS, because of probable overlap between the measurement of depression and that of rumination. The RRS-Revised, which removed 12 items of the RRS, is suggested as a more valid instrument for measuring rumination. Therefore, we translated RRS-R into Korean and explored the reliability, validity and factor structure in patients with major depressive disorders.

Methods Seventy-nine patients with major depressive disorder took the Korean version of RRS, RRS-R, State Trait Anxiety Inventory, Beck Depression Inventory and Penn State Worry Questionnaire. We performed exploratory factor analysis of RRS-R, and tested construct validity, internal reliability and test-retest reliability.

Results The internal and test-retest reliability of RRS-R was high. Factor analysis revealed that RRS-R is composed of two factors. “Brooding” factor explained 56.6% and “Reflection” factor explained 12.5%. RRS-R, especially “Brooding” factor, was highly correlated with other clinical symptoms such as depression, anxiety and worry.

Conclusions In this study, we find out the RRS-R is more reliable and valid than the original RRS in Korean patients with depression because the RRS-R is free from the debate about the overlap of item with BDI. We also revealed that “Brooding” is highly correlated with depressive symptoms. RRS-R may be a useful instrument to explore the implication of “Brooding” in depression.

The role of disturbed circadian clocks in the development of depression-like behavior and metabolic comorbidity in mice

D. Landgraf^{1,*}, R. Barandas², J.E. Long¹, C.D. Proulx³, M.J. McCarthy¹, R. Malinow³, D.K. Welsh¹

¹ *University of California- San Diego, Department of Psychiatry and Center for Circadian Biology, San Diego, USA*

² *Hospital de Santa Maria- Centro Hospitalar Lisboa Norte, Department of Psychiatry, Lisbon, Portugal*

³ *University of California- San Diego, Department of Neurosciences, San Diego, USA*

* *Corresponding author.*

Major depressive disorder (MDD) is often associated with disturbed circadian rhythms. However, a definitive causal role for functioning circadian clocks in mood regulation has not been established. We stereotactically injected viral vectors encoding short hairpin RNA to knock down expression of the essential clock gene *Bmal1* into the brain's master circadian pacemaker, the suprachiasmatic nucleus (SCN). In these SCN-specific *Bmal1*-knockdown (SCN-*Bmal1*-KD) mice, circadian rhythms were greatly attenuated in the SCN. In the learned helplessness paradigm, the SCN-*Bmal1*-KD mice were slower to escape, even before exposure to inescapable stress. They also spent more time immobile in the tail suspension test and less time in the lighted section of a light/dark box. The SCN-*Bmal1*-KD mice also showed an abnormal circadian pattern of corticosterone, and an attenuated increase of corticosterone in response to stress. Furthermore, they displayed greater weight gain, which is frequently observed in MDD patients. Since the circadian system controls important brain systems that regulate affective, cognitive, and metabolic functions, and neuropsychiatric and metabolic diseases are often correlated with disturbances of circadian rhythms, we hypothesize that dysregulation of circadian clocks plays a central role in metabolic comorbidity in psychiatric disorders. In fact, circadian rhythm disturbances have been linked to individual psychiatric and metabolic disorders, but circadian aspects of such disorders have not been considered previously in an integrated manner. Treating and preventing disturbances of circadian clocks in patients suffering psychiatric and metabolic symptoms may be a central element for therapies targeting both disorders concurrently.

Cerebral correlates of emotional interference processing in the elderly with subthreshold depression: A functional fMRI study

J. Li*, H. Zhou

Chinese Academy of Sciences, Institute of Psychology, Beijing, China

* *Corresponding author.*

Introduction Compared to healthy controls, adults with major depressive disorder (MDD) showed stronger activation in dorsolateral prefrontal cortex (DLPFC) and anterior cingulate cortex (ACC) in resolving emotional conflict. Whether subthreshold depression (StD) at an advanced age is also accompanied by similar changes in brain activation in coping with emotional conflict remained unknown.

Objectives By using face-word Stroop task, the current study explored the neural correlates of emotional interference processing in old adults with StD.

Methods Participants were 19 community-dwelling older adults with StD assessed by the Center for Epidemiologic Studies Depression scale (CES-D) scores. We collected magnetic resonance images of their brain compared to images of 18 healthy aged-matched adults. We used SPM to analyze differences in brain activations in emotional interference processing between the two groups.

Results Results showed that elderly individuals with StD have stronger activation in DLPFC, ACC, default mode network (DMN) and visual extrastriate cortex compared to healthy controls. Furthermore, the brain activations of the DLPFC, DMN and visual extrastriate cortex were significantly associated with participants' behavioral interference effect in StD.

Conclusions Stronger brain activation in DLPFC, ACC, DMN and extrastriate cortex in old adults with StD suggests that the working efficiency of their brain is quite low and their cognitive control is impaired to some extent.

Clinico-psychopathological features of the resistant depression

S. Lukmonov*, N. Yadgarova

Tashkent Medical Academy, Psychiatry and Narcology, Tashkent, Uzbekistan

* Corresponding author.

Objective To study the clinical - psychopathological characteristics of patients with resistant depression.

Materials and methods We examined 96 patients aged 18–48 years (mean age 34.70 ± 1.0 years). The investigated patients were divided into two groups: 1st -TRD with positive affectivity - 59 (61.4%); 2nd - curable depression - 37 (38.6%). Selection of patients was made according to following criteria: ICD - 10: (F31) - bipolar disorder; (F32) - depressive episode; (F33) - recurrent depressive disorder.

Results In group 1 patients received amitriptyline (TCA) - 50 mg - 2 times/day in one of 2 consecutive courses (within 6 weeks) and they showed no clinical benefit. In group 2 patients received amitriptyline - 50 mg 2 times/day for 2 consecutive courses. When analyzing the number of depressive episodes the statistically greater number was observed 1–3 episodes in group 2 - in 45.9% of patients than in group 1 - 16.9%, predominant 5–8 episodes - in 44.1% of patients in group 1, than in group 2 - 13.5%. Remissions, observed in group 2, were characterized by longer duration and have a higher quality than in patients of group 1.

Conclusion The highest correlation dependence showed such factors as: frequency of depressive episodes, duration of episode 1, severity of depressive episode 1, quality of remission after depressive episode 1, number of responders at early stages of antidepressant therapy of I-st attack.

Comparison of behavioral activation therapy and treatment as usual among depressed patients in secondary psychiatric care

K. Luoto^{1,2,*}, A. Koivukangas^{1,2}, A. Lassila², E. Leinonen¹, O. Kampman^{1,2}

¹ University of Tampere, Psychiatry, Tampere, Finland

² The Hospital District of South Ostrobothnia, Psychiatry, Seinäjoki, Finland

* Corresponding author.

Introduction Evidence-based brief therapies are needed to reduce a marked heterogeneity affecting treatment of depression within the public psychiatric care. They should be easy to implement and use for a large group of patients.

Objectives To develop and implement an effective brief treatment protocol for depressed patients treated in public psychiatric secondary care.

Aim To explore and compare the outcome of depressed patients receiving either behavioral activation therapy (BA) or treatment as usual (TAU).

Methods Two hundred and forty two depressive patients referred to adult public secondary psychiatric care formed the BA treated study group. The TAU treated control group ($n = 205$) was collected from the hospital districts database and matched by the hospitalization rate, Alcohol Use Disorders Identification Test (AUDIT) and Beck Depression Inventory (BDI). All patients received anti-depressive medications. In the study group, Montgomery–Åsberg Depression Rating Scale (MADRS) was conducted four times within 24 months follow-up. In both groups, the ability of functioning was controlled by Global Assessment of Functioning scale (GAF).

Results In the study group, depressive symptoms alleviated systematically and significantly during follow-up (Table 1). The improvement in GAF scores was significantly better in the study group throughout the follow-up (Table 1).

Conclusions BA can be implemented and used effectively for depressive patients in public psychiatric secondary care. BA is superior to TAU in terms of functional recovery.

Table 1

	Follow-up (months from baseline)	Group	N	Mean	SD	p	Effect Size
Δ MADRS ¹	6	study	156	9.9	9.8	<0.001	1.02 ³

Body appreciation: A buffer against the impact of shame on depression

J. Marta-Simões*, C. Ferreira, A.L. Mendes

Faculty of Psychology and Education Sciences, University of Coimbra, CINEICC, Cognitive-Behavioral Center for Research and Intervention, Coimbra, Portugal

* Corresponding author.

Shame is defined as a painful affect, associated with the perception that one's personal characteristics and/or behaviours are seen by others as unattractive. Since it signals the possibility of rejection, high levels of shame associate with high psychological suffering and several psychopathological conditions, namely depression. In contrast, body appreciation is considered a set of attitudes of acceptance and affection towards one's body image, even when one is displeased with certain body characteristics, being therefore a disposition to self-soothing and care. Taking into account the association of body appreciation with healthy mental functioning, this study aimed at exploring the buffering effect of body appreciation against shame's impact on the display of depression symptoms. This hypothesis was tested through path analysis in a community sample of adult men and women. Results revealed body appreciation as a significant moderator of the association between external shame and depressive symptomatology. The tested model explained 45% of the variance of depressive symptomatology. A graphical representation allowed understanding that this moderator effect is particularly expressive in those who experience medium to high levels of shame. In these cases, men and women who present higher body appreciation tend to display fewer depression symptoms. These results seem to emphasize the importance of establishing a positive relationship with one's own body image, which appears to be protective either for men's and women's mental health. Considering its buffering effect of shame's impact on depression, upcoming interventions in this area could benefit from the assessment and cultivation of positive body image.

EV0396

Type D personality and metabolic syndrome in patients with depressionM. Martinac^{1,*}, D. Babić², M. Pavlović²¹ Public Health Centre Mostar, Centre for Mental Health, Mostar, Bosnia and Herzegovina² University hospital Mostar, Department of Psychiatry, Mostar, Bosnia and Herzegovina

* Corresponding author.

Introduction Pathogenesis of metabolic syndrome (MS) and depression (MDD) is complex and insufficiently explored. In addition to chronic stress, psychotrauma, hypercortisolemia and immunological factors, some personality features may have an impact. Type D personality, most influential personality type in psychosomatic medicine, consists of two dimensions: negative affect (NA) and social inhibition (SI). Individuals with type D personality are more anxious, irritable and depressed and they do not share these emotions with others because of their fear of rejection. Type D personality was proven to be a risk factor for some MS components, as well as for the occurrence of depressive symptoms in cardiac patients.

Aim To investigate the association of type D personality with MS and its components in MDD patients.

Methods Cross-sectional study was conducted on the sample of 80 patients with depression and 40 healthy subjects as the control group. Mini International Neuropsychiatric Interview (MINI ques-

tionnaire) and Hamilton Rating Scale for Depression (HDRS-17) were used for the diagnosis of depression. Type D personality was determined by DS14 questionnaire. The MS diagnosis was made according to ATP III criteria.

Results The presence of type D personality did not significantly contribute to the probability of developing MS in patients with depression. NA was associated with abdominal obesity, low HDL-cholesterol and hypertension.

Conclusion Negative affect was proven to be an independent risk factor in the pathogenesis of obesity, hypertension, and reduced level of HDL-cholesterol, while type D personality in general did not have predictive value for the MS development.

Peculiarities of depressive disorders of “working” emigrants and re-emigrantsN. Maruta^{*,1}, O. Venger²¹ Institute of Neurology, Psychiatry and Narcology of National Academy of Medical Science of Ukraine, SI, Borderline pathology, Kharkiv, Ukraine² State Higher Educational Institution, I. Ya. Horbachevskyi's, Ternopil State Medical University of the Ministry of Health of Ukraine, Neurology, Psychiatry, Narcology and Medical Psychology, Ternopil, Ukraine

* Corresponding author.

Introduction The problem of emigration and re-emigration in Ukraine is among the most actual state and social problems.

Objectives To research clinical-psychopathological peculiarities of depressions in “working” emigrants and re-emigrants.

Methodology The investigation was carried out in Ternopil Region. Psychogenic depressive disorders (F43.21 and F43.22 according to ICD-10) were diagnosed in 69 non-emigrants, 68 emigrants, and 67 re-emigrants; endogenous ones (F31.3, F31.4, F32.1, F32.2, F33.1, and F33.2 according to ICD-10) were diagnosed in 65, 66, and 63 persons correspondingly; and organic ones (F06.3 according to ICD-10) were diagnosed in 64, 62, and 61 persons correspondingly.

Results It was found out an influence of emigration and re-emigration factors on psychoemotional sphere of the patients. The influence of the emigration factor was the most manifested in patients with psychogenic depressive disorders and was a less manifested in patients with endogenous and organic depression. Re-emigrants had the most severe depressive symptoms that might be explained by an impact of psychosocial factors. In the syndromological structure of depressive disorders it was determined that re-emigrants were more affected by typical affective syndromes – vital and apathic depression, whereas emigrants were more affected by atypical affective syndromes, including anxious-depressive and agitation ones. It might be explained by an influence of objective social-psychological factors as well as an intrapsychic transformation of actual stressors connected with emigration and re-emigration.

Conclusions Emigration should be considered as a factor promoting a pathologically characterological development towards anxious-depressive changes, whereas re-emigration should be considered as a factor of asthenic-depressive and apathic-depressive transformations.

* Corresponding author.

Introduction Data on accordance and clinical significance of objective (doctor, psychometric scales) and subjective (patient with depression) assessment of severity of depression are almost lacking. Aim of the multicenter study "EMOTION" was to compare prognostic value of doctor's and patient's assessment of depressive symptoms severity as for its grading and treatment outcome.

Method Study sample consist of 107 depressive patients. The study used clinical and psychometric (HDRS, SHAPS, CGI-S, CGI-I, PGI-S, PGI-I, Visual Analog Scale) methods.

Results Our data suggest that there's statistically significant ($P < 0.001$) discrepancy between doctors' (CGI-S) and patients' (PGI-S) assessment of depressive symptoms' severity at first visit. Concordant opinions were found only in "marked depression" (37.49% of doctors and 36.59% of patients) and in "borderline depression" (4.79% of doctors and 3.79% of patients). Otherwise, doctors' and patients' opinions were discordant. Doctors' scores were more extreme (severe and extremely severe depression); patients' scores were more "moderate". We have found inconsistency between HDRS and CGI-S scores. In the course of reduction of depression severity during antidepressive treatment (agomelatine) doctors' and patients' scores were more and more in line with each other.

Conclusion We have found leveling of prognostic value of psychometric assessment of depression severity by doctors and patients (in terms of reduction of depressive symptoms severity and treatment outcome) during antidepressive therapy. It is possible that in some HDRS items scores were overestimated.

Comorbid depression and ulcerative colitis – is there a connection?

A. Melada*, I. Krišto-Madžura, A. Vidović

CH Dubrava, Department of Psychiatry, Zagreb, Croatia

* Corresponding author.

Ulcerative colitis (UC) is a subset disorder of inflammatory bowel disease (IBD) with chronic course and symptoms such as fatigue, gastrointestinal pain, fever, etc. IBD is associated with psychological manifestations including depression and anxiety. There is an increased number of studies trying to link these comorbidities. The gut-brain axis is regulated by intestinal microbiota and this bidirectional communication including immune, neural, endocrine and metabolic mechanisms may bring us closer to

the answer. The following case concerns a 56-year-old patient with history of major depressive disorder who was in continuous psychiatric care and treated with antidepressants. Several years after the beginning of psychiatric treatment, he was hospitalized for diagnostic examination due to subfebrility of unknown etiology, but with no final somatic diagnosis. After two years he was referred to our department and at administration the patient showed symptoms of depression, anxiety, lack of motivation and suicidal thoughts and tendencies. Subfebrility was still present at that time. His psychopharmacotherapy was revised and there was a slight improvement in mood and behaviour. During outpatient follow-ups the symptoms of depression were still prominent and remission was not achieved even with modulation of antidepressant pharmacotherapy. The following year the patient was diagnosed with UC and started specific treatment after he presented with diarrhea in addition to subfebrility. Subsequently his mood improved, suicidal thoughts were diminished and ultimately remission was achieved. This case suggests that only after UC was being treated the psychiatric symptoms also withdrew which implicates that inflammatory mediators were involved in pathogenesis of depression.

C-reactive protein as predictor of antidepressant response in late onset depression

D.K. Mishra^{1,*}, U. Sardesai², R. Razdan³

¹ Resident, Department of Psychiatry, M.G.M., Medical College, Indore

² Assistant Professor, Department of Psychiatry, M.G.M., Medical College, Indore

³ Head Department of Psychiatry, M.G.M., Medical College, Indore

* Corresponding author.

Introduction Late-onset depression has been associated with history of vascular disease and atherosclerosis. As immune dysregulation is critically involved in vascular disease. We hypothesized that responsiveness of late onset depression can be associated with level of inflammatory markers in these subjects.

Objective Role of inflammatory mediator in antidepressant responses in late onset depression.

Aim To study C-reactive protein as predictor of antidepressant response in late onset depression.

Methods Depressed patient (as per ICD 10 DCR) age > 60 years recruited from department of psychiatry and complete clinical assessment done and base line depression severity measure on Hamilton Depression Rating Scale (HDRS). C reactive protein level was assessed at base line. Patient prescribed antidepressant medication and at 8 week follow up re assessed for depression severity in HDRS. Data analyzed with spss.21 and spearman correlation was used.

Result Mean age of responder ($n = 6$) 63.5 ± 4.9 year and HDRS at base line 16 ± 1.9 . Mean age of partial responder or non-responder ($n = 19$) 65.1 ± 6.1 year and HDRS at base line 18.5 ± 3.9 . Continuous decrease in depression severity during study period and antidepressant response rate was 24%. Base line CRP level had negative correlation with antidepressant responsiveness ($r = -0.6$, $P < 0.05$).

Discussion Late onset depression was less responsive to antidepressant medication and poor antidepressant response rate was associated with higher level of CRP in late onset depression. Document not received.

Comparison between patients with depressive disorders and healthy controls in resilience and coping skills

C. Molino*, P. Camera, L. Girardi, E. Gattoni, A. Feggi, C.M. Gramaglia, P. Zeppegno

University of Eastern Piedmont 'A. Avogadro', Traslational medicine, Novara, Italy

* Corresponding author.

Introduction Resilience in the psychiatric field, it is defined as the ability to recover from perceived adverse or changing situations through a dynamic process of adaptation. This process is influenced by personal characteristics, family and social resources and is expressed by positive coping skills. It is well known that resilience has an inverse relation with depression, however, the specific role of resilience in disorders like depression, personality disorders and psychosis is not fully understood.

Objectives Compare differences in resilience and coping skills in a sample of patients with depressive disorder in acute phase versus healthy controls.

Methods We are conducting a cohort study to the date we recruited 82 inpatients admitted in our psychiatric ward. The data have been gathered from the 1st December 2014 and they will continue to be collected until the 1st December 2016, the healthy controls are represented by 67 subjects with similar socio-demographic features.

Inclusion criteria are: diagnosis of depressive disorders or dysthymia according to DSM-IV-TR diagnostic criteria, age > 18 years, proper understanding of Italian language, willingness to give written informed consent. We compared them with healthy controls with similar socio-demographic features.

Patients' assessment includes the following tests:

- Resilience Scale for Adults (RSA);
- Brief-COPE Scale (Brief-COPE);
- Statistical analysis will be performed using SPSS for Windows, 21.0 (Armonk, NY: IBM Corporation).

Results Data collection is still ongoing.

Conclusions From a preliminary analysis of data, we assume that the levels of resilience and coping of our patients is reduced compared with controls, however the recruitment during the acute phase could significantly influence final results.

Efficacy of a hypericum extract (STW3-VI) – A reanalysis

J. Mueller*, C. Kolb

Steigerwald Arzneimittelwerk GmbH, Medical and Clinical Affairs Phytomedicine, Darmstadt, Germany

* Corresponding author.

Introduction The course of depression during therapy in studies is usually monitored by scales like HAMD. Also the course of single items of the HAMD during therapy might be of specific interest as some symptoms are of highly predictive value. Furthermore early improvement during antidepressive therapy is a new aspect which came into the focus.

Objectives The objectives of this study were to reanalyze clinical data regarding early improvement as well as specific symptoms or symptom cluster – like sleep disturbances.

Aims The aim of this study was to get deeper insight into the data structure of 2 RCTs ($n = 398$, 42 days treatment) comparing the efficacy of a hypericum extract (STW3-VI/900 mg once daily) to Placebo.

Methods Data structure was evaluated by comparing the total scores of the HAMD-17 to a single item analysis and by calculating the factorial structure of the end of treatment data. The treatment potential was evaluated by calculating a positive predictive value from day 7 to the end of treatment. ANCOVA, factor analysis and regression methods were used.

Results The single item analyses were widely comparable to the highly significant treatment differences of the total scores as it were the calculated subscales. The positive predictive value of the treatment was about 75%.

Conclusions The results underline the elsewhere proven treatment efficacy of STW3-VI regarding several new subscale aspects.

Disclosure of interest COI: The authors are employees of Steigerwald Arzneimittelwerk GmbH, Darmstadt, Germany.

Major depressive disorder history among patients who sought blepharoplasty operation in a private ophthalmology hospital in Saudi Arabia

D. Nagui Rizk^{1,*}, M. Abo Ghanima²

¹ Faculty of Medicine, Alexandria University, Neuropsychiatry, Alexandria, Egypt

² Magrabi Eye Hospital, Anesthesia, Jeddah, Saudi Arabia

* Corresponding author.

E-mail address: dalianagui82@hotmail.com (D. Nagui Rizk)

Background Much attention has focused on body dysmorphic disorder among patients undergoing plastic surgeries, but there has been little evaluation of their past history of major depressive disorder (MDD).

Aim To estimate the prevalence rate of past history of Major Depressive Disorder (MDD) in patients undergoing Blepharoplasty operation in a private ophthalmology hospital in Jeddah, Saudi Arabia.

Methods All patients who have undergone blepharoplasty operation during the period from 5 April to 4 October 2016 (6 months) were included. Previous psychiatric history was taken from the patients by psychiatric assessment and self-assessment questionnaire, diagnosis of Major Depressive Disorder (MDD) confirmed previously by consultant psychiatrists in patients' health records was included.

Results One hundred and forty-eight persons undergone blepharoplasty in the hospital from 5 April to 4 October 2016. They were 89 females (60%) and 59 males (40%). Among those 148 persons, 10 patients were previously diagnosed with major depressive disorder by consultant psychiatrists with a percentage of 6.8% where 5 were females (5.6% of 89 females) and 5 were males (8.5% of 59 males).

Conclusions The number of individuals who present for blepharoplasty operation with a history of Major Depressive disorder needs to take a special consideration. A link between MDD and cosmetic operation decision should be further studied.

Keywords Blepharoplasty; Major depressive disorder

Specificity in perceived social support in multiple sclerosis patientsE. Nikolaev^{1,*}, N. Vasil'eva²¹ Chuvash State University, Department of Social and Clinical Psychology, Cheboksary, Russia² Chuvash Republic Clinical Hospital, Neurology Unit, Cheboksary, Russia

* Corresponding author.

Introduction Social support is one of the functions of social relationships that modify stress. Social supportive resources play important role in helping patients to adjust to the disease. Not much is known about social support in multiple sclerosis patients while it is one of the available interpersonal resources.

Objectives and aims To examine the specificity in perceived social support in multiple sclerosis patients.

Methods The sample were 104 in-patients diagnosed with multiple sclerosis (both men and women; mean age 38, SD = 10). All patients included in this study filled out the 22-item Russian version of the social support questionnaire (F-SOZU-22, G. Sommer, T. Fydrich in 1989, adaptation developed by A. Kholmogorova in 2006). Among them there were patients with relapsing-remitting multiple sclerosis and secondary progressive multiple sclerosis.

Results The entire sample reported the normal level of social support. One can mention that multiple sclerosis patients did not differ in general level of perceived social support from the healthy subjects. The exception was the overall satisfaction of social support, which reflected its statistically higher level in multiple sclerosis patients ($P < 0.05$). Further analysis showed no significant differences in perceived social support in patients associated with gender factor and clinical forms of multiple sclerosis ($P > 0.05$).

Conclusions The perceived social support in multiple sclerosis patients is characterized by normal levels of its emotional and instrumental components and inclusion in the network of close social relationships. However, the patients of both genders do not feel stability of these relations and have a decreased sense of security that can be a significant risk factor for depression.

Personality disorders and affective temperament in unipolar and bipolar mood disorder

A. Nivoli*, L. Floris, M. Antonioli, L. Folini, L.F. Nivoli, P. Milia, L.I. Vento, C. Depalmas, L. Loretta

University of Sassari, Department of Psychiatry, Sassari, Italy

* Corresponding author.

Introduction Personality disorders (PD) and Affective temperaments (AT) have been considered vulnerability factors for the development of mood disorder (MD).

Objective To study the simultaneous presence of PD and AT in patients with DU and differences between unipolar depression (DD) and bipolar disorder BD.

Methods An observational study was conducted. Patients were administered the Temperament Evaluation of Memphis, Pisa, Paris and San Diego questionnaire (TEMPS-A) for AT and the Structured Clinical Interview for DSM IV Axis II Disorders (SCID-II) for PD. The interrelationships of the different PD and AT were studied by factor analysis (principal component analysis, PCA) (orthogonal rotation, Varimax).

Results Participants were 156 adult patients with MD, 37.1% with DD and 62.9% with BD. DD patients presented with significantly more paranoid PD ($P = 0.009$), depressive ($P = 0.029$), anxious ($P = 0.009$) and irritable temperament ($P = 0.006$) compared to BD.

PCA results showed four significant factors, explaining the 63.1% of total variance, corresponding to four potential groups of patients with specific PD and AT associations.

Conclusion The comorbidity between MD and PD and AT may differentiate DD from BD. Specific patterns of comorbidity may be useful as they may substantially influence the course of the mood disorders and how patients respond to treatment.

Depressive disorders: A multidimensional non-drug approach

S. Tafazzoli, A. Miloni, A. Quaderi, J. Palazzolo*

Universite de Nice, Psychology, Nice, France

* Corresponding author.

In Europe, 25% of the population suffers from one type of depressive disorders each year. When depression is diagnosed, one on two people will actually be given a medication e.g. antidepressant and benzodiazepine (when correlated to anxiety or sleep trouble); the relapse risk is about 50%. This pathology and its chemical treatment affect the individual's health and life balance, e.g. cognitive impairments, family circle and career. Plus, side effects might create dependence, inability to focus or drive, disinhibition leading to suicide attempts. In addition, it also affects society at an economic level.

Comparing prior research, there are many causes to depressive disorders, a fragile balance that allows depression to begin and last. These causes include psychological factors (personal history, loss, trauma) biological factors (genetic predisposition, neurochemical dysregulation, bacteria) and environment (stress, social interaction, family circle, physical environment). Due to their multiple causes and maintenance factors, we consider depressive disorders in a multidimensional clinic through non-drug approach treatment and prevention. In severe depressive disorders and resistant depression EMDR therapy has shown effective results. Taking in account the high chance of relapses (50%), we highlight regular physical activity as a prevention factor that diminishes relapses chances compared to medication. Furthermore, meditation practice impacts cerebral plasticity. Finally, an environmental approach through luminotherapy (increase serotonin precursor) or nutritherapy (bacterium balance) helps healing and prevents relapses. These therapies can be easily adapted to any population and institutional context.

Frequency of depressive disorders in a representative sample of Nicosia, CyprusI. Papapetrou^{1,*}, G. Charalambous², A. Sissouras³, E. Jelastopulu⁴¹ Frederick University of Nicosia, Cyprus, Postgraduate Program Health Management, Strovolos, Nicosia, Cyprus² Frederick University of Nicosia, Cyprus, Postgraduate Program Health Management, Nicosia, Cyprus³ University of Patras- Greece, Department of Operational Research and Management, Patras, Greece⁴ University of Patras, Greece, Public Health, Patras, Greece

* Corresponding author.

Introduction "Health Profile" of Nicosia was conducted in 2013–2014, within the framework of the program "Healthy Cities"

in order to collect and analyse information on the state of health and health-related behaviors of the citizens of Nicosia in Cyprus.

Aims To estimate the frequency of self-reported depressive disorders and examine burdening as well as factors influencing it.

Methods Based on the 2011 census, a cross-sectional study was carried out on a representative random stratified sample, which was selected to be interviewed, including 477 men and 525 women, from the city area. Participants answered a questionnaire, which required among other items on self-perceived physical and mental health. Participants were also asked the following questions: “Do you have/had in the past depression or/and anxiety?” and “Have you received a medical diagnosis for this disorder?”

Results Approximately 70% of the sample reported they had experienced anxiety and depression (37% moderate and 33% severe episodes). Diagnosed depression was reported by 4%. Severe depressive disorders were more frequently reported by women (41%, $P < 0.001$), older aged citizens (70.2%, $P < 0.001$) widowed/divorced (45.5%, $P < 0.001$), persons with lower family income (< 1000 €, 79.7%, $P < 0.001$) and among people with chronic diseases (45.3%, $P < 0.001$).

Conclusions The self-reported prevalence of anxiety and depression in the citizens of Nicosia is very high – probably reflecting a negative effect of the economic crisis –, and contrariwise diagnosis of the disorder is rarely provided and consequently therapy rarely offered. Specific population groups, such as women, elderly citizens, patients with chronic diseases are more vulnerable to depressive disorders requiring specialized medical attention.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Treatment with pegylated interferon alpha (PEG-IFN- α) in patients with chronic hepatitis C (CHC) is associated with depressive symptomatology more frequently than other inflammatory diseases treated with PEG-IFN- α .

Objectives To prospectively evaluate the onset, course and resolution of depressive symptomatology in CHC patients treated with PEG-IFN- α .

Methods Hamilton depression rating scale (HAMD) was used to assess depressive symptoms in 103 subjects with CHC prior to initiation of PEG-IFN- α (mean dose 152.6 ± 25.6 mcg; duration of therapy 48 weeks) and at the follow-up visits (4th, 12th, 24th, 48th and 72th week). Control group consisted of 103 CHC subjects, without PEG-IFN- α .

Results Our results showed a significant increase in HAMD scores as early as in the 4th week of PEG-IFN- α therapy compared to HAMD scores prior to initiation of PEG-IFN- α (38.8% vs. 24.3%). The peak of depressive symptomatology was evidenced in the 12th week (mean HAMD 9.34 ± 6.93), when almost 50% of patients had HAMD above 7. At the end of the treatment (48th week), 38.8% had HAMD above 7, and in the 72nd week (24 weeks after the therapy completion) prevalence of depression was decreased to the values lower than at baseline (23.3% vs. 24.3%). No change in prevalence of depression was detected in control group.

Conclusion Our results are important because they show the overall course of depressive symptomatology during the interferon therapy. These data also show spontaneously resolution of depression 6 months after the completion of PEG-IFN- α . This study is the longest study in this area.

⁴ University of Cádiz, Neuroscience Pharmacology and Psychiatry, Cádiz, Spain

⁵ CIBER of Mental Health CIBERSAM, Group 18, Cádiz, Spain

* Corresponding author.

Depressive Disorder, according to WHO will be one of the most disabling causes in the world. Depression includes psychological and somatic symptoms, like anhedonia or pain, and both have a bidirectional relationship, so that the presence and severity of one of them directly affects the other one, and both leads to a disruption in quality of life and increase health resources. The relationship between major depression and chronic pain has been widely investigated but few studies have focused on other depressive spectrum disorders, and never the possible relationship between pain and anhedonia in DD. Our aim is to analyse the presence of somatic symptoms (especially pain) in patients with DD and its impact on quality of life, and involvement with anhedonia. We analysed the correlation between the scores of the HADS, SSI-28, SHAPS and SF-36 scales. Results showed a significant correlation between SSI-28 and HADS-A ($r = 0.45$; $P < 0.001$), HADS-D ($r = 0.35$; $P < 0.001$) and with 7 of the 8 domains of SF-36: Bodily Pain ($r = -0.62$; $P < 0.001$), General Health ($r = -0.29$; $P = 0.003$), Role Physical ($r = -0.45$; $P < 0.001$) Mental Health ($r = -0.34$; $P = 0.003$), Vitality ($r = -0.403$; $P < 0.001$), Social Functioning ($r = -0.37$; $P < 0.001$). In addition, SHAPS correlates with 6 of the 8 domains of SF-36: PF ($r = -0.33$; $P = 0.001$), GH ($r = -0.27$; $P = 0.006$), Vit ($r = -0.41$; $P < 0.001$), SF ($r = -0.52$; $P < 0.001$), RE ($r = -0.24$; $P < 0.001$) and MH ($r = -0.49$; $P < 0.001$). The results demonstrate that both anhedonia and somatic symptoms negatively correlate with HRQoL, and that a bidirectional relationship between depression and somatic symptoms is clearly proven, which means that depression may be related with the presence of somatic symptoms, especially pain, and also somatic symptoms lead to an increase of depressive symptoms. This could impact on the diagnosis and treatment of depressed patients with somatic symptoms and anhedonia.

EV0410

The impact of depression on the human personality

M. Petrović

Specialized Psychiatric Hospital “Gornja Toponica”, APM, Gornja Toponica, Serbia

Depression is a common experience. We have all felt “depressed” about a friend’s cold shoulder, misunderstandings in our marriage, tussles with teenage children, sometimes we feel “down” for no reason at all. However, depression can become an illness when:

- the mood state is severe;
 - it lasts for 2 weeks or more and;
 - it interferes with our ability to function at home or at work.
- Signs of a depression includes:
- lowered self-esteem (or self-worth);
 - change in sleep patterns, that is, insomnia or broken sleep;
 - changes in appetite or weight;
 - less ability to control emotions such as pessimism, anger, guilt, irritability and anxiety;
 - varying emotions throughout the day, for example, feeling worse in the morning and better as the day progresses;
 - reduces capacity to experience pleasure: you cannot enjoy what’s happening now, nor look forward to anything with pleasure;
 - hobbies and interests drop off;
 - reduces pain tolerance: you are less able to tolerate aches and pains and may have a host of new ailments;
 - changes sex drive: absent or reduced;
 - poor concentration and memory: some people are so impaired that they think that they are becoming demented;
 - reduces motivation; it does not seem worth the effort to do anything, things seem meaningless;
 - lowers energy levels.

At the Institute, we believe that personality and temperament contribute to depression, particularly *non-melancholic* depression. Certain personality types are more at risk of developing depression than others.

Generally speaking, someone who is depressed would: have a low mood, be pessimistic, have lowered self-esteem and feel hopeless and helpless.

Introduction Antidepressant treatment, although it is effective to improve the manifestations of major depression, may also induce or exacerbate some symptoms of sexual dysfunction. Symptoms such as decreased libido, anorgasmia, delayed ejaculation, erection difficulty or dyspareunia, affect the quality of life of the subject who suffers and the self-esteem, can lead to lack of adherence to

treatment and in accordingly, the relapse of depressive symptoms. Serotonergic antidepressants are frequently associated with the onset of sexual dysfunction in sexually active patients exceeding 70%. Clinicians underestimate the actual incidence of dysfunction as the technical specifications of drugs show lower levels than 25% and spontaneous reports of patients do not exceed 20–40%.

Aims Vortioxetina is a reuptake inhibitor of serotonin (5-HT) and is also an agonist of the 5-HT1A partial agonist 5-HT1B and an antagonist of 5-HT3, 5-HT1D and 5-HT7. Apparently, this molecule at doses of between 5 and 15 mg is safe and effective and does not cause sexual dysfunction. It is a well-tolerated and safe, with low incidence of sexual dysfunction.

Methods To evaluate the action we have evaluated sexual dysfunction in patients with major depression before receiving treatment vortioxetina (whether state or not previously treated with other antidepressants) and at 2, 6 and 12 months after starting treatment with the drug. So we’ve used the SALSEx scale (Scale for measuring sexual dysfunction secondary to psychotropic drugs).

Results The results of this study are still being analyzed.

Introduction The major depression is associated with decreased cognitive functions in a range of areas, including attention, memory and executive functions. The cognitive symptoms of depression can have a profound effect on the ability of patients to keep out the tasks of daily living, and are significant factors that affect the ability to function both interpersonal and occupational level.

Aims Vortioxetina have a multimodal action acting on various serotonin receptors in addition to inhibiting serotonin reuptake. Vortioxetina, is a new therapeutic tool seems to have shown efficacy in the treatment of cognitive symptoms of depression.

Methods To evaluate this action we have evaluated the cognitive decline in patients with major depression before receiving treatment vortioxetina (whether state or not previously treated with other antidepressants) and at 2, 6 and 12 months after starting treatment with the drug. For that, we’ve used the Verbal Hearing Test King (RAVLT), which evaluates the auditory verbal short-term memory, the learning rate, the retention of information, and the differences between learning and recovery, and testing Digit substitution by symbols (DSST) that perform quick detection of brain dysfunctions by a conventional task.

Results The results of this study are still under analysis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The effect of subjective well being method on depression in high school studentsM. Pourshahriari^{1,*}, Z. Abrishami²¹ Alzahra University, Psychology, Tehran, Iran² Rozbeh hospital, Psychiatry, Tehran, Iran

* Corresponding author.

Introduction Depression has a large impact on individual, family and society. This disorder can start early in life and often go untreated. The aim of current research was to investigate the effectiveness of subjective well being method in reduction of depression in high school students by using a cluster random sampling four hundreds students were selected from five different areas. All subjects answered the Kovaks Depression Questionnaire and hundred (fifty boys and fifty girls) had been selected who were under the mean score. The subjects were randomly assigned to four groups, two experimental, two controls. The intervention was used in an hour and a half each week for twelve weeks fifteen.

Methods The data was analysed using manova that showed significant difference among experiment and control groups on depression scores. But there were no difference between sexes. The study suggest further study with longer intervention.

Standardization of Czech version of beck depression inventory (BDI II)R. Ptacek^{1,*}, J. Raboch¹, M. Vnukova¹, J. Hlinka², M. Cervenkova³¹ First Faculty of Medicine, Charles University, Department of Psychiatry, Prague, Czech Republic² Institute of Computer Science, The Czech Academy of Science, Prague, Czech Republic³ University of New York in Prague, Psychology, Prague, Czech Republic

* Corresponding author.

Introduction Depression is now the fourth most common cause of invalidity. World Health Organization (WHO) predicts that by 2020 it will be the second most common cause (WHO, 2001). Beck Depression Inventory (BDI II) is highly reliable tool for measuring the intensity of depression.

Methods The aim of this study was to assess the validity and reliability of the Czech version of BDI II. This was done on a representative sample of working population.

Results Results from 1027 participants were obtained. The sample was equally distributed among males and females. T-test showed that on average women suffered from higher depressive symptoms than males. Cronbach alpha showed high items consistency of 0,92 and confirmatory factor analysis found, as predicted, 3 factors: cognitive, somatic and affective.

Conclusion Cronbach alpha and factor analysis showed high internal consistency and reliability of Czech version of BDI II. Czech version of BDI II is thus not only a translation but can be considered a psychometric tool that is comparable with the original version. The results of this study are therefore comparable with other available results.

How does lifestyle affect depression?J. Raboch¹, R. Ptacek^{1,*}, M. Vnukova¹, S. Tkacova²¹ First Faculty of Medicine, Charles University, Department of Psychiatry, Prague, Czech Republic² University of New York in Prague, Psychology, Prague, Czech Republic

* Corresponding author.

Objective The aim of this study was to test the assumption that there seems to be association between depression and lifestyle choices. The hypothesis was that unhealthy lifestyle will have an association with increased score on BDI II.

Methods Czech version of BDI II was used and a questionnaire of lifestyle was distributed among Czech economically active population. Combination of interviews (for older population) and questionnaires (for younger population) was used. Stepwise multiple linear regression was applied to test whether and to what extent is lifestyle associated with depression.

Results In total data from 1027 participants was collected; 675 persons aged 25–50 years and 352 persons aged 51–65 years. The model explains 31% of variance of depression and the model is highly significant $F(8,1018) = 57.66, P = 0.001$. Lifestyle choices that were found to be associated with depression were sleeping habits, regular eating and drinking habits and generally conscious adherence to healthy lifestyle.

Conclusion Overall, an association was found between depression and certain lifestyle choices. Importantly it was also found conscious maintenance of healthy lifestyle is an important factor. This study thus confirmed the hypothesis that there is an association between depression and lifestyle. The most important factor of lifestyle in this study was shown to be regular sleeping pattern lasting at least 6 hours. Regular eating and maintaining drinking regime during the day were also found to be crucial.

Exploring perinatal depression symptom clusters as predictors of childbearing outcomesK. Records^{1,*}, M.J. Rice², Z.D. Apugan¹¹ University of Missouri St Louis, College of Nursing, St Louis, USA² University of Colorado Anschutz Medical Center, College of Nursing, Denver, USA

* Corresponding author.

Introduction Perinatal depression is related to poorer outcomes for women and their children. Measurement indices that categorize perinatal depression as present or absent are commonly used in clinical practice and research efforts. Categorization minimizes the health effects of potentially different symptom clusters and may confound understanding of health outcomes.

Objectives The objective of this investigation is to explore the symptom clusters resulting from administering two commonly used depression screening instruments during pregnancy and postpartum.

Aims (1) Identify the depressive symptom clusters for perinatal depression; (2) Test whether symptom clusters predict maternal and newborn outcomes, and if so, whether these differ from categorization analytics.

Methods A secondary analysis was conducted on data from a longitudinal study of 139 women. They participated from their 3rd trimester of pregnancy through 8 months after birth and completed surveys at five times using the center for epidemiologic studies Depressed Mood Scale (CES-D) and the Edinburgh Postna-

tal Depression Survey (EPDS). Analysis procedures included cluster analysis and hierarchical regression.

Results Individual symptoms were reported by 2.9–31.7% of the sample. Separate clusters (CES-D = 4; EPDS = 2) were identified and, of these, two clusters were primary predictors of maternal and newborn outcomes. Results differed from that obtained with cut-score analytics.

Conclusions Examination of depression symptom clusters as related to health outcomes during childbearing has significance for clinical practice and research, particularly for women who would not score as depressed on established screening instruments.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Health-related quality of life of primary care patients with depressive disorders

K. Riihimäki

Health Care and Social Services, MPY, Järvenpää, Finland

Background Depressive disorders are known to impair health-related quality of life (HRQoL) both in the short and long term. However, the determinants of long-term HRQoL outcomes in primary care patients with depressive disorders remain unclear.

Methods In a primary care cohort study of patients with depressive disorders, 82% of 137 patients were prospectively followed up for five years. Psychiatric disorders were diagnosed with SCID-I/P and SCID-II interviews; clinical, psychosocial and socio-economic factors were investigated by rating scales and questionnaires plus medical and psychiatric records. HRQoL was measured with the generic 15D instrument at baseline and five years, and compared with an age-standardized general population sample ($n = 3707$) at five years.

Results Depression affected the 15D total score and almost all dimensions at both time points. At the end of follow-up, HRQoL of patients in major depressive episode (MDE) was particularly low, and the association between severity of depression (Beck Depression Inventory, BDI) and HRQoL was very strong ($r = -0.804$). The most significant predictors for change in HRQoL were changes in BDI and Beck Anxiety Inventory (BAI) scores. The mean 15D score of depressive primary care patients at five years was much worse than in the age-standardized general population, reaching normal range only among patients who were in clinical remission and had virtually no symptoms.

Conclusions Among depressive primary care patients, presence of current depressive symptoms markedly reduces HRQoL, with symptoms of concurrent anxiety also having a marked impact. For HRQoL to normalize, current depressive and anxiety symptoms must be virtually absent.

Antidepressant withdrawal mania: Two case reports

D. Pereira*, I. Carreira Figueiredo, M. Marinho, R. Fernandes, V. Viveiros

Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisboa, Portugal

* Corresponding author.

Introduction Although rarely reported, antidepressant discontinuation may induce hypomania or mania even in the absence of bipolar disorder [1,2].

Objectives We report two cases of antidepressant withdrawal induced mania.

Methods Clinical process consultation and PubMed search were performed in November 2016 using the search keywords antidepressant, mania and discontinuation.

Results Case report 1: a dysthymic 60 years old woman with 20 years of psychiatric following had been treated with venlafaxine 150 mg/daily the past year. She abruptly stopped taking this drug, developing heightened mood, irritability and racing thoughts five days later. She was admitted at our hospital, initiating then valproate and antipsychotics. Two weeks later, the hypomania clinical state remitted completely.

Case report 2: a 64 years old woman, with a 12-year-old diagnosis of unipolar depression was brought to our emergency service with complaints of disorganized behavior, paranoid delusional ideas, excessive speech, irritable mood and reduced need for sleep, 1 week after abrupt trazodone 150 mg/daily discontinuation. Valproic acid 1000 mg/daily and olanzapine 20 mg/daily were introduced, with gradual improvement of symptoms. Two weeks later she was completely asymptomatic.

Conclusion Psychiatrists should be aware of the risk of antidepressant withdrawal induced mania. More studies should be conducted about this subject, aiming for the clarification of risk factors and the establishment of clinical criteria for this phenomenon.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Vortioxetine versus citalopram in treating major depressive disorder (MDD)

A. Rossi^{1,*}, E. Di Tullio¹, P. Prosperini², A. Feggi², C. Gramaglia¹, P. Zeppego¹

¹ Institute of Psychiatry, AOU Maggiore della Carità, Università del Piemonte Orientale-A. Avogadro, Traslational Medicine, Novara, Italy

² Institute of Psychiatry, AOU Maggiore della Carità, Traslational Medicine, Novara, Italy

* Corresponding author.

Introduction Citalopram is a widely used antidepressant (AD), indicated for the treatment of Major Depressive Disorder (MDD), with a high and Selective Serotonin Reuptake Inhibitory action (SSRI), good efficacy and safety profile. Vortioxetine is a novel multimodal antidepressant compound, with a mixed action on Serotonin (both 5-HT agonism and antagonism). Its clinical efficacy has been established in several short and long term trials; furthermore it proved effective at mitigating cognitive dysfunction, which is addressed to as one of the main causes of social impairment in MDD patients.

Objectives To evaluate the relative efficacy and safety of Vortioxetine versus Citalopram, in patients suffering from MDD.

Aims To assess whether Vortioxetine effectiveness and tolerability are comparable to those observed for previous antidepressants.

Methods The main outcomes were efficacy (variance from baseline to 1 month) in the Montgomery-Åsberg Depression Rating Scale (MADRS) and Hamilton Rating Scale for Depression (HAM-D) and tolerability (adverse events). Changes in cognitive performance were assessed using the following specific tools: Digit symbol substitution test (DSST), Trail Making Test A (TMT-A) and Hopkins Verbal Learning Test-Revised (HVLTR).

Results Data collection is ongoing. According to Literature we expect to find a significant number of MDD patients on Vortioxetine to achieve a reduction in depressive symptoms from baseline, to report poor adverse events and to increase their cognitive performance.

Conclusion As shown by recent literature, Vortioxetine might be an effective option in treating MDD with particular focus on cognitive dysfunction.

Depression and loneliness did not affect academic achievement among university students

D. Sadeghi Bahmani^{1,*}, R. Faraji², P. Faraji³, E. Holsboer-Trachsler¹, S. Brand¹

¹ University of Basel Psychiatric Hospital, Center for Affective- Stress and Sleep Disorders ZASS, Basel, Switzerland

² Islamic Azad University of Ardabil, Psychology, Ardabil, Iran

³ Ardabil University of Medical Sciences, Research and General Practitioner, Ardabil, Iran

* Corresponding author.

Background Many students experience symptoms of loneliness, either as a result of the new academic situation or due to the lack of social skills, which results in an inability to actively participate in community activities and socialization. Depression is another common problem that impacts students' ability to perform life activities. Further, while intuitively a negative association between loneliness, depression and academic achievement is assumed, consistent data are missing. Accordingly, the present study investigated the relationship between depression, and loneliness and academic achievement among undergraduate students.

Method This study was carried out on 240 university students (mean age: M=23.42 years), who completed the Beck Depression Inventory and the UCLA Loneliness Scale, while for academic achievement the average marks were used.

Result Increased age was associated with lower scores in loneliness and depression, and higher achievements. Higher scores of depression and loneliness were associated. Achievement scores were unrelated to loneliness and depression.

Conclusions Against intuitive expectations, academic achievement was unrelated to symptoms of depression and loneliness. Accordingly, we assume that academic achievement seemed to be related to further cognitive and emotional processes such as motivation, mental toughness, stress resistance, and goal oriented behavior.

An item response theory based analysis of the Hamilton depression rating scale-an Indian perspective

D. Sanyal^{1,*}, B. Mukherjee²

¹ KPC Medical College Jadavpur West Bengal, Department of psychiatry, Kolkata, India

² Malda Medical College, Psychiatry, Kolkata, India

* Corresponding author.

Introduction Hamilton Depression Rating Scale (HAMD) remains the most widely used outcome measure though many consider the scale to have many defects.

Objectives To use IRT analysis to identify HDRS items which are problematic in terms of IRT parameters, thus suggest changes to the scale.

Methods Patients attending psychiatric OPD meeting DSM-5 criteria for unipolar depression were selected for the study. Patients were between 18–65 years of age, had no major medical problems and were not on any medicines at present. 17 item HDRS was administered using the anchors developed by William Guy as part of the ECDEU NIMH Collaborative Study To determine the relationship between scores on the individual HAMD items and overall depressive severity in an outpatient population Option Characteristic Curve (OCC) which is a graphical representation of the probability of endorsing the different options for a given item across the range of depressive severity) and Item Characteristic Curve (ICC) which is a graphical representation of the mean item score (expected value) and confidence interval as a function of depressive severity was used.

Results Results showed that Items Depressed Mood, Work and Activities show good relationship between item responses and overall depressive severity. Items Hypochondriasis, somatic symptoms general and retardation appeared to be more problematic with regard to their ability to discriminate over the full range of depression severity.

Conclusions Further studies are needed to critically review one of the most commonly used scale for one of the commonest malady of humans.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Folate and pyridoxine to ssri in major depression and residual cognitive Decline

V. Savic^{1,*}, O. Golubovic¹, S. Nikolic²

¹ Special Hospital for Psychiatric Disorder, K, Vrsac, Serbia

² Special Hospital for Psychiatric Disorder, E, Vrsac, Serbia

* Corresponding author.

Introduction Depressive disorders are very common conditions, lifetime risk for experiencing major depression is approximately 15%.

Objective Patients with major depression having an insufficient response to SSRI may benefit from addition of methylfolate and pyridoxine.

Aim The aim of our study was to determine the effect of folate and pyridoxine augmentation to SSRI on emotional, physical and cognitive symptoms in major depression.

Methods Eighteen patients with MDD were enrolled, were on citalopram 20 mg/day when folate/15 mg per day/and pyridoxine/40 mg per day/were added. They have been monitored for three months using standard scales for depression and assessment by interview.

Results After three months of using folate and pyridoxine to SSRI there was a significant improvement in depression as measured by the scales. In 8 patients were recorded improvements of 30–50%. The most prominent changes were in cognitive sphere of depression such as attention, reasoning and problem solving, working memory and speed of processing.

Conclusion Low levels of folate and pyridoxine have been associated with the presence of depression and residual poor cognitive function. Our study confirms that folate and pyridoxine as adjunctive therapy to SSRI-partially refractory major depression is useful in particular to issues of residual cognitive interference conditions such as impaired concentration and memory, slow mentation, attention/vigilance, problem solving, working memory and speed of processing.

Clinical and neurocognitive characteristics associated with treatment-resistant depression

G. Serafini^{1,*}, G. Adavastro¹, G. Canepa¹, C. Conigliaro¹, M. Pompili², P. Girardi³, M. Amore¹

¹ University of Genoa, Neuroscience DINOGMI, Genoa, Italy

² Suicide Prevention Center, Sant' Andrea Hospital, Neurosciences, Rome, Italy

³ Sant'Andrea Hospital, Neurosciences, Rome, Italy

* Corresponding author.

Introduction Treatment resistant depression (TRD) is a disabling condition associated with a relevant psychosocial impairment worldwide.

Objectives This exploratory study is aimed to evaluate the main clinical and neurocognitive characteristics in a sample of 21 subjects admitted to the Psychiatric Clinic of University of Genoa as inpatients between 2015 and 2016 and diagnosed with TRD according to Thase and Rush staging method.

Methods Patients have been assessed using the Hamilton Depression Rating Scale (HDRS), Hamilton Anxiety Rating Scale, and Clinical Global Impression (CGI). The Continuous Performance Test (CPT), Trial Making Test (TMT-A/B), Stroop Color Word Interference Test, Verbal Fluency Test, and Rey auditory-verbal learning test (RAVLT) have been administered as well.

Results Subjects with early-onset (<50 years) depression had a longer illness duration, higher depressive episodes and more impaired performance at RAVLT while individuals with late-onset (>50 years) depression showed a higher severity of depressive symptoms and more anxiety symptoms. Depressive symptoms were positively associated with anxiety ($r=0.82$; $P=0.00$) and negatively with TMT-A/B ($r=-0.56$, $P=0.01$), Stroop Color Word Interference Test ($r=-0.72$, $P=0.005$ and $r=-0.616$, $P=0.008$), and RAVLT ($r=-0.60$; $P=0.02$) performances. According to regression analyses, anxiety symptoms were the only significant predictor of depression severity ($P=0.02$).

Conclusions Early-onset depression is associated with more disability and worse neurocognitive performance whereas late-onset depression is linked to more anxiety symptoms and more depressive symptoms severity. Clinicians should closely monitor patients with TRD for the presence of anxiety symptoms that may represent a significant risk factor of poorer long-term outcome.

Chronic benzodiazepine use in aged patients with depressive disorder

N. Smaoui¹, L. Zouari², M. Maâlej-Bouali², N. Charfi^{2,*}, N. Zouari², J. Ben Thabet², M. Maâlej²

¹ Hedi Chaker University Hospital, Department of Psychiatry- Hedi Chaker University Hospital, Sfax, Tunisia

² Hedi Chaker University Hospital, Department of Psychiatry C, Hedi Chaker University Hospital, Sfax, Tunisia

* Corresponding author.

Objective To identify predictive variables of chronic benzodiazepine use among elderly patients with depressive disorder.

Methods This was a cross-sectional, descriptive and analytical study, including 41 patients suffering from depressive disorders, aged 65 years or more, treated with benzodiazepine (BZD) and

followed-up in outpatient psychiatry unit at Hedi Chaker university hospital in Sfax in Tunisia. We used a standardized questionnaire including socio-demographic and clinical data. Chronic BZD use was defined as BZD availability at least 50% of the days between day 181 and day 365 following initiation.

Results The average age of patients was 69.29 ± 5.7 years. The sex ratio (M/F) was 0.5. The majority of them were married (78%), unemployed (82.9%) and living in urban area (61%). They had at most a primary degree (90.2%) and a low socioeconomic level (63.4%). The average time of BZD consumption was 4 years and 5 months.

The prevalence of chronic BZD use in our sample was 56.1%. Duration of benzodiazepine use was greater than 1 year for all chronic BZD users. The mean dose of Benzodiazepine (Lorazepam) consumed was 3.87 ± 2.8 mg per day. Chronic BZD use was correlated with low socioeconomic level (86.3% vs 36.8%; $P=0.000$), psychiatric comorbidity (72.7% vs 26.3%; $P=0.004$) and recent hospitalization (59% vs 15.7%; $P=0.023$).

Conclusion There is a high prevalence of chronic BZD use in our study. For the 65 years and older patients with depressive disorder, significant predictors of chronic BZD use were low socioeconomic level, psychiatric comorbidity and recent hospitalization.

Views of relatives and friends about the person who is having first episode of depression

S. Srivastava

Psychiatry, Lucknow, India

Introduction Major depressive episode is having highest lifetime prevalence almost about 18% of all psychiatric disorder. W.H.O has ranked depression the 4th leading cause of disability worldwide and projects that it will be 2nd leading cause of disability by 2020. a number of consistent socio demographic correlates have also been found across countries. Here I am going to give a glimpse of MDD i.e. Depression excluding Bipolar Depression. Although It is the commonest psychiatric disorder, but attitude views about disease is very unscientific and biased.

Objective Objective of this study was to know the views of relatives and friends about Depression, and acceptance of scientific view about depression.

Aims As various survey reports are projecting that Depression will be the 2nd commonest cause of disability by 2020. So to create an awareness about depression and its modalities of successful treatments.

Method In this study, 96 patients were selected who had first episode of MDD without any discrimination of male and female. Their relatives and friends were categorized by their socioeconomic status. All of them were put on open questions regarding the disease.

Results Amongst them 10% were from upper socioeconomic status, 68% were from middle socioeconomic status and 22% were from lower socioeconomic status. Only 36% accepted depression as a disease, 45.8% suggested to change behavior and thought to get rid off disease; 8.2% believed the disease is due to devils spirit; 20.1% had no comments.

Conclusion After explaining the disease psycho and pharmacopathology and showing the results of medicines 91.3% accepted it as a disease entity, 4.2% still in favor of devils spirit and 4.5% had no comments.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Memory, attention and language deficits in major depressive disorder

B. Suci^{1,*}, R. Paunescu², I. Miclutia²¹ Children's Emergency Hospital- Cluj-Napoca, Romania, Psychiatry Clinic- Cluj-Napoca, Romania, Cluj-Napoca, Romania² Iuliu Hațieganu University of Medicine and Pharmacy, Department of Neurosciences, Cluj-Napoca, Romania

* Corresponding author.

Objectives For a long time, cognitive deficits were considered as part of depressive episodes and were expected to improve as other affective symptoms diminished with treatment. Because of this, cognitive impairment was rarely assessed for Major depressive disorder, but in the present time this has changed.

Methods The study included 35 patients (age between 18 and 70) diagnosed with recurrent major depressive disorder (according to ICD-10 and DSM-V) which were evaluated during an acute depressive episode. The severity of depression was quantified clinically and with the help of Hamilton Depression Rating Scale -17 items- whereas cognitive functions were evaluated with standard cognitive tests.

Results Out of the 35 patients included, 25 were female patients, the rest of 10 being represented by male participants. A median score of 81.5 seconds on the Trail Making Test part A showed attention focusing deficits when compared with standard scores. For semantic fluency, ten words represented the mean score; whereas for phonemic fluency the mean score was lower (seven words). A median score of 5 words resulted from the assessment of the verbal learning and memory, these are considered to be associated with memorization and retention of a list of words given.

Conclusions These results sustain what the majority of studies revealed, that cognitive deficits are present in all cognitive domains, mostly in attention, verbal fluency and memory.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction The occurrence of chronic diseases, motor limitation, cognitive impairment and social isolation could be related to late life depression.

Objective To describe the pathologies related to elderly patients with depression. To study possible relationship between depression and others pathologies in elderly patients.

Methods This retrospective study included 124 geriatric patients enrolled in a private long-term care institution with mean age of 86.2 ± 6.5 years old, mean weight of 60.28 ± 2.00 kg and mean period of hospitalisation of 4.4 ± 2.3 years. For data analysis, double-entry tables and tests of proportion Qui-square were used.

Results Cardiovascular, respiratory, endocrine metabolic, skeletal muscle, sense organs, hematological, digestive tract; neuropsychological and genitourinary, diseases were analyzed.

We observed a significant correlation between depression and endocrine-metabolic (P value of 0.0003), sense organs (P value of $9.298 \text{ E-}5$) and skeletal muscle pathologies (P value of $6.843 \text{ E-}6$)

Conclusions We observed in that population that depression could be prevalent in elderly patients with endocrine-metabolic, sense organs and skeletal muscle pathologies.

Effect of yoga and meditation on accelerated cellular aging in major depressive disorder patients

T. Madhuri^{1,*}, R. Dada¹, R. Sagar²¹ All India Institute of Medical Science, Anatomy, Delhi, India² All India Institute of Medical Science, Psychiatry, Delhi, India

* Corresponding author.

Introduction Accelerated aging is associated with major depressive disorder (MDD) and studies of yoga and meditation based lifestyle intervention (YMLI) on biomarkers of cellular aging are lacking.

Aim and objectives To investigate the peripheral blood biomarkers of cellular aging in MDD patients after short term YMLI. Biomarkers include DNA damage, oxidative stress (OS), telomere attrition, and nutrition sensing assessed respectively by 8-hydroxy 2'- deoxyguanosine (8-OHdG); reactive oxygen species (ROS) and total antioxidant capacity (TAC); telomere length and telomerase activity; and sirtuin-1.

Methods We consecutively enrolled 33 MDD patients and 40 healthy subjects; 30 MDD patients were followed up with 12-week YMLI. Biomarkers of cellular aging in peripheral blood were measured with assay kits. All patients were evaluated by examining the correlation between cellular aging markers and Montgomery-Asberg Depression Rating Scale (MADRS) scores.

Results The levels of DNA damage, OS, and telomere attrition in MDD patients were significantly higher than healthy subjects (all $P=0.005$). The MADRS scores had a significantly positive association with 8-OHdG and ROS levels and negative association with TAC, telomerase and sirtuin-1 levels (all $P<0.01$).

Conclusions Peripheral blood biomarker levels in our results suggest significant cellular aging in MDD patients compared to healthy subjects. There was strong correlation between the changes in biomarkers of cellular aging and clinical improvement in MDD. Our study is the first to show significant increase in sirtuin-1 levels in MDD patients after yoga and meditation. Therefore, biomarkers of cellular aging might be indicators of MDD severity and clinical remission after YMLI.

Depression screening in primary care patients

J. Ben Thabet, M. Turki, M. Mezghanni, M. Maalej Bouali, N. Charfi*, S. Omri, N. Zouari, L. Zouari, M. Maalej

Hedi Chaker University Hospital, psychiatry "C" department, Sfax, Tunisia

* Corresponding author.

Introduction Depression is a common mental disorder that can be associated with more functional disability than most chronic medical illnesses and the increased reporting of medically unexplained somatic symptoms.

Aim To assess the prevalence of depression in a Tunisian population, as well as the associated factors.

Methods We conducted a cross-sectional, descriptive and analytic study, among 707 subjects consulting in 20 primary care

units in Sfax and Tunis, Tunisia. These participants, randomly chosen, were asked to answer a questionnaire after their consent. Depressive symptoms were evaluated using the “Beck Depression Inventory” (BDI).

Results The mean age of participants was 39.84 years. Among them, 38.6% had a low educational level (illiterate or primary school level); 45.3% were professionally inactive and 92.9% had a low to medium socio economic level. Medical, psychiatric and suicide attempt histories were reported respectively in 51.2%, 7.6% and 1.8% of cases. According to BDI, a mild depression was noted in 22.9%; moderate 16.1%; severe 4.1%. Among those presenting a moderate to severe depression (MSD), only 16.8% were followed up in psychiatry, 4.2% were receiving antidepressant and 9.8% benzodiazepine. MSD was associated with low educational level ($P < 0.001$); low to medium socio economic level ($P < 0.001$); psychiatric histories ($P < 0.001$); suicide attempt histories ($P < 0.001$); somatic histories ($P < 0.001$).

Conclusion Our study highlighted a high prevalence of depression that is still under diagnosed and therefore poorly managed. General practitioners should be made aware of the importance of screening for depression in medical patients because it not only complicates their overall medical treatments, but also impedes their physical and social functioning.

Depressive symptoms among genders

M. Vnukova^{1,*}, J. Raboch¹, R. Ptacek¹, I. Sebalo²

¹ Department of Psychiatry, First Faculty of Medicine Charles University in Prague and General University Hospital in Prague, Department of Psychiatry, Prague, Czech Republic

² Maastricht University, Faculty of Psychology and Neuroscience, Forensic Psychology, Psychology and Neuroscience, Maastricht, The Netherlands

* Corresponding author.

Introduction Depression is one of the most well-known psychological issues and is among the most severe ones. World Health Organisation's (WHO) report on health identifies 1.9% lifetime prevalence of depressive episode for males and almost twice as high—3.2% for females.

Methods This study aimed to map the depressive symptoms among working population in Czech Republic.

Results Analysis of covariance showed that there is significant effect of age $F(52) = 6.58, P = 0.010$ and gender $F(52) = 12.53, P < .001$ and t-tests showed the means of BDI II scores were significantly different for genders with females having higher mean (11.91) than males (9.80), $t(1025) = -3.42, P < .001$.

Conclusion The clinical burden of depression is still an increasing one in today's society and this research helped to identify the potentially most vulnerable individuals. These seem to be working women aged 35–44.

Core self-evaluation and depression among caregivers of Alzheimer disease patients

E. Wojtyna^{1,*}, A. Pyszkowska¹, M. Cembrzyńska¹, A. Wiszniewicz²

¹ University of Silesia, Institute of Psychology, Katowice, Poland

² Hospicy, Cordis, Katowice, Poland

* Corresponding author.

Introduction Caregivers of Alzheimer Disease (AD) patients suffer from chronic stress and psychophysical burden, which often lead to depression symptoms. It seems that core self-evaluation (CSE), coping with stress and social support might be modifying factors in coping with situation of caregiving.

Aims The aims of the study were to examine: (1) level of depression; (2) relationships between CSE, style of coping with stress, social functioning and depression severity among caregivers.

Methods The study involved 60 caregivers of AD patients who were children of the sick and have been caring for at least one year. It was cross-sectional and assessed by questionnaires. Following tools were used: Core Self-Evaluation, Beck Depression Inventory, Coping Inventory for Stress Situations, Distress Thermometer and an original questionnaire assessing the situation of caregiving.

Results A total of 51.7% of responders demonstrated severity of depression symptoms, associated to at least one mild clinical depression episode. The factors introduced to the model explained 65% variance of depression symptoms. Predictors of greater depression symptoms proved to be: low CSE ($\Delta R^2 = 0.32; \beta = -0.12$), low social support ($\Delta R^2 = 0.08; \beta = -0.27$), low life satisfaction ($\Delta R^2 = 0.02, \beta = -0.26$), high levels of distress ($\Delta R^2 = 0.12, \beta = 0.31$), coping style focused on emotions ($\Delta R^2 = 0.12, \beta = 0.17$).

Conclusions In the area of caregivers' psychological assistance and depression therapy, interventions leading to increase of CSE and providing adequate social support that contributes to better care provision and maintaining proper self-image, should be taken into consideration.

Neurometabolic alterations in a depression-like rat model of chronic forced swimming stress using in vivo proton magnetic resonance spectroscopy at 7 T

C.H. Yoo^{1,2,*}, K.H. Song¹, S.I. Lim^{1,2}, D.C. Woo², B.Y. Choe¹

* Corresponding author.

Although recent investigations of major depressive disorder (MDD) have focused on the monoaminergic system, accumulating evidence suggests that alternative pathophysiological models of MDD and treatment options for patients with MDD are needed. Animals subjected to chronic forced swim stress (CFSS) develop behavioral despair. The purpose of this study was to investigate the *in vivo* effects of CFSS in the rat prefrontal cortex (PFC) with 7 T and short-echo-time proton magnetic resonance spectroscopy (¹H MRS). Ten male Wistar rats underwent 14 days of CFSS, and *in vivo* ¹H MRS and forced swim tests were performed before and after CFSS. Point-resolved spectroscopy was used to quantify metabolite levels in the rat PFC. The spectral analyses showed that *in vivo* ¹H MRS can be used to reliably assess the Glu system. The rats showed significantly increased immobility times and decreased climbing times in the FST after CFSS, which suggested that the rats developed behavioral despair. The pre-CFSS and post-CFSS Glu and Gln levels did not significantly differ ($P > 0.050$). The levels of myo-inositol, total choline, and N-acetylaspartate, myo-inositol/creatinine, and total choline/creatinine increased significantly ($P < 0.050$). Similar findings have been reported in patients with MDD. Taken together, these results suggested that the CFSS-induced metabolic alterations were similar to those found in patients and that high-field and short-echo-time *in vivo* ¹H MRS can be used to investi-

gate depression-induced metabolic alterations. Such investigations might provide alternative insights into the nonmonoaminergic pathophysiology and treatment of depression.

⁴ Hospital del Mar, Institut de Neuropsiquiatria i Addiccions, Barcelona, Spain

* Corresponding author.

Introduction The application of scientific evidence in clinical practice management of Major Depressive Disorder (MDD) is complex. Generally, the usual dissemination process and implementation of Clinical Practice Guidelines (CPG) induce modest changes. A computerized version of a Clinical Practice Guideline for Major Depression (e-CPG-MD) has been integrated in Electronic Clinical Records of Primary Care in Catalonia (Spain). It offers an opportunity to improve clinical results. The design allows access to precise help in the visit itself, improving diagnosis, treatment and follow-up.

Objectives To evaluate the effects of a multifaceted implementation process of e-CPG-MD, analysing their use and changes in MDD diagnosis.

Methods A cluster randomized clinical trial was performed in 10 primary care centers (PCC) in Barcelona. In five of ten centers, a multifaceted implementation process of the e-CPG-MD was developed during 6 month. The active process includes: interactive training program, regular feedback audit, educational outreach visits and periodic reminders.

Results The multifaceted implementation of e-CPG-MD was associated with a significant increase in use during the first 6 months (4.1%+3.1% vs. 52.7%+7.3%, $P<0.001$). In the active centers, the MD diagnosis increased significantly (rate quotient = 1.56, $P<0.001$) and the proportion of moderate and severe MD increased (13.6% vs 41.1%, $P=0.002$).

Conclusions A multifaceted implementation method of e-CPG-MD increased significantly its use in active centers at 6 months. Diagnosis of MDD and the proportion of moderate and severe cases also increased significantly.

Using digital mood monitoring technology to support the assessment, engagement and empowerment of young people presenting to mental health services with mood instability

M. Dubad^{*}, S. Marwaha, C. Winsper

University of Warwick, Warwick Medical School, Coventry, United Kingdom

* Corresponding author.

Background Digital mood-monitoring technology, such as mood-monitoring applications, is increasingly advocated within clinical research and is a potentially effective method to engage and empower youth. However, limited evidence is available on this type of technology.

Objectives (1) To assess the evidence for the use of mobile mood-monitoring applications in youth; (2) to explore what available smartphone application would be most suitable to monitor mood from the perspective of young people; (3) to examine whether mood-monitoring applications are useful for investigating mood instability in youth; (4) to explore the utility and acceptability of using the mood-monitoring application from young people's and clinicians' perspectives.

Aim To investigate how mood-monitoring applications can be used to support the assessment, engagement and empowerment of young people presenting to mental health services with a range of diagnoses in which mood instability forms a key component.

Methods A systematic review using a Cochrane methodology was conducted. After obtaining ethical approval, this study will also employ a mixed methods approach, through which quantitative findings (e.g., digital mood-monitoring data) will be furnished with an in-depth understanding of young people's views on digital mood-monitoring technology.

Results Findings from a systematic review focusing on the evidence for the psychometric properties, usability and clinical impacts of applications in youth will be presented. Preliminary results from consultations groups and plans for future research will also be discussed.

Conclusions Evidence acquired through this research can potentially influence mental health policies and result in more innovative (adjunct) interventions and improved outcomes for young people with mood instability.

Aim With an increasingly growing population in Europe, cognitive impairment is a major social and health issue. According to the World Alzheimer Report (WHO, 2014), dementia, including Alzheimer's disease is one of the biggest global public health challenges our generation is facing. There are many efforts at European level to promote active and healthy ageing. This three-year project has the ambition to provide new services for integrated care with breakthrough research and radical innovation by employing user-friendly Information and Communication Technology (ICT)

tools, ultimately increasing patients' quality-of-life and autonomy at home.

Methods ICT4Life proposes an innovative platform for integrated care by the use of sensor-based analytics for human behaviour. Novel ICT services are used to determine the relation between cognitive decline, related psychopathological symptoms and the quality-of-life of the patients, and to assess how these affect patients' and caregivers' daily living. ICT4Life platform uses advanced sensor-based analytics; to maximize elderly empowerment and self-care abilities thanks to a properly designed and reconfigurable recommendation system that will be able to exploit user-generated data; and to improve decision-making processes in care professionals' daily activities. All solutions are developed following a user-centred methodology and tested in real-life scenarios.

Results The study design and the preliminary results of the ICT4Life project are presented on the poster.

Conclusion ICT4Life programme develops a solution for individuals with early stage cognitive impairment that will permit doctors and caregivers to extract useful information about patients, while contributing in a user-friendly way to extending their independence.

* Corresponding author.

Introduction Bariatric surgery is an effective treatment for obesity. It has been demonstrated that it improves the prognosis of vascular risk factors. However, the long term effect of surgery on psychiatric pathology, as depression, and the treatment adjustment needed is not clear.

Aim To describe the previous and posterior psychopharmacological treatment of patients operated of bariatric surgery in Hospital del Mar.

Material and methods We used a database of 292 bariatric surgery patients who have been operated in Hospital del Mar from January 2010 to November 2015. In this database, sociodemographic information, psychiatric antecedents, and anterior and posterior treatments among other data are included. We have made a descriptive analysis about more used treatments and their evolution.

Results In the sample, 27.1% of patients started with some psychiatric treatment the months before the bariatric surgery (16.4% had already a previous treatment prescribed). The medications the most frequently started before the surgery were selective sero-

tonin reuptake inhibitors (SSRI, 11%), second were benzodiazepines and third a combination of the two previous treatments. Among antidepressants, Fluoxetine was the most prescribed (45.5%). Six months after surgery, 72.9% of patients were not taking any treatment.

Conclusion The large variety of psychiatric drugs used in our sample indicates that clearer guidelines are needed about the most appropriated treatments for those patients. Further studies on the impact of this surgery on pathologies and their psychopharmacological treatments are needed.

* Corresponding author.

Introduction Eating disorders are pathologies with potentially serious psychic and somatic consequences, and high mortality. Lifetime prevalence in adults is about 0.6% for anorexia nervosa, 1% for bulimia, and 3% for binge eating disorder. However, the prognosis is improved if a suitable care is quickly established. Caregivers are often highly involved and helpless in facing such diseases. They often express a significant psychological distress. We must contribute to provide them answers, to strengthen their key role as a resource and support for the patient. It is found that carers themselves are poorly trained in screening, diagnosing and supporting eating disorders. There are effective therapeutic approaches, such as psychoeducation, to improve therapeutic alliance.

Objectives/aims This work aims to realize a French psychoeducational audio-visual tool for patients with eating disorders, their caregivers, and professional carers.

Methods We made an extensive review of literature (focus on the international practice guidelines, existing psychoeducational tools), and several consensus meetings. We decided of original directions to drive the psychoeducational approach of the movies, taking into account previous findings.

Results This tool includes three movies approaching the symptoms and the choice of treatment setting, based on the disease course and the care's goals. They may be broadcasted on a national level through professional networks and associations involved in the treatment of eating disorders.

Conclusion This work improves the knowledge of eating disorders in carers, patients and their families. The relevance and effectiveness of this tool on the course of the disease has to be further evaluated.

Disclosure of interest The authors have not supplied their declaration of competing interest.

An expressive group approach to borderline personality disorder in patients with bulimia nervosa: A clinical case

I. Baños Martín^{1,*}, E. Guerra Gómez¹, K. Eaton Itúvide², B. Unzeta Conde¹, P. Vilariño Besteiro², C. Pérez Franco³, P. García Jorge¹

¹ Psychiatrist, Santa Cristina university hospital, Madrid, Spain

² Psychologist, Santa Cristina university hospital, Madrid, Spain

³ Occupational therapist, Santa Cristina university hospital, Madrid, Spain

* Corresponding author.

Introduction It is widely known comorbid Bulimia Nervosa (BN) with Borderline personality disorders (BPD). This is associated with worse prognosis and resistance to pharmacological and psychotherapeutic treatments. In integrated treatment, both disorders are addressed, not being frequent psychotherapy groups that address only the personality traits. Some studies have proposed the brain basis of psychodrama intervention in both pathologies.

Objectives To highlight the clinical effectiveness of adding a non-verbal orientation (psychodrama) to the treatment of BN patients; to specifically address personality traits, by presenting a clinical case. We rely on studies.

Methods Clinical case: 42-year-old woman patient with BN (DSM-5) severe degree, BITE: Symptoms scale = 28; S. Severity = 13; and BPD (7 DSM-V); MCMI-III: BPD = 115 She is incorporated into a day hospital with integrated and multidisciplinary approach: psychotropic drugs, individual, group and family psychotherapy. This patient is added to an open psychodrama group; where he works exclusively personality pathology, during one year.

Results Improvement was observed in BN (she switched to intermediate grade); BITE: Symptom scale = 23, S. Severity = 8; also improves BPD criteria of DSM-V = 4 (minimum = 5) MCMI-III: BPD = 104.

Conclusions (1) Psychodrama psychotherapy groups to treat Bulimia and BPD could provide an added clinical improvement in both pathologies.

(2) Insufficient RCTs compared to other models of psychotherapy (mentalizing, interpersonal, dialectical behavior) do not allow to speak even scientific evidence of psychodrama.

A cognitive and behavioural group therapy for binge eating disorder: An original 12 sessions design

F. Boulet

Nîmes University Hospital, psychiatry, Nîmes, France

The Binge Eating Disorder (BED) consists in binge eating with a loss of control and guilty feeling. Weigh excessive preoccupation, psychiatric comorbidities and psychosocial impairment are associated to BED. BED prevalence is 3 to 5%, which is the more frequent eating disorder. The efficacy of CBT is well-known with several publications.

Method We have proposed 12 sessions of 1.30 hours for a 6 to 8 patients group, managed by a psychiatrist trained to CBT. Each session approaches a different topic (eating behavioural,

self-esteem, problem resolution, stigmatization, emotion coping, cognitive therapy. . .).

Assessment Patients are evaluated before and after therapy with Eating Disorder Inventory version 2 and Rathus Scale for self-esteem. Thirty patients were included.

Results Patients improve eating behavioural and other topics like self-esteem, social functioning, problem resolution and emotion coping. It appears that 12 sessions group CBT could be effective with patients who suffer of BED. Others studies are needed to evaluate the long-term outcome.

Avoiding refeeding syndrome in anorexia nervosa

D. Brigadeiro*, J. Nunes, T. Ventura Gil, P. Costa
Hospital Sousa Martins, ULS Guarda, Departamento de Psiquiatria e Saúde Mental, Guarda, Portugal

* Corresponding author.

The term refeeding syndrome has been used to describe the adverse consequences that can occur in all malnourished patients in the early stages of nutrition repletion whether the method of refeeding is oral, enteral or parenteral. Those consequences include acute thiamine deficiency resulting in Wernicke's encephalopathy and Korsakoff syndrome, with the potential for permanent cognitive impairment; hypophosphatemia, hypokalemia, hypomagnesemia and fluid overload resulting in cardiac failure. Adaptive changes in metabolism occur during a period of starvation or fasting: levels of glucose fall within 24 to 72 hours, as response, glucagon levels rise and insulin concentrations decrease. Glucose levels are maintained by glycogenolysis at first and gluconeogenesis latter. The reintroduction of nutrition leads to a switch from fat to carbohydrate metabolism and an increase of insulin concentration. Insulin stimulates the movement of potassium, phosphate, and magnesium into the cell leading to its depletion in extracellular compartment. Reactivation of carbohydrate metabolism increases degradation of thiamine, a cofactor required for cellular enzymatic reactions in Krebs's cycle. Deficiency in all these nutrients can then occur. Patients with anorexia nervosa are at risk of suffering from refeeding syndrome. This psychiatric disorder causes potentially life-threatening, physical complications and has the highest mortality rate among psychiatric disorders. The purpose of this review is to clarify recommendations for prevention and treatment of refeeding syndrome in anorexia nervosa.

Mercyism – A case report about rumination syndrome

M.C. Cochat Costa Rodrigues^{1,*}, I. Brandão²

¹ Magalhães Lemos Hospital, Psychiatry, Porto, Portugal

² Centro Hospitalar de São João, Clinic of Psychiatry and Mental Health, Porto, Portugal

* Corresponding author.

Introduction Rumination is a common phenomenon among ruminant animals but in humans, it is always regarded as a symptom indicative of abnormal function of the upper gastrointestinal track. It is characterized by recurrent regurgitation of recently ingested food into the mouth. This syndrome was previously described in children and adults with mental retardation, but this entity is becoming increasingly recognized in children, adolescents and adults with normal mental capacity.

Objectives/aims The authors describe a clinical case of a 51-year-old woman with rumination syndrome and bulimia nervosa.

Methods A detailed report of the clinical case was made as well as a literature review of articles published in Pubmed/Medline on the topic “Rumination syndrome” and “Merycism”.

Results The authors describe a clinical case of a 51-year-old woman who began ruminative behavior when she was 10 years old, describing the regurgitation of the swallowed food back to her mouth shortly after eating and the re-chewing of it. She states that the regurgitated food tastes the same as when she ate it and she denies any pleasure associated with this behavior. When she was 17 years old, by the time she was pregnant, she started bulimic behavior and, as the rumination, it never ceased. Her medical history is significant for chronic gastritis and type 2 diabetes mellitus.

Conclusions Although rare, merycism is an entity in the clinical practice of eating disorders. With this work, the authors share this case report as well as information concerning this topic.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Anorexia nervosa (AN) is characterized eating behaviors and body image disturbances. Given poor treatment outcomes are available for AN, treatment innovations are urgently needed. Recently, non-invasive neuromodulation tools have suggested having potential for reducing AN symptomatology targeting brain alterations.

Objectives The objective was to verify whether an excitatory transcranial direct current stimulation (tDCS) over the left prefrontal cortex may aid in altering/resetting inter-hemispheric balance in AN patients, re-establishing control over eating behaviors.

Aims Research is aimed to evaluate the potential of tDCS treatment in determining a more rapid improvement compared to classical treatments in adolescents with AN.

Methods Twenty-two adolescents with AN, underwent the treatment as usual (AU) plus the tDCS treatment (TDCS+AU: $n=8$, age $M 13.7 \pm 1.9$ years) or a family therapy (FT+AU: $n=14$, age $M 15.1 \pm 1.75$ years), for six weeks. Psychopathological scales (EDI-III, EAT 26, BUT, MASC, CDI) and anthropometric indicator of nutritional status (BMI) were assessed before and after treatment.

Results BMI improved only in the TDCS+AU group ($P<0.01$). Mean BMI percentage of improvement was $14.43\% \pm 10.8$ in the TDCS+AU and $4.83\% \pm 5.4$ in the FT+AU. Both groups improved in the total scores of the EDI, EAT-26, MASC and CDI scales (all $P<0.01$).

Conclusions tDCS treatment improved BMI values more than classical treatment and determined comparable to the classical treatment improvement in the psychopathological scales. This results may be an important starting point to further explore the beneficial effect of brain based treatments for AN.

² Università Cattolica del Sacro Cuore, patologia dell'obesità, Roma, Italy

³ Università Cattolica del Sacro Cuore, semeiotica chirurgica, Roma, Italy

* Corresponding author.

Introduction Body image is a multidimensional concept that has assumed a significant role in eating disorders in which affective and perceptual distortions have been documented. Obesity is not a psychiatric disorder according to DSM-5 but several studies highlighted the presence of body image diseases in obesity.

Objectives The aim of this work is to evaluate the presence of body uneasiness in obese seeking for Bariatric surgery and to correlate it with psychopathological symptoms, psychosocial and anamnestic variables.

Methods From June 2014 to June 2016, we enrolled 537 Bariatric surgery candidates. Body image was investigated using the Body Uneasiness Test (BUT-A), a 34-item self-report questionnaire which measures weight phobia (WP), body image concerns (BIC), avoidance (A), compulsive self-monitoring (CSM), detachment and depersonalization (D). Psychopathological symptoms and personality traits have been evaluated using SCL90R and MMPI-2.

Results Descriptive analyzes showed that BUT subscales were altered in most of our sample. Correlations of Pearson underlined significant associations between BUT subscales and SCL90R subscales. No correlation was found between BMI, marital status and BUT scores, while young, female and unemployed people had more difficulties with body.

Conclusions Our data highlight the presence of considerable body uneasiness in obese, correlated with the severity of psychiatric symptoms but independent from the severity of obesity. This seems to reflect the mind-body split detected both in obesity and in eating disorders. Therefore, a multidisciplinary integrated approach including psychological work on cognitive, emotional and perceptual aspects of body image will help patients to improve coping with corporeal changes achieved through surgery.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Gender is crucial in many aspects of life, including attitude towards body image perception. Although the well-known female preponderance, recent studies demonstrate an increasing Eating Disorders (EDs) incidence in males but scant literature attention.

Aims This study aims to highlight the growing phenomenon of EDs in males and shed light on sex-related clinical features and psychiatric co-morbidities.

Method Out of 280 persons aged 18–74, consecutively referred to Bologna's outpatients EDs clinic, 267 were included in this retrospective observational study.

Results The men/women ratio was one to five. The most frequent EDs in males was Binge Eating Disorder, whereas in females Anorexia Nervosa and Bulimia Nervosa prevailed. Excessive exercising and fasting were the most common dysfunctional behaviors in men, while self-induced vomiting and laxative-diuretic abuse were more typical in women. Mood and Somatoform Disorders were more common in women, whereas Anxiety and Psychosis Disorders in males. Within personality disorders, borderline and histrionic prevailed in female, while narcissistic and anti-social in males.

Conclusions Male compared to female EDs, show differences in clinical presentation, symptoms and co-morbidities. The increased proportion of affected men should alert general practitioners, clinicians and psychologists working in non-specialized settings to be more aware of the possibilities of encountering an ED in men and of the need of exploring the eating habits in all male patients. The finding of a more pronounced physical hyperactivity in men in order to achieve an ideal body shape which is muscular and athletic suggests the need of a deeper attention to sex-different symptoms and behaviors declination.

Shame traumatic memories and body image shame in Binge Eating Disorder: Can memories of warmth and safeness buffer this link?

C. Duarte*, J. Pinto-Gouveia

CINEICC, Cognitive and Behavioural Centre for Research and Intervention, Faculty of Psychology and Educational Sciences, Coimbra, Portugal

* Corresponding author.

Introduction Growing research show that body image-related shame plays a particularly important role in the vulnerability to and persistence of Binge eating symptoms. Also, shame experiences from childhood and adolescence were found to function as traumatic memories and are significantly associated with eating psychopathology. Nonetheless, little is known about the effect of shame traumatic memories in Binge Eating Disorder (BED), and whether early positive emotional memories of warmth and safeness may buffer against the impact of shame memories on body image shame.

Aims This study examined the moderator effect of positive emotional memories on the association between shame traumatic memories and current body image shame in women diagnosed with BED.

Methods Participants ($N=109$) were assessed through the eating disorder examination and the shame experiences interview, and answered to self-report measures assessing the traumatic features of a key shame memory, positive emotional memories and body image shame.

Results Body image-related experiences were most frequently recalled as significant shame memories. Positive emotional memories were negatively associated with shame traumatic memories and body image shame, and had a significant moderator effect on the association between shame traumatic memories and current body image shame.

Conclusions This study was the first to demonstrate that early shame experiences may contribute for BED patients' shame based on their body image. Data suggest that the access to memories of early feelings of affiliation and safeness may be key to tone down negative affect. These findings have important implications for the conceptualization and treatment of BED.

A new measure of psychological inflexibility related to eating behavior in adolescence: Confirmatory factor analysis and validity assessment

C. Duarte*, C. Ferreira, J. Pinto-Gouveia

CINEICC, Cognitive and Behavioural Centre for Research and Intervention, Faculty of Psychology and Educational Sciences, Coimbra, Portugal

* Corresponding author.

Introduction On the onset of adolescence there is an increased vulnerability for mental health problems, namely disordered eating symptomatology. Disordered eating symptomatology has been described as a problem of psychological inflexibility. Psychological inflexibility related to eating behaviors, i.e., the adoption of inflexible idiosyncratic dietary rules without considering external and internal contingencies, is associated with disordered eating symptoms in adult populations. Nonetheless, the study of psychological inflexibility related to eating behaviors in adolescence is scarce.

Aims The current study aimed at examining the factor structure and psychometric properties of the Inflexible Eating Questionnaire for Adolescents (IEQ-A).

Methods Participated in this study, 728 adolescents (513 girls and 215 boys), aged 14 to 18 years, who completed self-report measures of psychological inflexibility related to eating behaviors, body image, disordered eating symptoms and general psychopathology symptoms.

Results Results of the confirmatory factor analysis indicated that the IEQ-A replicated the 11-item one-dimensional structure previously identified in adult samples. A multigroup analysis also demonstrated the scale's structure invariance between genders. The scale presented high internal reliability for both boys and girls (95). Correlation analyses confirmed the scale's convergence with psychological inflexibility with body image. IEQ-A was also positively associated with disordered eating symptoms and depression, anxiety and stress symptoms.

Conclusions Findings corroborated the adequacy of the IEQ-A factor structure and supported that this is a valid measure to assess psychological inflexibility related to eating behavior in adolescence. This measure is therefore of potential utility for clinicians and researchers focusing on eating-related difficulties in this vulnerable developmental stage.

New technologies as risk factor for eating disorders

S. Fernandez Rojo*, F. Mora, C. Banzo, J. Quintero

Hospital Universitario Infanta Leonor, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Eating disorders (ED) have a significant prevalence in children and adolescents. The use of new technologies allows to access to a big amount of information. Excessive use of these technologies at this stage of life decreases social and family relationships and provides access to online content in favor of these disorders, which can affect to the development of an ED. The aim of this study is to analyze the relationship between the use of new technologies and the risk of developing an ED.

Material and method We have selected a sample of 500 patients who were in the 2nd year of secondary school to which has been applied a battery of scales, including the EAT-26 scale for ED; and has been collected socio-demographic data, including the use of internet and mobile phone. We used SPSS to analyze the relationship between these variables.

Results We have analyzed clinical and socio-demographic characteristics of the sample. In relation to the risk of developing an eating disorder we have found that high frequencies of use of the Internet and high frequencies of use of mobile phones (especially more than 4 hours a day) increases significantly the score in EAT-26 scale for ED ($P < 0.05$).

Conclusions Regarding the results, we can say that, in our sample, the use of Internet and/or mobile phone more than 4 hours a day significantly increases the probability of having a high score on the scale for ED. This data can be essential when planning treatment or establishing a preventive strategy.

The central role of body image in the explanation of the engagement in disordered eating attitudes and behaviors

C. Ferreira*, A.L. Mendes, J. Marta-Simões

Faculty of Psychology and Education Sciences - University of Coimbra, CINEIC, Cognitive Behavioral Center for Research and Intervention, Coimbra, Portugal

* Corresponding author.

Shame is a universal emotion, that has been emphasized as a pathogenic phenomenon in well-being and mental health. In fact, although shame has been considered an adaptive defensive response, higher levels of this painful emotion are strongly associated with different mental health conditions. The current study aimed to test whether the association of external shame with eating psychopathology would be explained by the mechanisms of body image-related cognitive fusion, psychological inflexibility, and also dietary restraint. A path analysis testing a mediational model was conducted in a sample of 787 women from the general community, aged between 18 and 51 years old. The tested model accounted for 71% of the variance of eating psychopathology and revealed an excellent fit to the data. Results demonstrated that external shame's impact on disordered eating attitudes and behaviors is indirect, carried through increased body image-related cognitive fusion, psychological inflexibility related to physical appearance, and dietary restraint. These findings seem to support the association between shame and eating psychopathology. Furthermore, these data add to literature by suggesting that individuals who present higher levels of shame may present increased tendency to engage in dietary restraint and other maladaptive eating behaviors, through higher levels of body image-related psychological inflexibility and cognitive fusion. The current study seems to hold important clinical implications, highlighting the importance of developing intervention programs in the community which target shame and body image-related maladaptive attitudes and behaviors and, in turn, promote adaptive emotion regulation strategies (e.g., acceptance abilities).

* Corresponding author.

Introduction Recently, anorexia nervosa (AN) has been conceptualized as a reward-related disorder, and brain imaging studies have shown functional and structural abnormalities in areas of the brain involved in reward processes in both acute and recovered AN patients. However, the role of endogenous biochemical mediators, such as Ghrelin, in the modulation of reward processes has been poorly investigated in this eating disorder.

Objectives Hedonic eating, that is the consumption of food exclusively for pleasure and not to maintain energy homeostasis, is a useful paradigm to investigate the physiology of food-related reward.

Aims We assessed the Ghrelin response to food-related reward in symptomatic AN women in order to further explore the modulation of reward processes in this severe and debilitating disorder.

Methods Plasma levels of Ghrelin were measured in 7 underweight and 7 recently weight-restored satiated AN patients before and after the ingestion of a favorite (hedonic eating) and non-favorite (non-hedonic eating) food. Ghrelin responses were compared it that of previously studied healthy controls.

Results We found that in satiated underweight patients with AN plasma Ghrelin levels progressively decreased after the exposure and the consumption of both the favorite and non-favorite food whereas in satiated weight-restored AN patients and satiated healthy controls plasma Ghrelin concentrations significantly increased after the exposure to the favorite food and after eating it, but decreased after the non-favorite food.

Conclusions These results suggest a derangement in the Ghrelin modulation of food-related pleasurable and rewarding feelings, which might sustain the reduced motivation toward food intake of acute AN patients.

Introduction Despite age at onset (AAO) of eating disorders (EDs) has classically been described in adolescence; to date there is not an univocal definition. While initial studies described a bimodal distribution of AAO for ED, recently several studies didn't confirm these findings.

Objectives AAO thresholds definition for anorexia nervosa (AN) and bulimia nervosa (BN) with statistical validation of proposed cut-offs is highly needed, since AAO represents a crucial clinical feature.

Aims We obtained data from subjects with AN and BN to perform a normal distribution admixture analysis to determine their AAO.

Methods A total of 806 ED patients (792 females; 379 AN and 427 BN) were recruited. Diagnosis of AN and BN were ascertained according to the DSM-IV-TR criteria by means of the SCID – Patient Edition. AAO was assessed by a clinical interview performed by a psychiatrist matched with a systematic review of medical records. To test AAO subgroups, we used a normal distribution admixture analysis.

Results A bimodal normal distribution of AAO with an early onset and late onset component was found for both AN and BN. Most of the subjects with AN (75.3%) and BN (83.3%) belonged to the early onset group. Both groups had a mean AAO of about 18 years. No significant differences were found concerning the AAO between groups.

Conclusion Consider clinical history and course of AAO for EDs may be crucial for planning treatment. To our knowledge, this is the first study that applied a validated statistical procedure to identify AAO cut-off points for AN and BN.

⁴ University Federico II of Naples, ENT Department, Naples, Italy

* Corresponding author.

Introduction The functional interplay between brain hemispheres is fundamental for behavioral, cognitive and emotional control. Several pathophysiological aspects of eating disorders (EDs) have been investigated by the use of functional Magnetic Resonance Imaging (fMRI).

Objectives The objective of the study was to investigate functional brain asymmetry of resting-state fMRI correlations in symptomatic patients with anorexia nervosa (AN) and bulimia nervosa (BN).

Aims We aimed at revealing whether brain regions implicated in reward, cognitive control, starvation and emotion regulation show altered inter-hemispheric functional connectivity in patients with AN and BN.

Methods Using resting-state fMRI, voxel-mirrored homotopic connectivity (VMHC) and regional inter-hemispheric spectral coherence (IHSC) analyses in two canonical slow frequency bands (“Slow-5”, “Slow-4”) were studied in 15AN and 13BN patients and 16 healthy controls (HC). Using T1-weighted and diffusion tensor imaging MRI scans, regional VMHC values were correlated with the left-right asymmetry of corresponding homotopic gray matter volumes and with the white matter callosal fractional anisotropy (FA). **Results** Compared to HC, AN patients exhibited reduced VMHC in cerebellum, insula and precuneus, while BN patients showed reduced VMHC in dorso-lateral prefrontal and orbito-frontal cortices. The regional IHSC analysis highlighted that the inter-hemispheric functional connectivity was higher in the ‘Slow-5’ Band in all regions except the insula. No group differences in left-right structural asymmetries and in VMHC vs callosal FA correlations were found.

Conclusions These anomalies indicate that AN and BN, at least in their acute phase, are associated with a loss of inter-hemispheric connectivity in regions implicated in self-referential, cognitive control and reward processing.

Investigation of endocannabinoids and endocannabinoid-related compounds in obese subjects during an hedonic eating experimental test

V. Ruzzi^{1,*}, A.M. Monteleone¹, F. Monaco¹, G. Fico¹, A. Cervino¹, U. Volpe¹, P. Monteleone²

¹ Second University of Naples, Department of Psychiatry, Naples, Italy

² University of Salerno, Department of Medicine and Surgery, Salerno, Italy

* Corresponding author.

Introduction Hedonic eating refers to the consumption of food just for pleasure and not for energetic needs. Endocannabinoids and endocannabinoid-related compounds play an important role in food-related reward and are likely involved in hedonic eating.

Objectives In a previous study we found that in normal weight healthy subjects plasma levels of 2 arachidonoylglycerol (2-AG) decreased progressively after food ingestion in both hedonic and non-hedonic eating condition, but they were significantly higher in hedonic eating. Plasma levels of anandamide (AEA), oleoylethanolamide (OEA) and palmitoylethanolamide (PEA), instead, progressively decreased in both eating conditions without significant differences.

Aims In order to investigate the physiology of endocannabinoids in obesity, we assessed the responses of AEA, 2-AG, OEA and PEA to hedonic and non-hedonic eating in obese individuals.

Methods Fourteen satiated obese patients consumed favorite (hedonic eating) and non-favorite (non-hedonic eating) foods in two experimental sessions. During the tests, blood was collected to measure peripheral levels of AEA, 2-AG, OEA and PEA.

Results Plasma levels of 2-AG progressively decreased in non-hedonic eating whereas they gradually increased after hedonic eating. Plasma levels of AEA decreased progressively in non-hedonic eating, whereas they initially decreased after the exposure to the favorite food and then returned to baseline values after its consumption. The responses of OEA and PEA to favorite and non-favorite food did not show significant differences.

Conclusions These findings demonstrate that, compared to normal weight healthy subjects, obese subjects exhibit different responses of peripheral endocannabinoids to the ingestion of food for pleasure and this could have implications for the onset/maintenance of obesity.

Introduction Attachment theory suggests that different attachment styles influence the development of individual's self-esteem and modulate the individual's ability to manage stressful events

by responding with adequate affective adjustment. High levels of insecure attachment are present in adults with Eating Disorders (EDs).

Objectives The variables that mediate the association between attachment style and EDs have not been investigated enough. The possibility exists that the endogenous stress response system is involved.

Aims To appraise the role of the endogenous stress response system, we studied the effect of attachment styles on the hypothalamus-pituitary-adrenal (HPA) axis functioning in ED patients.

Methods Fifty-two women with EDs and 25 healthy women completed the ECR questionnaire to assess their attachment style. Saliva samples were taken in the morning to measure the Cortisol Awakening Response (CAR). Moreover, the saliva cortisol response to the Trier-Social-Stress-Test (TSST) was measured in 30 ED patients and 15 healthy controls.

Results Patients with avoidant attachment showed an increased CAR compared to both healthy controls and to patients with anxious and secure attachment styles. In the initial TSST phase, cortisol levels decreased in the secure attachment group but not in patients with avoidant attachment. In the TSST stress response phase, the cortisol raise was higher in insecure patients and delayed in avoidant ones.

Conclusions In adults with EDs, attachment styles affect the HPA axis functioning and this could have a role in the pathophysiology of EDs.

Insidious: The relationship between patients and their eating disorders and its impact on ED symptoms, illness duration and self-image

E. Forsén Mantilla*, A. Birgegård

Karolinska Institute, Department of clinical neuroscience, Stockholm, Sweden

* Corresponding author.

Patients with eating disorders (EDs) often spontaneously talk about their disorder in terms of a symbolic other (a demon, a voice, a guardian). Further, externalizing exercises where patients are encouraged to separate their true self from their ED self are common in some treatment approaches. Yet, no previous quantitative study has investigated this phenomenon. We examined the patient-ED relationship (using the interpersonal structural analysis of social behavior methodology) and its implications for ED symptoms, illness duration and self-image. Participants were 16–25 year old female patients ($N=150$) diagnosed with anorexia nervosa ($N=55$), bulimia nervosa ($N=33$) or eating disorder not otherwise specified ($N=62$). Results suggested that patients had comprehensible and organized relationships with their EDs. EDs were primarily experienced as acting critical and controlling towards patients. Higher ED control was associated with more ED symptoms and longer illness duration, especially when coupled with patient submission. Patients reacting more negatively towards their EDs than their EDs were acting towards them had lower symptom levels and more positive self-images. Externalizing one's ED, relating to it like a symbolic other, seemed to make sense to patients and depending on its quality seemed to influence ED symptoms, illness duration and self-image. We put forward both clinical and theoretical implications based on the assumption that the patient-ED relationship may function in similar ways as real-life interpersonal relationships do.

Introduction Attachment is an innate programming whereby a child seeks for security. There is scientific and empirical evidence that insecure attachment is usual in eating disorder patients [1].

Objectives To highlight the relevance of attachment between child and caregivers, as well as its significance in therapeutic approach.

Methods A 17-year-old girl hospitalized after attending to emergency department due to fainting. BMI: 12.89. She reports restrictive behavior since age 11 that her mother regards as "child issues". Divorced parents, she grew up with her mother, diagnosed of hypochondria, who mentions not understanding why she is not the one who is hospitalized.

Results During hospitalization, she turned 18-years-old. Guardianship of her younger siblings was removed to her mother. She had a secure relationship with her 24-year-old sister, so she decided to move in with her. Later on, she had a positive progress, maintaining the gained weight and mood stability, although cognitive distortions persist.

Conclusions Among developmental and maintaining factors of eating disorders, impaired attachment is becoming increasingly interesting. Even though the main goal of treatment is weight restoration, exploring attachment patterns can facilitate to achieve that aim. This clinical case emphasizes the importance of attachment in eating disorders among child and young adults.

Introduction Recently, there is an increasing interest in the link between anorexia nervosa and autoimmune diseases. Studies show

significant association between anorexia nervosa, diabetes mellitus, autoimmune thyroid disease and Crohn's disease [1]. The findings of significantly elevated autoantibodies (anti α -MSH, anti ACTH) and cytokines (IL-1, IL-6, IFN- γ , TNF- α) support this relationship.

Objectives To illustrate with a clinical case the connection between eating disorders and Crohn's disease.

Methods Fourteen years-old boy with moderate depression syndrome after his grandfather's decease. Since overweight diagnosis by his pediatrician, he begins to restrict food intake with an important weight loss (19 kg in 9 months) and over exercising. Blood test reveals microcytic and hypochromic anaemia, rest of the examination shows no other disorder. Psychometric assessment EDI-3 suggests Anorexia Nervosa restricting type.

Results Two months after clinical stabilization, he is hospitalized due to abdominal pain. Exploration including blood test, serology, coproculture, sonography and colonoscopy reveals severe Crohn's disease.

Conclusions This case is about a patient diagnosed of moderate depressive syndrome, who develops anorexia nervosa and Crohn's disease during his follow up. It exemplifies the link between stress, immunity and eating disorders. Recent findings suggest that immune diseases are involved in onset and maintenance of eating disorders. More studies are required in order to inference its consequences in evaluation, prognostic, treatment and identification of subgroups of patients.

Alexithymia is a psychological construct characterized by difficulty describing emotions and distinguishing them from somatic components of the emotional activation. Patients with eating disorders (ED) or substance use disorders (SAD) commonly present also impairment of recognition of facial expressions and deficits in social inference. Patients with ED and SAD may present impulsiveness, difficulty in emotion-focused coping skills, and search for a concrete relief from psychological suffering. The purpose of study is to compare the ED, SAD and healthy controls (HC), in several variables, including Alexithymia, empathy, and ability to recognize

emotions, social inference. Thirty-two patients with ED, 27 patients with SAD and 31 HC were recruited between September 2016 and April 2016 at the psychiatric ward of Novara Hospital, nursing home of Nebbiuno and the nursing home of Viverone. We administered to patients the same battery of tests, composed by Toronto Alexithymia Scale-20 (TAS-20), Facial Emotion Identification Test (FEIT), the awareness of Social Inference Test (TASIT), temperament and Character Inventory (TCI), Interpersonal Reactivity Index (IRI), Symptoms Checklist-90 (SCL-90). The two clinical groups showed differences in TAS, FEIT and TASIT, highlighting Alexythimic traits, difficulty in recognizing emotions and deficit of social inference, compared to HCs. The TCI and SCL-90 have also highlighted the common psychopathological characteristics and temperamental in patients with ED and SAD. Alexythymia is particularly represented in patients with ED and SAD, and could represent a maintenance factor, together with deficits in emotions recognition and social inference. The similarities between ED and TD seem to suggest the possibility of shared core features.

A family-based intervention of adolescents with eating disorders: The role of assertiveness

A.L. Barrios-Hernandez^{1,*}, G. Gonzalez-Cuevas¹, M. Graell-Berna², A. Blanco Fernandez¹

¹ European University of Madrid, Psychology department, Madrid, Spain

² Hospital Universitario Niño Jesús, Psiquiatría y Psicología, Madrid, Spain

* Corresponding author.

Introduction One of the key profile features of adolescents with Eating Disorders (ED) is a difficulty with assertiveness. Indeed, current research points to the importance of these patients' perception of excessive control exerted by their families. Because these adolescents generally live with their families of origin, family-based variables may impact the development and evolution of psychosocial risk factors associated with this psychiatric disorder.

Objective To investigate whether adolescents with ED improve on assertive communication as a result of parental assertiveness training.

Methods The sample was comprised of 50 female adolescents with ED receiving group therapy treatment at Niño Jesús hospital in Madrid. Out of the 77 parents participating in the study, 36 were part of the experimental group and subjected to training in assertive skills (8-week sessions for about 2 hours). In addition, 41 parents formed the control group (with no assertiveness training). Before and after this training (or the same amount of time for the control group), adolescents were administered the psychometric test known as the Rathus Assertiveness Schedule (RAS).

Results A significant increase in RAS scores was found in adolescents whose parents were subjected to the assertiveness training. Moreover, there was a significant decrease in self-restriction scores in patients with ED after their parental assertiveness intervention. No significant changes were observed, however, in the control group.

Conclusions Our results indicate that providing families with educational tools that aim at developing assertive communication may boost the level of assertiveness in adolescents and, thereby, presumably help in the prognosis of ED.

Reconceptualization of recovery from anorexia nervosa: Patients' perspective

M. Jarrige

Toulouse University Jean-Jaurès, CERPPS, Toulouse, France

Outcome research has not found a consistent definition of recovery from anorexia nervosa by consensus of experts, or by empirical validation. Therefore, medical criterion of recovery varies between studies and results are not comparable. This poster refers to a study of 44 participants treated for anorexia nervosa and who believe they have recovered. The purpose of this study is to reconceptualize recovery from patients' perspective. The Free Association about Recovery – Questionnaire (FAR-Q) is a new tool by which to explore and understand the anorexic's account of recovery. Content analysis reveals four subjective definitions of recovery: (1). Return to the social normality; (2). Cohabit with eating disorder; (3). Self-acceptance; (4). Rebirth. This study assesses patients' stages of recovery process and gives recommendations to health professionals.

Long-standing Pica with compulsive features in a woman with iron and zinc deficiency

C. Kwok*, H.Y. Lee

Singapore General Hospital, Psychiatry, Singapore

* Corresponding author.

Introduction Pica is the consumption of non-nutritive substances, which is inappropriate to the individual's cultural practices or developmental level. It is frequently associated with mental retardation, and occasionally observed in pregnant women and children.

Objectives We describe a case of long-standing pica in a woman with no co-morbid psychiatric condition.

Case Madam NA is a 27-year old married Malay housewife, with 4 sons and 4 miscarriages. Her mother had addiction problems. She sought help from the Eating Disorders Clinic, Singapore General Hospital, for uncontrollably eating uncooked rice. This started at age 8, when she was left alone at home with no food. Since then, she had been eating up to 10 cups of raw rice daily. She was unable to leave the house without carrying a bag of raw rice; if she forgot, she would feel intense discomfort and would need to return to get the rice. She persisted in eating raw rice despite it causing friction in her marriage. When she tried to stop, she would get irritable and crave it. This behavior only ceased during her pregnancies but would restart soon after delivery. There was no other psychiatric history. Blood investigations showed anemia, with iron and zinc deficiency, as well as newly diagnosed Grave's disease. After iron and zinc supplementation, her raw rice intake decreased substantially.

Conclusions We report an unusual case of long-standing pica with compulsive features in a young woman with no psychiatric co-morbidity, which improved during pregnancy and with iron and zinc supplementation.

Eating disorders in Malays in Singapore

V. Kwok^{1,*}, H.Y. Lee², S.M. Tan², W.S.A. Chee¹, K. Ann², N.R. Binte Kamaruzaman³¹ Sengkang Health, Psychiatry, Singapore² Singapore General Hospital, Psychiatry, Singapore³ Singapore General Hospital, Nursing, Singapore

* Corresponding author.

Introduction The prevalence of eating disorders has been increasing in the Asian countries. Malays in Singapore are at the crossroads because they are largely traditional in practice and almost all are Muslim, but are exposed to western culture. Studies found that Malays at increased risk of eating disorders but yet those that present for treatment are very small, and this study aims to study Malays with eating disorders to unveil this contradiction.

Methods All Malay patients presenting to Singapore General Hospital (SGH), which hosts the only specialized eating disorder programme in Singapore, between 2003 and 2014 were identified and medical records studied retrospectively.

Results Malays constitute only 42 out of 1340 patients treated in the same period. The mean age at presentation is 18.81 years (SD=5.54) and the majority are students (78.6%). A total of 92.9% are single. There are more cases of bulimia nervosa than anorexia nervosa (45.2% vs. 26.2%). In total, 54.8% have psychiatric comorbidities, the most common is depression (31.0%), 38.1% have a history of deliberate self-harm and 21.4% attempted suicide. A total of 52.4% reported teasing as a trigger, while 16.7% were triggered by being overweight.

Discussion There is only a small number of Malays that presented. Fasting is commonly which may be confused with restriction. Other factors could be lack of awareness. The higher prevalence of bulimia nervosa suggests that purging is recognized as abnormal. High prevalence of co-morbidities suggests that family members recognize co-morbidities better. Outreach programs for Malay will help increase awareness.

Use of atomoxetine in eating disorders. A case report

R. Landera Rodríguez^{1,*}, M. Juncal Ruiz¹, L. Sánchez Blanco¹, G. Pardo de Santayana Jenaro¹, O. Porta Olivares¹,M. Gómez Revuelta², I. Madrazo del Río Horteiga¹,M. Pérez Herrera¹, D. Abejas Díez¹, J. González Gomez¹¹ Hospital Universitario Marqués de Valdecilla, Psychiatry, Santander, Spain² Hospital Universitario Álava-Sede Santiago, Psychiatry, Vitoria-Gasteiz, Spain

* Corresponding author.

Introduction Eating disorders (EDs) are an important public health problem and not all patients respond adequately to psychotherapy. In the last decade, researchers report a significant comorbidity of EDs and attention-deficit/hyperactivity disorder (ADHD), especially binge eating disorder and bulimia nervosa. Some studies postulate the hypothesis of a common neurobiological substrate, such as noradrenergic pathways among others.

Objectives To revise the possible use of atomoxetine, a highly selective noradrenergic reuptake inhibitor, for the treatment of EDs.

Methods We describe the effect of atomoxetine in a young woman with purging disorder and history of ADHD in childhood added to cognitive behavioural therapy (CBT).

Results patient had selective/restrictive eating behaviours, daily purges and occasional binges for last five years. At age 14 she was diagnosed with ADHD by impulsivity/aggressiveness and poor school performance, but she did not take drugs and left medical consultations. She came to our specific unit of EDs in november-2015. Her BMI was 24.88 kg/m². We initiated CBT and atomoxetine (80mg/day). In this first year of treatment binges and purges have disappeared and exposure to new foods and body image have improved partially. We found clear improvement in mood, motivation and attention/concentration in relation with introduction of atomoxetine. These facts have positive impact on the clinical evolution. Her current BMI is 26.90 kg/m².

Conclusions Identify comorbid ADHD to assess the use of specific drugs for this disorder could be beneficial in the treatment and prognosis of EDs. However, more studies are needed to determine effectiveness, particularly of non-stimulant drugs.

³ Vita-Salute San Raffaele University, University Statistical Center for Biomedical Sciences, Milan, Italy

* Corresponding author.

Introduction to date, studies on the relationship between Theory of Mind (ToM) and eating disorders (ED) have never considered binge eating disorder (BED).

Aims a) to assess ToM abilities in a sample of patients suffering from BED comparing them with healthy controls; b) to evaluate the influence of several variables (demographic, clinical and neuropsychological dimensions, attachment styles, traumatic events, comorbid Axis I and II disorders) on ToM abilities.

Methods we assessed ToM in a sample of 20 BED patients and 22 women from the general population using the Reading the Mind in the Eyes Test (RMET) and the Faux Pas Test (FPT).

Results regarding the first aim, the comparison between groups showed that the clinical group scored significantly lower than the control group on the RMET as well as on FPT. Regarding the second aim, two different multiple regression models were performed: one for the RMET and one for the FPT. Both of them led to significant results. When modeling RMET score, it emerged that age and Binge Eating Scale significantly reduce the score, while vocabulary and drive for thinness have a positive effect ($r^2 = 0.62$). When modeling FPT score, we found that central coherence and binge eating significantly reduce the total score ($r^2 = 0.33$).

Conclusions our study begins to shed light on the relationship between ToM and BED; in particular, it suggests that BED patients have lower mentalization skills than healthy controls and ToM abilities are partially influenced by clinical variables related to eating pathology.

Some stay the same: Personality change after treatment for eating disorder

J. Levallius^{1,*}, W. Mu², C. Norring¹, D. Clinton¹, B. Roberts²

¹ Karolinska Institute, Clinical Neuroscience, Stockholm, Sweden

² University of Illinois, Psychology, Urbana-Champaign, USA

* Corresponding author.

Introduction Strong evidence establishes a close relationship between personality traits and mental illness; where personality can be said to influence the likelihood, severity and longevity of a mental disorder. Personality is usually seen as fixed, yet there is a growing body of evidence for the changeability of personality, though this has rarely been studied in relation to mental disorders.

Objective To study the longitudinal interplay between personality and eating disorders (EDs), particularly the associations between personality, recovery and treatment modality.

Aims To investigate changes in the five domains and thirty lower-level facets of personality in non-underweight EDs, and its associations to intervention and outcome.

Methods Two hundred and nine adults with EDs enrolled either in a four-month multimodal psychodynamic group-therapy (DAY) or four-six month internet-based supported cognitive behavioural therapy (iCBT). ED diagnosis and personality (by the five-factor model) were assessed at baseline, termination and 6-month follow up. Structural equation modeling was used to analyze domain-level development, and reliable change (RCI) for facet-level development.

Results Remission rate at end of treatment was 71% in DAY and 55% in iCBT. Over time, Neuroticism decreased significantly while Extraversion, Openness and Conscientiousness increased ($P < 0.01$). Treatment and outcome had little influence on domain-level change. At the facet-level, 28% of patients reliably changed in any given facet, and there were several differences in pattern based on treatment and outcome.

Conclusions This study lends support for the possibility of personality change and its relevance for recovery from EDs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Run for it: Compulsive exercise in adolescents with eating disorders – a nationwide longitudinal study

J. Levallius*, C. Collin, A. Birgegård

Karolinska Institute, Clinical Neuroscience, Stockholm, Sweden

* Corresponding author.

Introduction Rigorous exercise to control weight and/or shape and to avoid negative affect has been proposed as significant in the etiology, development and maintenance of eating disorders (EDs), resulting in more severe and enduring pathology. However, few studies have investigated compulsive exercise (CE) among adolescents with EDs.

Objective To study the longitudinal relationship between EDs and CE in adolescents.

Aims to investigate if adolescent ED patients show a similar relation between EDs and CE as previous research has found in adults.

Methods A total of 3116 girls and 139 boys from a nationwide clinical EDs database were investigated on CE prevalence and frequency in relation to ED diagnosis, psychiatric symptoms, associated features and outcome. Denial of illness in self-ratings was adjusted for.

Results Adjusted CE prevalence in girls was 44%; with high prevalence in bulimia nervosa. Average CE frequency was 3.9 times/week (SD=2.6). Those with CE scored significantly higher than non-CE on total ED severity, dietary restriction and negative perfectionism ($P<0.001$). There were only minor differences between CE and non-CE patients on emotional distress, hyperactivity, suicidality and self-esteem. Among boys, adjusted CE prevalence was 38%, and only total ED severity was significantly related to CE ($P<0.05$). Initial CE did not impact prognosis, yet cessation of CE during 1-year follow-up was associated with ED remission.

Conclusions CE is a common clinical feature in adolescents with EDs, as previously found in adults. CE had less detrimental impact on EDs than predicted and cessation was associated with better outcome.

The role of interoceptive awareness in eating disorders: A study on a group of binge eaters

G.M. Longo^{1,*}, J. Falcone¹, R.M. Martoni¹, L. Bellodi², A. Ogliari², S. Erzegovesi¹

¹ IRCCS San Raffaele, Department of Clinical Neurosciences, Milan, Italy

² Vita-Salute San Raffaele University, Faculty of Psychology, Milan, Italy

* Corresponding author.

Introduction Interoceptive awareness is defined as the ability to perceive the body states. Such ability is provided by the interoceptors, organs and structures specifically designated to receive both internal and external stimuli. This capability, especially the perception of satiation, seems to be lacking in individuals suffering from Eating Disorders and there is no procedure to increase this ability.

Objectives The primary purpose is to improve patient's interoceptive awareness. We tested whether patients diagnosed with binge eating disorder (BED), while deprived of eyesight, would better focus on their internal signals, such as the satiation feeling, and therefore eat less and slower.

Methods For the first time, 29 patients with BED were deprived of vision during a meal. In a standardized procedure, participants ate two different meals, the first one while deprived of eyesight, the second one, a week later, in normal conditions. Both the amount of eaten food and the total time to complete the meal were taken into account during each of the meals. The patients filled in a Visual Analogue Scale (VAS) questionnaire at the end of each meal, in order to evaluate the experience and their internal feelings.

Results The results show that patients suffering from BED, when deprived of eyesight, eat less food, take more time to finish the meal and experience the same level of satiation with respect to the normal condition.

Conclusion This procedure could be of great interest for the implementation of specific intervention protocols that are aimed at the recovery of interoceptive awareness in patients with eating disorders.

Confirmatory factor analysis of the eating attitudes test short version in a sample of Portuguese women

C. Marques*, A.T. Pereira, M. Marques, M.J. Soares, C. Roque, A. Macedo

Faculty of Medicine, University of Coimbra, Department of Psychological Medicine, Coimbra, Portugal

* Corresponding author.

Introduction The Eating Attitudes Test-40 (EAT-40) is a valid index of symptoms frequently observed in eating disorders. The EAT-40 was adapted and validated for the Portuguese population. Thereafter a short-version composed of 25 items selected from the exploratory factor analysis (EAT-25) was developed. Apart from the total score, the TAA-25 evaluates three dimensions: Diet, Bulimic Behaviours and Social Pressure to Eat.

Objective To examine the factor structure of the EAT-25 using confirmatory factor analysis (CFA) in a sample of Portuguese women.

Methods The sample was composed of 433 women (mean age = 36.07; SD = 15.15). CFA was used to test the model suggested by prior exploratory factor analyses of EAT-25. AMOS software was used.

Results After four items were deleted and some errors were correlated, CFA indicated a good fit for the second-order factor ($\chi^2/df = 3.066$; CFI = 0.918; GFI = 0.883, RMSEA = 0.069; $P[\text{rmsea} \leq 0.05] < 0.001$). The 19-item TAA showed excellent internal consistency ($\alpha = 0.91$) and the three dimensions presented good Cronbach's alphas ($\alpha > 0.80$).

Conclusions These findings suggest that the 21-item TAA model obtained through CFA is a reliable and valid measure to assess disordered eating attitudes among women.

Cognitive fusion: Maladaptive emotion regulation endangering body image appreciation and related eating behaviours

M. Marta-Simões*, C. Ferreira, A.L. Mendes

Faculty of Psychology and Education Sciences, University of Coimbra, CINEICC, Cognitive-Behavioral Center for Research and Intervention, Coimbra, Portugal

* Corresponding author.

Body image-related cognitive fusion is described as the perception that undesired and distressing internal events related to body image are reliable representations of reality. This maladaptive emotion regulation process is known for its impact on human suffering, namely eating psychopathology. On the contrary, body appreciation is a positive body image construct, defined as an attitude of acceptance and affection toward one's body image characteristics, despite some level of dissatisfaction. Although body appreciation associates negatively with several pathogenic processes, its relationship with body image-related cognitive fusion is still unexplored. The present study intended to analyse the power of body image related cognitive fusion regarding its impact on body appreciation, and also on the engagement in disordered eating. The study's sample comprised 308 women, aged between 18 and 35. A path model tested the mediator role of body image related cognitive fusion in the relationship between body image dissatisfaction and body appreciation, and eating disorders symptomatology, controlled for the effect of body mass index.

The tested model accounted for 67% of the variance of disordered eating. Body image related cognitive fusion appeared as a significant mediator of the association between body dissatisfaction and body appreciation. Body appreciation presented a significant direct effect on eating disorders symptomatology. These findings highlight the disturbing effect of cognitive fusion related to body image

on the construction of a positive body image, presenting an impact on the engagement in disordered eating. In this line, cognitive fusion may be a pertinent target in clinical practice and also within eating disorders prevention.

What relationship between eating disorders and alexithymia among medical students?

N. Messedi*, I. Feki, R. Masmoudi, B.N. Saguem, J. Masmoudi
Hedi Chaker University Hospital, Psychiatry A, Sfax, Tunisia
* Corresponding author.

Introduction The student population seems to be vulnerable to eating disorders (ED) but is this in relation to their ability to express their emotions or alexithymia?

Objectives Studying the prevalence of ED and alexithymia among medical students, and establish the relationship between these entities.

Methods It was a cross-sectional study of 97 students in Sfax University Medicine (Tunisia). We used:

- a questionnaire containing demographic and clinical data;
- Eating Attitudes Test (EAT-26): a score ≥ 20 indicates ED;
- Toronto Alexithymia Scale (TAS-20): a score ≥ 61 indicates alexithymia.

Results The average age of participants was 24.07 years (± 2.71); the sex ratio (M/W) was 0.4. Their average BMI was 22.85 kg/m² (± 3.36). They were smoking in 36.1% and sedentary in 43.3% of case. They had a nibbling activity in 57.7%. The average score of the EAT-26 was 11.66 \pm 8.66 and prevalence of TCA was 19.6%. The average score of TAS-20 was 50.92, 0.46 and alexithymia was found in 16.5% of students. ED was significantly correlated with nibbling ($P=0.02$), BMI or overweight ($P=0.012$), smoking ($P=0.006$) and physical inactivity ($P<0.00$). Also alexithymia was significantly correlated with smoking ($P=0.003$) and physical inactivity ($P=0.025$). A significant correlation was found between alexithymia and ED ($P=0.008$).

Conclusion It is clear from our study an association between alexithymia and the ED. Psychological support aimed specifically alexithymic dimension is indispensable, not only for decreasing the emergence of ED but also contributing to lower any addictive behavior.

University of Padua, Department of Neurosciences, Padua, Italy
* Corresponding author.

Introduction Prenatal risk factors, such as gestational complications and exposure to stress during pregnancy, may have a role in the development of many psychiatric disorders including eating disorders.

Aim To investigate the impact of prenatal stress exposure on the development and clinical features of anorexia nervosa.

Methods One hundred and nine patients with a lifetime diagnosis of anorexia nervosa and 118 healthy controls underwent a clinical assessment, which included interviews, questionnaires and a

neuropsychological battery. The mothers of the patients and controls underwent a specific interview focused on stressful life events, which occurred during pregnancy. Obstetric and neonatal records were consulted.

Results The mothers of patients experienced more severe stressful episodes during pregnancy than the mothers of controls and the perceived distress showed significant positive correlation with both total number of obstetrical complications and placental weight. In patients, the severity of stressful events was strongly associated to cognitive rigidity and perseverance.

Conclusions Prenatal stress exposure might be a risk factor for the development of anorexia nervosa and it is associated with cognitive traits of rigidity and perseverance.

⁴ University of Salerno, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana" Section of Neurosciences, Salerno, Italy

* Corresponding author.

Introduction According to the trans-diagnostic perspective, disturbances in eating patterns of eating disorders (EDs) are considered as epiphenomena secondary to the patient's overvaluation of his/her body shape and weight.

Objectives The phenomenological theory states that the main feature of ED psychopathology is a disturbance in the way affected persons experience their own body (embodiment). Insecure attachment may promote the development of unstable self-identity leading to use body weight as a source of self-definition.

Aims The aim of our study was to assess the role of embodiment impairments in the relationships between attachment styles and ED psychopathology.

Methods One hundred twelve ED patients and 108 healthy subjects filled in the Identity and Eating Disorders (IDEA) questionnaire, which assesses embodiment and personal identity abnormalities, the eating disorder inventory-2 (EDI-2) and the experiences in close relationships (ECR) scale, which defines attachment styles.

Results ED patients showed IDEA, EDI-2 and ECR scores significantly higher than controls. Significant correlations between IDEA scores, insecure attachment and almost all EDI-2 sub-item scores emerged in ED patients but not in controls. IDEA total score mediated the relationship between avoidant attachment and EDI-2 interoceptive awareness.

Conclusions These findings demonstrate that in ED patients insecure attachment is correlated to disorder of identity and lived corporeality that, in turn, mediates the association between attachment and a specific ED psychopathological trait. Therefore, we suppose that early relationships, through the development of disturbances in identity and embodiment, lead to altered perception of bodily signals and deranged discrimination of one's emotions, which could contribute to EDs.

The impact of self-esteem on eating disorders

F. Mora*, S. Fernandez Rojo, C. Banzo, J. Quintero
Hospital Universitario Infanta Leonor, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Eating disorder (ED) are an important mental health problem because of their overall prevalence, especially in children and adolescents. Low self-esteem is considered, along with others, one of the risk factors for the development of these disorders, without having clarified the real impact of low self-esteem on the development of ED. The aim of this study is to analyze the relationship between self-esteem and the risk of developing an eating disorder.

Material and method We have selected a sample of 500 patients who were in the 2nd year of secondary school to which has been applied a battery of scales including the Rosenberg self-esteem scale, and the EAT-26 scale for ED. We used logistic regression using SPSS to analyze the relationship between both variables.

Results In addition to analyzing clinical and sociodemographic characteristics of the sample, we have found that for every decrease of 1 point in Rosenberg scale, there is an increase of 9% in the probability of being a case of ED for the EAT-26 scale ($P < 0.05$).

Conclusions Regarding these results, we can conclude that, in our sample, having low self-esteem score, significantly increases the likelihood of having a high score on the scale of ED. This data can be useful in establishing a preventive strategy and an adequate treatment.

Cortisol awakening response in binge-purging and restrictive anorexia nervosa

M. Nigro^{1,*}, A.M. Monteleone¹, F. Pellegrino¹, M. Cimino¹, V. Di Maso¹, U. Volpe¹, P. Monteleone²

¹ Second University of Naples, Psychiatry, Naples, Italy

² University of Salerno, Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Section of Neuroscience, Salerno, Italy

* Corresponding author.

Introduction Anorexia nervosa (AN) is a complex psychiatric disorder characterized by severe restriction of food intake and aberrant behaviours. The endogenous stress response system, including the hypothalamus-pituitary-adrenal (HPA) axis, may have a role in the pathophysiology of AN.

Objectives It has been shown that specific clinical traits of AN, such as binge-purging behaviours, may be associated with higher psychopathology and poorer outcomes. Therefore, the HPA axis functioning could differ between patients with restrictive AN (ANR) and those with binge-purging AN (ANBP).

Aims In order to evaluate whether HPA axis functioning differs between the two subtypes of AN, we assessed the cortisol awakening response (CAR) of symptomatic ANR and ANBP patients.

Methods Our sample included 17 ANBP and 18 ANR patients, and 42 healthy women. All of them filled in the Eating Disorder Inventory-2 (EDI-2). For CAR assessment, participants collected saliva samples at home. Saliva cortisol concentrations were measured by an enzyme immunoassay method.

Results ANR and ANBP patients exhibited a CAR significantly higher than healthy women. Furthermore, the CAR of ANBP women was higher than that of ANR women and positively correlated with the bulimia subitem score of the EDI-2.

Conclusions Present findings show, for the first time, differences in the CAR between ANBP and ANR subtypes supporting the idea that binge-purging behaviours may have a specific connection with HPA axis.

Association between eating disorders and 5-HTTLPR polymorphism: The experience of an Italian eating disorders unit

M.G. Oriani^{1,*}, M. Barchiesi², L. Sabbatini², B. Nardi²

¹ Centro Salute Mentale Ancona AV2 ASUR MARCHE, Department of Mental Health, Ancona, Italy

² Clinica Psichiatrica, Az. Ospedaliero-Universitaria Ospedali Riuniti, Ancona, Italy

* Corresponding author.

Introduction Eating Disorders (ED) as Anorexia Nervosa (AN), Bulimia Nervosa (BN) and Binge Eating Disorder (BED) are severe and debilitating psychiatric diseases whose etiology is complex and still largely unknown. Several studies seem to suggest that serotonin could be involved and notably there are several associations with 5-HTTLPR polymorphism, especially with the S allele and the S/S genotype.

Objectives The purpose of this study is to evaluate if an association between ED and 5-HTTLPR (especially the S allele frequency) can be shown.

Material and methods A group of about 100 subjects attending the eating disorders unit of Ancona will be tested. Their DNA will be taken and the frequency of the S allele will be compared with a control subjects group negative for ED. Then, the ED group will be divided, according to the DSM-5 criteria, in 3 subgroups (AN, BN, BED) and potential differences will be evaluated.

Results At the moment, we are still collecting patients. According to other studies involving 5-HTTLPR, the S allele frequency in Italy is comparable with the European one, so there is reason to believe that an association could be found.

Conclusions Serotonin involvement in ED in literature is shown, but it still has to be completely expounded. Studies as this one could help in describing the etiology and the development of this disease.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Several studies recently investigated how Anorexia Nervosa patients (ANp) process multimodal information. Longo (2015) hypothesized that ANp might be less reliant on visual perception of bodies than healthy controls (HC). Case et al. showed that processing of multimodal information might be disrupted in ANp. Literature lacks of studies that measure precisely and compare directly the contributions of each sensory input.

Objective To investigate the integration of visual and haptic inputs in ANp compared with HC and measure the weight of each input.

Method We used a visuo-haptic integration task with a setup adapted from Gori et al. (2008) to measure each sensory input's when judging the size of a cube according to Maximum Likelihood Estimation theory which describes the optimal multimodal integration behaviour (Ernst and Banks, 2002). Fifteen ANp and 16 HCs were recruited.

Results Regardless the group, we found considerable individual variability about the integration processes; moreover, many participants did not integrate optimally. Correlation analysis suggested that ANp rely less on visual information than HC.

Conclusions Despite using a setup previously validated with children, the observation that many HC did not integrate optimally is not in line with the results of previous studies, making it difficult the comparison with the AN group. The setup might not be adapted to adults and it needs to be improved. Our study shows for the first time how it might be possible to measure and compare directly the contribution of two different sensory modalities. This could provide precious information to deeply investigate the pathology.

The research has the intention to determinate the prevalence, risky factors of overweight and obesity in a sample of six hundred people between seven (7) and eighteen (18) years old, chosen by a simple random sampling with exclusion criteria, pathologies that affect the weight and size (diabetes paralysis; malformation or physic limitations). The data was collected through national poll of the nutritional situation and Colombia ENSIN, in the demographic and anthropometric information register and poll identification of food habits and physical activity questionnaire for children PAQ-C. The comparative analysis was made through SPSS in two determined populations by the low and medium social status criteria in the overweight and obesity variables, risky factors related with physical activity food habits and gender. It can be concluded that the population presents normal weight, prone to obesity. Based on the medium socioeconomic status, the percent of male obese teenagers is higher than the female one. Children independent of the socioeconomic status, present a higher percentage of obesity than teenagers. A high percent of population do not do physical exercise. There is no evidence of the relation between socioeconomic level and the presence of unhealthy food habits.

Introduction Family members of patients with Eating Disorders (EDs)–in dealing with the relatives' disease–report negative feelings such as self-blame and criticism, but little is known regarding their coping strategies.

Objectives To describe coping strategies in a sample of relatives of patients with EDs using the Family Coping Questionnaire–Eating Disorder version (FCQ-ED).

Aims (1) To evaluate coping strategies in relatives of patients with EDs; (2) to describe differences in coping strategies according to type of kinship with the patient; (3) to identify correlations among socio-demographic characteristics, patients' clinical characteristic, and type of coping strategies.

Methods Relatives' coping strategies were evaluated using the FCQ-ED, a self-administered questionnaire, consisting of 32 items, grouped in 5 subscales: coercion; positive communication; collusion; seeking for information; avoidance, plus one item on seeking for spiritual help.

Results Seventy-two patients and 127 relatives were recruited. The most frequently adopted coping strategies were seeking for information, positive communication, seeking for spiritual help; the former were positively correlated with the level of education of both patients and relatives. Mothers avoided the patients less frequently than other relatives.

Discussion This is one of the first studies focused on coping strategies in families of patients with EDs showing that problem-oriented ones are used quite often. Socio-demographic characteristics and type of kinship can have an impact on the adoption of coping strategies, but further longitudinal studies are needed in order to identify other possible factors implied in their development.

Conclusions This represents an initial attempt to understand how clinical, social and personal variables can have an impact on the development of coping strategies.

Turkish version of body attitude test: Its reliability and validity

M. Huri¹, S. Sahin¹, S. Akel¹, M. Slepceky^{2,*}, A. Kotianova³

¹ Hacettepe University, Faculty of Health Sciences, Occupational Therapy, Ankara, Turkey

² UKF Nitra, psychology, Liptovsky, Mikulas, Slovak Republic

³ UKF Nitra, psychology, Nitra, Slovak Republic

* Corresponding author.

Introduction Breast cancer (BC) may cause problems on body perception and awareness which can be perceived as a threat on body attitude among women with breast cancer.

Objectives The Body Attitude Test (BAT) assesses subjective attitude toward women's own body.

Aim The aim of the present study was to develop the Turkish version of the BAT and examine its reliability and validity.

Methods The study group (SD) consisted of 72 women diagnosed with BC while 100 healthy women (HW). The women evaluated by BAT, Eating Disorder Inventory (EDI) and Self Esteem Inventory (SEI) in 7–10 days intervals. Internal consistency was determined with Cronbach's alpha coefficient. Factor analysis was conducted on BAT ratings given by control group.

Results The mean age was 43.7 ± 8.76 of women with BC while 46.4 ± 10.84 in HW. Mean duration of cancer was 2.4 ± 0.7 years. Factor analysis showed BAT was composed of two factors as body dissatisfaction and lack of familiarity with one's body. The BAT demonstrates satisfactory level of internal reliability ($\alpha = 0.932$). BAT was related with EDI subscales: drive for thinness ($r = 0.741$, $P < 0.001$), ineffectiveness ($r = 0.736$, $P < 0.001$) and body dissatisfaction ($P = 0.718$, $P < 0.001$) and SEI subscale: familial self-esteem ($r = -0.629$, $P < 0.001$).

Conclusion The results support the validity and reliability of BAT which is able to differentiate the clinical and non-clinical form of subjective attitude toward women's own body. Turkish version of BAT could be used as an appropriate measure for assessing subjective attitude towards own body in women with and without breast cancer in Turkey.

Eating problems and body image among Finnish adolescents

A. Sourander^{1,*}, J. Maezono²

¹ Child Psychiatry, Turku University, Turku, Finland

² Turku University, Child Psychiatry, Turku, Finland

* Corresponding author.

Objective To study prevalence of self-reported body image and eating distress symptoms among Finnish adolescents, and to study associations between psychopathology, body image and eating distress.

Design Cross-sectional population-based, survey subjects, 7th to 9th grade students aged 13–15: 3154 in Finland in 2014.

Methods Data were collected by student self-reported questionnaire including scale designed for evaluating attitudes and behaviors towards body shape and eating, and Strengths and Difficulties Questionnaire (SDQ) for assessing emotional and behavioral problems.

Results The female adolescents reported much more dissatisfaction and concerns with their bodies than the males, high levels of distress with body emotional, behavioral and peer problems measured with SDQ. Body image and eating problems were higher in Finnish than Japanese females with peer problems.

Conclusion The finding was in accordance with previous studies that found that body image and eating distress are associated with to gender and wide range of psychiatric problems.

Self-admission to in-patient treatment: Patient experiences of a novel approach in the treatment of severe eating disorders

M. Strand^{1,*}, C.M. Bulik², Y. von Hausswolff-Juhlin¹, S.A. Gustafsson³

¹ Stockholms Centre for Eating Disorders, Research and Development Unit, Stockholm, Sweden

² Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden

³ Örebro University, School of Medical Sciences, Örebro, Sweden

* Corresponding author.

Introduction The course of an eating disorder is often prolonged and can lead to enduring disability for many years, with some patients requiring lengthy periods of in-patient care. Unfortunately, there is still little evidence concerning the optimal model of in-patient care for these patients.

Objectives Self-admission is a novel treatment tool, whereby patients who have high health care utilization are offered the possibility to self-admit to an inpatient ward for up to seven days, because of deteriorating mental health or any other reason. Purposes behind the model are to increase the availability of in-patient care, to promote autonomy and agency, and to decrease total inpatient care utilization.

Aims To investigate whether self-admission can be beneficial for patients with severe eating disorders.

Methods Two beds out of eleven at a specialist eating disorders inpatient unit were reserved for self-admission of well-known patients. All participants were interviewed about their experiences in the program at 6 months.

Results Participants described an increased sense of agency and safety in their everyday lives. Suggestions were also made, such as a more active outreach approach in promoting admission, providing a continual staff contact during the brief admission episode, and offering a similar self-admission model for day treatment.

Conclusions Self-admission is a viable tool in the treatment of severe eating disorders and can increase quality of life by providing a safety net and promoting agency. However, logistical obstacles must be addressed in order to promote a constructive use.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Eating Disorders (ED) affect an individual's physical and mental health with abnormal eating habits. Traumatic life events may underlie the development of ED as many studies document [1]. In the present study, we examined the effectiveness of EMDR therapy that was originally used to treat Post-Traumatic Stress Disorder (PTSD) [2], on restrictive eating symptoms associated with trauma. Cases B.Ö. (18) and B.S. (20) came to the clinic consecutively for resembling complaints about the sense of food sticking in their throat, breathing difficulties, raised heart beatings, unease to swallow, and choking fear. The patients revealed past traumatic events about being out of breath while swallowing

their bites. Then, they have started to restrict their food intake and the types of food consumed, which led to emaciation with health problems, interrupted daily routines, and social isolation; meeting the diagnosis of avoidant/restrictive food intake disorder (ARFID) in DSM-5. Due to traumatic experiences, EMDR therapy was applied.

Discussion After five EMDR therapy sessions, patients turned back to healthy eating habits, normal BMI, and effective daily life. As expected, EMDR therapy made significant improvements in the treatment of ARFID.

Conclusion EMDR can be useful to treat ED with traumatic background.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Sleep disturbances in anorexia nervosa

M.F. Vieira^{1,*}, P. Afonso²

¹ Centro Hospitalar de Lisboa Central, Child and Adolescent Psychiatry, Lisboa, Portugal

² Centro Hospitalar de Lisboa Norte, Psychiatry, Lisboa, Portugal

* Corresponding author.

Introduction In clinical practice, insomnia is a common feature in anorexia nervosa (AN). Sleep self-reports in AN suggest that these patients report poor sleep quality and reduced total sleep time. Weight loss, starvation and malnutrition can all affect sleep. Patients with eating disorders who have sleep disturbances have more severe symptomatology.

Objectives The authors intend to review sleep disturbances observed in AN, describe possible pathophysiological mechanisms and evaluate the clinical impact of sleep disturbances on the treatment and prognosis of the disease.

Methods In this study, a non-systematic search of published literature from January 1970 and August 2015 was carried out, through PubMed, using the following keywords: 'sleep', 'anorexia nervosa' and 'insomnia'.

Results These patients subjectively report having poor sleep quality, with difficulty falling asleep, interrupted sleep, early morning waking or reduced total sleep time. Sleep disturbances found in AN using polysomnography are: reduction in total sleep time, decrease in slow wave sleep, slow wave activity and reduced sleep efficiency.

Conclusions Privation of adequate and restful sleep has a negative impact on the quality of life of patients, may contribute to the appearance of co-morbidities, such as depression and anxiety, and to a poor prognosis for AN.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Eating disorders symptoms related to gestational BMI in breastfeeding mothers

F. Volpe*, L. Giliberti, G. Soldera, G. Straface, V. Zanardo
Policlinico Abano Terme, Divisione Medicina Perinatale, Padova, Italy

* Corresponding author.

Background and aims Research has shown that maternal obesity and underweight are major risk factors for reduced initiation, duration, and exclusivity of breastfeeding. This prospective, cohort study analysed the association between gestational body mass index (BMI) and symptoms of eating disorders (ED) in breastfeeding women.

Methods The study involved 1318 consecutive, at term, healthy mothers, who delivered at the division of Perinatal Medicine of Policlinico Abano Terme, located in a North-Eastern Italy industrialized area, supporting advanced educational levels, good socio-economic status and low and late fertility. The day of discharge mothers completed the eating disorder examination-questionnaire (Fairburn and Beglin, 2008), including four subscales, restraint (R), shape concerns (SC), weight concerns (WC), eating concerns (EC) and a global score (GS). Mothers' BMI groups were categorized as underweight, normal weight, overweight and obese, according to 2009 IOM guidelines.

Results EDE-Q mean values (\pm SD) significantly increased with BMI increasing categories. Compared to normal weight mothers ($n=290$, 22.0%), obese women ($n=273$, 20.7%) had higher significant GS (0.6 ± 0.7 vs. 0.2 ± 0.3 ; $P=0.006$), R (0.6 ± 0.9 vs. 0.3 ± 0.6 ; $P<0.0001$), EC (0.4 ± 0.6 vs. 0.3 ± 0.5 ; $P<0.0001$), SC (0.9 ± 1.0 vs. 0.3 ± 0.5 ; $P<0.0001$) and WC (0.7 ± 0.8 vs. 0.1 ± 0.3 ; $P<0.0001$). In addition, formula-feeding adoption at discharge significantly increased with BMI increasing categories (P per trend = 0.01).

Conclusions We present evidence that gestational obesity is associated with reduced breastfeeding rates at discharge and higher ED symptomatology. Women need information and support to gain adequate weight during pregnancy.

Bulimia nervosa in Singapore: Clinical profile, comorbidity and gender comparisons

K.A. Zainal*, K.W. Ng, H.Y. Lee

Singapore General Hospital, Psychiatry, Singapore

* Corresponding author.

Introduction Though eating disorder cases have been on the rise in Asia, little is known about them. Bulimia nervosa (BN) has been associated with poor treatment outcome and high mortality risk, and is the second most commonly diagnosed eating disorders in Singapore, after anorexia nervosa (AN), yet no report thus far has explored this condition.

Objectives The current study seeks to describe the clinical population diagnosed with BN in our hospital treatment program, as well as to compare their clinical characteristics with a previously published local study on patients with AN.

Method Retrospective medical records review was carried out for patients diagnosed with BN in our hospital's eating disorders treatment program. Patient records from 2003 to 2013 were retrieved and analyzed. We also further compared presenting characteristics across genders and with AN patients.

Results Between 2003 and 2013, 348 patients were diagnosed with BN by psychiatrists based on the Diagnostic and Statistical Manual of Mental Disorders (DSM IV-TR). BN patients presented with high rate of self-harm behaviors (37.1%), previous suicide attempts (19.0%) and psychiatric comorbidities (67.5%), many of which require inpatient treatment. Significant differences were found between genders and in comparison with the AN patients.

Conclusion Our results suggest that many patients with BN present with severe psychiatric comorbidities, in some aspects more severe than the AN population. The current study appeals for the development of more effective detection and treatment of vulnerable populations in Singapore. We further discuss about

the potential roles of mental health literacy and stigmatization in influencing treatment-seeking behaviors.

What is commonly missed in the suicidal risk assessments in the emergency room?

N. Alavi^{1,*}, T. Reshetukha², E. Prost², A. Kristen², D. Groll²

¹ University of Toronto, Psychiatry, Toronto, Canada

² Queen's University, Psychiatry, Kingston, Canada

* Corresponding author.

Introduction Suicidal behaviour remains the most common reason for presentation to the emergency rooms. In spite of identifiable risk factors, suicide remains essentially unpredictable by current tools and assessments. Moreover, some factors may not be included consistently in the suicidal risk assessments in the emergency room by either emergency medicine physicians or psychiatrists.

Method Step 1 involved the administration of a survey on the importance of suicide predictors for assessment between psychiatry and emergency medicine specialties. In step 2 a chart review of psychiatric emergency room patients in Kingston, Canada was conducted to determine suicide predictor documentation rates. In step 3, based on the result of the first 2 steps a suicide risk assessment tool (Suicide RAP [Risk Assessment Prompt]) was developed and presented to both teams. A second patient chart review was conducted to determine the effectiveness of the educational intervention and suicide RAP in suicide risk assessment.

Results Significant differences were found in the rating of importance and the documentation rates of suicide predictors between the two specialties. Several predictors deemed important, have low documentation rates. Thirty of the suicide predictors showed increased rates of documentation after the educational intervention and the presentation of the suicide RAP.

Conclusion Though a surfeit of information regarding patient risk factors for suicide is available, clinicians and mental health professionals face difficulties in integrating and applying this information to individuals. Based on the result of this study suicide RAP and educational intervention could be helpful in improving the suicidal risk assessment.

Antipsychotic drugs in pregnancy

S. AlDakheel

King Fahd Hospital of the University, Psychiatry, Dhahran, Saudi Arabia

Background There has been significant increase in prescription of antipsychotic medication in the community for females in child-bearing age the problem is we do not have clear guidelines because we do not have a control group.

Objectives To evaluate maternal psychiatric, medical and perinatal outcomes associated with antipsychotic drugs in pregnancy.

Aim To use wisdom when the risk is minimal for both mother and child.

Method We study 3 pregnant women, one with a 6 years old, one with a 2 years old child and one still pregnant. We measure their blood sugar, blood pressure, fetal heart, movement, ultrasound using first generation antipsychotic (FGA).

Results Patient became less psychotic then back to normal and fetal development is normal till now, no diabetes mellitus or hypertension, no malformation or abortion.

Conclusion It is still too early to reach a clear and absolute use of safe antipsychotic drugs in pregnancy. A large sample is needed for a study and a control should be needed.

Neuroleptic malignant syndrome: A rare, life-threatening and not fully understood condition

P. Cabral Barata*, J.C. Melo, T. Maia

Hospital Prof. Doutor Fernando Fonseca, Serviço de Psiquiatria, Amadora, Portugal

* Corresponding author.

Introduction Neuroleptic Malignant Syndrome (NMS) is a rare life-threatening idiosyncratic reaction associated with the use of neuroleptics. It is characterized by delirium, muscular rigidity, fever and autonomic nervous system dysregulation. Its diagnosis represents a significant challenge for clinicians and many aspects regarding its epidemiology, etiopathology and nosology remain controversial.

Objectives Summarize current knowledge to facilitate NMS diagnosis and allow a fast onset of therapeutic and life-saving interventions.

Methods Non-systematic review of the literature—scientific publications from Pubmed and a Psychiatry Textbook.

Results NMS typically develops during the first week after the neuroleptic is introduced, although it may also appear after years of treatment. Its incidence is of 0.02 to 3% in patients taking antipsychotics; the mean age of its patients is 50 years. Typical symptoms are muscle rigidity and temperature greater than 38°C in a patient on antipsychotic; however, recent reports indicate that these core symptoms may not always be present. Several risk factors have also been identified and must be addressed. NMS may be fatal in 10 to 20% of cases or may produce residual sequelae, like cognitive dysfunction or neurological deficits. NMS must be managed by aggressive use of supportive measures, as well as specific interventions. It recurs in 30% of patients, which can be diminished by specific measures.

Discussion NMS requires timely and accurate diagnosis and treatment. Antipsychotics should be used cautiously in patients at increased risk. When recognizing this condition, prompt withdrawal of the offending agent is the most important step. Wise approaches can diminish morbidity, mortality and recurrence.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Evaluation of experts' clinical practice in crisis unit and psychiatric emergency technical and therapeutic principles to better intervene

J. Denis*, S. Hendrick

University of Mons, Systemic and Psychodynamic Clinical Psychology Department, Mons, Belgium

* Corresponding author.

Introduction Clinical practice in emergency room and crisis unit is often fraught with pitfalls (Immediate demands, accelerated temporality, difficulties working with family and care network). This practice contains specific clinical therapeutic interventions based on recognized theoretical frameworks. These theoretical frameworks constitute “formal knowledge”. They help to diagnose but have got limitations. In fact, clinical competence requires also technical and interpersonal skills (“know-how”) as well as reasoning skills and clinical intuition (“Informal knowledge”). All these knowledge and skills are built over clinical experience based on trainings and supervisions, continued clinical reasoning and exchanges with colleagues.

Objectives Our research aims to capture therapeutic processes in clinical crisis intervention by illustrating what experts really do in their clinical practice and above all, how they do.

Aims Our study illustrates several crisis situations, moment-by-moment, by analyzed experts’ voices.

Method Our method is grounded in a first person epistemology and used a qualitative methodology focused on explication interview. Ten crisis interviews were analyzed in a micro and macro perception.

Results Our research based on experts’ voices has identified a series of therapeutic techniques and principles who are essential to better intervene in clinical crisis intervention. A model of intervention was developed to train debutant clinician.

Conclusion We believe that reflexivity is a powerful attitude to understand and transform practices in a lasting way.

Interpersonal sensitivity in the at-risk mental state for psychosis in Karachi, Pakistan

A. Mushtaq, B. Fatima*, A.A. Fatema, H. Syed, H. Sohail
Bahria University, Institute of Professional Psychology, Karachi, Pakistan

* Corresponding author.

Introduction Interpersonal sensitivity can be explained as a personality trait in which there is an excessive and expanded awareness of the behavior and emotions of others. Individuals having high interpersonal sensitivity are sensitive to interpersonal relationships and self-deficiencies in comparison to others. Studies report that high interpersonal sensitivity can cause low self-esteem and feelings of insecurity.

Objectives The objective of this study was to examine the level of interpersonal sensitivity in individuals with an at-risk mental state (ARMS) for psychosis compared to the individuals not at risk for psychosis.

Methods A total sample of 50 individuals was recruited from Bahria University, Karwan-e-Hayat and Karachi Psychiatric Hospital: 25 with ARMS for psychosis and 25 participants who were not ARMS, according to scores on Schizophrenia Proneness Inventory-Adult (SPI-A). All of the participants then responded to self-report questionnaire on Interpersonal Sensitivity Measure.

Results Results showed that the group with ARMS had a significantly higher interpersonal sensitivity on average (112.5) as compared to healthy individuals (91.8). Results show significant difference in both of the groups ($t = -5.049$; $P < .0001$) indicating that interpersonal sensitivity in people with ARMS was relatively high compared to those who were not at risk.

Conclusion This study suggests that being ‘hypersensitive’ to interpersonal interactions is a psychological feature of the potentially prodromal phase of psychosis. Addressing difficulties in interpersonal relationships and offering early psychotherapeutic

interventions can be beneficial, not only in averting serious illness, but preventing loss to individual and national productivity.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Reducing restraint with clozapine in involuntarily admitted patients with schizophrenia

P. Ifteni*, A. Teodorescu

Universitatea Transilvania din Brasov, Facultatea de Medicina, Brasov, Romania

* Corresponding author.

Introduction In the entire world, restraint and seclusion are common interventions in psychiatric in-patient settings due to aggressive behavior.

Objectives Our objective was to test for the immediate anti-aggressive property of clozapine compared to other antipsychotic treatments in an enriched cohort with high rates of restraint during early hospitalization.

Methods We present a retrospective chart review in all involuntary admissions with schizophrenia during 2011–2014 in Psychiatry and Neurology Hospital, Brasov, Romania. Timing and number of restraints in addition to clinical, demographic and treatment characteristics were extracted. Based on our earlier observation of clinical efficacy of early, fast titration of clozapine, we tested the hypothesis that clozapine treatment was associated with reduced use of restraint, and with longer restraint-free periods.

Results In 115 patients with schizophrenia (age = 39.7 ± 11.1 years; male = 59%) involuntarily admitted due to externalized (74.78%) or self-directed violence (25.22%), restraint was used in 89.6%; with a median duration of 3 hours until restraint past admission. Antipsychotics used immediately after hospitalization included haloperidol (70.4%), clozapine (11.3%), olanzapine (10.4%) and other second-generation antipsychotics (7.9%). Comparison of restraint characteristics favored immediate clozapine use with highly reduced rates of restraint (38.5% vs. 95.6%. $P < 0.001$) and significantly extended hours until restraint ([118 h, 24 h, 426 h] vs. [3 h, 0.25 h, 48 h]; median; 25th, 75th percentile; $P < 0.001$) relative to the remaining cohort. These effects remained highly significant after controlling for potential moderators of restraint use in multivariate models.

Conclusions These retrospective data suggest an early anti-aggressive effect of clozapine during the immediate use of clozapine in highly problematic patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0491

The 4-hour window: UK Government targets versus clinical priorities

D. Cumming

Forth Valley Royal Hospital, Psychiatry, Larbert, United Kingdom

Introduction In 2002, the Department of Health (United Kingdom) introduced a 4-hour target due to long waiting times. It is expected that 95% of patients who attend the A&E (Emergency) Department should be registered and admitted/discharged within 4 hours. Exceeding this is termed a “breach”.

Objectives The aim of this re-audit was to assess for a response following recommendations after an initial audit with concerning results. Forth Valley Royal is an acute public hospital in Central Scotland with 860 in-patient beds, covering a population of 300,000. It

contains two general adult wards (42 beds), one IPCU (12 beds) and two Elderly wards (40 beds).

Methods Referral data was sourced across 4 consecutive months: April–July 2015 (initial audit) and October 2015–January 2016 (re-audit). These included all referrals from A&E to Psychiatry. Times were calculated for the 4 subprocesses listed in Table 1 below.

Conclusion/discussion Following the initial audit, interventions such as training A&E staff to better manage psychiatric patients and encourage earlier referrals, led to a positive response in the re-audit (Subprocess 1). Breach rates reduced to 28% (from 35%) on re-audit. Less breaches (81% compared to 88%) were referred after 2-hours by A&E. Overall, the breach rates have reduced and they are less attributable to the A&E referring patients late. The outcome of patients leaving A&E without being seen by a psychiatrist was unknown – adverse outcomes would strengthen the debate to enforce the 4-hour window.

Table 1

Initial audit = 222 referrals (35% breach rate)
Re-Audit = 348 referrals (28% breach rate)

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Neuroleptic malignant syndrome: Case report and literature review

R. Martín Gutiérrez^{1,*}, R. Medina Blanco¹, P. Suarez Pinilla¹, R. Landera Rodriguez¹, M. Juncal Ruiz¹, I. Madrazo del Río Horteiga¹, M. Gómez Revuelta¹, O. Porta Olivares¹, J. González Gómez¹, J. Vázquez Bourgon¹, R. Hernando Fernández²

¹ Hospital Universitario Marques De Valdecilla, Psychiatry, Santander, Spain

² Hospital Universitario Marques De Valdecilla, General Practitioner, Santander, Spain

* Corresponding author.

Introduction Neuroleptic malignant syndrome (NMS) is an uncommon but potentially fatal adverse effect of neuroleptic, both classic and atypical drugs.

Objective To review the incidence, clinical characteristics, diagnosis and treatment of NMS.

Aim We have described the case of a man of 32 years of age diagnosed with bipolar disorder treated with lithium. He presented high-dose corticosteroids after having tonsillitis. Then, he presented manic decompensation requiring neuroleptic treatment (oral risperidone). After 72 hours, he presented an episode characterized by muscular rigidity, fever, altered mental status and autonomic dysfunction. Life support measures and suspension of neuroleptic treatment were required.

Methods A literature review of the NMS was performed using the PubMed database.

Results The frequency of NMS ranges from 0.02 to 2.4%. The pathophysiology is not clearly understood but the blockade of dopamine receptors seems to be the central mechanism. Some of the main risk factors described are: being a young adult, the concomitant use of lithium and metabolic causes, among others. NMS occurs most often during the first week of treatment or after increasing the dosage of the neuroleptic medication. Some issues of NMS are those related with diagnosis, treatment and reintroduction of antipsychotic treatment or not.

Conclusions NMS can be difficult to diagnose due to the variability in the clinical symptoms and presentation. Because of it diagnosis is of exclusion, clinicians should always take it into consideration

when a patient is treating with neuroleptic, especially when the dosage has been recently increased. NMS is a clinical emergency.

The correlation between mood disorders and suicide attempts for the period 2013–2015 at “Mother Teresa” hospital center, Fatbardha Myslimaj, Psychiatrist, Mirela Gokaj, Deana Rama

F. Myslimaj*, M. Gokaj, D. Rama

Mother Teresa Hospital, Psychiatry Adult, Tirana, Albania

* Corresponding author.

Background People, who have tried to commit self-injurers or suicidal attempts, refer symptomatic presence of disorders of humor and numerous problems social as factors precipitant to suicidal thoughts and actions. It is important recognition of the signs of suicide and self-inflicting behavior to help prevent suicide.

Materials and methods The study includes a period of 3 years of cases hospitalized in the psychiatric clinic UHC, since 2013–2015. The data are taken from the records of admissions at the Psychiatric Clinic at the University Hospital Center. Results are grouped and studied issued by mood disorders, sex, age, place of residence and social status.

Results The influence of mood disorders is recently estimated very important in causing suicide attempts compared with other mental illnesses, similar values with contemporary literature.

Conclusions The majority of suicide attempts do not result in death. Many of these efforts are made in a way that makes salvation possible. These efforts are often a cry for help. Suicide is a social phenomenon different cognitive aspect such as ethical, philosophical, legal, psychiatric, etc. Employees of psycho-social care should be informed about this phenomenon and finding the diagnosis, prevention and treatment of suicidal attempts by persons at risk of suicide.

EV0494

Peculiarities of providing care in various emergencies

S. Shport

V.P. National Research Center for Social and Forensic Psychiatry, administration, Moscow, Russia

Air crashes Attention is focused on providing care to the relatives (identifying the bodies of the perished, talking to investigators, filling out the requisite documentation, etc.), resolving social issues (organizing funerals, informing various services of what had happened, etc.).

Fires Special attention is paid to the victims with burns at the inpatient facilities of hospitals.

Terrorist acts Provision of care depends on the duration of the emergency and the number of people involved; in the case of a continual stress, in the phase of isolation the medical-psychological care is provided to victims' relatives. At later stages—it is provided to the victims and their relatives.

Natural disasters Are of a special nature, as they are always sudden and there exists a threat that a great number of people may become victims.

Organizational measures in the acute period of an emergency:

- coordinating the work of specialists of the local, regional and federal level;
- interacting with non-governmental organizations;
- setting up a 24-hour “hotline” service (“HL”) on the basis of a medical institution;
- deploying facilities for providing care to victims, their relatives, and to “secondary victims”.

Principles of medical-psychological care:

- urgent care must be provided jointly with psychiatrists/psychotherapists at the places, where the victims are located;
- individuals with the most severe stress reactions must be identified and observed by psychiatrists/psychotherapists;
- appropriate and prompt intervention should be made to relieve acute stress disorders;
- therapeutic interventions should not be a hindrance to victims' participation in the urgent evacuation and interrogation expedients as well as completing social tasks.

* Corresponding author.

Introduction Disasters and emergencies generate a psychological impact on both survivors and response teams. Traumatic events and his memory would be a risk factor for anxiety disorders.

Objectives Describe the most common post emergency anxiety signs in a sample of Spanish people who responded directly to emergencies.

Methods Study carried out by survey filled through Google Forms application; in this survey, we retrospectively value anxiety using the screening scale for generalized anxiety disorder of Carroll and Davidson.

Results The survey was answered by 20 people, of whom 60% were women 68.20% age range between 18–6 years and with university studies in the 70% of the interviewees. Four nurses, 2 doctors, 4 emergency assistants workers, 2 civil protection workers, 1 ambulance worker, 1 military, 3 policemen, 1 fire-fighter and 2 others. Sixty percent of cases did not received specific aid. The anxiety scale items that are most affected are musculoskeletal stress and sleep, with lower prevalence of psychological anxiety (Fig. 1). Women showed higher prevalence of psychological anxiety, muscle tension, and sleep disturbance.

Conclusions The data reveals that the staff responding to emergencies recalled experienced musculoskeletal problems or sleeping disturbance better than psychological anxiety which was relegated to the background. Post-emergency treatment should be provided to all participants in emergencies including specific interventions for musculoskeletal stress and insomnia.

Change with the times exploring psychiatric inpatients' attitudes towards physical restraint

Y. Spinzny^{1,*}, S. Maree¹, A. Segev², G. Cohen-Rappaport¹

¹ Shalvata mental health center, A, Tel Vviv, Israel

² Shalvata mental health center, Emergency, Tel Aviv, Israel

* Corresponding author.

Introduction When other options fail, physical restraint is used in inpatient psychiatric units as a means to control violent behavior of agitated inpatients and to prevent them from harm. The professional and social discourse regarding the use of restrictive measures and the absence of the inpatients' attitudes towards these measures is notable. Our research therefore tries to fill this gap by interviewing inpatients about these issues.

Objectives and aims To assess the subjective experience and attitudes of inpatients who have undergone physical restraint.

Methods Forty inpatients diagnosed with psychiatric disorders were interviewed by way of a structured questionnaire. Descriptive statistics were conducted via use of SPSS statistical software.

Results Inpatients reported that physical restraint evoked an experience of loneliness (77.5%) and loss of autonomy (82.5%). Staff visits during times of physical restraint were reported as beneficial according to 73.6% of the inpatients interviewed. Two thirds of the inpatients viewed the use of physical restraints as justified when an inpatient was dangerous. Two thirds of the inpatients regarded physical restraint as the most aversive experience of their hospitalization.

Conclusions Our pilot study explored the subjective experience and attitudes of psychiatric inpatients towards the use of physical restraint. Inpatients viewed physical restraint as a practice that was sometimes justified but at the same time evoked negative subjective feelings. We conclude that listening to inpatients' perspectives can help caregivers to evaluate these measures.

The psychiatric emergency service in the Netherlands

S. Streitz

Mediant Enschede, ACC, Enschede, Netherlands Antilles

Every region in The Netherlands has got an emergency service. This is a team of people that immediately goes to see the psychiatric patient after an instruction of for instance the general practitioner or the police. This special team works 24 hours a day, 7 days a week. The patient is then visited by members of the team, a social worker accompanied by a psychiatrist, or the patient will go to the ambulant unit (the polyclinic) directly. This is a very effective procedure, because behind the two people that visit the psychiatric patient, is a whole team of people who have the opportunity to start an ambulant treatment the day after. Through this team we have the opportunity to treat patients intensively without a needed admission in the clinic. The basis of this team are social-nurse-therapists who are very skilled. These people take lead in the treatment and have a psychiatrist as a back-up. Suicidal patients are through a special procedure included in a clinic upon a juridical decision. If it is expected that the patient is dangerous, the police will accompany the emergency teams. If psychiatric medication is needed, the treatment will start directly. Other forms of treatment are psychotherapy, a short treatment by conducting 5 meetings with the patient, or intensive ambulant treatment. In my opinion it is a very good example of how ambulant treatment of psychiatric patients works and is effective for everybody involved.

Algorithm-based protocol for the identification, management and treatment of psychiatric patients with acute psychomotor agitation

E. Vieta^{1,*}, M. Garriga¹, L. Cardete², M. Bernardo¹, M. Lombrana¹, J. Blanch¹, R. Catalán¹, M. Vázquez¹, V. Soler¹, N. Ortuño¹, A. Martínez-Arán¹

¹ Hospital Clinic de Barcelona, Psychiatry/Bipolar Disorders Program, Barcelona, Spain

² Hospital Clinic de Barcelona, Enfermeria de Psiquiatria Infanto-Juvenil, Barcelona, Spain

* Corresponding author.

Introduction Psychomotor agitation is the most common behavioural disorder observed in emergency and psychiatry departments. This syndrome is characterized by excessive or inappropriate motor or verbal activity and important emotional tension. Psychomotor agitation may be associated with medical conditions, substance intoxication/withdrawal and in a significant number of cases with schizophrenia or bipolar I disorder.

Objectives The objective of this protocol was to provide up-to-date guidance to identify, manage and treat patients with an episode of acute agitation, considering the consensus clinical knowledge, current ethical standards and available therapies. This protocol is aimed to be a patient-centric tool helping to anticipate and prevent the escalation of agitation symptoms.

Methods The method followed to elaborate this document was through a combination of comprehensive bibliographical review (compiled in the article "Assessment and management of agitation in psychiatry: expert consensus" by Garriga M. et al. (World J

Biol Psychiatry, 2016), interaction with patients, and the clinical experience in our centre.

Results The elaboration of this protocol resulted in a document that contains guidelines to identify, manage and treat patients efficiently, ethically and safely. One of the novelties of the protocol is the addition of dichotomies based on the patients' willingness to cooperate. The information is summarized in easy-to-use algorithms for non-specialized healthcare professionals.

Conclusions This protocol may provide the basis of a new standardized treatment paradigm for psychomotor agitation which may help improve the patient's experience and therapeutic alliance with the healthcare professional and optimize resources in healthcare centres.

Maladaptive and addictive Internet use in zagazig university students, Egypt

M. Abdelghani*, G. Salah El-Deen

Zagazig College of Medicine, Psychiatry Department, Zagazig, Egypt

* Corresponding author.

Background Internet use has increased broadly worldwide. There are growing concerns about problematic Internet use (PIU) among youth. Among undergraduate students, excessive Internet use can adversely affect their interpersonal relations and academic achievements.

Aim To estimate the prevalence of PIU among Zagazig university students, and to identify the possible associations between sociodemographic and Internet-related factors and PIU.

Methods A cross-sectional study included a total of 732 undergraduate students, aged 17–34 years, from various colleges in Zagazig University. Participants were randomly selected and assessed for their internet use and abuse using the Internet Addiction Test (IAT), along with a semi-structured questionnaire for sociodemographic and Internet-related factors.

Results Maladaptive Internet use was found in 37.4% of respondents, and addictive Internet use was found in 4.1% of respondents. Logistic regression showed the predictors of PIU were: using the Internet throughout the day (OR 3.34, 95% CI: 1.75, 6.38), the number of hours spent daily using the Internet (OR 1.17, 95% CI: 1.10, 1.25), the number of days/week using the Internet (OR 1.28, 95% CI: 1.04, 1.58), accessing the Internet using multiple devices (OR 1.55, 95% CI: 1.21, 1.98), and accessing the Internet both indoors and outdoors (OR 1.57, 95% CI: 1.13, 2.19).

Conclusion This is the first prevalence study of PIU at an Egyptian university. PIU was common among university students.

Addressing this issue and its predictors could eventually help to enhance academic performance and achievement among those students.

Social and economical impact about problems with therapeutical adherence

A. Alonso Sánchez*, H. De la Red Gallego, A. Álvarez Astorga, C. Noval Canga, R. Hernandez Antón, S. Gómez Sánchez, G. Medina Ojeda

Hospital Clínico Universitario de Valladolid, Psychiatry, Valladolid, Spain

* Corresponding author.

Introduction Psychotic spectrum diseases are one of the most expensive illnesses in our society. Being able to recover as much social and laboral activity as possible has to be the goal. Trying to achieve this objective, we face different problems, as for example therapeutic adherence.

Objectives Show the importance of an adequate treatment and adherence in order to keep the patient as much integrated in the society as possible, and in order to reduce the economic and social cost of the psychotic spectrum diseases.

Methods Case report and bibliography review.

Results The patient of this case is a 34 year old woman with a schizophrenia diagnosis given after 4 hospitalizations in psychiatry units. She had 4 years of stabilization taking an injectable antipsychotic, in which she was able to study and keep adequate familiar and sentimental relationships. After being badly recommended to retire her medication for some who identified himself as member of the “new psychiatry”, she began with new delusions and hallucinations which had to be treated at the Hospital Psychiatry Unit. She was close to get a statal job related to her architecture studies, but she was not able to go to the exam due to the exacerbation of her illness. In the review we see that the average economic cost per schizophrenic patient in developed European countries such as Germany is, at least, 14000€ per patient.

Conclusions Adequate treatment adherence is highly important to keep an adequate control of the illness in order to sustain the better social live and job function.

* Corresponding author.

Introduction Portugal is among the European countries with higher prevalence of mental disorders, associated with substantial unmet needs for treatment. Literature on the impact of the economic recession shows that an increased risk of mental health problems is likely to occur. Despite possible growing needs, the budget cuts at the health system level may have decreased the adequacy of care response. Understanding the impacts of the recession

in psychological distress and in access and quality of care is imperative to set public health priorities.

Objectives Resorting to a qualitative approach, this study aims to explore the perceptions and experiences of primary health care users and professionals during the recession in the Lisbon Metropolitan Area.

Aims Provide in depth information regarding the specific contexts and subjective experiences of key informants during the economic recession that started in 2008.

Methods This study design resorts to focus groups with primary health care users and semi-structured interviews with health professionals. All interviews were recorded and transcribed verbatim. Inductive approach and thematic analysis were performed, using NVivo 10.

Results This study explores the views and insights of users and health professionals regarding their socio-economic context, mental health needs, changes in health services and possible solutions to alleviate the impact of the economic recession.

Conclusions Being based on the perspectives of users and health professionals, this approach will complement epidemiological evidence for policy-making.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Financial difficulties, economic hardship and psychological distress during the economic recession in Portugal

A. Antunes*, D. Frاسquilho, M. Silva, G. Cardoso, J.M. Caldas-de-Almeida

Chronic Diseases Research Center CEDOC, NOVA Medical School, Faculdade de Ciências Médicas, NOVA University of Lisbon, Lisbon, Portugal

* Corresponding author.

Introduction Portugal is one of the European countries most affected by the Great Economic Recession. Mental health outcomes are likely to deteriorate during this period, with greater proportional impact among those more socially disadvantaged. Self-reported measures of financial difficulties and economic hardship are likely to be associated with psychological distress during this period.

Objectives To characterize the relationship between psychological distress and self-reported measures of financial difficulties and type of material deprivation during the Economic Recession in Portugal.

Methods A follow-up epidemiological survey was conducted in 2015, with a probability sub-sample of 911 respondents of the 2008 World Mental Health Survey Initiative Portugal. Psychological distress was evaluated by the Kessler-10 scale. Financial difficulties were assessed by asking the responds if they had enough money for their daily activities. Type of material deprivation considered difficulties in acquiring essential goods, paying debts or buying other goods (clothes or leisure activities). Chi-square analysis were used to evaluate the association between psychological distress, financial difficulties and type of material deprivation.

Results A statistically significant association ($P < 0.05$) between psychological distress and financial difficulties was found. Among the respondents that reported not having enough money, 22% reported psychological distress. Regarding the type of material deprivation, a statistically significant association was only found for essential goods.

Conclusions During the economic crisis, financial difficulties and material deprivation in essential goods were associated with increased levels of psychological distress, potentially widening social and health inequalities across the Portuguese population.

Mental health and human rights in Morocco: The urgent need for new policy

C. Aroui*, A. Khoubila, K. Mchichi Alami, M. Agoub, O. Battas, D. Moussaoui

Faculté de Médecine et de Pharmacie, Hassan II University, Neuroscience Laboratory, Casablanca, Morocco

* Corresponding author.

Introduction All over the world, there is global emergency when it comes to respecting human rights in providing good mental health services. Morocco as an African and a developing country has always had a mental health policy defined by several glitches and failures, which had not helped him improve its mental health services quality. Nevertheless, huge improvements were achieved through time.

Objectives This report, aims to draw attention on how compulsory it is to think and act all together to promote mental health and provide patients with better health services in Morocco.

Methods The National Human Rights Council conducted an information and investigation mission in Morocco's main mental health hospitals and facilities between March 27 and July 6, 2012.

Results Structures are insufficient and inadequate in terms of geographical distribution, architecture and equipment. There is a big shortage of medical and paramedical staff and little interest is given to vulnerable groups. Nevertheless, huge improvements have also been achieved through time with mental health issues becoming a cornerstone of the ministerial program, the involvement of the NGOs, the construction of newer facilities, the implementation of an information gathering system and the presence of a substance use policy.

Conclusion Psychiatry in Morocco has come a long way since it was firstly implemented in the country as a medical specialty. Undoubtedly, a lot has been done but much more remains to be achieved. The current situation requires relevant actions and that clearly includes the implementation of a new mental health policy and the update of the legal framework.

Epidemiological study of disability from mental disorders in children and adolescents population in Saratov region in 2000–2014

Y. Barylnik*, V. Popkov, N. Filippova, Y. Abrosimova, E. Kolesnichenko, S. Pakhomova, D. Samoilova, A. Antonova, E. Bachilo, M. Deeva, S. Sizov

Saratov State Medical University, Department of psychiatry, narcology, psychotherapy and clinical psychology, Saratov, Russia

* Corresponding author.

Introduction Children and Teenager's disability is an extremely important medical and social problem, being very characteristic of the state of public health in the country and the level of social well-being of society.

Objectives An epidemiological study of the structure of disability due to mental disorders in children and adolescent population of the Saratov region for the period from 2000 to 2014.

Methods The analysis of the statistical data reporting forms "Information on the health care system" and "Information on the groups of the mentally ill" in the Saratov region in 2000–2014 by epidemiological, demographic and mathematical-statistical methods.

Results Number of children and adolescents (0–17 years), recognized as disabled by mental illness, increased both in absolute numbers (growth rate-12.86%), and the intensive indicators (49.88%). Increasing the number of disabled children and adolescents registered in schizophrenia, schizoaffective psychosis, schizotypal disorder, affective psychosis with delusions incongruent the affect. The most significant increase is observed in the group of chronic nonorganic and childhood psychoses. In epilepsy and mental retardation in the analyzed period was a slight decrease in total disability.

Conclusions The most significant increase in disability in the group of chronic nonorganic and childhood psychosis, most likely due not only to a true increase in morbidity and disability, but also with a great attention of both the public and the country's health services to the problems of childhood autism and, as a consequence, greater detection of children with this category of disorders.

The psychiatric services of Saratov region and directions of its' improvement (Clinical, statistical and epidemiological aspects)

Y. Barylnik*, D. Samoylova, S. Pakhomova, J. Abrosimova, E. Kolesnichenko, N. Filippova, M. Deeva, E. Bachilo, A. Antonova, S. Sizov

Saratov State Medical University, Department of Psychiatry, Narcology, Psychotherapy and Clinical Psychology, Saratov, Russia

* Corresponding author.

Introduction The determining of the actual number of people with mental disorders and their spreading by nosology still remains actual, especially according to different regions.

Objectives The determining of the psychiatric services effectiveness in Saratov region on the basis of comprehensive analysis of its' clinical, statistical and epidemiological characteristics.

Methods The analysis of mental state indicators based on the example of adults' schizophrenia Saratov region in dynamics for 10 years (2005–2015) in comparison with Russian Federation.

Results Over the past 10 years the number of clinically supervised patients with schizophrenia decreased at 0.9% in the city and 2.2% in region population. This is consistent with the tendency of schizophrenia morbidity in Russian Federation over the same period. The number of supervised adult patients with primary diagnosed schizophrenia in Russia remained at the same level and amounted to 10.8 per 100 thousand population. At the same time the noticeable fluctuations in the number of this patients' category were observed in Saratov and Saratov region. Over the past 10 years, the proportion of patients with primary diagnosed schizophrenia disability in the class structure of mental disorders is quite high, averaging of 41.1% in Saratov region. Analyzing the number of patients with re-confirmed disabilities the gradual decline from 1846 to 755 people (at 59.1%) was found.

Conclusions The mental health analysis of Saratov region population allows to suggest the long-term forecast of mental disorders' morbidity, to analyze the level of disability due to schizophrenia, to develop recommendations for the optimal regional model of psychiatric services.

Prevalence of depression in psychiatry trainees in 22 countries: Findings from the international burnout syndrome study (BoSS)

J.N. Beezhold^{1,*}, D. Durant², A. Ginzler², R. Sherman², A. Podlesek³, N. Jovanovic⁴

¹ Norfolk and Suffolk NHS Foundation Trust, Mental Health Liaison Service, Norwich, United Kingdom

² University of East Anglia, Norwich Medical School, Norwich, United Kingdom

³ University of Ljubljana, Department of Psychology, Ljubljana, Slovenia

⁴ London, United Kingdom

* Corresponding author.

Aims The Burnout Syndrome Study screened for burnout in psychiatric trainees in 22 countries, along with associated factors. This paper reports the results of the PHQ-9 depression screen that formed part of the study.

Background It is well documented that physicians have higher rates of mental illness compared to the general population. Post-graduate medical trainees may work long hours and be exposed to stressful or saddening situations regularly. Their environment and workload means they may not exhibit appropriate help-seeking behaviours and be at significant risk of depression.

Methods The study used a cross sectional, multi-country online survey. Participants were asked to participate via an email invitation. The participants were asked to complete the PHQ-9 questionnaire, which is validated as a primary care self-administered screen for depression. Mixed methodology was used when recruiting trainees to obtain the most representative sample possible from each country. Statistical analysis was performed using SPSS.

Results Complete data was obtained from 1980 trainees with an average age of 31.9 years and with 2.8 years of training. The prevalence of depression in psychiatric trainees varied by country from 50% in Latvia to 7.1% in Belarus. The average rate of depression was 20.8%.

Conclusions Prevalence of depression in the US general population is estimated at 6.7%, making the prevalence of depression in trainees of 20.8% a sign that action needs to be taken to reduce depression rates in trainees.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Paranoidism and memory deficits: An epidemiological study

C.M. Calahorra^{1,*}, M. Guerrero Jiménez², B.M. Girela Serrano², J.E. Muñoz Negro³

¹ Hospital Universitario San Cecilio, Unidad de Salud Mental, Granada, Spain

² Santa Ana Hospital, Psychiatry, Motril- Granada, Spain

³ University Hospital Complex of Granada, Psychiatry, Granada, Spain

* Corresponding author.

Background The Green et al. Paranoid Thought Scales (GPTS) was developed to fulfill a need for a tool that was adapted to the current dimensional definition of paranoia, capable to assess dimensions of preoccupation, conviction, and distress, valid and

reliable for the assessment of both clinical and healthy populations, and precise enough to detect subtle clinical change. It has recently been validated for the Spanish population (S-GPTS) with very good psychometric properties. Numerous studies suggest that patients with severe psychiatric disorders have impaired sustained attention and memory. A wide spectrum of executive deficits have also been described (goal-oriented tasks, recognizing priority patterns, planning, etc.) Very few studies have attempted to identify whether these same relationships between neuropsychological deficits and psychotic symptoms also occur in general population.

Methods This is a cross-sectional study. We undertook a multi-stage sampling using different standard stratification levels and out of the 5496 eligible participants finally approached, 4507 (83.7%) agreed to take part in the study, completed the interview and were finally included in the study ($n = 4507$).

Results Individuals with high cut off S-GPTS scores showed lower scores in working memory subtest verbal statistically significant ($P > .05$). While no significant difference was found among for immediate verbal learning subtest and high S-GPTS scores ($P > .05654$).

Discussion This information can improve the clinician's understanding of patient's cognitive strength and weaknesses, put patients' cognitive abilities into perspective for their diagnosis, and facilitate multidisciplinary treatment decisions as we improve our ability to distinguish clinical cases from non-clinical population.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Risk factors of self-injury behavior among psychiatric inpatients

N. Charfi*, S. Hentati, M. Maâlej Bouali, L. Zoauri, N. Zouari, J. Ben Thabet, M. Maâlej

Hedi Chaker University Hospital, Psychiatry "C" department, Sfax, Tunisia

* Corresponding author.

Background Self-injury behavior among mental patients has been recognized for several years, yet our understanding of its mechanisms and its risk factors remains limited.

Objectives This study aimed to assess the prevalence of deliberate self-harm (DSH) among psychiatric inpatients and to identify its association with personal and clinical factors.

Methods It was a descriptive and analytic study. It included 87 psychiatric inpatients followed in the psychiatry department "C" at the Hedi Chaker University Hospital of Sfax in Tunisia. Barratt Impulsivity Scale (Bis11) and the 28-items Childhood Trauma Questionnaire (CTQ) were used to assess respectively impulsivity and child maltreatment.

Results The average age of patients was 29.32 ± 8 years. Most of them were male (75%) and single. Fifty-nine percent of patients had previously attempted suicide. A history of DSH was found in 60.9% of cases. The most frequent trauma types were emotional abuse and physical neglect with respectively 58.7% and 69.8%. Factors positively correlated with DSH were: male gender ($P = 0.026$), father alcoholism ($P = 0.024$), history of suicide attempts ($P = 0.017$), borderline personality ($P = 0.00$) and history of emotional abuse ($P = 0.008$) or physical abuse ($P = 0.04$) or neglect ($P = 0.004$). Score "Bis11" was significantly correlated with suicide attempts ($P = 0.00$) and presence of childhood abuse ($P = 0.00$) or neglect ($P = 0.01$).

Conclusion DSH seems to be a prevalent problem among psychiatric inpatients. It concerns mainly patients with a history of child abuse and impulsive behavior such as suicidal attempts underlying borderline personality disorder. Patients with these risk factors warrant specific attention in mental health services.

¹ APA, International Member, Santiago del Estero, Argentina

² APSA, Psychiatry, Santiago del Estero, Argentina

* Corresponding author.

Background and aim Suicide is a serious and growing problem worldwide. According to the World Health Organization, for each death there are twenty attempts on record. Every year over 800,000 people commit suicide, that is, one in every forty. 45% of the people who commit suicide visit their Primary Health Care physician in the previous month. Seventy-five percent of suicides take place in countries with medium or low income and Argentine heads the suicide rate in Latin America. In the last twenty years the death by suicides rate in young people (aged 15–35) and has decreased in older age groups (+55), which historically presented the highest rates. In the inner zone of the province of Santiago del Estero, suicides have increased among teenagers [1].

Aims To know suicide statistics in young people in the last decade so that a prevention scheme can be produced.

Methods Descriptive observational study.

Results In the province of Santiago del Estero suicides occur more frequently among young people, aged 15–35, and the rate has increased significantly in the inner zone of the province.

Conclusions The analysis carried out reveal that this problem is increasing in our province and it requires analysis and consensus in order to design a model of Primary Health Care Prevention.

Disclosure of Interest The authors have not supplied their declaration of no competing interest.

EV0510

Incidence of dissociative stupor and possession in a private psychiatry clinic

D. Dua^{1,*}, P. Dua²

¹ Kripya- Dua Neuropsychiatric Centre, Psychiatry, Lakhimpur Kheri, India

² Nimhans, Psychiatry, Bengaluru, India

* Corresponding author.

Introduction Dissociative and conversion disorders are reported to have a present incidence of about 85–100 per 1000 by different studies, which are very few. The present research is a part of a longitudinal study of 15 years but here; only 3 years are represented, which could be briefly analyzed.

Objective Latest reports suggest a decline in incidence of hysteria (conversion and dissociation) and this research just tries to reconfirm.

Methods All new patients attending a private psychiatry OPD in a small township of India at Lakhimpur Kheri in Uttar Pradesh, were screened to identify cases of dissociative disorder according to ICD 10, F44.2 and F44.3 from the 1st of January 2016 to 31st of October 2016 (10 months). These screened cases, only those presenting with fits of unconsciousness and possession, were analyzed and compared with the previous years for the same period.

Results Out of a total of 3671 patients seen, (2122 males and 1549 females) a total of 319 presented with the above mentioned symptoms (58 males and 261 females) about 87 per 1000 of psychiatric patients.

Conclusion The results, when compared with two previous years for the same period were quite similar, 2015 getting incidence of 97 per 1000 and 2014, an incidence of 89 per 1000. The inference thus is that there does not seem to be any decline of incidence and the figure would be much higher if both conversion and dissociative symptoms are included – a really serious situation.

EV0511

Is early life environment a risk factor for psychiatric disorder?

T. Duarte*, A. Ferreira, S. Paulino, L. Câmara Pestana

Centro Hospitalar Lisboa Norte, Hospital de Santa Maria, Serviço de Psiquiatria e Saúde Mental, Lisboa, Portugal

* Corresponding author.

Introduction Season of birth, an exogenous indicator of early life environment, has been related to higher risk of adverse psychiatric outcomes. According to literature, an excess of 5–8% of winter-spring births is found in individuals who later develop schizophrenia and bipolar disorder; this seasonal birth excess is also found in schizoaffective disorder (winter), major depression (March–May), and autism (March).

Objectives The objective of this study was to analyze the seasonal birth patterns of in-patients with psychiatric disorders.

Aims Understand the relation between psychiatric disorders and season of birth during a 10 year period in a Portuguese University Hospital.

Methods Analyze the birth date distribution of 2202 in-patients between 2007 and 2016 and compare with the psychiatric diagnosis.

Results Patients' diseases analyzed by birthday season: 60% of patients with schizoaffective disorder were born in winter-spring, 48.4% of mental retarded patients were born in autumn, 37% of dementia patients in winter, 77% of patients with delusional disorder in winter-spring, 78% of patients with Cluster A personality disorder in spring-summer and 71% of patients with substance abuse conditions in autumn-winter. No seasonal birth excess was found for bipolar affective disorder, schizophrenia, alcohol abuse, major depressive disorder or Cluster B personality disorder.

Conclusions Our sample data shows evidence for a potential link between season of birth and risk for schizoaffective disorder, dementia, mental retardation, Cluster A personality disorder, delusional disorder and substance abuse. The attempt to explain seasonal birth patterns in psychiatric illnesses could serve to clarify the etiological bases of such disorders.

Screening for mental health problems as indicator for evaluation of needs for mental health services

N. Fanaj^{1,*}, S. Mustafa¹, F. Shkëmbi², B. Kabashaj³, B. Fanaj³

¹ Community Based Mental Health Center, Mental Health Center, Prizren, Kosovo

² European University Of Tirana, Social Sciences, Tirana, Albania

³ University Of Prishtina, Social Sciences, Prishtina, Kosovo

* Corresponding author.

Background Screening questionnaires for mental health problems are useful tools for research and clinical practice.

Objectives To identify mental health problems and overall emotional functioning among general population samples in Kosovo as indicators for evaluation of needs for mental health services.

Methods It is cross-sectional quantitative study. Participants from two samples: students (filled-out directly) and online respondents ($n=540$; mean age = 24.84; SD = 8.29) were included in this study. All participants were asked to complete the Albanian translation of Mental Health Inventory (MHI-38). Data processing was done with SPSS 21.0 and Microsoft Excel 2007.

Results In total 11.2% of participants ranged at low level of mental health index. Regarding anxiety the high level is found at 51.3% and regarding depression high level is found at 24.5% of participants. A significant gender difference is found whereas females show greater depression ($P=.022$, $r=.09$), greater psychological distress ($P=.000$, $r=.17$) and lower mental health index ($P=.000$, $r=.17$), than males. A significant difference between samples is found whereas online sample show greater psychological distress ($P=.000$, $r=.18$), less anxiety ($P=.001$, $r=.13$) and lower mental health index ($P=.000$, $r=.22$) than direct sample.

Conclusions The findings are quite intriguing. Future research is needed to find out more understanding on gender, anxiety, depression, psychological distress and mental health. Socio-cultural aspects can be of great importance to be examined. Despite this, needs for mental health services are inevitably and must be addressed properly.

The assessment of social disabilities with GSDS-II in persons hospitalized in psychiatric day units and inpatient wards

T.M. Gondek^{1,*}, A. Królicka¹, B. Misiak², A. Kiejna¹

¹ Wroclaw Medical University, Department of Psychiatry, Wroclaw, Poland

² Wroclaw Medical University, Department of Genetics, Wroclaw, Poland

* Corresponding author.

Social disabilities due to mental disorders have a similar or even more severe impact on daily activities than some of the chronic, severe somatic disorders. The second version of the Groningen Social Disabilities Schedule (GSDS-II) is used in the assessment of social disability in persons with mental disorders. To date, in Poland the conducted research studies focused on this matter only in patients consulted in outpatient clinics and day units. Our study is the first in the country that aims to measure the social disabilities in persons hospitalized in psychiatric inpatient wards. The objective of the study is to assess the degree of social disability using GSDS-II as well as to analyze the impact of clinical, socio-demographic and economic factors on social disabilities in patients diagnosed with psychotic, mood or anxiety disorder (diagnostic codes: F20-F29, F30-F39 and F40-F48, according to ICD-10), aged 18–65, in a day unit and an inpatient ward settings. The excluding criteria are: substance abuse co-morbidity and/or a diagnosed dementia process. The study presents the data gathered from a sample of 50 patients of both genders diagnosed with the aforementioned mental disorders who gave their informed consent to participate in the study. Due to important socio-economic implications of mental disorders that frequently result in the loss of ability of the patients to fulfill their societal roles, a study leading to a better insight on social disabilities will provide useful data for the possible improvement of the mental health care and social policy designed for these persons.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0513

The impact of stigma and discrimination on the quality of life and social disability in persons with a diagnosis of mental disorder. A pilot study

T.M. Gondek*, K. Kotowicz, A. Kiejna

Wroclaw Medical University, Department of Psychiatry, Wroclaw, Poland

* Corresponding author.

Stigma and discrimination of persons diagnosed with mental disorder is a common issue. In many European countries, research studies on the prevalence and implications of this problem are conducted in order to better understand how to overcome it. In Poland, there is a scarcity of such studies, what results in neglecting this issue by the policy makers. The objective of the study is to assess the prevalence of stigma and discrimination affecting the patients hospitalized in psychiatric day units and in-patient wards between 2016–2017 as well as to analyze the relationship between the stigma and the quality of life and social disability in persons with a mental disorder diagnosis of F20–F48 according to ICD-10, aged 18–65, in a day ward and an in-patient ward settings. The pilot study presents the data gathered from a preliminary sample of 20 patients of both genders diagnosed with the aforementioned mental disorders, equaling 10 per cent of the targeted total study sample. The quality of life is assessed with WHOQOL-Bref, WHO-5 questionnaire and Rosenberg self-esteem scale, while social disability is measured with the second version of the Groningen Social Disabilities Schedule. The assessment of the impact of stigma on the social disability of persons with mental disorders and their quality of life can be useful in the context of developing evidence-based interventions for these persons, while it could also provide the scientific data to support public information campaigns aiming at tackling the stigma against persons with mental disorders in Poland.

Attitude to and social distance from schizophrenic patients as forms of stigmatization, investigated by a group of medical professionals and a group of non-professional subjects

G. Grbesa*, M. Simonovic, M. Stankovic

University of Nis, Faculty of Medicine, Psychiatry, Nis, Serbia

* Corresponding author.

Introduction The attitude to schizophrenic patients has always been considered a significant indicator of stigmatization of mental patients. The social aspect of stigmatization involves the social distance when speaking about the attitudes towards mental patients. The social distance is defined as “a various degree of understanding and feelings existing among the groups”.

Objectives The investigation included 120 participants divided into two groups. The first group included 60 participants; psychiatrists (38) directly involved in treating schizophrenia and 28 nurses working in wards where schizophrenic patients were treated. The second group of 60 participants included non-professionals divided according to age and gender to match the experiment group.

Aims Investigating the correlation between the proclaimed attitudes to and social distance from schizophrenic patients: medical professionals and non-professional subjects.

Methods Semantic differential scale was used to examine the personal attitudes towards a stigmatized group. To examine social distance, the modified Bogardus Social was used.

Results The results obtained using the Semantic differential scale to examine the attitudes did not show statistically significant score difference between the two groups of patients Bogardus Social Distance Scale score showed statistically significant difference ($P > 0.03$). A significant score on the scale of social distance can be recognized in both psychiatry professionals and non-professionals.

Conclusion Stratification of items on the social distance scale shows a great social distance in the sphere of intimacy and slightly lower score on the level of social relations. The group having competent knowledge concerning the disease shows sophisticated way of hiding behind professional reasons.

Health intervention in gender violence

R. Hernandez Anton*, C. Noval Canga, N. De Uribe Vitoria, I. Sevillano Benito, J.A. Espina Barrio, P. Marques Cabezas, L. Gallardo Borges, A.I. Segura Rodriguez, M. Gomez Garcia, F. Uribe Ladron De Cegama

Hospital Clinico Universitario Valladolid, Psiquiatria, Valladolid, Spain

* Corresponding author.

Introduction Male and female social roles were built on a historical inequality. Gender violence is a public health problem of the first order. We consider it important to conduct a study to improve diagnosis and interventions. From the Theory of Roles Moreno, each role has a complementary role that maintains the link. In gender violence predominates control, domination, submission and asymmetry of functions as dysfunctional elements of a relationship, which should be symmetrical.

Methodology We reviewed 48 stories of women who come for abuse mental health team from 2013 to 2016. We analyzed the following aspects: socio-demographic data (age, nationality, marital status, education, jobs, dependent children); reason for

consultation and number of queries; violence; roles, because of maintenance and interventions.

Results Eighty percent Spanish. It occurs at all levels of education; 60% have children; 70% were derived from primary care for others reasons; almost 90% suffered psychological violence, 25% physical and economic, sexual only 3 women, 52.08% of women adopt a submissive role, passive-aggressive 20.83% and 25% ambivalent; maintenance of the violence is reinforced by the psychological dependence that occurs in all women (one in 45.83%).

Conclusions Roles analysis is an effective method in the diagnosis of abuse and designing appropriate intervention. Psychotherapy, benefits of a psychopharmacological treatment that lessens the suffering and lets face their difficulties. It is important to ask about abuse at any level of care, because it contributes more to cover a hidden reality. The Psychological and economic dependence. They establish and maintain the mistreatment.

Protective and risk socio-economic – environmental factors affecting mental health

M.I. Hussain

Khyber pakhtunkhwa Health care commission, Iftikhar Psychaitric Hospital, Peshawar, Pakistan

Over all generic, biological, environmental and socio-economic factors are attributing towards mental health and well being of a person. But among these socio-economic – environmental factors play a great role. It is very important to understand socio-economic – environmental protective and adverse factors affecting mental health. There is very dynamic interaction between individual attributes like socio-economic circumstances and environmental factors. The dynamic interactions of all these three factors determine the final outcome and status of mental health social well being. So, for our professionals particularly and community in general, it is very important to have full knowledge about all these factors. Because lack of managing and integrating of socio-economic-environmental factors, we will not be able to deliver quality psychiatric/psychological services. Community at large will also be ignorant of it and will not be able to play their roles towards healthy mental health formation. Moreover, these socio-economic – environmental factors are within our reach and can be modified.

Social rituals as an early indicator of mental illness

A. Janca*, J. Gaspar

The University of Western Australia, School of Psychiatry, Perth, Australia

* Corresponding author.

Introduction Social rituals refer to routine and expected social activities that are practiced in all communities in a culturally recognized manner (e.g., social greetings, eating customs, attention to dress, sleeping rituals etc.). Persistent departures from or disregard of these social rituals may be an early or prodromal sign of the onset of mental illness.

Objectives (1) To develop and evaluate psychometric properties of a measure of social rituals entitled, Social Rituals Schedule (SRS);

(2) to evaluate the reliability and cross-cultural applicability of this measure.

Methods The SRS was administered to 30 psychiatric patients and their nominated relative/friend. The cross-cultural evaluations were conducted using focus groups of Ethiopian ($n = 30$), Australian Indigenous ($n = 100$), Iranian ($n = 22$), and Indian ($n = 50$) participants.

Results The SRS demonstrated moderate to high inter-rater reliability and patient-informant concordance. The social ritual domains were found to be valid, well understood and applicable across the sampled cultures [1].

Conclusions The concept of social rituals and the SRS instrument were demonstrated to be feasible, reliable and cross-culturally applicable tools for measuring changes in people's appearance and behavior that might be indicative of emerging mental illness.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Stigmatization of mental health problems in Albania, ways of diminishing it

T. Jupe*, F. Elezi, B. Zenelaj, E. Myslimi
 UHC 'Mother Tereza', Psychiatry, Tirane, Albania
 * Corresponding author.

Background and aim More recent definitions of stigma focus on the results of stigma – the prejudice, avoidance, rejection and discrimination directed at people believed to have an illness, disorder or other trait perceived to be undesirable.

Methods During this study, we used Attitudes to Mental Illness Questionnaire (AMIQ), which helped us to understand the differences in the acceptance by the population for 3 different types of diseases: addiction, diabetes and schizophrenia.

Results (1) Alban has diabetes. (2) Besnik has schizophrenia.

Conclusions (1) The patients with schizophrenia have higher levels of stigma compared diabetic patients or those alcoholics (Tables 1 and 2 and Fig. 1). (2) Statistical processing carried out concluded that have statistically significant differences between gender-stigma ($P = 0.001$), age-stigma ($P = 0.0001$) and education-stigma ($P = 0.001$) (Fig. 2). (3) Health care workers stigma is exactly the same as in general population ($P = 0.01$) (Fig. 2).

Recommendations – Support recovery and social inclusion and reduce discrimination.

– Do not label or judge people with a mental illness, treat them with respect and dignity as you would anyone else.

– Do not discriminate when they come participation, housing and employment.

An explorative look at Jerusalem syndrome and its validity?

S. Kumar

5 Boroughs Partnership NHS Foundation Trust, University of Liverpool, General Adult Psychiatry, Liverpool, United Kingdom

Introduction The aim of the explorative study poster is to look into the phenomenon of psychotic disorder/manifestations collectively termed as Jerusalem syndrome – a psychotheological condition characterized by temporary psychosis like symptoms upon visiting Jerusalem.

Aim The primary aim is to explore the theories pertaining to the possible causes and psychopathology involved in Jerusalem syndrome with a view to contextualize their credibility and weightage against the extant evidence in neurological science. It would also look at the possible treatments used.

Method A detailed literature search has been undertaken to identify variety of case reviews and publications about Jerusalem syndrome and case interviews of psychiatrists in Jerusalem: dealing with neurological, psychological explanations of the condition; have been proposed by psychiatrist or psychologist and neurologists as a possible psychopathological manifestation.

Discussion The results are synthesized and presented in a tabular form. The discussion expands on the various theories and their relevance with a view to establish the nosological validity of the condition and the viable treatment models available.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Public beliefs and attitudes towards schizophrenia and major depression: Findings from a representative population-based study

Y.J. Lien^{1,*}, Y.C. Kao^{2,3}

¹ National Taiwan Normal University, Department of Health Promotion and Health Education, Taipei, Taiwan ROC

² Tri-Service General Hospital Songshan Branch, Department of Psychiatry, Taipei, Taiwan ROC

³ National Defense Medical Center, Department of Psychiatry, Taipei, Taiwan ROC

* Corresponding author.

Introduction Previous studies have suggested that public beliefs and attitudes toward mental illness may be influenced by country-specific social and cultural factors.

Objectives This study aimed to carry out a national survey to assess people's beliefs and stigmatizing attitudes toward schizophrenia and major depression in Taiwan.

Methods We randomly recruited participants aged 20–65 ($n = 1600$) in Taiwan, using a computer-assisted telephone interviewing. Participants were presented with a case vignette for major depression and schizophrenia. Questions were asked about causal attributions, emotional reactions, and social distance of individuals afflicted by psychosis or depression.

Results In respect of causal attributions, respondents were more concerned with the likelihood of biogenetic explanations for schizophrenia as compared with depression. The same applied to other explanations such as god's willingness and being possessed or haunted. In contrast, psychosocial factors were more likely to be endorsed as a cause of depression than as a cause of schizophrenia. For perceived dangerousness, significantly more respondents considered schizophrenia likely to be violent toward others and to be unpredictable. In terms of emotional reactions, respondents were significantly more likely to express anger or fear for schizophrenia vignette. A similar pattern was shown for the social distance, where respondents were also significantly less likely to express a willingness to contact people suffering from schizophrenia within different social relationships.

Conclusions The findings from this study may enhance our knowledge of community beliefs and stigmatizing attitudes towards people with mental disorders in Taiwan and highlight the importance of understanding these issues in context.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Protecting the incapable—Interdiction of in-patients in centro hospitalar De São João in the last two years

A.S. Machado^{1,*}, E. Pereira¹, R. Grangeia^{1,2}

¹ Centro Hospitalar de São João, Clínica de Psiquiatria e Saúde Mental, Porto, Portugal

² Centro Hospitalar de São João, Liaison Psychiatry Unit, Clínica de Psiquiatria e Saúde Mental, Porto, Portugal

* Corresponding author.

Introduction The interdiction of citizens is embodied in the Portuguese civil code and is untouched since 1966 regardless of the profound changes in our society. In 2006, Centro Hospitalar de São João (CHSJ) created protective measures for inpatients that are incapable; the procedure encompasses multidisciplinary evaluation of patients and the elaboration of a final report by liaison psychiatrists.

Objectives To describe the interdiction proceedings initiated at CHSJ in the last two years, establishing parallels with our socio-demographical and epidemiological reality.

Methods Retrospective study of the internal requests for psychiatric consultation concerning interdiction proceedings made in the CHSJ from January 2015 to December 2016.

Results During the study period, the liaison psychiatry service received 37 requests for evaluation of patients' decision-making capacity through the internal consultation system. The typology of the patient targeted in the interdiction process is male, more than 70 years old, hospitalized due to infectious intercurrents whose dependency of others enables him to return to his residence. More than a half (51%) of the requests were performed by internal medicine services. Twenty-one reports declaring the

patient's inability to govern his person and property were made. The most common pathology underlying this cognitive impairment was dementia (57%).

Conclusion Our results reflect the aging of Portuguese population and the increased prevalence of dementia. The evaluation of the capacity for self-governance will be increasingly required in our clinical practice and demands a holistic approach to the patient while taking into account the preservation of his autonomy, dignity and rights.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Epidemiology of depression in Azerbaijani urban female population. Cross-cultural comparison of depression incidence/prevalence indicators

F. Mammadova^{1,*}, M. Sultanov², A. Hajiyeva³, M. Aichberger⁴, A. Heinz⁴

¹ Central Hospital of Oil Workers, Psychiatry Liaison, Baku, Azerbaijan

² Republic Psychiatry Hospital, general, Baku, Azerbaijan

³ Republic Diagnostic Centre, outpatient, Baku, Azerbaijan

⁴ Charité Universitätsmedizin Berlin- Campus Charité Mitte, psychiatry, Berlin, Germany

* Corresponding author.

Introduction The aim is to determine the prevalence and incidence of depression for an Azerbaijani female sample and explore the impact of cultural factors on depression.

Objectives To determine: the optimal cut-off point of ZDRS; the point prevalence and 3 month incidence of depression; risk factors for depression. To compare the depression prevalence in the two language groups of the Azerbaijani population (Azerbaijani-speaking and Russian-speaking) for determining possible impact of cultural factors on depression.

Methods The first screening with ZDRS (Az) and ZDRS (Ru) were carried out with 1500 research participants, who filled out the questionnaires at their homes. All the screened subjects who score 40 and more on ZDRS were examined by MINI. True-positive and false-positive results were defined. Ten percent of the screened subjects, who score less than 40 on ZDRS were randomly chosen for clinical interviews to define true-negative and false-negative results. According to the analysis the optimal cut-off point of ZDRS in the Azerbaijani female population was found with the definition of its sensitivity, specificity, positive predictive value and negative predictive value. Based on the optimal cut-off point of ZDRS, point prevalence and incidence of depression was determined in Azerbaijan. The follow-up screening was conducted to determine the 3 month incidence of depression.

Results The determined prevalence and incidence of depression will be reported with the optimal cut-off point of ZDRS.

Conclusions The results of the current study suggested that the ZDRS was a valid tool for use in screening patients with depression disorders but need a modification.

Social stigma and disclosure of diagnosis among women with breast cancer in Azerbaijan

G. Mammadzada

Azerbaijan Medical University, Boston Children's Hospital, Harvard Medical School, Department of Developmental Medicine, Baku, Azerbaijan

Objective The current practice in medical and surgical care of women with breast cancer in Azerbaijan is to hold back disclosure of cancer diagnosis unless the patient actively asserts full disclosure. This study aimed to serve as a pilot, to appraise the level of anxiety and depression in women diagnosed with breast cancer and explore ways to develop approaches to further elucidating the important issue of cancer information disclosure.

Methods The subjects in the study were women recruited consecutively with confirmed oncological diagnosis of breast cancer ($n=23$; mean age = 50 (SD \pm 11; range 27–73 years) and who were scheduled for mastectomy. All the subjects consented to be directly interviewed. The interview comprised of a socio-demographic questionnaire and inquiry regarding the subjects' understanding of the nature of their breast condition. All the subjects were also administered the Hospital Anxiety and Depression Scale (HADS) in Azerbaijani. The patients who knew their diagnosis of cancer were ascertained subsequently from the record ($n=11$ [42.3%]).

Results There was a significant correlation between anxiety scores ($P=0.006$) and anxiety/depression scores combined ($P=0.009$) with the level of subjects' awareness regarding diagnosis of cancer; the correlation was not significant for depression scores alone ($P=0.068$).

Conclusions The findings are consistent with studies from culturally similar regions and reflect the need for improvement on disclosure, patient participation, and family support in treatment of women with breast cancer.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Objective To determine trends and impact on outcomes of atrial fibrillation (AF) in patients with pre-existing psychosis.

Background While post-AF psychosis has been extensively studied, contemporary studies including temporal trends on the impact of pre-AF psychosis on AF and post-AF outcomes are largely lacking.

Methods We used Nationwide Inpatient Sample (NIS) from the healthcare cost and utilization project (HCUP) from year's 2002–2012. We identified AF and psychosis as primary and secondary diagnosis respectively using validated international classification of diseases, 9th revision, and Clinical Modification (ICD-9-CM) codes, and used Cochrane–Armitage trend test and multivariate regression to generate adjusted odds ratios (aOR).

Results We analyzed total of 3,887,827 AF hospital admissions from 2002–2012 of which 1.76% had psychosis. Proportion of

hospitalizations with psychosis increased from 5.23% to 14.28% (P trend <0.001). Utilization of atrial-cardioversion was lower in patients with psychosis (0.76% vs. 5.79%, $P < 0.001$). In-hospital mortality was higher in patients with Psychosis (aOR 1.206; 95%CI 1.003–1.449; $P < 0.001$) and discharge to specialty care was significantly higher (aOR 4.173; 95%CI 3.934–4.427; $P < 0.001$). The median length of hospitalization (3.13 vs. 2.14 days; $P < 0.001$) and median cost of hospitalization (16.457 vs. 13.172; $P < 0.001$) was also higher in hospitalizations with psychosis.

Conclusions Our study displayed an increasing proportion of patients with Psychosis admitted due to AF with higher mortality and extremely higher morbidity post-AF, and significantly less utilization of atrial-cardioversion. There is a need to explore reasons behind this disparity to improve post-AF outcomes in this vulnerable population.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Comparison between patients who did not show up for their first visit and the ones who did

B. Mata Saenz*, L. Nuevo Fernández, L.M. Asensio Aguerri, L. Beato Fernández, T. Rodríguez Cano
Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain

* Corresponding author.

Introduction Referrals to psychiatry from primary care has increased in recent years. This can be the result of the global economic situation and represents a problem for specialized care, because patients can't usually be correctly attended to. On the other hand, patients who don't come to visits make up other important issues that we must analyze.

Objectives To analyze the differences between patients who did not come for their first visit and those who did in order to try to describe variables that could be affecting them.

Methods This is an epidemiological, analytic, prospective study of patients referred to our department. The following variables were collected: (1) referral protocol, (2) reason, (3) demographic data, (4) attendance to appointment, (5) diagnosis impression and (6) destination of referral. The SPSS 19.0 was used to analyze the data.
Results We studied a total of 1.048 patients for 15 months, of which 20.6% did not come to their first visit. A statistically significant relationship between attendance and gender, year of the appointment, adequate demand or not, previous follow-up and diagnosis was found (χ^2). However, if a logistic regression was carried out, only the adequacy of the demand was included in the model.

Conclusions Coordination with general practitioners is essential to improve referrals and, most importantly, the attention to patients. If we can agree on the referral criteria, a better-personalized assistance can be offered to patients who have more difficulties in coming (because of characteristics of illness, place of residence, and other variables).

Analysis of geographical distribution of referrals to psychiatry from primary care

B. Mata Saenz*, V. Muñoz Martínez, L. Nuevo Fernández, E. Lopez Lavela, L.M. Asensio Aguerri
Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain

* Corresponding author.

Introduction The distribution of the demand from primary care in the mental health units could be a way of facilitating the coordination and improving the attention to patients. For this reason, in our unit we have made a repartition of the areas among the different psychiatrists.

Objectives To analyze if there was a correlation between the geographical origin of the patients or their primary care areas and the referrals, and between them and their attendance.

Methods This is an epidemiological, analytic, prospective study of patients referred to our department. The following variables were collected: (1) referral protocol, (2) reason, (3) demographic data (origin, gender, age), (4) Primary Care area, (5) attendance to appointment, (6) diagnosis impression and (7) destination of referral. The SPSS 19.0 was used to analyze the data.

Results A total of 1048 patients were sampled. A statistically significant relationship hasn't been found between place of residence, primary care area or areas of distribution in the Unit and attendance (χ^2). If we analyze the population of each distribution, we can describe similar percentages depending on the size of these.

Conclusions Although a different distribution and a relationship is thought between some areas and the attendance or the number of referrals, we didn't find out them in our sample.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁵ University of Helsinki, Department of Neurological Sciences, Helsinki, Finland

* Corresponding author.

Introduction Depression is a common disorder among the unemployed, but research on identification of their depression in health care (HC) is scarce.

Objectives The present study aimed to find out if the duration of unemployment correlates to the risk for unidentified major depressive disorder (MDD) in HC.

Methods Sample of the study consisted of long-term unemployed who were in screening project diagnosed as having MDD ($n = 243$). The diagnosis was found in the records of HC in 101 (42%) and not found in 142 (58%) individuals. Binary logistic regression models were used to explore the effect of the duration of unemployment to the identification of MDD in HC.

Results The odds ratio (OR) for non-identified MDD in HC was 1.060 (95%CI 1.011–1.111, $P = 0.016$) per unemployment year and when unemployment had continued, for example, five years the OR for unidentified MDD was 1.336. The association remained significant throughout adjustments for the set of background factors (gender, age, occupational status, marital status, homelessness, self-reported criminal records, suicide attempts, number of HC-visits).

Conclusions This study among depressed long-term unemployed indicates that the longer the unemployment period has lasted, the greater the risk for non-identification of MDD is. HC services should

be developed with respect to sensitivity to detect signs of depression among long-term unemployed.

Who's lost in waiting?

P. Ossola^{1,2}, N. Jovanovic³, H. McColl², V. Giordano²,  CrossMark
C. Johnston Webber², M. Steel², N. Ramjaun², O. Andlauer^{2,*}

¹ University of Parma, Psychiatry Unit- Department of Neuroscience, Parma, Italy

² East London NHS Foundation Trust, Early Intervention City and Hackney, London, United Kingdom

³ Queen Mary University of London, The Barts and London School of Medicine and Dentistry, London, United Kingdom

* Corresponding author.

Introduction Early intervention services (EIS) can significantly reduce the rate of relapse, risk of suicide and number of hospital admissions for people with first episode of psychosis (FEP). However, care pathways in FEP can be complex, thus extending the period before patients commence appropriate treatment. Recently in the UK, guidelines have set a limit of two-weeks before patients with a FEP receive treatment at EIS.

Objectives We explored the impact of this new policy on referrals to an EIS in the area City and Hackney, London, which has one of the highest incidence of psychosis in the UK.

Methods Referrals from 6 months of 2015 have been compared with the data from the same period of 2016, once the waiting standard had been implemented.

Results We observed more than a two-fold increase in the monthly number of referrals (9.4 in 2015; 20 in 2016) and this wasn't due to a rise of inappropriate referrals (2.23% in 2015; 1.53% in 2016). Moreover the number of referrals doubled further when, in addition, the City & Hackney EIS went from a 18–35-year-service to an "ageless" adult service.

Conclusion The recent focus on FEP in the UK might have increased awareness and reduced stigma, leading to the increment in referrals. Also, shortening the waiting time made the service more accessible for those that would have gave up in front of a longer waiting list. Interestingly enough a peak in the number of referrals has been observed from September 2016 when another standard was implemented.

Social stigma in severe mental illness in Tunisia: Clinical and socio-demographic correlates

U. Ouali*, R. Jomli, R. Nefzi, H. Ouertani, F. Nacef
Razi Hospital, Psychiatry A, Mannouba, Tunisia

* Corresponding author.

Introduction Mental patients generally internalize some of the negative conceptions about how most people view them: they might be considered incompetent or untrustworthy or believe that people would not want to hire, or marry someone with mental illness. A lot of research on stigma has been conducted in western countries; however, little is still known on the situation in Arab-Muslim societies.

Objectives To evaluate social stigma as viewed by patients suffering from severe mental illness (SMI)

Methods This is a cross-sectional study on clinically stabilized patients with schizophrenia and Bipolar Disorder (BD) according to DSM IV, who were interviewed in our out-patients clinic with

the help of a semi-structured questionnaire, containing 8 opinions on the social inclusion and stigmatization of psychiatric patients, with special reference to the local cultural context (e.g.: "It is better to hide mental illness in order to preserve the reputation of my family")

Results We included 104 patients, 51% with schizophrenia and 49% with BD. Mean age was 38.4 years (18–74 years); 59.6% were males. Overall social stigma scores were high. Social stigma in patients was correlated with gender, age, place of residence and diagnosis. Patients with BD showed significantly less social stigma than patients with schizophrenia.

Conclusion Our results show the need for a better understanding of this phenomenon in patients with SMI, but also within Tunisian society, in order to elaborate anti stigma strategies adapted to the local context.

* Corresponding author.

Abstract

Introduction Teachers serve as models for young people and significantly influence their health behavior.

Aim We were interested in conducting the first epidemiological survey about tobacco smoking among Greek teachers.

Methods A total of 1032 teachers of the two biggest cities of Greece participated in the study. A questionnaire was created to include questions regarding tobacco smoking, history of tobacco use, nicotine dependence as well as health attitudes. Frequencies and relative frequencies were determined for all the questions. Pearson's Chi² and Chi² adjusted tests were used to examine the potential association of current smoking status with gender, age and school level in a statistical significance level of 0.05.

Results Prevalence of current smokers in the sample was 25.6%. Cigarette emerged as the tobacco product of choice reported by 88.3% of the respondents, followed by e-cigarette (5.2%), cigar (2.4%), hookah (2.4%) and pipe (1.7%). The highest prevalence of current smoking was found in the age group of 40–49 years old (46.1%). Current smoking proportion was higher among female (26.0%) than male teachers (24.9%). Intention to quit smoking was reported by 18.1% of the sample.

Conclusions As compared to other countries, teachers in Greece have a moderate percentage regarding tobacco smoking. A concerted effort must be made towards smoking cessation in this population with gender specific interventions. It is of great importance for teachers to act as public health promoters, as performers of tobacco prevention curricula and as leaders in the implementation of school tobacco control policies.

EV0533

A literary exploration of British cultural attitudes to psychiatry during the late 1800s and their development over the following century

A. Pittock

NHS Lothian, Child and Adolescent Mental Health, Edinburgh, United Kingdom

Introduction British psychiatry was in its embryonic stage in the late nineteenth century. Early psychiatrists employed radical treatments with little success and not much is documented about public attitudes. Using fictional depictions of madness and physicians allows us to explore cultural attitudes to psychiatry at the time.

Objectives First, to analyze the portrayal of madness and physicians in the island of Dr. Moreau and Dr. Jekyll and Mr. Hyde; second, to use this to provide insight into the public opinion of psychiatry and third, to evaluate the development of attitudes using twentieth century media.

Aim To provide an insight into the social perspective of mental illness in the late nineteenth century and consider its evolution over the last one hundred years.

Methods Two famous, well-received novels of the time were chosen for analysis. Historical knowledge of the period was sought using JSTOR, NHS Scotland's The Knowledge Network and Google Scholar. Novels and media depictions were analysed in relation to the scientific understanding at the time.

Results The novels show two ways of control: surgical (Moreau) and chemical (Jekyll). Both are unsuccessful, as were physician's attempts in reality. The narrators' concerns mirror the cultural anxiety at the time surrounding containment and treatment of mental illness. Media portrayal of cruel, unsuccessful treatment continues throughout the twentieth century.

Conclusions Nineteenth century cultural attitudes to mental illness show a distinct anxiety and concern with barbaric treatments and their inefficacy. Despite psychiatric progress, the media have continued to portray mental illness and its treatment in a negative light, suggesting continued levels of societal concern.

Demographic characteristics of the cohort of patients, receiving out-patient psychiatric help in regional medical consultative and diagnostic center of sub-arctic territory

K. Shapovalov^{1,*}, L. Shapovalova²

¹ State Education Agency of Additional Professional Education of Republic of Komi "Komi Republican Institute for Development of Education", Chair of Economics, Management and Law in Education, Syktyvkar, Komi Republic, Russia

² State Autonomous Health Agency of the Republic of Komi "Consultative and Diagnostic Center of the Republic of Komi", Consultative and diagnostic department, Syktyvkar, Komi Republic, Russia

* Corresponding author.

The analysis of mental health 5356 patients referred to the out-patient reception of a psychiatrist in the structure of the regional

consultative diagnostic center. The structure of the patient, the psychiatrist received increased by 14.0% the proportion of initial applications (59.6%). The number of men has decreased in absolute terms, 1.84 times, and the relative by 10.4%, which led to the formation of a clear trend dominance of the female population of the territory. Men are turning mainly in the active working age 18–44 years (54.2%), while women are turning mainly aged 50 years and older (59.3%). This is explained by the peculiarities of the physiological, mental and emotional state at a certain age period of the female orgasm, as well as the prevailing female population of the region (5.6%) over the masculine. Statistically significant difference on the prevalence of urban agriculture is not set. Reduction adopted children under the age of 17 years from 62% to 16% is a result of filling in the municipalities vacancies child psychiatrists and can be evaluated as a positive result of the dynamic development of mental health services. At present, it formed the objective necessity of the development of community mental health as a result of growth in the number of mental illnesses. But this comes at the expense of lighter forms (outpatient options). Most exacerbations do not require compulsory hospitalization, as a rule.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Structure of psychic sphere pathology of patients of the regional medical consultative and diagnostic center of sub-arctic territory

K. Shapovalov^{1,*}, L. Shapovalova²

¹ State Education Agency of Additional Professional Education of Republic of Komi "Komi Republican Institute for Development of Education", Chair of Economics, Management and Law in Education, Syktyvkar, Komi Republic, Russia

² State Autonomous Health Agency of the Republic of Komi "Consultative and Diagnostic Center of the Republic of Komi", Consultative and diagnostic department, Syktyvka, Komi Republic, Russia

* Corresponding author.

In the structure of pathology 5356 psychiatric patients according to nosology forms, the first place ranking diagnosed by a psychiatrist of the regional advisory diagnostic center occupy organic, including symptomatic, mental disorders (F00–F09) to 48.2%. The second place ranking occupied by neurotic, stress-related and somatoform disorders (F40–F49) to 37.8%. This pathology includes various phobic, anxiety, depressive, hypochondria, obsessive-compulsive, dissociative (conversion), somatoform disorders, as well as response to heavy stress and adjustment disorders. The combination of anxiety and depression observed took place in 70.0% of patients. The majority of patients with anxiety disorders only part of the symptoms is found, however, and they are extremely painful. These people are in most cases not immediately come to the attention of psychiatrists, moving from a general practitioner to a neurologist, cardiologist and doctors of other medical specialists. They have initially diagnoses as vegetative-vascular dystonia, and then diencephalic crises, etc. The third rank place took patients with mental retardation - the proportion of an average of 1.3%. Mental disorder primarily characterized by impaired ability, manifested in the ripening period, provides a common level of intelligence: cognitive, speech, motor and social abilities. For the most part the clinical manifestations of these patients there are two groups of disorders: (1) Disorders of cognitive functions (memory, intelligence, learning, attention); (2) perception of disorder, the content of the thoughts, emotions and behavior.

The impact of the economic crisis on the use of psychotropic medication in Portugal: Preliminary results of the national mental health survey follow-up

M. Silva*, A. Antunes, D. Frasilho, G. Cardoso, J.M. Caldas-de-Almeida

Nova Medical School, Faculdade de Ciências Médicas UNL, Chronic Disease Research Center Cedoc, Lisboa, Portugal

* Corresponding author.

Introduction Economic crises can contribute to a worsening of mental health problems and, consequently, to a possible increase of the use of psychotropic medication.

Objectives To assess the use of psychotropic medication in Portugal before and after the onset of the economic crisis, and to better understand the impact of the economic crisis in this highly hit country.

Methods This 2015 follow-up epidemiological study re-interviewed a probability sub-sample of respondents to the 2008 national mental health survey, the first nationally representative study of psychiatric morbidity and treatment patterns in Portugal. Socio-demographic and clinical variables were assessed using a structured interview in 2008 ($n=2060$) and 2015 ($n=911$). All participants were questioned about the last 12 month use of psychotropic medication for mental health problems. Descriptive analysis was conducted to assess the use of psychotropic medication by group and gender in 2008 and 2015.

Results Between 2008 and 2015 there was an overall increase in the use of the main groups of psychotropic medication (22.5% to 28.6%), with a particularly relevant increase in the consumption of anti-depressants and anxiolytics. The use of psychotropic medication was higher among women in 2008 and 2015 (31.1% and 36.7%) compared to men. However, the increase in consumption was more relevant in men (13.3% to 20.0%), particularly in relation to anxiolytics (6.0% to 11.6%).

Conclusions The economic crisis was associated with a substantial increase of psychotropic medication's use in Portugal, consistent with the increased prevalence of mental health problems that this study also found.

Services utilization for mental health problems in Portugal during the economic crisis: Preliminary results of the national mental health survey follow-up

M. Silva^{1,*}, A. Antunes², D. Frasilho², G. Cardoso², J.M. Caldas-de-Almeida²

¹ Nova Medical School, Faculdade de Ciências Médicas, Chronic Disease Research Center Cedoc, Lisboa, Portugal

² Nova Medical School, Faculdade de Ciências Médicas UNL, Chronic Disease Research Center Cedoc, Lisboa, Portugal

* Corresponding author.

Introduction During economic crises additional mental health risks emerge and social inequalities in health can widen. In order to

ensure universal coverage of mental health care and to reduce the impact of the crisis, it is crucial to assess the needs of the population to be able to reorganize mental health care accordingly.

Objectives To analyse the use of services for mental health problems in Portugal during the economic crisis.

Methods In this follow-up epidemiological study, a probability sub-sample of respondents to the 2008 national mental health survey ($n=911$) was re-interviewed in 2015. Socio-demographic variables and treatment patterns were assessed using a structured interview, and psychological distress was measured using the Kessler-10 Scale. Descriptive analysis was conducted to characterize the use of services for mental health problems.

Results In total, 27.9% of the respondents sought treatment for mental health problems in the previous 5 years, and GPs were the most contacted professionals. Only 57.7% ($n=119$) of the respondents with moderate or severe psychological distress ($n=197$) reported recognizing they needed treatment. Among people with moderate or severe psychological distress who recognized their need for treatment, most received treatment (80.5%, $n=105$), which was minimally adequate for 74.4% ($n=81$). Low perceived need and structural barriers were the main obstacles for access to care.

Conclusions Under-treatment, low continuity of care and low adequacy of treatment are problems that the Portuguese health system must address in order to meet the mental health challenges of the economic crisis.

A biopsychosocial look on the violence in Colombia. Understanding violence to understand the role of psychiatrist in the post-peace agreement era

M.J. Suel

Colombian Institute of nervous system, Clinical Montserrat, Bogota, Colombia

Introduction The armed Colombian conflict is one of the bloodiest and most extensive in the contemporary history of Latin America, with multiple factors and causes implicated.

Objectives Determine the factors involved in the emergence of Colombian political violence from neurobiological, anthropological, social and psychoanalytic models.

Methods We revised the report Basta Ya! of The National Center for Historical Memory, which approximates the casualties and victims of the armed conflict in Colombia. In addition, we conducted a rigorous review of current scientific and clinical literature on the neurobiology of violent behavior, social psychiatry and psychoanalytic papers about war, death, and survival instincts.

Results Violent behavior can be explained by the neurobiological model of aggressive response as an imbalance between the prefrontal cortex and the limbic system. There is evidence to support a geographically-based violence in Colombia with a fragmentation of the territory, the State, and the Colombian identity. Moreover, we found the psychological component raised by Freud and in psychoanalysis, about war, and life and death instinct, as antagonistic manifestations of life-present in acts of violence.

Conclusions The violence from the armed Colombian conflict has been one of the longest in modern history, determining its causality has been complex. However, understanding violence multifactorially allows us to improve social psychiatry and our role as clinicians in this new post-agreement era, in order to better estab-

lish mental health policies for victims and perpetrators in future reparation.

EV0539

Is a psychiatrist-patient confidentiality relationship subservient to a greater good?

G.E. Berrios

University of Cambridge, Robinson College, Psychiatry, Cambridge, United Kingdom

Before embarking in a fruitless exchange the title question must be unpacked:

– is the ‘psychiatrist-patient confidentiality relationship’ a subset of the general doctor-patient confidentiality relationship?

– if different, what causes the difference? Is it the nature of mental disorder, for example the fact that some mental disorders may impair ‘mental capacity’ in ways different from general medicine? – given that in addition to psychiatrists, psychologists, nurses, and social workers also enter into ‘confidentiality relationship’ with patients, should all be considered as tokens of the same type or as different types? If the latter, should such differences be considered as intrinsic or extrinsic? Intrinsic differences refer to structural dissimilarities; extrinsic differences to dissimilarities created by the respective legal frames imposed by each profession to its practitioners.

– is ‘subservience to a greater good’ an acceptable good way to describe the metier upon which the ethical scrutiny will be applied? Given that it does describe a ‘consequence’ of the process then it would seem that it prematurely opts for utilitarianism, an ethical theory that many may feel is not adequate to the case.

The general question and the pre-formulated debating positions are setting up a pseudo-debate. A more useful question should be: “Given the strong political and economic pressures being currently brought to bear upon all confidentiality relationships (held by priests, medics, lawyers, bank workers, etc.), what ethical system may be more convenient to:

– justify blatant breaches in confidentiality relationships;
– placate our moral conscience?”

Disclosure of interest The author has not supplied his/her declaration of competing interest.

500 years of reformation: The history of Martin Luther’s pathography and its ethical implications

B. Braun*, J. Demling

Psychiatry and psychotherapy, Friedrich-Alexander University, Erlangen, Germany

* Corresponding author.

Introduction In the context of the 500th anniversary of the Reformation, it is time to take a survey of the history of Martin Luther’s (1483–1546) pathography.

Method Relevant writings were evaluated.

Results While in a 1035 page work written in German between 1937 and 1941, the Dane Paul Reiter retrospectively diagnosed

Luther as manic-depressive, Kretschmer (1888–1964) in 1955 saw in Luther “a great polemic and organizer”. In 1956, Grossmann was unable to prove persistent synchronicity of depressive mood and reduced motivation in Luther in the key years 1527 and 1528, which led him to conclude that Luther had a cyclothymic personality with a pyknic constitution. In Roper’s view in 2016, Luther suffered from “a condition [...], that we would call depression today”.

Discussion In 1948, Werner concluded that Reiter’s pathography was based on an incorrect assumption: Luther’s solution of the cloister conflict as a dilemma situation between paternal and clerical authority was not a flight into “the mysticism of despair”. Hamm adopted this interpretation in 2015 in viewing the escalation of the emotional conflict potential as a logical consequence of an interiorized and individualized intensified piety. In 2015, Scott saw a cyclothymic temperament in Luther starting in about 1519, but emphasized the elasticity of Luther’s emotional reserves: “For the rest of his life, Luther oscillated between euphoria and dejection but not to the point of dysfunction”.

Conclusion Luther can be used as an example of the importance of religiousness as a curative resource for the psyche.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Emotional decision for accepting patients in the ICU in Greece – where are the guidelines?

I. Christodoulou*, G. Dounias, I. Tsakiridis, N. Peitsidis, C. Lahana, D. Gonezou

G. Papanikolaou General Hospital, Thessaloniki, Greece, B’surgical Department, Thessaloniki, Greece

* Corresponding author.

Introduction It is not a rare phenomenon to ask a bed in the ICU in a basis of emergency. Then, the answer coming from the intensivists may be more than surprising. Objective of our study is to highlight the fact that emotional reasons and not medical criteria are the dominant ones for accepting a patient in the ICU.

Methods We present 4 cases of interest.

Results A poor Russian 75-year-old man with gastric cancer, anemia and haemodynamic instability was not accepted in the ICU with the oral and not written rejecting answer that he suffers from advanced cancer. A 35-year-old transplanted patient with bone marrow, fever, severe lactic acidosis, was not accepted in the ICU for hours because the intensivist would give her consent only if the patient would undergo a cholecystectomy first! The intensivist was a pneumonologist! In the end multiple liver abscesses were discovered, so an operation would not help. An 80-year-old man operated for colon cancer with haemodynamic instability was accepted in the ICU without delay. A 72-year-old with colon cancer, cachexia, thrombopenia and severe dementia, coming from the Psychiatric Hospital where he remained for months, was accepted in the ICU without delay.

Conclusions If there is not an Ethics Committee to examine these unexpectability matters concerning patients needing a place in ICU, then a psychiatric evaluation of Intensive Unit physicians might help, for the good of patients. Would a member of the Parliament or a celebrity receive a “No” from the ICU?

Disclosure of interest The authors have not supplied their declaration of competing interest.

Decisional capacity in patients with acute delirium. A Rawlsian approach

S. Hostiuc¹, I. Negoii², E. Drima^{3,*}¹ Carol Davila University of Medicine and Pharmacy, Legal Medicine and Bioethics, Bucharest, Romania² Carol Davila University of Medicine and Pharmacy, Surgery, Bucharest, Romania³ Clinical Hospital Of Psychiatry "Elisabeta Doamna", Psychiatry, Galati, Romania

* Corresponding author.

Delirium is characterized by a temporary, usually reversible, cause of mental alteration; it can occur at any age, but affect most often the elderly. Delirium patients may also present acute psychotic episodes, which might make them decisionally incompetent. In order to assess decisional capacity, Fan et al developed a two-stage approach, which tries to analyse:

- the presence of delirium, using the Confusion Assessment Method;

- a proper analysis of the decisional capacity.

Often, in patients with decreased decisional capacity, physicians must assess which ethical principle should respect first – the principle of autonomy, whose practical implementation is informed consent, or beneficence – the good of the patient, irrespective of the its declared wishes. In this poster, we will look at the issue of decisional capacity in patients with acute delirium from a Rawlsian point of view, and will try to give an answer based on what is just – to respect the autonomy of the patient, or the moral duty to do good to the patient.

Fitness to practice and fitness to regulate

R. Kurz

Cubiks, IPT, Guildford, United Kingdom

Introduction In 2012, forensic psychology Professor Jane Ireland published initial research claiming that two third of psychological assessment reports sampled from UK family courts were 'poor' or 'very poor'. 'Fitness to practice' concerns were raised by vested interest and dismissed after a 1-week hearing – four years later.

Objectives The presentation outlines the nature of various UK institutions, such as family courts, HCPC and GMC as well as their practices which raise questions about their fitness to regulate.

Aims Delegates will start to learn how institutions that purport to serve public interest yet can be easily exploited by vested interests.

Methods Case studies are used to illustrate how extremely serious concerns were ignored but persecution concerns upheld.

Results In one case, four courts appointed experts ignored an obvious child trafficking process where a toddler was raped to cover up birth and disappearance of a newborn baby that succeeded from incestuous rape. In spite of a clinical psychologist failing to cover the two index incidents, the concerns did not meet the HCPC 'Standard of Acceptance'. A 'revenge concern' was raised by vested interests. In another case, the GMC refused to investigate a psychiatrist who had lied and rather absurdly claimed that repeatedly seeking return of her children was evidence for a mother's personality disorder. In a widely publicized case Psychiatrist Dr Hibbert accused of unnecessarily, breaking up families was investigated but cleared of misconduct by the GMC.

Conclusions Institutions tasked with protecting public safety and fairness appear to be unduly biased towards shielding inadequate professionals and persecuting whistle-blowers.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

On purpose of multiple cases: Quaternary prevention on mental health – "Primum non-nocere"

K.L. Lazo Chavez

Hospital Universitario Principe De Asturias, Psychiatric, Alcala De Henares, Spain

Introduction Quaternary prevention, concept coined by the Belgian Marc Jamouille, are the actions taken to avoid or mitigate the consequences of unnecessary or excessive intervention of the health system. The concept alludes to actions to avoid the over-diagnoses and over-treatment, trying to reduce the incidence of iatrogeny in patients, which is a serious public health problem and even more in mental health.

Methods Systematic review of bibliography.

Objectives Do a systematic review of bibliography and through the results invite to the analytic and critic reflection of our professional activities and the current situation of mental health.

Results There is not enough studies about quaternary prevention in mental health.

- Some studies found that about one-third of diseases of a hospital are iatrogenic, most of them for pharmacological causes.

- There is iatrogeny at different levels of the attention of mental health: primary prevention, diagnosis and treatment.

- Non-treatment indication avoids in multiple cases iatrogenesis and contributes to the correct distribution of the economic and care resources.

Conclusions Since one of the fundaments of medicine is "primun non nocere" that means "first do no harm" and one of principles of bioethics is "non-maleficence", quaternary prevention should prevail over any other preventive or curative option.

- We should define in a more realistic way the limits, benefits and damages of our interventions in order to not promote a passive and sick role.

- Must be recognized the non-treatment intervention as a therapeutic and useful intervention, and one of the best tools of quaternary prevention.

Multidisciplinary approach in old aged dying patients

N. Ogando Portilla*, S.M. Bañon González, M.G. García Jiménez

Hospital Universitario Rey Juan Carlos, psychiatry, Mostoles, Spain

* Corresponding author.

Introduction Over centuries, clinicians have had the responsibility to take care of dying patients. Lately, the withdrawal of life sustaining treatments have assumed a main role in these patients because of ethical aspects. Competent patients have the right to refuse medical care but not always these rights are respected or even explained to them, especially if they are old or they don't have any close family. A multidisciplinary team should agree on how they think it is best to care for the patient and whether withdrawal of medical interventions is appropriate by using patient's wishes.

Objectives To identify the most relevant aspects to deal with in old aged dying patients.

Methods Systematic literature review in Up-to-date and Pubmed.

Clinical case 83 years-old-man with a gastric cancer state IV. Married with a woman with Dementia who is waiting for a long stay public residence. No children. No cognitive damage. Fatal prognosis with a need of permanent enteral nutrition, which, he doesn't want to use and clinicians strongly recommends. Great anxiety and suffering. Decision making capacity. Wish to die.

Discussion Patients with the capacity to make medical decisions can refuse medical care even if this refusal results in their death. Sometimes, a “comfort measures only” can be a better option than trying to keep life. Old people with no family are often less informed and taken in count in making decisions. A symptom management, good patient-clinicians communication, psychosocial, spiritual, and practical support and respecting patient's wishes and decisions is a main goal in any medical care.

Defensive psychiatry. An ethical perspective

A. Riolo, F. Babici, F. Tassi*

ASS 1 Triestina, Department of Mental Health, Trieste, Italy

* Corresponding author.

Introduction The legal dispute between doctors and patients is increasing. The “frivolous lawsuit” is spreading and the psychiatrist is being dragged to court in the dock. Guidelines and operational protocols become the bastions of the defensive psychiatry. Defensive psychiatry involves, for example, a larger number of hospitalizations, also involuntary admissions, and psychopharmacological prescriptions.

Objectives We want to see if the issue of defensive psychiatry is perceived by psychiatrists as a risk in their clinical practices and what consequences may result in the relationship with the patient.

Methods Through an audit and through a literature review get to define the defensive psychiatry.

Conclusions Though there is much confusions and uncertainty in this field, the defensive psychiatry distorts the relationship with the patients and proposes the questions of social control.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction There is little research comparing patients' views with those of their treating psychiatrists. In a survey of patients' views conducted in 1993 for MIND (UK) by Rogers, Pilgrim and Lacey only 10% saw their problems in terms of mental illness. This highlights the tension between psychiatric codifications of mental abnormalities and explanations provided by patients themselves.

Aims This pilot project explores the perceptions of mental health issues in patients and their psychiatrists in a regional Western Australian setting.

Methods A mixed methods approach including semi-structured interviews of patients and their treating psychiatrists. Recruiting 5 consecutive people in the categories of involuntary in-patients, voluntary in-patients, patients on CTO, community patients and their psychiatrists.

Questions asked of the patients were:

- Why are you here?
- What problems do you have?
- What can be done?
- What control do you have?
- What control do other people have?

Psychiatrists were asked similar questions. Responses were recorded, transcribed and thematically analyzed to reveal key themes. Quotations are used to illustrate points participants wished to make.

Results We report on differences in understanding in both groups. This study reveals areas for further enquiry.

Conclusions Considerable diversity is revealed. A key conclusion is that insight is a concept relevant both for treated and treating.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psycho-social factors associated with maternal neonaticide

T. Amirejibi

Ilia State University, Mental Health, Tbilisi, Georgia

Current research presents five case studies of maternal neonaticide in Georgia. Participants were under the age of thirty, with incomplete secondary education, unemployed, dependent on their families' low income, living in the rural areas of Georgia. In three cases, participants resided with their family of origin. They were not married or in a relationship with the father of the child. They described their families and communities as conservative, holding strong cultural/religious beliefs against premarital sexual relations/childbirth out of wedlock. They lacked problem solving and coping skills, avoided making decisions concerning the pregnancy by concealing it. This being their first pregnancy, they gave birth alone followed by panic and fear of detection, committed neonaticide and hid the body of the infant. None of them had a prior criminal record. In the remaining cases, participants were married, lived with their spouses and children, had financial hardships. Both reported psychological and physical abuse from their spouses. One of them had a prior criminal offense for possessing controlled substances. The motive for neonaticide was an unwanted child due to an extramarital affair and threat of financial abandonment from extended family. In both cases, infants suffered fatal injuries. All participants reported lack of social support and emotional neglect from family members. These results are in line with international research, suggesting that certain patterns among these mothers are shared. Psychosocial factors associated with neonaticide should be utilized in the process of planning and implementing preventive strategies in health, social and legal frameworks.

² *Medical Faculty, Forensic Medicine, Prishtina, Kosovo*

* *Corresponding author.*

The court may impose a measure of mandatory psychiatric treatment in custody in a health care institution on a perpetrator who has committed offense while in a state of mental incompetence or substantially diminished mental capacity. An offense should be punishable by imprisonment of at least 3 years and is necessary to avoid a serious danger. Implementation of this measure can be difficult if surrounded by unsuitable psycho-social circumstances. Patient N.N, Albanian, 22-years-old, was born in Kosovo and raised in Germany. During this period, he only visited Kosovo 2–3 times. A few weeks before admission in the Institute (year 2014), he came in Kosovo willingly, to escape a prison sentence in Germany. Due to a fight, he was arrested and because of resistance that he showed, in the court – psychiatrist proposes mandatory psychiatric treatment. In admission was quiet, but after being told the rules of the Institute, he started to become aggressive, refusing to speak and eat. After refusal, his medical condition deteriorates. After “therapeutic weekend”, we saw improvement. The Court approved the doctor's proposal to change the measure. The measure must be appropriate for the patient in order not to cause more harm than good.

Background In the society we belong to, elders are the target of abuse which is many times generated by the social cultural

tendency which promotes different expressions in terms of age, a tendency which also measures capacity in terms of age.

Objective To evaluate elder physical abuse – cases reviewed at the Forensic Institute, Tirgu Mures County, Romania.

Methods An experimental design was used, focusing on elder physical abuse cases involving victims aged 65 or older, who requested a forensic certificate. All cases were reviewed at the Forensic Institute Tg. Mures, Mures County, Romania between 1st of Jan–31st Dec 2014. Variables included: age, gender, environmental origin, physical abuse, sexual abuse, relationship with the perpetrator (relative, known person/neighbor, unknown person, husband/wife), the required number of days of hospitalization, victim previous psychiatric diagnosis, aggressor previous psychiatric diagnosis.

Results A total of 5252 forensic medical certificates were issued at request by the Forensic Institute of Tg Mures. One hundred and twenty (2.28%) were related to acknowledgement of the aggression of an elderly person (≥ 65 years, with an average age of 69.89 years CI: 68.8903–70.8930). The majority of subjects were males (65%), of rural origin (64.17%). The same address as the aggressor's was identified in most of the cases (41.66%). 35.83% were hurt by neighbours/acquaintances, 22.5% were attacked by strangers.

Conclusion We are aware of that an elder abuse appears to occur most often in domestic home situations, men from rural, more often than women, are involved that victims and may be perpetrated by adult family members, or other persons.

¹ Azienda Socio Sanitaria Territoriale di Mantova, Sistema REMS, DSM, Mantua, Italy

² Usl Centro Toscana, Usl 11 Empoli, Empoli FI, Italy

* Corresponding author.

Introduction Forensic psychiatric care is aimed at improving mental health and reducing the risk of recidivism of mentally ill offenders. For some mentally disordered offenders long forensic psychiatric care is required. Due to different legal framework, policies and resources in member countries, treatment programs and care provided for these subjects may vary substantially across Europe.

Objectives COST Action IS1302, a EU project aimed at establishing a European network of researchers, clinicians and service providers about long-term forensic psychiatric care, has involved nineteen European countries for 2013 to set the basis for comparative evaluation and research on effective treatment and the development of best practice in long-term forensic psychiatry in Europe.

Method It is constituted by three main areas of interest and research. One group works on determination of patient characteristics, looking into prevalence, duration of stay and the most determinant characteristics of long term patients. The second area of research aims at obtaining better understanding of complex external factors that influence the poor progress of patients residing for an above average time in forensic services. Third group of research focuses on knowledge about specific needs brought about by psychiatric symptoms and how these specific needs might optimize the quality of life of patients in long term forensic psychiatric care.

Results/conclusions Launched four years ago, the action is at its last of activities. We display features, activities and data emerging from the research conducted so far.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Use of new synthetic drugs in Slovenian prisons

K. Ceranic Ninic^{1,*}, K. Jecic¹, E. Glavnik², M. Pustoslemsek¹

¹ University Medical Centre Maribor, Department of Psychiatry, Maribor, Slovenia

² University of Maribor, Faculty of Medicine, Maribor, Slovenia

* Corresponding author.

Introduction Prisons are a specific environment, in terms of population and various factors that affect health in the broader sense. According to the report of the board of prisons for Slovenia in 2013, 1 078 people who have had problems with illicit drug use were identified, representing 23.04% of all incarcerated persons. Moreover, an increase in the use of various types of new psychoactive substances, the so-called designer drugs, was recorded in recent years.

Aims The research aimed to point out the psychoactive drugs most used in Slovenian prisons and to explore whether these pose a public health issue.

Methods We conducted statistical research with semi-standardised epidemiological and psychoeducational questionnaires, which were distributed among prison population in Maribor region, Slovenia.

Results The analysis of the questionnaires received, which was completed by 54 prisoners, has shown that 54.55% of people aged between 18 and 35 years take synthetic drugs regularly, 30.30% of the population enjoys synthetic drugs occasionally. In the category of over 50 years, no one enjoyed these drugs. The most popular synthetic drugs were synthetic cannabinoids. Although a third of the users of these drugs has experienced at least one side effect, as many as 55.56% do not know how to act in such a case.

Conclusions This study confirmed that the majority of users of synthetic drugs are young adults who are convinced that their use is less harmful than the use of "ordinary" psychoactive substances. A surprisingly low awareness of side effects measure was stated.

Head banging as a form of self-harm among inpatients within forensic mental health and intellectual disability services

V. Chester^{1,*}, R. Alexander^{1,2}

¹ Partnerships in Care Learning Disability Services, Psychiatry, Palgrave-Diss-Norfolk, United Kingdom

² Leicester Partnerships NHS Trust, Psychiatry, Leicester, United Kingdom

* Corresponding author.

Introduction "Head banging" is a common form of self-harm, linked to numerous negative outcomes including significant brain damage. However, little research has investigated the prevalence and correlates of head banging behaviour in clinical populations.

Method Head banging episodes were identified from the incident records ($n = 5417$) of two inpatient forensic services (one intellectual disability and one mental health), using relevant search terms. Rates were compared between individual patients, by gender, diagnosis and level of security. Incident accounts were analysed qualitatively using thematic analysis.

Results Two hundred and twenty nine incidents of head banging were recorded, occurring approximately every three days in each service. The prevalence of the behaviour between individual patients varied widely, ranging from one to 38 incidents within one year. Women and patients with intellectual disability appeared more likely to engage in head banging. Qualitative incident reports indicated that head banging was associated with mental distress, anger, and psychotic experiences.

Discussion Head banging occurs frequently in forensic services, and has documented associations with traumatic brain injury in affected individuals, thus negatively impacting progress through the care pathway and treatment outcomes. Further research should investigate short and long term management strategies and treatment approaches, in order to minimise harm.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0554

The prevalence of obesity among forensic intellectual disability inpatients

R. Denman¹, V. Chester^{1,*}, J. Watson¹, C. Nyakunuwa¹, R. Alexander^{1,2}

¹ Partnerships in Care Learning Disability Services, Psychiatry, Palgrave-Diss-Norfolk, United Kingdom

² Leicester Partnerships NHS Trust, Psychiatry, Leicester, United Kingdom

* Corresponding author.

Background Inpatient mental health settings have been described as “obesogenic” environments, due to factors including psychotropic medication, high calorie food, restricted physical activity and sedentary lifestyles. No research has investigated obesity among forensic intellectual disability inpatients, despite this populations’ increased risk. Therefore, this paper aims to evaluate the prevalence and correlates of overweight and obesity on, and during admission.

Method The weight and body mass index data of 46 inpatients (15 women and 31 men) within a specialist intellectual disability forensic service was examined for the study.

Results Only six patients (13%) were a normal weight at admission, whereas 40 (87%) were overweight or obese. During their admission, 28 (61%) gained weight (average 11.8 kg), and one (2%) maintained. However, 17 patients (37%) lost weight (average 6.2 kg), though 16 remained in overweight/obese categories. There was no correlation between length of stay and weight/BMI.

Conclusions The majority of patients were overweight or obese on admission, and approximately 60% gained weight during their admission. Women appeared at greater risk of obesity. There was no relationship between length of stay and weight. This is potentially due to the high prevalence of obesity on admission and the impact of previous admissions on weight. The results highlight the need for effective weight management interventions with this population.

* Corresponding author.

Objectives The aim of this paper is to make a comparative study on serial killers from different countries and link them to one of the traditional seven deadly sins in the Judeo-Christian culture.

Methods Firstly, it was necessary to define each different deadly sin and establish its behavioural correlate. This was achieved thanks to a questionnaire designed to measure the interrate agreement within a sample population. Once the categories were defined (pride, lust, envy, sloth, wrath, gluttony and greed), 30 serial killers from America and Europe were analyzed in order to determine the sin behind their motivation to commit a crime. The evaluation was based on the Coding Guide – Serial Killers Research Project – created by the unit of analysis of criminal behavioural (University of Salamanca, Spain). Afterwards, an ex post facto descriptive non experimental study was carried out to find out the relation between the serial killer’s own characteristics and the deadly sin linked to their motivation.

Results/conclusions The results show a clear predominance of pride, lust and greed as the main motivations within the study sample. As well as some possible dependency relations between killers’ motivations and some other variables, which could be helpful when applied to the offender profiling field like sex or personality.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Serial killers: Relation between childhood maltreatment and sexual relations with the victims

F.J. De Santiago Herrero^{1,*}, C. Torres Delgado², M. García-Mateos³

¹ Salamanca University, Personalidad, Evaluación y Tratamientos Psicológicos, Salamanca, Spain

² Universidad de Salamanca, Máster de Psicoanálisis Clínico, Salamanca, Spain

³ Universidad Pontificia de Salamanca, Facultad de Educación, Salamanca, Spain

* Corresponding author.

Introduction Serial killer’s (SK) familiar relations often present a disorganized adherence characterized by the paternal absence and the excessive maternal coldness or over-protection. This familiar diagram, joined to mistreatment situations, could generate different antisocial conducts in the child because of the vacancy of a significant strong figure.

Objectives To study, in the SK, the relation between having suffered childhood mistreatment and the sexual aggression to the victims before killing them.

Method A study is realized between the variables of childhood mistreatment and sexual aggression to the victims. The data has been extracted from 100 protocols of SK with different nationalities elaborated by the unit of analysis of criminal behavioral (University of Salamanca, Spain).

Results The results show a significant relation between both variables.

Conclusions It can be confirmed that the SK who have suffered childhood mistreatment sexually attack their victims before killing them while those who did not experiment it during their childhood do not realize that conduct.

Intergenerational transmission of antisocial personality disorder: Maternal role and its declination

E. Di Giacomo^{1,*}, M. Clerici²

¹ PhD program in Neuroscience, Doctorate School of the University of Milano-Bicocca, Psychiatric Department, S. Gerardo Health Care Trust-Italy, Milan, Italy

² University of Milano Bicocca, School of Medicine and Surgery, Monza, Italy

* Corresponding author.

Antisocial personality disorder is a well-established disease which features space from cruelty to lack of empathy and remorse. Its etiology has been deeply analyzed both for genetic and environmental implications. The role of family context has been underlined throughout the whole psychopathology as an explanation to the etiological conflict between nature and nurture. Even if this conflict seems to be apparently solved, it is still possible to ponder about family implications in terms of causes and consequences. In the antisocial field, maternal role may offer interesting and surprising food for thought. Even if it is commonly believed an intergenerational transmission of aberrant behaviors, particularly in terms of learning behaviors and lack of empathy assimilation, it exists a side part of maternal pathological expression that may play a role in the intergenerational transmission and it is extremely difficult to be detected. Female declination of this disorder may be expressed also through somatic implications and complaints, leading to the hypothesis of a self-reflection of the lack of consideration for other's needs, which is distinctive. It is of extreme importance, particularly in terms of prevention, to consider and identify these connotations of the disorder to be able to try to interrupt the cycle of transmission through generations.

Paranoia: When criminology predicts vocational prognosis

B. Ghajati*, G. Sahar, B. Imen, R. Rim

Razi Hospital, Forensic Psychiatry Department, Tunis, Tunisia

* Corresponding author.

Patients with paranoia have always been a group of exiting but daunting patients for mental health professionals. Indeed, the risk of a violent acting out with important aggressive discharges confers to these patients an elevated dangerousness potential. If various criminological aspects of violence in paranoia have been described, their link to functional prognosis of patients have been seldom addressed.

Aim To determine if criminological details of violence acts in paranoia patients predict their functional prognosis.

Methods A retrospective, descriptive and analytic study have been conducted, based on a chart consult. Twenty-three patients with paranoia (i.e. Chronic delusional disorder jealousy or erotomania in DSM IV) patients have been included. These patients have been hospitalized in the forensic psychiatry department of Razi hospital of Tunis (Tunisia), between 1995 and 2015, after not being held by reason of insanity, according to article 38 of the Tunisian Criminal Code.

Results Delusional disorder types were: jealousy (17), persecution (4), erotomania (1) and claim (1). The majority were married

(18), undereducated (17), with irregular work (13). Forensic acts were uxoricide (15), attempted murder (5), violence against people (2) and destruction of public properties (1). Patients used bladed weapon in most of the cases (13), in the victim's residence (19), with premeditation in (17) of the crimes. Only 5 patients worked regularly after discharge.

Conclusion If our results expose further data concerning potential dangerousness of patients with delusional disorders, they also highlight the marginalized situation of these patients when released back into society.

Forensic neuropsychiatry and neurocrimen applied to the study of violent, criminal and corrupt behavior

G.N. Jemar^{1,*}, I. Ramiro², G. Bartoli², M. Ezequiel²

¹ Hospital Jose Tiburcio Borda, Guardia Medica, Ciudad Autonoma De Buenos Aire, Argentina

² Sociedad Argentina De Trastornos De La Personalidad Y Psicopatias, Docencia, Buenos Aires, Argentina

* Corresponding author.

Objectives – Define the scope of the study of Forensic Neuropsychiatry inherent in violent, criminal and corrupt behavior psychopathological processes;

- characterize to Neurocrimen;
- describe the neurobiological underpinnings of violence;
- analyze the corrupt behavior as a derivation of cognitive bias and distorting processes that lead to social maladjustment;
- propose therapeutic tools addressing violent, criminal and corrupt behavior.

Development Violent, criminal and corrupt behavior currently occupy an enormous preponderance in terms of distorting behaviors collevan degradation of the harmonic organization of social convivencia frequently appear in the media presented under the judicative and moral value, preventing a comprehensive analysis of this issue. We intend dilucidar under this scenario if these behaviors have a neurobiological basis, or if we neuropathological arguments that lead us to interpret any of these processes in terms signosintomatológicos, and therefore be liable to approach from mental health. For this analysis we implement knowledge from cognitive neucociencia, specifically forensic neuropsychology and neuropsychiatry, the neurocrimen and neuroderecho.

Conclusions Violent, criminal and corrupt behavior have a neurobiological support in statistical terms that allow us to infer distortionary neurobiological processes that result in changes in adaptation to social life. Many of these neurobiological aspects may be characterized in terms neuropathological and, therefore, make some of these behaviors in symptoms and signs. These findings implanted the need to revise legal conclusions static, although still insufficient to transform legal medical paradigms, but we require constant analysis and case by case ratification thereof.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Gender diversity set a new paradigm in terms of challenge and study for mental health. The analysis includes everything from basic parameters such as shed prejudices and preconceptions, to question old concepts rooted yet even from the proposed DSM, understanding gender diversity not just in terms of behaviour, choices or sexual conditions but from the integration of this in cognition and social inclusion, and finally understand that the nosological processes become in fact they do not have their origins in the diversity of gender, and that this per se does not constitute a pathology. The main issues addressed are the social marginalization, the problems of co-existence, discrimination, external and internal positioning for their conduct, election or sexual and gender perceptions and ways of adaptation are implemented, in addition to nosological processes current mental health, which are influenced but not because of the above. The population Trans in penitentiary system frequently mental health care for problems such as substance abuse, convivial and adaptive circumstances, being achieved in most cases a specific record of the particular problems and behavioral system that allows the convivial adaptation, with the limiting variables that negatively influence (discrimination, marginalization, etc). The binary logic in the current psychopathology as well as society and culture in general prevents nosological analyze processes of these patients regardless of their behavior, sexual choice or self-perception of gender. They should consolidate new paradigms of psychopathological analysis to achieve a more comprehensive understanding of the nosological processes in these patients to achieve effective therapeutic targets.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Researches on female offenders have indicated a high degree of psychiatric morbidity amongst women. Since the rates of female criminality are rising it would appear important to conduct the study of the relationship between criminal behaviour and psychiatric diagnoses in female offenders.

Objectives The main purpose of this investigation is to find out origins of crimes in women and to reveal the influence of child and adolescent maltreatment on personality disorders in adult women.

Methods Clinical psychopathological, psychological, statistical.

Results A cohort of 24 females with diagnosis of personality disorders was examined. All of them had committed crimes of violence. In the majority of the sample women had a previous history of psychiatric admissions (child psychiatric hospitals, adolescent units). The retrospective review revealed that the majority of women in their childhood were exposed to emotional, physical and sexual abuse in their families. Our results point that maltreatment may distort personality formation and social adjustment and contribute to behavior problems, negative relation to socialization and criminal behavior in adulthood.

Conclusion The study revealed that psychiatric disorders in childhood and adolescence are predictive of adult criminality in females. This findings may be used as prognostic indicators of development of aggression in female forensic patients.

The study is supported by the Russian Fund of Fundamental Investigations 6-06-00314

False memories, false innocence belief syndrome (FIBS) and ‘mind control’

R. Kurz

Cubiks, IPT, Guildford, United Kingdom

Introduction Child sexual abuse allegations are extremely tricky matters to deal with as situations can range from ritual violence at one extreme to complete fabrication by vested interests at the other. A level headed approach is required that does not fall into the trap of categorizing all early childhood memories as ‘false memories’ while also being alert to possible ‘mind control’ coaching of false allegations.

Objectives The presentation covers the origins of the false memory syndrome group and the implantation of false memories that is seemingly practiced by vested interests.

Aims Child custody and criminal cases are frequently decided based on testimony of mental health professionals who routinely appear to be poorly informed and blatantly biased.

Methods A review of articles in the BPS publication ‘The Psychologist’ uncovered a large amount of materials written by advocates of the BFMS prompting further research.

Results There appears to be a multitude of articles written by BFMS associates in The Psychologist. Furthermore, instances of BPS ‘censorship’ are disconcerting. On top of this, concerns have been raised in the US about the ethics of Elizabeth Loftus—the academic ‘darling’ of the false memory movement. Finally cases have come to light where false memories were seemingly implanted by vested interests to ‘snatch’ children into authority care.

Conclusions The mine field of child sexual abuse needs to be tackled with an even-handed manner considering the full range of possibilities in assessment.

How to interview terrorists? A forensic psychiatrist experience

S. Leistedt

Forensic Mental Health Hospital Les Marronniers, Forensic Department, Tournai, Belgium

Introduction Because of their intrinsic characteristics, forensic interviews with terrorist suspects are perhaps one of the most challenging interviews forensic psychiatrists and psychologists will experience.

Objectives This work presents a theoretical and practical framework for understanding terrorist individual psychology and effective interviewing techniques. It will show how the psychopathology of the terrorist, as well as social factors, have to be integrated in the preparation of the interview and in the interviewing process itself.

Methods Forty-eight incarcerated Middle Eastern terrorists (1 women and 47 men) have been interviewed. These terrorists were involved – directly or indirectly – in several attacks claimed by Al-Qaeda or ISIS. Verbal communications were evaluated through questions and key points related to personality disorders described

in the DSM-V. Non-verbal communications were analyzed through modalities such as facial expressions, eye contact, and body gestures.

Results Several verbal and nonverbal characteristics have been identified as common in all the interviewees.

Conclusions In a way to improve the quality and the quantity of the information gathering, it is suggested, especially with terrorists (but not only), to based the investigative and forensic interviewing on a personality-focused approach. Further studies are also needed to evaluate if terrorists have specific communication skills. Finally, this work proves that indirect assessment, such as consulting records, interviewing partners, family members or friends, is very important in the terrorist forensic assessment.

Specifics of the implementation of the security measures of medical nature in the Republic of Serbia

P. Mistic

Specialized Hospital for Psychiatric Disorders "Gornja Toponica", The Forensic Psychiatry Male Department, Nis, Serbia

The medical security measures in the Republic of Serbia include:

- mandatory psychiatric treatment and confinement in a medical institution;
- mandatory psychiatric treatment at liberty;
- mandatory treatment of alcoholics and;
- compulsory Drug Addiction Treatment.

The aim of this presentation is to explain how the medical security measures are implemented in the Republic of Serbia. The methods used in this study are analysis and synthesis of the implementation of security measures in the Republic of Serbia based on many years of practical work in forensic centre for the implementation of security measures. By duration of medical security, measures may be twofold:

- of unlimited duration, when the offender is undergoing medical treatment and keeping in a medical institution, while there is a need for treatment, or until there is no threat to the environment (the length of time is difficult to determine, however, that the most common word on the permanent indefinite treatment and storage required special caution and detailed analysis of all the elements relevant for this decision).
- limited duration, where the duration of treatment is determined by the court and to no longer than three years as provided in the current The Criminal Code of the Republic of Serbia.

The basis of every civilized society make the legal and moral norms governing the relations within the community, and thus regulate and protect their most essential element – the man – his physical and psychological integrity.

Incest in the Schizophrenic patient: Case report

M. Mezghani*, F. Fekih-Romdhane, F. El Ghali, M. Zghal, G. Jmii, L. Jouini, I. Ghazeli, R. Ridha

Razi Hospital, Forensic psychiatry, Tunis-Mannouba, Tunisia

* Corresponding author.

Introduction Incest may be defined as sexual relations between close blood relatives. Legally, incest and sexual aggression toward

minors are classified as a criminal behaviour. Tunisia is among the countries from which incest cases are rarely reported.

Objectives and method The aim of this study is to investigate the relationship between the psychotic structure and incest, and to describe the individual, clinical, and criminal traits of the incestuous father through clinical observation.

Case report Mr T.G is 46 years old. He is married and has six daughters. His wife appears to be passive, and largely dependent on her husband. Mr T.G has had incestuous relationships, initially, with his two eldest daughters. The acts were followed by the mother's complicit silence and the non-denunciation of the daughters. Two years later, he starts an incestuous behavior with his third daughter. Incest took place in the context of delusion. The patient was convinced that he is responsible of his daughters' sexuality education. He develops an incoherent theory of purification with a tendency towards morbid rationalism. It is only after four years of insufferable paternal incestuous relationships that the third daughter filed a complaint to the police. A psychiatric expertise concluded that the accused is exempt from criminal responsibility.

Conclusion Incest is a multi-faceted phenomenon, which makes its approach, comprehension, and treatment quite complex. For a psychotic patient incest is a means to deny alterity by crushing other. It also allows him to find, in this complete power, control over his annihilation anxiety.

Substance use among male forensic patients

M. Mezghani*, F. Fekih-Romdhane, F. Ghali, G. Jmii, M. Zghal, L. Jouini, I. Ghazeli, R. Ridha

Razi Hospital, Forensic psychiatry, Mannouba, Tunisia

* Corresponding author.

There is a widespread use of substances abuse which might cause violence, suicide, interpersonal conflicts, lawsuits, psychiatric commitment, and even crimes. Psychiatrists are under increasing pressure to develop strategies to address the problem of co-existing criminal behaviour, addiction, and mental illness. The aim of this study was to examine the association between demographic profile, psychiatric symptomatology and substance use in forensic psychiatric inpatients, and to consider the treatment needs and opportunities for intervention among the same sample.

Methodology A retrospective study was done on patients admitted to the department for Forensic Psychiatry at the Razi Hospital from 1996 to 2016, initially jailed for detention and drug consumption and judged irresponsible by reason of insanity. Data were collected by record review.

Results Thirty-two patients were included in the study. Mean age was 27.81 years. Thirty-six percent of the participants were illiterate and 45% were single. More than half of the subjects (54%) had personal psychiatric history and 27, 27% had family history of psychiatric problems. About one third (31.81%) of participants had judicial background: 33% were arrested for public drunkenness, 44% were arrested for violence, and 22% were arrested for theft. Concerning the diagnosis, 45% were suffering from schizophrenia, 22.77% were diagnosed with personality disorder and 27.27% of them would not have any mental trouble. About 50% of the patients did not follow up with treatment.

Conclusion Addictive disorders are authentic psychopathological disorders. Effective treatment is hindered by the paucity of research on clinical application of treatment models for addictive disorders in this population.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Violent incidents within psychiatric settings

B. Motamedi*, A. Mahmoudi, M. Motamedi

Faculty of Nursing, Chiang Mai University, 110 Inthawaroros Road, Sriphum District, A. Mueang, Chiang Mai, Thailand

* Corresponding author.

Objective To determine the frequency and types of aggressive and violent behaviors in acute psychiatric inpatient settings and potential interactions between staffing and patient mix and rates of the behaviours were explored.

Methods Data on violent incidents were gathered prospectively in two acute psychiatric units in two general hospitals and two units in a psychiatric hospital in Isfahan, Iran. Staff recorded violent and aggressive incidents by using Morrison's hierarchy of aggressive and violent behavior. The classification ranged from level 1, inflicted serious harm to self or others requiring medical care, to level 8, exhibited low-grade hostility. They also completed weekly reports of staffing levels and patient mix. Regression analysis was used to calculate relative rates.

Results A total of 400 violent incidents were recorded over a three-month period. Based on the scale, more than 50 percent of the incidents were serious. Seventy-eight percent were directed toward nursing staff. Complex relationships between staffing, patient mix, and violence were found. Relative risk increased with more nursing staff (of either sex), more non nursing staff on planned leave, more patients known to instigate violence, a greater number of disoriented patients, more patients detained compulsorily, and more use of seclusion. The relative risk decreased with more young staff (under 30 years old), more nursing staff with unplanned absenteeism, more admissions, and more patients with substance abuse or physical illness.

Conclusions Violent incidents within psychiatric facilities were frequent and serious, with great significance for occupational health. Some clues were found in the prediction of violence.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Differences in current psychological and physiological subclinical stress levels in forensic patients with psychopathic personality traits

S. Nigel*, J. Streb, K. Leichauer, B. Hennig, S. Otte, M. Dudeck

Ulm University, Department of Forensic Psychiatry and Psychotherapy, Günzburg, Germany

* Corresponding author.

Stress and its associations with psychopathic traits have been widely studied. However, recent research suggests the distinction between psychological and physiological symptoms of subclinical stress experience. Possible differences regarding these two dimensions of stress and their relations to psychopathy factors have not been investigated yet. Hence, this is the first study on psychological and physiological subclinical stress levels of forensic patients with psychopathic personality traits. We expected to find distinct associations between stress dimensions and psychopathy factors. Therefore, we examined 164 forensic patients with a substance use disorder regarding their psychopathy scores and current stress levels, using the Psychopathy Personality Inventory (PPI) and the Subclinical Stress Questionnaire (SSQ). Our results indicate that only the experience of psychological stress and not physiological stress is predicted by psychopathy. More precisely, the psychopathy factor "Impulsive Antisociality" is a positive predictor of subclinical psychological stress symptoms, while the factor "Fearless Dominance" is a negative predictor. Thereby, gender has

an influence as females are more likely to experience psychological and physiological stress. In conclusion, these results imply that forensic patients scoring high on the psychopathy factor "Impulsive Antisociality" experience high levels of psychological distress. This is in line with previous findings describing Impulsive Antisociality as a generally maladaptive trait manifesting in low adaptability and insufficient coping strategies.

The profile of sexual abusers of minors: A forensic-psychiatric studyJ. Nunes^{1,*}, D. Figueiredo¹, T. Ventura Gil¹, M. Colón², A. Pissarra da Costa¹¹ Hospital Sousa Martins, Department of Psychiatry and Mental Health of Sousa Martins Hospital, U.L.S. Guarda, Guarda, Portugal² Delegação do Centro do INMLCF, I.P., Psiquiatria, Coimbra, Portugal

* Corresponding author.

The World Health Organization (WHO, 2006) defines sexual abuse as the involvement of a child in sexual activity that he or she does not fully comprehend, being unable to give informed consent to, or for which the child is not developmentally prepared, or else that violates the laws or social taboos of society. In Portugal, the law that regulates the sexual abuse of underage people (minors) is enclosed in crimes of sexual auto-determination, which are described as child sexual abuse (article 171°) and sexual acts with a teenager (article 172°), and those are applied to the person that has copulation, anal intercourse and oral intercourse with underage abusing from their inexperience. Our objective is to investigate the profile of sexual abusers of minors, namely, the socio-demographic features, clinical correlations, and the level of penal responsibility of sexual offenders who were referred by court to forensic psychiatric assessment in the Institute of Legal Medicine of the City of Coimbra. Moreover, verify if these individuals present mental disorders at the time of the offence. The present study is of descriptive nature, being based on the observation and consultation of 30 clinical processes of sexual abusers. All written reports were obtained from 2005 to 2015 by court-appointed psychiatric experts on individuals that have been charged of committing sexual crimes against minors and referred to the main forensic institute in the city of Coimbra. This study will contribute to the increase of more information on these offenders, promoting the development of more adequate contingency plans for this population.

Predicting offense recidivism in Schizophrenia patientsB. Oueslati^{1,*}, M. Ali², R. Ridha¹¹ Razi Hospital, Forensic psychiatry department, Manouba, Tunisia² Faculty of Medicine of Tunis, Preventive medicine department, Tunis, Tunisia

* Corresponding author.

Introduction Schizophrenia increases the risk of offending. Recidivism rates are significant.

Aim Identifying general and violent recidivism risk factors in schizophrenia patients.

Methods We conducted a case control study. All included patients were admitted, at least once, to the forensic psychiatry department in Razi Hospital between January 1st, 1985 and December 31st, 2014 after a decision of irresponsibility by reason of insanity. All those who reoffended during this period were con-

sidered as cases. A draw was performed to create the control group. Both groups were matched according to their first offences' types as well as to their ages. A multivariate analysis was performed.

Results We included 25 cases and 38 controls. Eight recidivism risk factors were identified. Living in urban poor neighbourhoods ($P=0.039$; $OR=1.23$), having been unemployed ($P=0.047$; $OR=1.22$) and not having lived with the family ($P=0.039$; $OR=1.36$) after discharge were considered as risk factors. The same applied to alcohol ($P=0.032$; $OR=1.29$) and cannabis use disorders ($P=0.005$; $OR=1.34$). A hospitalization shorter than 6 months increased the risk by 1.44 ($P=0.039$). A combination of conventional antipsychotics ($P=0.003$; $OR=1.36$) and a poor adherence ($P=0.006$; $OR=1.36$) were considered as recidivism risk factors too.

Conclusions All eight recidivism risk factors are dynamic. This makes recidivism prevention conceivable. Measures involving the patient, the health care system, patients' families, society and the government should be taken.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Decision making in structure of self-regulation of persons with mental disorders at assessment of capacity

Y. Perepravina

The Serbsky State Scientific Center for Social and Forensic Psychiatry, Laboratory of Psychology, Moscow, Russia

The paper is based on the conception of Luria's neuropsychological theory, the conception of self-regulation (Nikolaeva V.V.), the model of decision making (Kornilova T.V.), methodological basis of psychological and psychiatric assessment of capacity of The Serbsky State Scientific Center for Social and Forensic Psychiatry (Kharitonova N.K.).

Research goal To study neuropsychological factors in persons with mental disorders who are involved in forensic assessment of capacity and find out correlation between decision-making and neuropsychological factors.

Research subject The three levels of self-regulation (the level of regulation of mental status, the operational level, the motivational level) and the role of decision making in this structure in persons with mental disorders who are involved in forensic assessment of capacity.

The research methods Neuropsychological methods by Luria A.R., patopsychological methods for assessment Higher Psychological Functions (Zeigarnik B.V.), Melbourne decision making questionnaire (a Russian adaptation, Kornilova T.V.).

According to Luria's neuropsychological theory, series of the basic neuropsychological methods include: (1) determine arithmetic task using an algorithm, (2) tests for study of praxis and gnosis, (3) tests for study of memory and attention, (4) test for study of comprehension of logical-grammatic expressions.

Results – The three levels of self-regulation correspond to the three functional brain's areas (according to Luria's neuropsychological theory)

– Decision making correlation with factors of the third brain's area (the frontal lobe)

The conclusions Our research considers neuropsychological factors like possible medical criterion for assessment of capacity.

Spitefulness and psychopathy: A contribution for an Italian adaptation

C. Garofalo¹, G. Rogier^{2,*}, P. Velotti³

¹ Tilburg University, Department of Developmental Psychology, Tilburg, The Netherlands

² La Sapienza, Psicologia clinica e dinamica, Roma, Italy

³ University of Genoa, Educational Sciences, Psychology Unit, Genoa, Italy

* Corresponding author.

Introduction Psychopathy has been individuated as an important predictor of criminal recidivism. As a consequence, a growing number of studies has examined factors associated with psychopathic traits in criminal population. While spitefulness has been associated with a range of destructive behaviors, there is a paucity of instruments that evaluate the spitefulness (Marcus & Zeigler-Hill, 2015).

Objective Testing the validity and reliability of an Italian version of the Spitefulness Scale.

Aims Correlate Spitefulness Scale scores and other indices of psychological functioning. We recruited an offenders sample ($n=400$) and a community sample ($n=400$). We administered the Spitefulness Scale (Marcus, 2014), along with the following measures: Dirty Dozen (Carmines & Zeller, 1979), Aggression Questionnaire (Buss & Perry, 1992), Difficulties in Emotion Regulation Scale (Gratz & Roemer, 2004), and SRP (Hare, 1980).

Results Offenders participants showed higher levels of spitefulness. Further, the construct validity of the scale was confirmed by associations with measures of psychopathy, emotion dysregulation, and interpersonal problems.

Conclusions The use of the Italian version of the Spitefulness Scale seemed promising for the study of emotion recognition in both clinical and nonclinical samples.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The role of spitefulness in personality disorders: Toward a better comprehension of the cluster B

Velotti¹, G. Rogier^{2,*}, C. Garofalo³

¹ University of Genoa, Educational Sciences, Psychology Unit, Genoa, Italy

² La Sapienza, Psicologia clinica e dinamica, Roma, Italy

³ Tilburg University, Department of Developmental Psychology, Tilburg, The Netherlands

* Corresponding author.

Introduction Cluster B personality disorders (i.e., Antisocial, Borderline, Histrionic, and Narcissistic Personality Disorders), is characterized by a dramatic pattern of relating to others, with symptoms characterized by a difficulty regulating emotional states and behavior (APA, 2000). The desire to cause pain often characterized these disorders (i.e. borderline) involving vindictively harming another with serious and often negative interpersonal consequences. Nevertheless, there is a paucity of research about the nature of relationships between spitefulness and personality disorders.

Objective This study aims to investigate the association between spitefulness and personality disorders in an offenders samples ($N=305$).

Aims To investigate the associations among spitefulness and personality disorders. We hypothesized that spitefulness would be differently associated with emotional and impulsive personality disorders (cluster B: antisocial, borderline, histrionic and narcissistic).

Results As expected, spitefulness and some personality, disorders were positively associated. Specifically, ASPD and Borderline are strongly associated with high levels of spitefulness.

Conclusions Such results confirm the theorization that the assessment of spitefulness improve the accuracy of diagnosing of these personality disorders.

Evaluation of a court liaison and diversion service in London over a quarter of a century

H. Ryland^{1,*}, T. Exworthy², G. Shaun³, A. Khan³, R. Lynne⁴

¹ South West London and St. George's Mental Health NHS Trust, Forensic Department, London, United Kingdom

² Institute of Psychiatry- Psychology and Neuroscience, Forensic Department, London, United Kingdom

³ Oxleas NHS Foundation Trust, Forensic Department, London, United Kingdom

⁴ Ministry of Justice, Forensic Department, London, United Kingdom

* Corresponding author.

Introduction Oxleas NHS Foundation Trust has run a Court Diversion Service in South East London since 1991. It provides services for people within the earlier stages of the Criminal Justice System.

Objectives This evaluation aims to combine data from across the 25-year period since the introduction of the diversion scheme. It

seeks to provide a longitudinal picture to elucidate the impact of service changes during this time.

Methods The evaluation uses data obtained from a variety of sources for four points in time: 2015/2016, 2011, 1999 and 1991. Data across domains was collated to allow longitudinal analysis.

Results After the initial introduction of the scheme in 1991, the total mean time on remand was noted to drop from 67.1 days to 49.5 days ($P<0.001$). There were 280 referrals over 18 months in 1991, 210 per year in 1999, 190 in 2011 and 174 between April 2015 and March 2016. Violent crimes increased from 29% in 1991 to 47% in 2011. The proportion with schizophrenia decreased from 31% in 1991 to 18% in 1999, before increasing again to 25% in 2011. The use of Section 37 hospital order disposal decreased from 15% in 1991 to just 4% in 2011.

Conclusions The court diversion scheme has produced significant benefits since it was introduced in 1991, despite a rise in the proportion of violent alleged offences. Changes to the service have seen decreased use of hospital orders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The acting out in patients with Schizophrenia examined in a forensic psychiatric assessment

S. Khoudja*, S. Younes, S. Chatti, R. Ben Soussia, L. Zarrouk, M. Nasr

University Hospital, Psychiatry, Mahdia, Tunisia

* Corresponding author.

Introduction Many studies have shown that schizophrenic patients are responsible for the highest rates of violence among all the mentally ill patients.

Aims of the study Describe the socio-demographic and clinical characteristics of patients with schizophrenia examined in a forensic psychiatric assessment and identify the risk factors of violence in these patients.

Methodology A retrospective study carried out in the psychiatric department of university hospital of Mahdia during fifteen years involving 40 patients with schizophrenia examined in a forensic psychiatric assessment following a forensic act. These patients were compared to a population of 40 patients followed in the same establishment for the same disease and without criminal record.

Results Age average of 36.08 years, male (95%), rural origin (65%), primary level education (47.5%), single (65%), unemployed (65%) and average socio-economic level (65%). Personal psychiatric history (87.5%), personality disorder (12.5%), judiciary history (12.5%) and substance abuse (57.5%). Subtypes of schizophrenia: undifferentiated (52.5%) and paranoid (30%). They have committed serious physical assaults (55%) and aggression against property (27.5%). The victim was mostly a family member (40%), under the influence of toxic (22%), driven by delusions of persecution (61%), with hallucinatory mechanism (55%). The psychiatric expert has concluded an abolition of discernment in 77.5% of cases. Risk factors of acting out were: rural origin, alcohol and psychoactive substances use, productive forms of schizophrenia, poor adherence and irregular monitoring.

Conclusion The knowledge of risk factors improves the management and allows us better prevention of violence among our patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Sexual abuse is of great public and high degree of public danger.

Objectives The aim of this study was to evaluate the influence of specific socio-demographic factors among sex crime offenders.

Material The subjects of study are 66 individuals in total, testified by expert psychiatrist and subsequently charged by law as of December 2010, up until today.

Methods Patient record, providing information about different socio-demographic factors. Retrospective research of the available medical documentation. A statistician conducts data research analysis, using specialised software statistical packages for Statistics.

Results The highest percentage of the participants are from the age groups between 15–24 and 45–54 years old. Both age groups consist of 18 people (27%). The two groups with the lowest percentage of sex offenders are the ones between 25–34 –6 (9%) and above 64–6 (9%). The biggest share have secondary education–26 (40%), followed by those with elementary education–24 (36%). The smallest percentage are those with higher education – 2 (3%). There is no statistically significant correlation between the research sample and their residence–34 (51%) live in a city and 32 (49%) – In a village. There is also not a significant difference in their ethnical origins. The biggest percentage of sex offenders have been raised by both parents – 54 (82%).

Conclusions Sex offenders represent an exceptionally heterogeneous group, our study did not find significant correlation of socio-demographic factors and the profile of the rapist.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0578

Personality type of homicide offenders based on psychiatrist expert reviews

P. Szilágyi

Szent János Hospital Budapest, Psychiatric Department, Budapest, Hungary

Despite the relatively prudent regulations and dissuasive punishments worldwide, the number of homicide offenses are not decreasing. In my study those psychiatrist expert opinions were reviewed, which were created in closed homicide cases in the institute of forensic medicine of Debrecen over five years from 2007.

The subject of my study was that what kinds of personalities these crime offenders have, and whether they were in a pathological mental state while committing the crime. The majority of the offenders were from the most active age group between 20 and 40, for the victims, however, the opposite can be said, as the most common homicide acts were committed against the older age group, because due to their age they are less able to defend themselves than the truly active age group. Out of 25 committers, 9 had psychiatric treatment in its antecedents – mostly suicidal intentions or attempts, alcohol dependence or depressive episode. Among

the cases examined, antisocial personality disorder was only made probable in 42% of the perpetrators; however, it was not qualified as restrictive factor in neither case. 43.5% of the offenders were under the influence of alcohol at the time of committing the act, and 58.3% had no criminal record before.

The public believes about the homicide offenders that only people with abnormal mental condition can commit them – however, based on the reviewed psychiatrist expert opinions, the limitation of imputation ability can rarely be established professionally. Milder or more severe limiting factor were established in only 12% of the offenders.

Forensic psychiatric expertise of patients with anti-social personality

M. Turki*, N. Charfi, M. Maalej Bouali, J. Ben Thabet, N. Zouari, L. Zouari, M. Maalej

Hedi Chaker university hospital, psychiatry “C” department, Sfax, Tunisia

* Corresponding author.

Introduction Epidemiological studies in the general population confirm the indisputable link between criminological dangerousness and mental disorders especially anti-social personality, which increase clearly the prevalence of violent behavior.

Aim To dress socio-demographic, clinical and medico-legal profile of offenders, with anti-social personality, in forensic psychiatric examination.

Methods It was a retrospective study of a series of 195 patients with antisocial personality (DSM-IV). They were examined, during the period, from 2009 to 2013, on the occasion of a penal expertise in the department of psychiatry C in the Hedi Chaker university hospital, Sfax, Tunisia.

Results The mean age of patients at the offense moment, was 29.58 years, with a sex ratio of 26.85. Among them, 66.2% were single, 49.2% had a primary school level and 41% had no profession. Between the patients, 58.5% lived in urban area and 38.5% in a high crime area. Addictive behaviors were reported in 80% of cases. Self-injury behaviors were noted in 33.8% of offenders. Psychiatric histories were reported in 66.2%, and 25.6% of patients have been already hospitalized in psychiatry department. 64.1% had already committed forensic acts, and 36% had been imprisoned at least once. The current offense was: homicide 16.9%; sexual offense 9.2%; violence 18.5%; theft 30.2%. The offense was related to impulsivity (40%) or utilitarian purpose (39%).

Conclusion A young single man with no profession, a limited educational attainment and a history of impulsive behaviors, such is the profile most frequently encountered among offenders with anti-social personality. Interventions for reducing forensic behavior should focus on those social and clinical characteristics.

Demographic and criminal data among psychiatric patients in Greece

G. Tzeferakos^{1,*}, M. Papagaliaga², C. Papageorgiou³, P. Bali¹, A. Douzenis¹

¹ University of Athen, Medical School, 2nd Department of Psychiatry, Attikon General Hospital, Athens, Greece

² University Hospital of Larissa, Department of Psychiatry, Larissa, Greece

³ University of Athens, Medical School, 1st Department of Psychiatry, Aeginition Hospital, Athens, Greece

* Corresponding author.

Introduction To our knowledge, a limited number of studies address criminality among psychiatric patients as depicted in legal files.

Objectives The objective of the present study was to provide demographic, psychiatric, legal/criminal data about psychiatric patients in Greece.

Methods Legal case files of 100 adult subjects, 90 male/10 female, 88 Greeks/12 foreigners were reviewed.

Results Seventy eight percent of the subjects had at least one psychiatric evaluation prior to the commitment of the crime. The main diagnoses at the time of the criminal act were: schizophrenia spectrum psychosis (18%), anti-social/borderline/mixed personality disorder (15%), substance use disorder (15%), alcohol use disorder (10%), depressive affective disorder (6%), mixed anxiety/depressive disorder (6%), bipolar disorder (5%), anti-social personality disorder/substance use disorder (5%), schizophrenia/substance use disorder (3%). In 11% the diagnosis was unknown. Eighty four percent of the crimes committed were homicides/attempted homicides, 6% assaults/(attempted) homicides, 3% property crimes/(attempted) homicides and below 3% assaults, property crimes, sexual offences, drug crimes. The weapon used was a knife/sharp object (42%) or a gun (40%). Perpetrator and victim were strangers in 25% of the cases, just acquaintances in 14%, had a professional relationship in 7%, their relationship was conjugal (15%), they were partners (13%) or relatives (7%). In persons with schizophrenia spectrum psychosis the victims were relatives/spouses in 41.2%, while in other diagnoses the respective percentage was 21.5% ($P=0.044$).

Conclusions In accordance to the international literature, there is a vast need for further research in order to improve forensic psychiatric services and prevent criminality among psychiatric patients.

Criminal insanity and psychiatric diagnoses in Greek penal cases

G. Tzeferakos^{1,*}, M. Papaliaga², C. Papageorgiou³, P. Bali¹, A. Douzenis¹

¹ University of Athens, Medical School, 2nd Department of Psychiatry, Attikon General Hospital, Athens, Greece

² University Hospital of Larissa, Department of Psychiatry, Larissa, Greece

³ University of Athens, Medical School, 1st Department of Psychiatry, Athens, Greece

* Corresponding author.

Introduction To our knowledge, few studies address the issue of criminal responsibility among psychiatric offenders. In Greece, articles 34 and 36 of the penal code regulate criminal insanity and diminished responsibility, respectively.

Objectives The objective of the present study was to provide psychiatric/legal data considering the appeal to articles 34/36 of the Greek penal code.

Methods Legal case files of 100 adult subjects, 90 male/10 female, 88 Greeks/12 foreigners were examined.

Results According to the first degree court, one defendant was found criminally insane, 29 with partial responsibility, while the rest were regarded as fully capable. The decisions of the court of appeal/the supreme court of appeal were 2 criminally insane, 36 partially responsible and 62, fully criminally responsible. The decisions were unanimous in 78% of the cases.

The most common diagnoses were schizophrenia spectrum psychosis (18%), antisocial/borderline/mixed personality disorder

(15%) and substance use disorder (15%). Court decisions of criminal insanity/diminished responsibility were higher when the perpetrator had an Axis I diagnosis (47.5%), significantly lower in cases of personality disorder (22.2%) and even lower in cases of substance use disorder (16.7%). In patients with prior hospitalizations the percentage of criminal insanity/diminished responsibility was 55.6%, significantly higher than in cases without (24.4%).

Conclusions Schizophrenia is the most common mental disorder correlated with offenders criminally insane/partially responsible, while a history of psychiatric hospitalization is a very strong positive predictive factor for the successful appeal of the aforementioned articles.

EV0582

Agreement between psychiatric evaluations and court decisions concerning criminal responsibility

G. Tzeferakos^{1,*}, M. Papaliaga², C. Papageorgiou³, A. Douzenis¹, P. Bali¹

¹ University of Athens, Medical School, 2nd Department of Psychiatry, Attikon General Hospital, Athens, Greece

² University Hospital of Larissa, Department of Psychiatry, Larissa, Greece

³ University of Athens, Medical School, 1st Department of Psychiatry, Aeginition Hospital, Athens, Greece

* Corresponding author.

Introduction To our knowledge, a relatively small number of studies address the agreement between psychiatrists and court decisions concerning criminal responsibility among psychiatric offenders.

Objectives The objective of the present study was to examine the agreement between psychiatric evaluations and court decisions in Greek penal cases.

Methods Legal case files of 100 adult subjects, 90 male/10 female, 88 Greeks/12 foreigners were studied, and agreement was assessed by the κ (kappa) statistic.

Results Seventy eight percent of the subjects had had contact with psychiatric services before the commitment of the crime. The most common diagnoses were schizophrenia spectrum psychosis (18%), antisocial/borderline/mixed personality disorder (15%) and substance use disorder (15%). In 30% of the cases criminal insanity/partial responsibility was attributed in the first-degree court. The presence of a psychiatrist ($n=63$), attending, defense, prosecution or appointed by the court, significantly increased the possibility of such an attribution (41.3% versus 10.8%).

The highest agreement ($\kappa=0.780$) was observed between court's decision and the evaluation of the psychiatrist appointed by the court, in the 35 cases in which such an expert was present ($P<0.001$). Very significant agreement ($\kappa=0.805$) was observed between the decisions of second and first-degree courts ($P<0.001$). In 91% of the cases, the decisions remained unchanged.

Conclusions Criminal insanity/diminished responsibility, were attributed in 30% of the reviewed cases. The presence of a psychiatrist already at the first-degree court is a prerequisite for such an attribution, especially when, he is appointed by the Court.

Persons with mental disorder in jails and prisons – legislation and practice in Georgia

N. Zavadashvili^{1,*}, M. Eliashvili², E. Zhorzholadze³, N. Makhashvili⁴

¹ Ilia State University, Social psychiatry, Tbilisi, Georgia

² Acad. O. Gudushauri National Medical Center, Department of Psychiatry, Tbilisi, Georgia

³ Parliament of Georgia, Committee of Health and Social Issues, Tbilisi, Georgia

⁴ Ilia State University, Mental Health Resource Centre, Tbilisi, Georgia

* Corresponding author.

Introduction Statistics shows that in most countries prevalence of mental health problems are much higher among prisoners than the general population. Country approach to regulating mental health needs of persons with mental disorder who come into contact with justice system depends on variety of cultural or legal traditions, as well as on different concepts and structures of mental health care delivery.

Objective The aim of the survey was to study and assess the established practice of implementation of the legal procedure relating to individuals who commit crime and have mental health problems in Georgia.

Methods Qualitative analysis including desk review, in-depth interview and focus group discussion was conducted. Preceding from the research objectives the current legislation with regard of people with the mental disorder has been analyzed; the interviews on the shortcomings and problems of the implementation of the law in practice have been conducted with key informants.

Results The study acknowledges that recent changes in Georgian legislation imports much of the civil law standards and processes relating to admission, detention and compulsory treatment of criminal detainees with mental health problems. However, due to the ambiguous, ambivalent and incomplete nature of the aforementioned changes, the penal and administrative courts, as well as the clinicians are facing serious difficulties and confusions in their work.

Conclusions It is discussed that there is a strong need for closer cooperation between mental health and justice systems to treat mentally disordered persons both in the system and after they are released into the community.

Sadistic sexual assault, perversion and schizophrenia: A case report

M. Zghal^{1,*}, F. Fekih Romdhane¹, G. Jmii¹, F. El Ghali¹, A. Belkhiria¹, L. Jouini², I. Ghazeli¹, R. Ridha¹

¹ Razi hospital, Forensic Psychiatric, Tunis, Tunisia

² Razi hospital, consultation and emergency department, Tunis, Tunisia

* Corresponding author.

Introduction In some forms of sexual perversion, sexual satisfaction is achieved only by treating one's partner violently (sadism) or conversely, by suffering pain (masochism).

Objective and method The objectives of our study were to understand the complex relationship between psychotic and perverse structures, and discuss the importance of some criminal risk factors for psychotics who have sexually perverse behaviors, through clinical observation and review literature.

Case report Mr AB was 35-year-old, single and unemployed. He was hospitalized in our forensic psychiatric department following a dismissal for criminal responsibility for an act of emasculation on

a child aged 5 years without sexual abuse. In his biography we have objectified cruelty to animals, charged judicial history (imprisonment for theft, murder and escape from prison, hetero aggressive acts) and substance use.

The patient explained with indifference that he heard voices making fun of his "sexual impotence and loss of his manhood". The day of the forensic act, he got an uncontrollable urge to emasculate the first man he met on his way at the behest of this hearing hallucinatory activity. Psychiatric experts retained the diagnosis of psychosis with perverse arrangements. Under neuroleptic treatment, psychotic symptoms disappeared but the patient's sadistic problems remained present and active throughout his hospitalization.

Conclusion The following case illustrates the issue of dangerousness and responsibility in a perverse psychotic author assault of a sexual nature. Given their clinical history, the path between perversion and psychosis shows that perverse manifestations are prior to the first psychotic symptoms and the perverse constitution is developed parallel to the psychotic illness.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Homicide, borderline personality disorder and paraphilic disorder: A case report

M. Zghal^{*}, F. Fekih Romdhane, F. El Ghali, M. Mezghani, L. Jouini, I. Ghazeli, R. Ridha

Razi hospital, Forensic Psychiatric department, Tunis, Tunisia

* Corresponding author.

Introduction Zoophilia consists of sexual intercourse by a human being with a lower animal. There is a paucity of literature on this paraphilia.

Method In this paper, we report an uncommon case of homicide committed by a man with co-morbid borderline personality disorder and paraphilic disorder, and review the literature.

Case report Mr SH was a single and unemployed 30-year-old male. He was hospitalized in our forensic psychiatric department following a dismissal for criminal responsibility for an act of attempted murder with premeditation. There was no history of any other psychiatric disorder, chronic physical illness or drug dependence. He complained that he had been suffering for the past ten years from sad mood, sleeplessness, loss of interest, and feelings of guilt worthlessness, and hopelessness. He had started sexual intercourse with animals eight years ago. He harbored feelings of guilt for his sexual experiences with animals. There was no formal thought disorder or perceptual abnormality. At the beginning of bestiality, he explained his unconventional behavior, by the fact that he had been bewitched, by his uncle's wife. Projective tests found borderline psychopathology. The crime occurred after a zoophilic sexual intercourse. Mr SH was obsessed with bewitchment thoughts, and got an uncontrollable urge to kill his uncle's wife. The crime was impulsive and violent. Psychiatric experts retained the diagnosis of co-morbid borderline personality disorder and other specified paraphilic disorder (DSM-5).

Conclusion In this case, we discuss the clinical and therapeutic challenges of this complex case, and the legal liability of Mr SH.

Adult with autism – oxidative stress, co-morbidity and predisposition

M. Bækgaard Thorsen^{1,*}, N. Bilenberg², P. Munk-Jørgensen¹, Å. Fex Svenningsen³, N. Heegaard⁴, T. Maria Michel¹

¹ Institute of Clinical Research, University of Southern Denmark, Research Unit of Psychiatry, Odense, Denmark

² Institute of Clinical Research, University of Southern Denmark, Research Unit of Child, and Adolescent Psychiatry, Odense, Denmark

³ Institute of Molecular Medicine, University of Southern Denmark, Department of Neurobiology Research, Odense, Denmark

⁴ Institute of Clinical Research, University of Southern Denmark, Research Unit of Clinical Biochemistry, Odense, Denmark

* Corresponding author.

Introduction The etiology of autism spectrum disorder (ASD) is unclear. Studies involving children with ASD suggest that oxidative stress could explain some of the pathology. Few reports have investigated the role of oxidative stress into adulthood. Furthermore, the knowledge on psychiatric and somatic co-morbidities, as well as socio-economic status in a trajectory across lifespan is sparse.

Objectives Investigating oxidative stress related markers in ASD, along with trajectories in socio-economic functioning and co-morbidities.

Aims To evaluate the importance of oxidative stress in the neurobiology of adults with ASD and assess the socio-economic level of functioning and co-morbidities.

Methods Plasma levels of antioxidant super-oxide-dismutase isoenzymes (SOD1 and SOD2) and pro-oxidant xanthineoxidase (XO) were measured in 56 patients ≥ 18 years of age, diagnosed in childhood with ASD (F84.0, F84.1, F84.5 or F84.8), along with gender and age matched controls. Participants were interviewed regarding their health, familial predisposition and social status.

Results Cases showed higher levels of SOD1 (268.2 ng/mL vs. 205.6 ng/mL). We found no differences regarding SOD2 and XO. Patients had a higher BMI (27 vs. 24), fewer drank alcohol (40% vs. 75%), more had a psychiatric co-morbidity (50% vs. 2%), more had family member with a psychiatric diagnosis (80% vs. 50%). None of the bio-psycho-social factors showed association with biomarker levels.

Conclusion Oxidative stress seems to play a role in ASD. Furthermore, patients with ASD often have psychiatric co-morbidities; more often have a family history of psychiatric diagnoses, and are less healthy physically.

Evaluation of serum microRNA expression profile in panic disorder patients

F.P. Çökmüş^{1,*}, E. Özmen¹, T. Alkın², M.B. Batır³, F.S. Çam³

¹ Celal Bayar University School of Medicine, Psychiatry, Manisa, Turkey

² Dokuz Eylül University School of Medicine, Psychiatry, Izmir, Turkey

³ Celal Bayar University School of Medicine, Medical Genetic, Manisa, Turkey

* Corresponding author.

Introduction Even though it has begun to be investigated in recent years, studies of microRNA (miRNA) in anxiety disorders are limited. Our research is the first miRNA expression study in panic

disorder, which excludes of drug use and additional psychiatric disorders.

Objective We aimed to determine the availability of miRNAs as biomarkers in the serum levels of panic disorder and to demonstrate the changing expression of miRNAs.

Methods In the research, 35 panic disorder patients and 35 healthy controls were administered a socio-demographic and clinical information form, SCID-I, PDSS. 2 tubes of peripheral venous blood were taken from each group for genetic evaluation. miRNA expression analysis was performed in those samples by the RT-PCR method.

Results Compared with the healthy control group, 8 miRNA expression levels were found different in panic disorder group. Five of them were up-regulated and 3 of them were down-regulated. There was no correlation between the level of miRNA expression and PDSS total score and PDSS sub-items. miR-1297 and miR-4465 expression levels were statistically significant between the two groups. Both miRNAs are also known to arrange the gene regions that affect GABA_A receptor subtypes.

Conclusions miR-1297 and miR-4465 regulate the GABA_A gene that is thought to play a role in the etiology of panic disorder (Wong et al., 2014, Wang 2016). In panic disorder group, miR-1297 and miR-4465 expression levels were found to be up-regulated from the healthy control group.

Keywords Panic disorder; miR-1297; miR-4465; GABA

SHANK3 mutation in consanguineous schizophrenia family in northwest Algeria

A. Dahdouh^{1,*}, J. Prados², M. Guipponi², F. Bena², W. Adouan², S. Antonarakis²

¹ University of Oran, department of psychiatry, Oran, Algeria

² University of Geneva, department of medical genetics, Geneva, Switzerland

* Corresponding author.

Introduction Several studies have asserted the existence of a strong and complex genetic component in the determination of psychotic disorders. GWAS studies conducted over the past decade lead to the identification of only a few low effect associations, calling questioning the hypothesis of “common disease – common variants” for a model involving a large number of rare variants.

Aims Here, we studied a multigenerational multiplex family with schizophrenia a high rate of consanguinity, located in the northwest of Algeria. This study aims to identify inherited rare variants of schizophrenia using new genetic technologies.

Methods This family has received complete clinical (DIGS, DSM-IV criteria), genealogical investigations, CNV analysis using CGH Microarray Kit 244K (Santa Clara, CA) and WES (by GAllx Illumina/HiSeq 2000) focused in CNV regions, that were performed in the department of genetics in the university hospital of Geneva.

Results We identify 11 affected members by psychotic disorders. The main CNVs analysis results found in a schizophrenic member a Del 22q13.33 affecting SHANK3 gene. WES regarding these regions identified a mutation at position 511178000 in SHANK3 gene in all the selected affected relatives.

Discussion Several studies have asserted the association of SHANK3 mutations with schizophrenia and autism disorders. This is the first observation of rs511,178,000 in schizophrenia phenotype.

Conclusion In total, this highly informative family have identified new rare genetic variant of schizophrenia. The search for this mutation in wider control population in would be useful to validate these data.

Genetic determinants of psychic resilience after a diagnosis of cancer

M. Christensen¹, A. Drago^{2,*}

¹ Via University College, Via University College, Holstebro, Denmark

² Psykiatrisk Forskningsenhed Vest, Department of Clinical Medicine, Aarhus University, Herning, Denmark

* Corresponding author.

Introduction Co-morbidity between cancer and psychiatric disorders including adjustment disorder, depressive disorders or angst can seriously influence the prognosis and the quality of life of patients.

Aim The identification of the psychological and biological profile of patients at risk for such co-morbidity is not yet available. Classical candidate genes such as the BDNF, the 5-HTLPR and genes whose products are involved in inflammatory events have received some attention, but results are inconclusive.

Object and methods In the present review the association between cancer and psychiatric disorders is reviewed, a focus on the investigation of the Gene X environment and the epigenetic control over the activation of the HPA axis is proposed as a tool to refine the definition of the biologic profile at risk for co-morbidity between psychiatry and cancer.

Results and conclusion A number of genes and socio-demographic variables that may influence risk to suffer from a psychiatric disorder after a diagnosis of cancer is identified and discussed. The identification of such biologic and socio-demographic profile is instrumental in the identification of subjects at risk of a double diagnosis, both somatic and psychiatric. An early identification of such profile risk would pave the way to the implementation of early intervention strategies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Is 22q11.2 deletion syndrome a genetic subtype of schizophrenia?

R. Hernandez Anton^{1,*}, H. De La Red Gallego¹, M. Gomez Garcia¹, A. Alonso Sanchez¹, E. Mayor Toranzo¹, J.A. Blanco Garrote¹, M. De Lorenzo Calzon¹, M. Hernandez Garcia¹, E. Dominguez², F. Uribe Ladron De Cegama¹, V. Molina Rodriguez¹

¹ Hospital Clinico Universitario Valladolid, Psiquiatria, Valladolid, Spain

² Hospital La Mancha Centro, Psiquiatria, Alcazar De San Juan, Spain

* Corresponding author.

Introduction 22q11.2 deletion syndrome is a primary immunodeficiency due to micro-deletion on the large arm of chromosome 22. Patients suffer from several anomalies, including mental illness, that such the case we present, mean a warning sign for further study.

Methods Twenty-one years-old male, with psychotic symptoms, typical of schizophrenia, behavioral disorders and mental confusion, plus epileptic episodes and psychomotor agitation. Two previous incomes with the diagnosis of psychotic disorder not otherwise specified. Treated with anti-psychotics at low doses with inter-episode stability.

Background Prematurity, low birth weight, neonatal asphyxia, generalized seizures, otitis and recurrent urinary tract infections, hypernasal voice, poor academic performance, difficulty relating. Physical examination: hypernasal voice, furred tongue, dysmorphic

faces, scoliosis, hipotania, stereotypes, delusions, auditory hallucinations and negative symptoms.

Results We considered the possibility of a neurodevelopmental disorder, with a multidisciplinary approach, resulting in the diagnosis of paranoid schizophrenia and velocardiofacial syndrome, which had gone unnoticed. Mean doses of clozapine, haloperidol and topiramate were used. He accepted psychiatry and other specialties follow-up, since it requires a complex and multidisciplinary approach.

Conclusions Definition of velocardiofacial Syndrome and lack of consensus on terminology:

- syndrome 22q11.2 DS as genetic subtype of schizophrenia?
- Opportunity to study the pathogenesis of schizophrenia;
- the importance of a comprehensive approach to early diagnosis, clinical improvement and preventing complications.

* Corresponding author.

Introduction Addiction to computer games (CA) is growing with a lightning speed in whole world. Very few studies are focused in the genetic basis of this disorder.

Objectives To study the COMT and MAOA polymorphism in addicts to computer games.

Methods Totally 42 persons were included in this study, 22 of them had CA and 20 were totally healthy. Out of 22 gamers, 10 persons had only CA. The rest of 12 patients suffered from another psychiatric disorder besides of CA (Schizotypal disorder, depression, bipolar disorder). Their mean age was 16 years (15; 17) and all of them were males.

Results The total frequency of alleles 3R and 5R of MAOA gene in patients with CA was 30.0%, which doesn't have any statistical difference with the healthy persons. The genotype frequency of Val158Met of COMT gene is high in CA rather than in healthy persons ($\chi^2 = 6.85$, $P = 0.03$). Also, the homozygotes Val are much more in CA patients (59.1%) than in healthy persons (25%). On the other hand, the Val/Met combination is lower in CA patients (18.2%) than in healthy persons (55.0%).

Conclusion The Val158Met polymorphism of gene COMT may lead to CA formation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Family-based association study between the brain derived neurotrophic factor (bdnf) gene and the attention deficit hyperactivity disorder in a Mexican population

J.P. Sánchez de la Cruz^{1,*}, A. López López², C.A. Tovilla Zárate¹, R. Molina Sólis², A. Valencia Hernández², L. Gómez Valencia², M.M. Rivera Angles², M.L. López Narváez³, D.Y. Bermúdez Ocaña¹

¹ Universidad Juarez Autonoma de Tabasco, Division Academica Multidisciplinaria de Comalcalco, Villahermosa, Mexico

² Hospital Regional de Alta especialidad "Dr. Rodolfo Nieto Padrón", Servicio de Citogenética, Villahermosa, Mexico

³ Hospital General de Yajalón- Secretaría de Salud, Servicio de Pediatría, Yahalón, Chiapas, Mexico

* Corresponding author.

The attention deficit hyperactivity disorder (ADHD) is a common neuropsychiatric disease in infancy and adolescence, its world prevalence in the general population is high 3.4%. There is genetic evidence that consistently supports the polygenic nature of ADHD with a heritability estimated between 75% and 91%; literature proposes that the brain derived neurotrophic factor (BDNF) is a candidate gene that participates in the ADHA pathogenesis. One of the most studied polymorphisms is the Val66Met. The aim of this study was to determine a family-based an association between the rs6265, rs122,733,63 and rs110,301,19 polymorphisms of the BDNF gene and the ADHD in a Mexican population. The ADHD diagnose was performed by a pedopsychiatrist utilizing the diagnostic and statistical manual of mental disorders (DSM-V) who selected 35 patients; along with the biological parents, a total of 105 individuals grouped in family-trios (mother, father and ADHD patient) were studied. Of the 35 probands, 32 were men and 3 were women (average age 7.7 years; age range 4–14 years). Subsequently, no statistically significant association was observed between the BDNF gene polymorphisms and the ADHD etiology in Mexican families: rs6265 ($\chi^2 = 1.33$; $P = 0.24$); rs122,733,63 ($\chi^2 = 1.33$; $P = 0.24$); rs110,301;19 ($\chi^2 = 0.66$; $P = 0.41$). Furthermore, no preference of transmission was observed for any of the haplotypes. In conclusion, it was not possible to prove any association between the BDNF gene polymorphic variants and ADHD in a Mexican population. Future studies comprising larger samples are necessary to determine the potential role of the BDNF gene in ADHD.

Pregabalin use in adults with intellectual disabilities

K. Courtenay^{1,*}, S. Jaydeokar², B. Perera³

¹ UCL, Division of Psychiatry, London, United Kingdom

² Cheshire and Wirral Foundation Trust, Department Intellectual Disabilities, Cheshire, United Kingdom

³ Barnet Enfield Haringey Mental Health NHS Trust, Department Intellectual Disabilities, London, United Kingdom

* Corresponding author.

Introduction Pregabalin is a well-established anti-epileptic drug in the treatment of epilepsy. It is also indicated for the treatment of generalised anxiety disorder and neuropathic pain. In addition, it has mood modulating properties. In people with intellectual disabilities it is used to treat epilepsy. There is little evidence of the use of pregabalin in managing mental health difficulties in people with intellectual disabilities.

Objectives To describe the use of pregabalin in adults with intellectual disabilities.

Method A descriptive case series of adults with intellectual disabilities living in the community, under the care of a community psychiatrist, who are prescribed Pregabalin. Outcomes of treatment were measured using the health of the nation outcome scale for people with intellectual disabilities (HoNOS-LD).

Results Fourteen cases were identified in the community service of adults with Intellectual Disabilities. Twelve were men and two were women. The average age of the sample was 29 years. The range in duration of using pregabalin was from 3 to 72 months. Thirteen adults had a diagnosis of Autism of which three also had ADHD. The indications for using pregabalin and numbers were : anxiety (12); liability of mood (2); generalised anxiety disorder (1); epilepsy (1). The daily dose range was from 150 mg to 300 mg The mean change in HoNOS-LD scores was 32%.

Conclusions Pregabalin is a useful treatment in people with intellectual disabilities who experience anxiety. It is especially effective among adults with ID and autism to modulate mood and anxiety symptoms.

Introduction In Germany, mental health care in people with IDD is mostly determined by experts' opinions. Particularities of the psychiatric assessment and treatment of people with IDD and a comorbid psychiatric disorder are taught neither at medical schools nor in the scope of the medical training of psychiatrists.

Objectives The present study examined the influence of socio-political aspects of health care on quality and organisation of mental health care in people with IDD.

Methods Various aspects of health care systems in Germany and three other European countries were explored and juxtaposed subsequently with a special developed questionnaire.

Results The health care systems of four different European countries differ in socio-economical, educational and system-financed aspects.

Conclusions Differing organisational levels of national health care systems and socio-economical aspects within these countries contribute to the organisation of the mental health care system in people with IDD. Suggestions for a better harmonisation of European mental health care in people with IDD are offered.

Preliminary study on the analysis of cognitive profile in subjects with ASD: WISC-IV

D. Galletta

University of Naples Federico II, Neuroscience, Naples, Italy

Autism spectrum disorder (ASD) is a neurodevelopmental disorder, observed in several contexts and characterized by persistent deficits in the communication, social interaction and behavioral areas (DSM V, 2013). ASD includes a wide range, "a spectrum," of symptoms, skills, and levels of disability. In the last years, we have noticed a substantial change in the diagnostic criteria due to the fact that, although the huge heterogeneity shown by the disorder, in the majority of autistic subjects, both those with high and low IQ, we can identify a common profile of functioning, as regards communicative, social, motor and behavioral skills (Sharma et al., 2012). As reported by Frith (1989; 2003), this kind of functioning is based on a different cognitive style, characterized by a strong prevalence of "bottom-up" elaboration processes, coexistent with the inability of the subject to integrate perceptual data into a global and coherent representation (weak central coherence theory). In this study, we have administered WISC IV to two adolescents (16 years old), already diagnosed for ASD with a low functioning. As expected, results have evidenced the presence of a rigid cognitive style with impaired conceptualization abilities and high attention to details. Specifically main falls have occurred in the area of visual-perceptual reasoning, underlining a lack of visual-spatial processing skills, as well as a lack of fluid reasoning skills. Particularly deficit resulted in the categorization capabilities and abstraction.

Occupational activation centers as a solution to improve vocational rehabilitation of patients with intellectual disabilities in Poland

J. Krysta¹, K. Krysta^{2,*}

¹ *Polish Association for Persons with Mental Handicap, PSOUU, Branch in Bytom, Bytom, Poland*

² *Medical University of Silesia, Department of Rehabilitation Psychiatry, Katowice, Poland*

* *Corresponding author.*

Introduction Since the 1990's the main form of vocational rehabilitation centers in Poland were occupational therapy workshops (OTW), but the low ratio of the employment of the participants of OTW's led to the creation of newer, more effective institutions called Occupational Activation Centers (OAC). They were expected to be professional activity establishments, aimed at launching new career paths of people with intellectual disabilities, enabling the candidates to pass through various stages of rehabilitation and vocational activation.

Materials and methods The analysis of available statistical data concerning the activity of OAC's in Poland was done.

Results In the whole country the number of these facilities is 53, while the number of occupational therapy workshops is 665. The Law on OAC's restricts the employment of people with moderate disability in total employment to 35%, this indicator covering not only the persons with mental retardation, but also people with autism and mental illness. In addition the OAC's activity generates the cost of creating them inadequate for the quantity and quality of jobs being created.

Conclusion It turned out that the creation of OAC's occurred too slowly in relation to the already operating OTW's and the weaknesses in the Polish system of rehabilitation and employment of people with intellectual disabilities necessitates the need to find innovative ways to solve this problem.

Prevalence of intellectual disability (ID) ranges from 0.05 to 1.55%. A total of 10–15% of the people with ID present with challenging behavior (CB). This causes a significant strain on mental health services. People with ID; end up staying in psychiatric inpatient units for longer periods. Most people with ID move out of their family home to various care settings due to severity of their behavior difficulties. Few European countries have specialist services for people with ID whereas most countries manage people with ID and CB using adult mental health services. There is ongoing debate whether patients with ID and CB need to be managed by specialist services. There are significant financial implications looking after people with ID and CB. This has often led to over prescribing of psy-

chotropic medications to people with ID without a mental disorder to manage their behaviors. There are significant strains on mental health services to manage people with ID and CB. This presentation discusses. Describe people with CB and ID and their characteristics including mental disorder, use of psychotropic medications, socio demographic factors and financial costs to look after them. Social and health care approach to look after people with CB in the UK, Challenges to develop services for people with CB in ID in Germany and Poland. Do we need specialist services for people with ID and CB? Pros and cons.

An evidenced based checklist to support anti-dementia medication withdrawal in people with down syndrome (DS), intellectual disability (Id) and dementia

R. Shankar^{1,*}, S. Ram²

¹ Cornwall Foundation NHS Trust, ID neuropsychiatry, Truro, United Kingdom

² Somerset Partnership Nhs Foundation Trust, Intellectual Disabilities, Taunton, United Kingdom

* Corresponding author.

DS with aging is associated with greatly increased risk of developing dementia similar to Alzheimer's. Anti-dementia drug discontinuation is recommended when clinical benefit is not determined. In DS it is more complex as medication ill effects of stopping needs to be weighed in balance to extraneous processes such as environment changes, sensory impediments and physical ill health and natural progression of dementia.

Aim Can identified risk factors extracted from a comprehensive literature review be developed into an evidence based check list to support risk minimized person centered withdrawal of anti-dementia drugs when considered not to be efficacious in DS?

Method A detailed literature review using Medline, PsychInfo, CINAHL and Embase with relevant search terms in various permutations and combinations without any date limit enquiring current evidence base on anti-dementia medication withdrawal was conducted. The review also looked to extract the common risk factors in stopping medication. All risk factors were collated, reviewed by a focus group of experts, developed into a checklist.

Results Thirty abstracts were obtained following the search. Six papers were short-listed. No papers identified a structured approach to medication reduction. An 18-factor checklist was applied prospectively to 30 cases. The checklist was sensitive to identify change to guide clinical decision-making.

Conclusions Currently, decision to peg medication withdrawal risk is arbitrary and clinical in dementia especially in DS dementia. The evidenced based developed checklist is useful to support and structure clinical decisions. It helps clinicians and patients to focus on promoting safety, reduce harm and guide treatment.

* Corresponding author.

Introduction The rate of mental illness among people with intellectual disability is at least 2.5 times higher than in the general population [1].

Objective To describe the clinical and sociodemographic characteristics of all patients with intellectual disability treated in a community mental health care center (CMH) located in a city of 120,000 inhabitants on the outskirts of Barcelona with a high poverty index.

Methods Documents and patient records were reviewed. Clinical, sociodemographic and other treatment data of patients with intellectual disability treated at the CMH were collected.

Results The sample consisted of 118 patients. Mean age: 39.5 (SD: 15), 54% men. 92% single and 23.7% legally incapacitated. 46.6% never completed basic education and 44.1% completed primary school. Employment status: 14.4% unemployed, 14.4% currently active, and 50% pensioned. Patients living mainly with their family (parents:) 86%. 68.6% of patients showed aggressive behavior, but the rate of hospital psychiatric admissions was low (mean: 1.1 (SD: 2.3)). Organic comorbidity: 44.9%. Functionality measured with GAF mean: 45 (SD: 12). Level of intellectual disability was mostly mild (62%). Psychiatric diagnoses were: psychotic disorders: 49.25%, affective disorders: 6.8%, personality disorder: 3.4%, Obsessive-compulsive disorder: 3.4%, autism: 11.9% and other diagnoses: 37.3%. Patients treated with anti-psychotics: 78.8%, anti-depressants: 40.7%, and mood stabilizers: 70.5%.

Conclusions Intellectually disabled patients from our sample showed high comorbidity with psychotic disorders, were highly medicated and often exhibited aggressive behavior.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0602

Effect of chronic exposure of Losartan in mouse prenatal alcohol exposure (PAE) model

A. Takyi

Brighton Pharmacy School, Pharmacy, Solihull, United Kingdom

Background and aims Foetal alcohol syndrome (FAS) is a condition that currently affects 1% of babies born in Europe and North America. It is characterised by memory impairment, developmental delay and distinctive facial features. This research uses a mouse prenatal alcohol exposure (PAE) model to explore the effects of PAE on learning, memory and to explore the potentially beneficial effects of common drugs previously shown to have cognitive enhancing effects in both humans and animals.

Methods Sixty mice ($M=30$ $F=30$) C57 mice were exposed to 5% ethanol throughout pregnancy. After weaning the offspring received Losartan (10 mg/kg) via their drinking water for 8 weeks. At 3 months, learning and memory was assessed using the novel object recognition paradigm.

Results PAE caused a significant decrease in offspring body weight. Treatment with Losartan caused no growth impairment or renal damage. Novel object recognition indicated that PAE caused male offspring to spend significantly less time exploring the novel object than controls and that treatment with Losartan had the effect of improving awareness of the novel object both in the control and alcohol group and decreasing anxiety ($P \leq 0.05$). A significant opposite effect was noticed in the female alcohol progeny when compared to the male alcohol progeny ($P \leq 0.05$). Losartan in female alcohol progeny had no effect on anxiety. Male control Losartan spent more time exploring the novel object than male alcohol Losartan ($P \leq 0.05$).

Conclusions Losartan had no deleterious effects on the development of the animals, and was able to improve learning and memory in control animals without effect in PAE mice.

Kleefstra syndrome: Considerations about treatment strategy in 2 patients with a causative Ehmt1 mutation and apathy

W.M.A. Verhoeven^{1,*}, J. Egger¹, N. De Leeuw², T. Kleefstra²

¹ Vincent van Gogh Institute for Psychiatry, Centre of Excellence for Neuropsychiatry, Venray, The Netherlands

² Radboud University Medical Centre, Department of Human Genetics, Nijmegen, The Netherlands

* Corresponding author.

Introduction Kleefstra syndrome [OMIM: 610253] is caused by a 9q34.3 micro-deletion or an intragenic mutation in the EHMT1 gene. Its core phenotype comprises intellectual disability, childhood hypotonia and distinct dysmorphisms. The syndrome can be associated with congenital anomalies, epilepsy, cardiac arrhythmias and a typical sleep pattern. Starting from adult age, a regressive phenotype may develop.

Objectives Further delineation of the neuropsychiatric phenotype.

Aims Formulating a comprehensive treatment approach.

Methods Detailed examination of two patients with EHMT1 mutation.

Results Patient 1, male aged 34 years, showed recurrent behavioral problems with aggression and self-injuries as well as obstipation. Elsewhere, a diagnosis of autism was established. Aged 24, he suffered from some epileptic seizures. Recently, paroxysmal atrial fibrillation was diagnosed. Neither treatment with pipamperone and risperidone nor with valproate was effective for behavioral control. Array analysis and metabolic screening did not reveal abnormalities. Whole exome sequencing revealed an intra-genic EHMT1 mutation. Patient 2, female aged 53 years, was known with childhood epilepsy and developed gradual decline of general functioning with motor slowing from her third decade. In her thirties, a mood/anxiety disorder was suspected for which several antidepressants were given without any effect. Array analysis was normal. A pathogenic nucleotide deletion was identified resulting in a frame-shift in exon 21 of the EHMT1 gene. In both patients marked apathy was observed (AES = 62 and 64, respectively).

Conclusions Apathy syndrome in Kleefstra syndrome should be differentiated from depression and autism. Apart from treatment with selected psychotropics, individually targeted contextual measures should always be implemented.

Innovative home based assertive outreach service for treatment of schizophrenia in Larkano, Pakistan (SOUL): Programme implementation and outcomes at the end of five years

S. Afghan

Dorothy Pattison Hospital, Psychiatry, Walsall, United Kingdom

Introduction There is a significant service gap in provision of essential treatment to patients with severe mental disorders in low-income countries, which leads to increased mental health disability and bigger disease burden on the families and society. The SOUL programme is a first of its kind in the country, which utilizes assertively engaging patients at their homes.

Objectives The key objectives are early recognition, treatment and psychosocial support to patients with the diagnosis of schizophrenia. Additional objectives include social recovery of the patients, psycho education to family members and generating clinical and functional outcomes.

Methods Programme design developed by host psychiatry department through stakeholder consultation. Training was undertaken for programme team and included training on use of outcome measures namely Brief Psychiatric Rating Scale (BPRS), Clinical Global Impression (CGI) and Global Assessment of Functioning (GAF). Hosting carers and families meetings on regular intervals serve the purpose of family psycho-education and receiving informal feedback about the service.

Results Preliminary findings on clinical and functional outcomes of cohort of 125 patients recruited over continual basis over 5 years are presented. Complex community intervention shows significant change in all outcome scales (with good effect size) with before and after analysis at one year. The programme demonstrated excellent engagement with patients and very low dropout rate.

Conclusions Low cost community intervention involving trained doctor and psychiatric nurses working under close supervision of a

senior psychiatrist is feasible and achievable and can lead to robust improvements in symptoms and functional outcomes for patients with schizophrenia.

Improving oral health care in mental health service – A retrospective study of oral health care monitoring for service users accessing community mental health team

U. Ahmed*, S.K. Siddiqui, K. Tabani

Mersey Care NHS Foundation Trust, Mental Health, Liverpool, United Kingdom

* Corresponding author.

Introduction Poor oral health can have a serious impact on quality of life, social inclusion and self-esteem. There is evidence to suggest that people with serious mental illness have a greater risk of experiencing oral disease and have greater oral treatment needs than the general population. Oral health problems are not well recognized by mental health professionals. We therefore conducted a retrospective study to review oral health care monitoring within the community mental health team.

Aims and objectives To review the oral health care monitoring for patients accessing the community mental health team.

Methodology Audit tool was developed based on oral health care guidelines outlined by the department of health, and literature review. We then retrospectively review medical records of 25 patients against following standards:

- every client should have the most basic of oral hygiene equipment—toothbrush;
- clients should have basic oral hygiene knowledge, (i.e. brush twice or at least once a day);
- every client should be registered to a dental practitioner;
- every client should have at least one dental check-up per year;
- clients with dentures should have their dentures checked up at least once in five years;
- have a tooth brush less than three months old.

Results Out of the 25 patients none had met the standards. It could be a reflection of lack of documentation rather than not providing appropriate information.

Conclusion Oral health care advice should be part of care plan for people accessing mental health service.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychiatric social work needs of families having children with mental diseases in Turkey

E. Arslan, F. Akgül Gök*, V. Duyan

Ankara University, Social Work, Ankara, Turkey

* Corresponding author.

Introduction Generally mental health patients continue their lives with their families after they completed their treatments. Therefore it means that they are spending their mental care process with their families. That process psychosocially, economically and physically affects every member of the family, especially primary care taker. These families need services provided by psychiatric social work services.

Objectives This study planned to determine psychosocial needs of the families and develop some solutions.

Method This study is conducted with methods of qualitative research. One of the family members of six young adults with mental diseases has been interviewed face to face. Snowball sampling method is used to reach participants. Qualitative methods are used in order to deeply analyze emotions and thoughts of family members while determining the needs of these families.

Conclusion This study is conducted with parents of children who were treated at any inpatient treatment facilities and continue to live with their families after being released from these facilities. According to results psychiatric social work needs of these families are below: (1) these families and care takers suffer from problems resulting from lack of information on mental diseases and processes of these diseases; (2) also these families suffer from problems of social environment and lack of sufficient social work services. According to results of this research it is suggested that families should be informed about the mental diseases, treatments and process after treatment and also families should supported by raising coping strategies. The new service models should be developed accordingly.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Adult ADHD and the use of mindfulness-based practice: A pilot study

A. Allen*, R. Ansari, J. Thurley, L. Murphy, E. Chan,

C. McKinnon, R. Fitzgerald, A. Deeley, R. Wachter, J. Rajewski

The ADHD Clinic, Psychiatry, Toronto, Canada

* Corresponding author.

Educational objectives The goal of this poster is to discuss a brief pilot study in which mindfulness – and yoga-based practices were utilized with a group of adult ADHD patients.

Methods A sample of 10 adults participated in a pilot group which utilized the use mindfulness-based and yoga practices to address ADHD. This group was a single 2 hour session which was a pilot for a future 6-week psycho-educational group. The participants completed the following questionnaires: the Cognitive and Affective Mindfulness Scale (CAMS-R), the Freiburg mindfulness inventory and the Mindful Attention Awareness Scale (MAAS) in addition to a survey regarding levels of knowledge of yoga and mindfulness prior to the beginning of the session. The participants completed a survey at the end of the session.

Results In our small sample group, all respondents reported that they found the session helpful (43% strongly agreed; 57% agreed). When asked if the participants were likely to explore and learn more about ADHD and meditation on their own based on what they learned in the session, most indicated that they were likely to (43% strongly agreed; 43% agreed and 14% were neutral).

Conclusions The use of treatment modalities involving the use of meditation and mindfulness-based techniques in a group setting are thought to be helpful in addressing some of the target symptoms of ADHD. Based on the preliminary data collected in our small pilot study, our group intends to further explore the efficacy of meditation-based groups in the form of a 6-week training program in 2017.

A qualitative study of attitude towards people with mental illness among nurses in Saudi Arabia

A. Alshowkan

University of Dammam, College of Nursing, Qatif, Kingdom of Saudi Arabia

Introduction Nurses are the most important contributor of care during patients' hospitalization and have become an important source in the delivery of mental health care. However, the attitudes and ability of many nurses in providing this care have been shown to be deprived, and this may have a negative effect on providing patients' care. There is a little is known about the attitude of nurses toward people with mental illness in Saudi Arabia.

Objective This study has a qualitative research design. The main aim of this study is to explore the attitude of nurses toward people with mental illness in Saudi Arabia.

Method Data were collected through semi-structured fact to face interviews with nurses. Thematic analysis was used for data analysis.

Results Data analysis identified three main themes that affect nurses' attitude toward people with mental illness. The identified themes are: 1) personal factors, 2) social factors, and 3) factors related to the view of mental illness.

Conclusion This study concluded that there are a number of factors that affect nurses' attitude toward people with mental illness. Several recommendations were discussed related to nurses' education, continuous mental health training courses, public education about mental health and mental health nursing, and mental health care and resources.

Keywords Nurses; Attitude; Mental illness; Qualitative; Saudi Arabia

Nursing practice in mental health at family health strategy

P. Amaral Mussumeci^{1,*}, N. De Almeida Nassif Rodrigues², B. Gerbassi Costa Aguiar¹, S. Maria do Amaral Chaves², W. Maria Antunes Ramos¹, T. Quinellato Louro², Y. Cristiane Ribeiro², D. Conrad¹, C. Baptista Pinto¹

¹ Federal University of Rio de Janeiro State/Unirio, Postgraduate nursing program, Rio de Janeiro, Brazil

² Federal fluminense university/uff, nursing department, Rio Das Ostras, RJ, Brazil

* Corresponding author.

The nurse practice model at the family health strategy is characterized by direct involvement in the patient's health-disease recovery process, deconstruction of social stigma involving mental health disorders, and the restoration of patient autonomy their social ties. This descriptive study follows a qualitative approach to document and analyse practices performed by mental health nurses at the family health strategy (FHS) in Rio das Ostras, Brazil. The study identifies practices implemented by Mental Health Nurses at FHS and the nurses' own reflection and analysis on these mental health practices. Data was collected through semi-structured interviews. All interviewed nurses had worked in the primary mental health care for at least one year at the FHS units in Rio das Ostras. Data was analysed, grouped, and coded according to two categories: 1) The nurses' professional practices in mental health at the FHS, and 2) The nurses' view on mental health practices at the FHS. Results show that the main activities in mental health at FHS involve working with the matricial team, continuing education, reception, home visits, referrals, therapeutic workshops and community therapy.

Nurse perspectives on professional practices involve prevention, establishment of bonds with patient, and nurses' training to deliver care to patients who are suffering. The bond with and care for the patient, family and community, is one of the FHS differentiators. In that vein, the study looks at the link between health care delivery, territory and population attended. The health care based on territoriality, allows increased patient and family confidence.

Community mental health services in the eyes of community mental health centers staff

S. Attepe Ozden*, A. Icagasioglu Coban

Baskent University Faculty of Health Sciences, Social Work, Ankara, Turkey

* Corresponding author.

Introduction Community mental health centers (CMHC) are established for providing services to individuals with serious mental illness. In these centers, individual's need of treatment and care are expected to be met with a mental illness in the community as possible. The process of community mental health service creation in Turkey is relatively new and gaining popularity in last 7–8 years. First CMHC was established in 2008. After this date CMHCs' have been opened and the target of 2016 is reaching across 236 CMHC in Turkey.

Objectives In this context, this study aims to provide views of psychiatrists, nurses, social workers, psychologists and occupational therapists who work in CMHC for the services that provided to individuals in these CMHC's and learn how to define their professional roles and responsibilities in CMHC.

Methods This paper used qualitative research design. Data was collected from 7 CMHC in Ankara through in-depth interviews with a total of 30 people consisting of psychiatrists, nurses, social workers, psychologists and occupational therapists.

Results The participants look positively about given services, however, financial pressure in the creation process of services, problems in employee personal rights and lack of policies and services related to mental health forced employee and reduce the quality of services provided.

Conclusions Through understanding perspectives of the professional staff toward community-based services will help to determine current problems in CMHC for policy makers.

Comparing the educational impact of simulation training to role play and didactic teaching for integrating mental and physical healthcare

C. Attoe*, A. Vishwas, S. Cross

South London & Maudsley NHS Foundation Trust, Maudsley Simulation, London, United Kingdom

* Corresponding author.

Introduction Addressing the interaction between mental and physical health to provide more integrated healthcare has been highlighted as an international priority for health and education systems. Educational interventions focusing on multi-disciplinary, interprofessional approaches to integrated mental and physical

healthcare are an essential part of transforming health systems. Simulation training is one tool by which such training can be delivered, in contrast to traditional teaching methods. However, simulation training can be high-cost and clarity over the impact is required.

Aim To compare simulation training for integrating mental and physical health to role-play and didactic teaching, on their effect on confidence, knowledge, and attitudes of participants.

Methods Participants in simulation training ($n = 24$) and role play plus didactic teaching ($n = 87$) both completed self-report measures of confidence and knowledge in working with mental and physical health needs, as well as the Readiness for interprofessional learning scale (RIPLS) collecting attitudes towards interprofessional collaboration. All participants also completed post-course qualitative feedback form with open questions.

Results T-tests found statistically significant increases in confidence and knowledge following both educational interventions. T-tests showed statistically significant increases in attitudes to interprofessional collaboration (RIPLS) following simulation training, while there were no statistically significant changes after role-play and didactic teaching. Thematic analyses of post-course open questions demonstrated differing learning outcomes.

Conclusions Simulation training appears to have a different and beneficial impact to role play and didactic teaching alone, when training participants on integrating mental and physical health.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Mental health simulation training in psychiatric skills for police and ambulance service personnel

C. Attoe*, M. Fisher, A. Vishwas, S. Cross
South London & Maudsley NHS Foundation Trust, Maudsley
Simulation, London, United Kingdom

* Corresponding author.

Introduction UK healthcare policy has highlighted a shift in mental health services from hospital to community, stressing the importance of training for professions not traditionally associated with healthcare. Recommendations have been made to introduce training for the police force designed with experts. Similarly, the value of further training for ambulance clinicians in assessing mental health, capacity, and understanding legislation has been highlighted.

Aims To investigate the effect of simulation training on the confidence, knowledge, and human factors skills of police and ambulance service personnel in working with people experiencing mental health conditions.

Methods On completion of data collection from 14 training courses, approximately 90 police and 90 ambulance personnel ($n = 180$) will have completed the human factors skills for healthcare instrument, confidence and knowledge self-report measures, and post-course qualitative evaluation forms. A version of the hfshi for non-clinical professions will hopefully be validated following data collection. Results will also be compared by profession.

Results Analyses have not been fully completed, although preliminary statistical analyses demonstrate promising findings, with increases post-course for human factors skills, confidence and knowledge. Furthermore, qualitative feedback initially illustrates valuable learning outcomes and interesting findings from comparisons by professions.

Conclusions Mental health simulation training appears to have a promising impact on the confidence, knowledge, and human factors skills of police and ambulance personnel for working with people experiencing mental health conditions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A Proposal of an innovative program for informal caregivers of patients with mood disorders

J. Cabral^{1,*}, C. Barreto Carvalho¹, P. Castilho Freitas², C. Pato³

¹ University of Azores, Social sciences and humanities, Ponta Delgada, Portugal

² University of Coimbra, Psychology and science education, Coimbra, Portugal

³ SUNY Downstate Medical Center, College of Medicine Suny Downstate, New York, USA

* Corresponding author.

Introduction Intervention with informal caregivers (IC) of psychiatric patients is internationally recognized as relevant and a priority. However, the existing responses in this area are still insufficient, especially regarding caregivers of individuals with mood disorders (MD). Mindfulness and compassion focused therapy have proven to be an effective approach in stress reduction and in improving emotional and social well-being of caregivers of patients with other conditions. However, no studies testing these new approaches in IC of patients with MD have been carried out. The objective of this work is to present a research project that aims to develop, implement and empirically test the effectiveness of an innovative group program to help informal caregivers of individuals with mood disorders to cope with the negative impact of the disease and reduce caregiver burdens.

Methods The design of this experimental study to test the program's efficacy is a non-randomised controlled trial (nrct) with 12 months follow-up, with a mixed assessment methodology (quantitative and qualitative analysis). A sample of 60 informal caregivers of individuals with chronic MD will be constituted ($n = 30$ Control group; $n = 30$ Experimental group).

Results We expect the program to promote significant changes in participants in terms of several emotional variables (eg: burden, stress, resilience, compassion and quality of life).

Conclusions Further efforts to continue studying the impact of interventions in caregivers should be carried out, as a way to improve the quality of life of caregivers and their ability to provide informal care to MD patients.

Help-seeking for sleep problems among psychiatric outpatients

S. Chang*, E. Seow, Y.W. Lau, S.A. Chong, M. Subramaniam
Institute of Mental Health, Research Division, Singapore, Singapore

* Corresponding author.

Introduction Though sleep disturbances are common among psychiatric patients, some patients may trivialize their problem and not discuss it with their doctors. This study thus aimed to assess patient profile that is associated with help seeking for sleep problems among psychiatric patients.

Methods Outpatients from a tertiary psychiatric hospital were recruited for this study ($n = 400$). The pittsburgh sleep quality index was administered to identify cases of probable insomnia, and daytime impairment due to sleep disturbances was recorded. Participants were asked if they have ever consulted a doctor or any health professionals for their sleep problems. Sociodemographic information was recorded and clinical profile was obtained

from the patient's medical records. Multivariate logistic regression was used to examine correlates of help-seeking behaviour among patients with probable insomnia.

Results 275 cases of probable insomnia were identified. Among this group of patients, 38.9% had never sought help for their sleep problems. Participants who were single were less likely to seek help as compared to those who were widowed/separated/divorced (OR= 0.319, $P=0.023$). Having a comorbid psychiatric condition was independently associated with increased odds of help seeking (OR= 1.952, $P=0.027$). Participants who perceived greater daytime impairment due to sleep problems were more likely to seek help (OR= 1.465, $P=0.007$).

Conclusions The majority of psychiatry patients with sleep problems sought professional help, though there remained a substantial group that did not do so. There is a need to educate and create awareness of potential sleep problems among psychiatric patients, and to inform them of the availability of treatment.

Andalusian music is the name of the classical music in Morocco. It grown in Andalusia, but we still find it just in Morocco and some other countries of North Africa. A music that related with soufisme and Marestans: hospitals at that era. A music which is also called "al-Ala" means the machine. It has 24 "Naoubas": rythme as much the hours of the day and each Naoubas can be played in just an hour in the day.

It was played for patients in Marestans. This music was played by all the factions of the great Morocco (actual Morocco and Spain) society: including Muslims, Christians and Jews, with a variety of instruments this music did imposed itself, and still one of landmarks of Morocco.

We will talk about the specificities and also the particularities of this kind of chromomusicotherapy.

Mental health in republic of moldova: The way from in-patient to community-based care services

J. Chihai

State University of Medicine and Pharmacy "Nicolae Testemitanu", Psychiatry- narcology- medical psychology, Chisinau, Moldova

Introduction The history of mental health in Moldova has been centered on psychiatric institutions. Current reform goals are centered on the reduction in psychiatric hospital beds, shifting the focus towards outpatient therapy, where community mental health centers have a central role in coordinating recovery and social reintegration.

Objectives to collect different data according guidance for establishing a situational analyses about Moldova.

Methodology we elaborated a guidance with outline: the historical perspective:

- a. back a 5–10 years events/developments; epidemiologic data;
- b. the service delivery system;

- c. mental health system: laws/regulations, role of the government as well as civil organizations, mechanisms for data collection, monitoring of performance, costs, quality of care and outcomes;

- d. opportunities, barriers, and needed changes/innovations needed to address these.

Results The current focus is on moving from a relatively centralized system towards a more community-based approach to psychiatric care and community supports, as well as deinstitutionalization and integration of mental health care with primary care. Besides over reliance on institutionalization, the Moldovan mental health care system faces other challenges, including access to care, workforce limitations, and stigma.

Conclusion Looking forward, success in these efforts will require continued strong political will to bring domestic law, policies and practices into line with international standards in the field of human rights for persons with disabilities. By supporting deinstitutionalization and improving the accessibility of mainstream services, more people will have the opportunity for social inclusion and the ability to contribute to the communities' social and economic growth.

* Corresponding author.

In this workshop, we will present the assertive community treatment (ACT) model in both Japan and Toronto, Canada. We will compare the adaptations of ACT models in both teams in order to serve their target populations efficiently and effectively.

We will also compare the demographic data, clinical data and the outcomes of both ACT teams by analysing the hospitalisation days, number of emergency admission and the number of admissions into hospitals. We will also highlight differences in the mental health systems in Japan and Canada in an attempt to formulate guidelines to ensure the effectiveness of ACT Teams in both countries. We would also like to open up discussion with the audiences and incorporate their ideas and suggestions in an attempt to formulate a competent mental health system which would effectively cater to the needs of people suffering severe mental health symptoms to ensure successful integration into the community.

Learning objectives:

- To explore adaptation in implementation of ACT in Japan and Canada;
- to develop a framework or model for assessing issues critical in establishing ACT in different countries;
- to develop guidelines to establish programs which will continuously be revised implementation based on needs, systems and feedback from the field.

Nursing care to the person with mental disorder: Experience report

S.C. Vasconcelos^{1,*}, A.E.M. Santos², K.N. Maranhão², A.V. Lordão², Z.F.D. Carvalho³, S.A. Almeida¹, J.C. Neves³, M.J.J. Alves³¹ Federal University of Paraíba UFPB, Public Health Nursing, João Pessoa, Brazil² Federal University of Paraíba UFPB, Nursing, João Pessoa, Brazil³ Psychosocial Care Center, Health's Secretary, João Pessoa, Brazil

* Corresponding author.

Introduction The formation of nursing professionals requires a dynamic teaching that provides the acquisition of skills and abilities to execute care, management, teaching and research activities. In this perspective, the operative groups are a teaching and nursing care strategy, performed by a knowledge exchange and collective interventions.

Aims Discuss the experience in nursing care to the person with mental disorder.

Methods It is about a fourth year undergraduate nursing students' experience report. The activities were developed at a center of psychosocial attention in João Pessoa, Paraíba, Brazil. Once a week, four operative group sessions were held under the theme "men's health". In the first session were agreed norms of behavior and activities plans on which the participants chose the subjects.

Results The operative group provided a friendly environment to exchange knowledge, in which the contents were addressed from the participant's acquirements and experiences. There was a good group interaction. The students conducted the activities under the teacher and monitor's supervision.

Conclusion This report provided experiences that contributed to the students' teaching-learning process as well as for understanding the nurse's insertion in the care scenario and the use of soft technologies to an efficient care to the person with mental disorder. The students also noticed the operative group's impact in the user's lives through sentences such as "It was fun", "I won gifts", "liked it", "I learned".

Interdisciplinarity on the care of a mentally disordered person

S.C. Vasconcelos^{1,*}, A.S.B. Correia², B.G. Gouveia², I.J. Silva², M.S.G.C. Mendes², M.A.S.P. Moreira³, E.S. Domingos⁴, A.S.L.G. Leal²¹ Federal University of Paraíba UFPB, Public Health Nursing, João Pessoa, Brazil² Federal University of Paraíba UFPB, Study Center of Collective Health, João Pessoa, Brazil³ Federal University of Paraíba UFPB, Speech Therapy, João Pessoa, Brazil⁴ Federal University of Paraíba UFPB, Nursing, João Pessoa, Brazil

* Corresponding author.

Introduction Brazilian's humanization policy offers the extended clinic as acting tool in health services, which advocates the use of soft technologies to provide care to its clientele.

Aim Discuss the interdisciplinary mental health residents approach to the care of the person with mental disorder.

Methods Experience report, accomplished by experiences of mental health's multidisciplinary residency members, which is in a lato sensu postgraduate linked to the study center of collective health, of the Federal University of Paraíba, Brazil. Structured on two axes: face meetings; and singling out actions in the daily work.

Results From the understanding of the extended clinic as a light technology interdisciplinary approach, in which different professional specialties share knowledge and co-responsible themselves for the mentally disordered patients' care, Residents have used it as an articulation tool and insertion in the different care scenarios. When developing activities, the residents use guidelines indicated by the extended clinic in order to leverage the work done by the person with mental disorders. Among which stands out: the host, building links, qualified listening, the sensitization for the care co-responsibility, construction of the unique therapeutic project, intersectional actions and sharing care with other services that make up the health system.

Conclusion Experiences like these made it possible to perceive the applicability of the National Policy of Humanization through its main tool, which is the extended clinic that contributes to the work process of a health team, promoting interdisciplinarity and raising the prospective to the look of transdisciplinary.

Long-acting injectable antipsychotics and global functioning in north western italian public health service

M. Probo, V. Dalo^{*}, F. Facchini, M. Rudoni, V. Preziosi, D. Nano ASL NOVARA, Department of Psychiatry, Novara, Italy

* Corresponding author.

Introduction Long-acting injectable antipsychotics (LAI-APs) should be the first choice therapy in the treatment of schizophrenia, however their use in outpatient's psychiatric services remains limited.

Objective Observational study in schizophrenic patients of the northwestern public health service.

Aim To assess demographic and psychopathological features in patients treated with LAI haloperidol (H-LAI) and second-generation LAI antipsychotics (SG-LAI).

Methods We recruited 105 schizophrenic patients upon LAI-APs treatment, and we assessed socio-demographic data, medical comorbidity, substances use, time from admission, treatment length, and per os augmentation therapies. All participants were

assessed for global functioning and severity of illness by CGI-SCH and PSP, respectively.

Results Of all patients, 52% were treated by H-LAI, 48% by SG-LAI. No statistical differences ($P > 0.05$) were found between the 2 groups for age, gender, other demographic variables, substances use, somatic comorbidities. Both groups were homogeneous for severity of illness (CGI-SCH score = 4.20 in H-LAI vs. 4.38 in SG-LAI) and global functioning (PSP score = 49.1 in H-LAI vs. 54.4 in SG-LAI). Compared with the H-LAI group, SG-LAI-treated patients were characterized by shorter time from admission (>10 yrs) and treatment length (>1 yr), and less frequent anticholinergic drug co-prescription. We counted only 6 LAI-APs treatments started in the last year.

Conclusions Despite of the literature support, LAI-APs treatment for schizophrenia is still limited in our service. Our data suggest that SG-LAI-APs are used as first choice of LAI-APs treatment, although maintained for short time, while H-LAI are reserved to long-standing patients and are burdened by side effects needing anticholinergic treatment.

Introduction Test anxiety is a multidimensional phenomenon, including concerns about conflicts lead to negative emotional and behavioral responses in academic scores.

Aim Current study examines the influence of educating time management on decreasing exam Anxiety and educational negligence of conditioned university students on Tehran.

Methods The method of doing study is of testing in which statistical society includes conditioned university students of Tehran. Of general statistical society, we have selected 20 persons by in access sampling method. Gathering information instrument in this study is Solomon and Roth bloom's educational negligence questionnaire and sarason test anxiety in which has been in access of studied sample after testing its stability and narration.

Result After education, the result of t-test dependent and covariance analysis has shown time management education does have meaningful influence on decreasing test stress and conditioned university students negligence on Tehran universities.

Conclusion Dropped students compared to other students, provided a significant contingent of students had less time management and procrastination.

Developing community mental healthcare: Kosovo case

G. Halilaj

Kosovo Forensic Psychiatry Institute, Forensic Psychiatry, Prishtina, Kosovo

Background Community mental healthcare in Kosovo is still in its developmental stage and thus pose an ongoing challenge for the health system and population.

Objectives The purpose of this study is to describe the processes of preparation, implementation, challenges and future of community mental health service in Kosovo as an economically struggling society with underdeveloped health care system.

Methods Review of the current state of community services provision for mentally ill peoples in Kosovo in the light of the objectives and targets of the WHO comprehensive mental health action plan 2013–2020.

Results The implementation of a new community mental health service in Kosovo still is characterized by considerable shortages, beside substantial effort on various levels. On the policy and financial level, it was made possible by a clear intent/initialization of international bodies and coordinated commitment of all responsible national stakeholders and authorities. Obstacles remain regarding improvements of service development indicators: financial and human resources; capacity building; stakeholder involvement and service availability. Lack of strategies for promotion and prevention in mental health and lack of information systems, evidences and research for mental health is vital need.

Conclusions Community mental healthcare in Kosovo despite struggles faced is successfully installed and represents one of Kosovo health system achievements. Comprehensive, integrated and responsive mental health services in community-based settings in line with international and regional human rights instruments is goal to be addressed.

Expanding the role of primary health care in the provision of mental health services to the population of the Kyrgyz republic

T. Galako

Kyrgyz State Medical Academy, Psychiatry, Bishkek, Kyrgyzstan

Providing comprehensive, integrated services in the field of mental health in primary health care (PHC) is a component of the state mental health program for the population of the Kyrgyz republic (KR) in the 2017–2030 biennium. In order to develop an action plan in this area a situational analysis of resources of psychiatric care at PHC level was carried out. There was revealed a significant deficit of specialists, such as family doctors, mental health care professionals. In spite of the need for 3,300 family doctors, only 1706 work, and 80% of them are of retirement age.

The results of a research showed a low level of knowledge and skills of family physicians for the early detection of mental disorders and provision of appropriate medical care. There are also a limited number of psychiatrists, especially in rural regions (77% of the required quantity).

During recent years, there have been implemented significant changes in the system of mental health services, aimed at improving its quality, the approach to the place of residence of the patient and the prevalence of psychosocial services.

Since 2016 in 8 southern regions in the Kyrgyz Republic has been introduced a new model for the provision of comprehensive health

care services. Piloting this model involves psychosocial rehabilitation of patients with mental disorders, the help of mobile teams at the place of patient residence, as well as psychoeducation, training, and support to family doctors. These and other measures will help to optimise mental health care at PHC level.

Formative exploration of the relationship between waiting times and attendance at general adult psychiatry clinics, at a hospital in pennine care NHS Foundation Trust

M. Gani^{1,*}, S. Salujha²

¹ Greater Manchester West Mental Health NHS Foundation Trust, Chapman Barker Unit- Prestwich Hospital, Manchester, United Kingdom

² Pennine Care NHS Foundation Trust, General Adult Psychiatry, Stepping Hill hospital, Stockport, United Kingdom

* Corresponding author.

Introduction An audit was done to assess new patient wait times. As part of this project we reviewed possible relationships between wait times and clinic attendance.

Objective To examine available data, for possible explanations of patients' attendance behaviour at outpatient clinics.

Aims To identify possible correlation between length of waiting time for adult psychiatry appointments and status of attendance.

Method Service Line: New patient referrals to adult outpatient psychiatry (January–December 2015)

Sample size: 401.

Results Fig. 1 and Table 1 show wait times compared with clinic attendance outcome. Percentage attendance appeared to gradually fall as wait times increased; while cancellation (%) by the NHS, and DNAs (did not attend) by the patient, appeared to rise over time.

Conclusions This review has demonstrated a possible correlation between wait time for a clinic appointment and how patients behave. The shorter a patient has to wait; it appears they are more likely to actually attend clinic. If so, this potentially has implications for discussions around possible reorganization of services, to improve engagement and outcomes, by coming up with innovative ways of reducing wait times.

Table 1

Clinic Attendance	Attended	Cancelled by NHS	Cancelled by Patient	Did Not Attend	Not Specified	Grand Total
0-3 weeks	88% (n=28)	3% (n=1)	3% (n=1)	3% (n=1)	3% (n=1)	100% (n=32)
4-6 weeks	71% (n=36)	10% (n=5)	10% (n=5)	8% (n=4)	2% (n=1)	100% (n=51)
7-9 weeks	57% (n=51)	21% (n=19)	6% (n=5)	16% (n=14)	1% (n=1)	100% (n=90)
10+ weeks	53% (n=120)	21% (n=48)	8% (n=18)	17% (n=39)	1% (n=3)	100% (n=228)
Grand Total	59% (n=235)	18% (n=73)	7% (n=29)	14% (n=58)	1% (n=6)	100% (n=401)

Descriptive study of adjustment disorders in a mental health unit.

L. González*, B. Pecino, C. Gomez, M. Anibarro, C. Ortigosa
San Juan Alicante Hospital, Psychiatry, San Juan Alicante, Spain

* Corresponding author.

Introduction Adjustment disorders are a common psychiatric disorder in primary care and mental health units, with point prevalence estimates ranging from 0.9% to 2.3%. These disorders have been recently defined as a stress response syndrome in the fifth edition of the DSM, causing emotional and social difficulties and also a large economic burden on society.

Objectives The aim of this descriptive study was to analyse the socio-demographic characteristics and treatment of the patients diagnosed with adjustment disorders in the first visit in a mental health unit.

Methods The study sample consisted of 128 patients admitted for a psychiatric consultation in a mental health unit in Alicante (Spain) from their primary care physician, between February and July 2016. Variables of gender, age, current employment status, diagnosis and treatment were measured. Data analysis was conducted using SPSS software.

Results The data from 31 patients who were diagnosed with adjustment disorders meant a 24% of the sample. The median age was 47 years old in the adjustment disorders group. Among those with adjustment disorders, 61% were women, and 52% of them were unemployed. Almost 60% of them had at least one psychotropic prescription and only 22% were derived to psychology.

Conclusions Adjustment disorders are considered as an intermediate category between no mental disorder and affective disorders. Most authors recommend to start with a psychotherapeutic intervention. Despite starting with medication has not proved effectiveness in the studies, most of the patients had at least one psychotropic prescription before the psychiatric evaluation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Mental health of college students: Five-year experience of the university psychiatric outpatient clinic of São João hospital centre

R. Guedes*, M. Mota-Oliveira, E. Pereira, M.J. Peixoto, I. Ferraz, M. Oliveira, C. Silveira

Centro Hospitalar de São João, Clínica de Psiquiatria e Saúde Mental, Porto, Portugal

* Corresponding author.

Introduction The clinic of psychiatry and mental health of São João hospital centre (Oporto, Portugal) has implemented a psychiatric consultation to support college students since 2007. This consultation is open to all of the universities in the metropolitan area of Oporto.

Aims/objectives This specific consultation aims to detect and intervene early in the treatment of psychiatric illness and to promote mental health in this specific population.

Methods Retrospective study conducted in the São João hospital centre, Oporto, Portugal. Patients attending university student's specific consultation between January 1st 2011 and March 31st 2016 were included. Data collection included sociodemographic variables, clinical diagnosis (ICD-10, WHO, 1992) and psychological scales (WAIS-III, BSI, HADS, SF-36 and NEO-PI-R). SPSS® software (v. 20.0, 2011) was used for statistical analysis.

Results In this study, 139 patients were included (66.2% female, medium age 23.1 years old). The majority of patients were medical, engineering or nursing students (respectively 20.9%, 18.0% and 17.9%). The most frequent diagnosis was adjustment disorders, anxiety disorders, mood disorders and personality disorders. 54.6% completed all the psychological scales.

Conclusions The number of students with mental health issues is increasing. Early detection and treatment of these pathologies may allow improvements on the educational, economic and social levels, as well as in the quality of life.

Burnout of caregivers in geriatric Institution: "Coping" strategies

H. Ben ammar, G. Hamdi*, Z. El hechmi

Razi Hospital, F, Mannouba, Tunisia

* Corresponding author.

Introduction The health sector has long been recognized to be a very stressful work environment for teams that can lead to "burnout". Geriatric institutions are no exception to this observation; this state has deleterious effects on health care as on the quality of care.

Objectives Measure the burnout rate among caregivers in geriatric institutions and identify associated factors and coping strategies specific to this population in order to provide the necessary preventive measures.

Subjects and method A cross-sectional study, conducted among caregivers exercising at the shelter for aged subjects of Manouba, Tunisia. We used a pre-survey exploring the socio-demographic data associated with two validated scales: the Maslach Burnout Inventory assessing the level of burnout and the Brief COPE assessing coping strategies.

Results Thirty-one subjects were recruited. The prevalence of burnout was 45.16%. Respectively 32.26%, 25.80% and 45.16% of the respondents had high scores in dimensions emotional exhaustion, depersonalization and personal accomplishment at work. The analytical study revealed that seniority in work increased the risk of

burnout. The coping strategies of caregivers in geriatric institution facing burnout were mainly centered on emotion. The number of years of experience has been associated with burnout in our study.

Conclusion This work reaffirms that the population of caregivers in geriatric institution is at risk of burnout and allows to identify predictors. The establishment of individual and collective measures is essential for appropriate treatment references (In the body text, a publication should be referred to by a consecutive number between bracket)

The relationship between happiness, general health and life expectancy of cancer patients

S. Heydari

Islamic Azad University, Clinical Psychology, Qazvin, Iran

Introduction Cancer is a disease that all human beings are afraid of it and anyone, of any age may be affected.

Objective The objectives of this research are relationship between well-being and life expectancy in patients with cancer in Noshahr Shahid Beheshti hospital is the general purpose of this research.

Aim Studying the relationship between happiness, general health and life expectancy of cancer patients.

Method The method used in this research is descriptive and correlation. Statistical population contains all the patients who were diagnosed with cancer in Shahid Beheshti hospital Noshahr. The panel sampling used as sampling method and the sample size was limited to 50 people.

In order to collect the data, we used Oxford's happiness questionnaire containing 29 multiple-choice phrases, Life expectancy questionnaire by Schneider (1991) and general health questionnaire (GHQ-28). In descriptive review of the collected data the mean, standard deviation and frequency tables were used and in inferentially section in order to determine and compare the obtained scores in these 3 tests, according to the findings, parametric methods were used.

Result The results show that the correlation between mental health, happiness and life expectancy was significant.

Conclusion As life expectancy increases accountability; Happiness and mental health in patients with cancer increases by the same amount.

Keywords Happiness; General health; Life expectancy; Cancer

Does the use of psychotropic medication go up during focused efforts to bring coercion and restraint down?

M. Højlund^{1,*}, L. Høgh², P. Munk-Jørgensen³, E. Stenager¹

¹ Mental Health Services, Region of Southern Denmark, Research Unit Department of Psychiatry, Aabenraa, Denmark

² Mental Health Services, Region of Southern Denmark, Department of Psychiatry, Aabenraa, Denmark

³ Mental Health Services, Region of Southern Denmark, Department of Psychiatry, Odense, Denmark

* Corresponding author.

Introduction Antipsychotic or anxiolytic medicine is widely used in agitated patients in risk of coercion. However this medication is

also known to contribute to cardio-vascular disease and reduced life expectancy. Department of Psychiatry in Aabenraa, Denmark participates in a nation-wide Danish project supporting efforts to reduce coercion and restraint. Our hypothesis is that reduction of coercion might lead to unwanted increase in doses of psychotropic medication.

Objective To document the use of psychotropic medication during the project period, in order to learn more about the impact of interventions to reduce coercion and restraint on psychopharmacological treatment.

Aim To compare type and doses of psychotropic prescriptions during the project period with the time before implementation.

Methods Cohort study of patients in risk of agitation and coercion admitted to the wards during first quarter of 2013 and 2016. Eligible patients were diagnosed as having organic mental disorders, substance abuse, psychotic disorders, mania, bipolar affective disease or personality disorders (ICD-10: F0x, F1x, F2x, F30-31, F60). Primary outcome is the exposure to antipsychotic medication measured as defined daily doses, and secondary outcomes are exposure to benzodiazepines, polypharmacy and compliance with guidelines on agitated patients.

Results Data collection is carried out during autumn of 2016, and the results will be presented at the congress.

Conclusions Results from this study will contribute to our understanding of the implications of the initiative to reduce restraint and coercion in psychiatry. The results will also sharpen our awareness of possible inexpedient practice.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction The medical and scientific communities are continually reporting that night work can increase the risk of certain disorders and have a negative impact on the overall well-being of employees.

Objectives This study wanted to examine the impact of night work on physical and psychological well-being of hospital staff.

Methods We carried out a cross-sectional study about a representative sample of hospital staff. We used validated self-reporting instruments: the Perceived Stress Scale (PSS) and the Subjective Well-being Scale (SWS). Data were analyzed using SPSS-20.

Results Our study concerned 519 hospital staffs. More than half were male (53%) and 83.1% had worked in the same position for more than two years. More than half of the participants (51.3%) considered themselves in very good health. Also 41.5% of participants had a well-being index reduced and 26% of personal had high perceived stress. Correlation analysis had shown that more than one guard at week was associated with high levels of perceived stress ($P=0.004$) and well-being index reduced ($P=0.000$). After adjusting for categories, more than one shift work at week was associated to well-being index reduced with odds ratios of 1.57 (confidence interval 95% [1.07 to 2.30]).

Conclusion There is a clear correlation between night work, perceived stress and subjective well-being of different categories of hospital staff. Shift work interferences on health and well-being are complex and multifaceted in their origins and time manifestations, dealing with several aspects of personal characteristics, and working and living conditions.

A meta-analysis of cognitive training on memory functioning in normal elderly adults

S. Piryaei*, M. Khademi Ashkzari

Alzahra university, educational psychology, Tehran, Iran

* Corresponding author.

Introduction The major issues in cognitive literature related to memory and aging concentrate on the different methodological issues in research examining the effectiveness of memory training programs in improving memory performance of older adults along with the clinical implications of this kind of research.

Objectives The review will address how researchers differ within their collection of participants, the various aspects of memory intervention programs by a systematic review on recent researches.

Aims The present study aims to review the cognitive literature related to memory and aging through a meta-analysis in recent years.

Method Meta-analysis was conducted of researches on memory training interventions for cognitively normal/healthy older adults published in 1995–2014. Computerized databases (e.g PsychInfo) were searched using combinations of these key words in English: memory, mnemonic, rehabilitation, older adult, aging, elderly and impairment. All participants must be at least 55 years old at the time of training/intervention. Due to the fact and Studies must have used a non-pharmacological approach toward memory or memory problems. Between-study heterogeneity was quantified using χ^2 and I2 statistics. All analyses were performed utilizing the CMA2.

Results Effect sizes with 95% confidence intervals for each study indicated that the overall pre-post training gain was 0.37 SD (95% CI: 0.18, 0.47) and the mean retest effect among control groups was 0.11 SD (95% CI: -0.11, 0.16) and this difference was statistically significant ($P < 0.001$).

Conclusion The key challenge of memory training studies is that they often don't train abilities that generalize to everyday functioning. These results have numerous clinical and practical implications.

Mental health of management staff in the closed environment of construction

N. Kornetov*, O. Pushpusheva

Siberian State Medical University, Psychiatry, Addiction and Psychotherapy, Tomsk, Russia

* Corresponding author.

Introduction it is difficult to overestimate the role of social, cultural and environmental conditions in evaluation of psychological health in hard intellectual work.

Objectives Research of construction staff in far taiga conditions using PHQ и GAD-7.

Aims to investigate the correlation between major depressive disorder, anxiety and somatoform disorders and gender and marital status.

Methods we studied 119 people who live in concentrated social environment and in conditions of hard work and lack of relaxation. In order to study depression, anxiety, and somatoform disorders we used PHQ и GAD-7 rating scale.

Results we noted that distribution of depression according to gender has statistically significant differences. In the men group the number of depressive individuals is 5 (11.1%; $P < 0.01$). In the women group the number is 28 (37.8%; $P < 0.01$). Also it was stated, that marital status does not influence the distribution of depressive symptomatology level ($P > 0.05$). Distribution of anxiety symptoms significantly differs by gender. In the group of men anxiety observed in 1 patient (2.2%; $P < 0.05$), whilst in the group of women – in 13 patients (17.6%; $P < 0.05$). Gender proved to be irrelevant in the occurrence of somatoform disorders ($P > 0.05$); it is also not dependent on marital status ($P > 0.05$).

Conclusion Staff employed into hard working social environment experience a range of negative psychological effects such as depressed mood, fatigue, and insomnia. Lack of leisure and lack of time for walking cause dissatisfaction with life, which contributes to the development of depression, anxiety and somatoform disorders.

Aspects of recovery and resilience—factors enabling an independent and fulfilling life

J. Krieger^{1,*}, V. Rößner-Ruff², D. Hoins², I.T. Graef-Calliess²

¹ *Klinikum Warendorff, Forschung und Entwicklung, Sehnde, OT, Ilten, Germany*

² *Klinikum Warendorff GmbH, Forschung und Entwicklung, Sehnde, OT, Ilten, Germany*

* Corresponding author

Introduction The concept “recovery” takes the position that individuals with severe chronic psychiatric disorders can recover and establish a certain degree of mental stability that can enable an independent and fulfilling life. To sustain recovery different variables and interdependent factors are needed, f.e. psychological resilience and empowerment. Actually, there are few studies focusing on the interdependency of recovery and resilience in patients with severe chronic psychiatric disorders, especially with an emphasis on overall psychiatric diagnosis and a longitudinal section.

Objective The study examines residential patients with severe chronic psychiatric disorders who lived in a long-term care institution for psychiatric rehabilitation (SGB XII) in Lower Saxony and who were able to move out and live by themselves in 2016. Persons with mental retardation and patients who have spent more than 30 years in a long-term care institution will be excluded.

Methods Randomised controlled trial based on a mixed-methods-design and a longitudinal course (5 follow-ups within 24 months after the first interview).

Aims Investigate factors for independent living on different levels (like micro, meso, macro) with focus on recovery and resilience by patients with severe chronic psychiatric disorders.

Results First results of a pilot study and focus groups will be presented.

Conclusion Results of investigation should be used in different subject areas like identification of factors enabling independent living and creation of effective therapy interventions for patients with severe chronic psychiatric disorders who have lived in a long-term care institution.

The effects of a brief educational programme added to community mental health treatment to improve patient activation and attendance: A randomized controlled trial

M. Lara-Cabrera^{1,*}, M.B. Nasset²

¹ *St Olavs University Hospital, Department of Psychiatry, Tiller CMHC, Trondheim, Norway*

² *Faculty of Medicine, Norwegian University of Science and Technology, Department of Neuroscience, Trondheim, Norway*

* Corresponding author.

Introduction Though interest grows in improving patient activation in general medical health services, there is little evidence from randomised controlled trials in mental health settings of how to achieve this.

Objective We aimed to evaluate the effects of a brief pre-treatment peer-co-led educational intervention added to mental health treatment. The intervention was developed and carried out in cooperation with user representatives, peer educators and health professionals, and aimed at activating and preparing patients to participate in own treatment.

Aims To assess the 4 months and 12 months effects on patient activation measure-13 (PAM-13) and attendance.

Methods Patients from two community mental health centres were randomised to a control group (CG, $n = 26$) receiving treatment as usual, or an intervention group (IG, $n = 26$), consisting of four-hour group pre-treatment educational seminar (peer-support and encouragement to adopt an active role) followed by treatment as usual.

Results At 4 months follow-up only the IG improved significant on PAM-13. Preliminary results at 12 months on PAM-13 and attendance will be presented.

Conclusion Brief pre-treatment education improves patient activation at 4 months and could potentially have an effect on attendance at 12 months follow-up.

Practice implications Pre-treatment education co-led in cooperation with user representatives, peer educators and health professionals is a rational and easy way to activate and engage outpatients in their own health care process.

* Corresponding author.

Introduction Integral nursing for an individual with a mental disorder requires care, management and educational skills to improve the quality of life of the patient.

Objectives Describes a health education experience in caring for an individual with psychic suffering.

Methods Activities were developed at a psychosocial care center in the city of João Pessoa, Brazil, with students in the third year of nursing school. Three sessions were held on the topic “self-efficacy in the use of psychoactive drugs”. Related factors, such as motiva-

tion, self-esteem and support, were chosen by the participants and discussed at each weekly session.

Results In the discussion groups, the students were able to exercise care based on the exchange of knowledge with the patients who use the service. The ties established in each session enabled the identification of the specific needs of each individual, such as the desire to learn how to improve one's self-esteem, and the active participation of the patients.

Conclusions The experiences assisted the students in developing the role of the nurse as an educator. The group actions underscored the importance of the skill of health education among nurses.

Specialist clinic dedicated to chronic mental illness and metabolic monitoring

B. McCafferty

Sligo Mental Health Services, General Adult Psychiatry Sligo Town Dr Adamis Service, Sligo, Ireland

Introduction People with serious mental illness exhibit higher morbidity and mortality rates of chronic disease than the general population. A significant proportion of premature deaths has been related to modifiable cardiovascular risk factors and may be related to medications taken for mental illness.

Objectives Establish a clinic for a cohort of patients with chronic mental illness dedicated to monitoring physical health focusing on modifiable risk factors.

Methods Patients with chronic mental illness taking psychotropic medications long term were invited to attend clinic.

The following areas were examined: History focusing on current mental state, cardiovascular history assessing diet, exercise, personal and family history of cardiovascular disease, Exam including waist circumference, BP, pulse, ECG and calculation of BMI. Laboratory tests including HbA1c, Lipid profile, and other tests as appropriate such as serum lithium. Examination for tardive dyskinesia (Abnormal Involuntary Movement Scale (AIMS)), outcomes, (Health of the Nation outcome scale (HoNos)) and quality of life (WHOQOL-Bref) were performed also performed as additional indicators of global health.

Results Sample consisting of 47 patients. Mean age 56.1 (SD: 13.6) males 27 (60%). Mean years of illness 23.1(SD:12.2). Mean HoNos 2.7 (SD 2.5). Four cases prolonged QTc, 5 HbA1c > 6% (2 no prior record of elevation); 18 abnormal lipid profiles, (12 no prior record of elevation); 4 blood pressure readings \geq 140/90, 3 no prior diagnosis of hypertension; 18 BMI > 25.

Conclusions This is a newly established clinic. Preliminary results have highlighted modifiable risk factors some of which may represent new diagnoses. Close liaison with General Practice is of importance.

EV0638

Quality of life in people with chronic mental illness

B. McCafferty

Sligo Mental Health Services, General Adult Psychiatry Sligo Town Dr Adamis Service, Sligo, Ireland

Introduction An association between chronic mental illness and significantly reduced quality of life in relation to the general population is speculated in the literature internationally.

Objectives To investigate the quality of life of people with chronic mental illness taking psychotropic medication living in the community and attending the Mental Health Services of Sligo town.

Methods Review of data including demographics, diagnoses and World Health Organisation Quality of Life Bref scale (WHOQOL-Bref) scores from consecutive patients attending specialist outpatient clinics dedicated to the care of people with chronic mental illness. Raw scores for each WHOQOL-Bref domain were converted to transform scores in the range 0–100 for ease of comparison with other validated instruments tools.

Results Total number of patients: 47. Mean age: 56.1 (SD: 13.6), males: 27 (60%). Mean years of illness: 23.1 (SD: 12.2). Primary psychiatric diagnosis: psychotic disorders 26 (57.8%), mood disorders 16 (35.6%), others 3 (6.6%). WHOQOL-BREF Domain transformed scores: physical health mean: 68.1, SD: 19.92, psychological health mean: 68.2, SD: 19.62, social relationships: 66.2, SD: 21.44, environment: 76.8, SD: 19.5.

Conclusions Quality of life is a complex multidimensional entity and its assessment relies on subjective reporting and analysis as supported by validated instrument tools. Our results suggest that quality of life is reasonably high among this cohort of patients, contrasting much of the current literature in similar populations. The mean score for social relationships was lower than other domains. This may suggest that a lack of socialisation may be associated with chronic mental illness and identifies a clinical focus for improvement of quality of life.

Correlation between resilience with aggression and hostility in university students

F. Mojriani^{1,*}, A. Homayouni², Z. Rahmedani², M. Alizadeh²

¹ Department of Psychology- Bandargaz Branch, Islamic Azad University, Bandargaz, Department of Psychology, Bandargaz, Iran

² Department of Psychology, Bandargaz Branch- Islamic Azad University, Bandargaz, Iran

* Corresponding author.

Resilience as a capacity to withstand stress and calamity is one of the important components of mental health and aggressive is a negative behaviour that can threaten human health. So, the purpose of this study was to investigate the correlation between resilience with aggression and hostility in university students. The research method is correlation, 155 university students were selected by convenience sampling method and responded to Corner & Davidson resilience questionnaires and Boos & Perry aggression and hostility questionnaire. The data were analysed by correlation formula. The results showed that there is a significant and negative correlation between resilience with aggression and hostility, which means when the score of resilience is high, people's aggression and hostility decreases. Therefore, it is recommended to increase the resilience of people by specific teaching programs to reduce the basis of aggression and hostility.

A fuller picture: Evaluating an art therapy programme in a multi-disciplinary mental health service

H. Moss^{1,*}, C. Brady², B. Kelly³

¹ University of Limerick, Irish World Academy of Music and Dance, Limerick, Ireland

² Tallaght Hospital, Art Therapy, Dublin, Ireland

³ Trinity College Dublin, School of Medicine, Dublin, Ireland

* Corresponding author.

Art therapy has a long history in mental health care but requires an enhanced evidence based in order to better identify its precise role in contemporary services. This paper describes an evaluation of an art therapy programme in an acute adult psychiatry admission unit in Ireland. A mixed method research design was used. Quantitative data were collected through a survey of 35 staff members and 11 service-users. Qualitative data included free-text comments collected in the survey and individual feedback from service-users. Both methods aimed to assess the role of art therapy as part of a multidisciplinary mental health service. Thematic content analysis was employed to analyse qualitative data. Staff demonstrated overwhelming support for art therapy as one element within multidisciplinary services available to patients in the acute psychiatry setting, qualitative feedback associated art therapy with improvements in quality of life and individual support, and emphasised its role as a nonverbal intervention, especially useful for those who find talking therapy difficult. Creative self-expression is valued by staff and service-users as part of the recovery process. Recommendations arising from the research include continuing the art therapy service, expanding it to include rehabilitation patients, provision of information and education sessions to staff and further research to identify other potential long-term effects. The low response of staff and small sample in this study, however, must be noted as limitations to these findings.

As India hurtles on into the 21st century with dizzying speed, the constantly evolving ethics, law and its interpretations fall behind. The cut and paste policy makers constantly impose regulations out of sync with the geopolitical realities. The Mental Health Care Bill now awaiting approval arose because we signed first on a global body convention and now are forced to comply. The family, a ubiquitous feature of our patient support system is slowly being derecognized. Instead, NGOs are the new approved caregivers. Our patriarchal society, earlier a repository of warmth and security is now jeered at. The mental health professional, the last mile delivery of mental health is in a quixotic position and some of the tantalizing issues of surreptitious drug administration, informed consent, the newer laws enacted or being enacted, narcoanalysis and drug trials will be discussed with pragmatic solutions offered to a disinterested regulator.

Surreptitious drug administration: Collective decision making over riding personal autonomy

R. Nagpal (M.D) (Psychiatrist)^{1,*}, V.G. Jhanwar (M.D) (Psychiatrist)²

¹ New Delhi, India

² Varanasi, Uttar Pradesh, India

* Corresponding author.

A quaint problem indeed. This is an issue where ethical and practical management issues lock horns. An individual with no insight on a rampage, a threat to self and others cannot be given medicines without consent except in an indoor facility and admitted under a specific provision of the current statute. Contrary to the law, the mental health policy envisages community care of the individual. For a time defined interval, surreptitious medication can be administered providing much needed relief to the caregivers and calms the recipient. Surreptitious medication can of course be an instrument of control and hence would necessitate a system of checks and balances. Surreptitious medication tests legal and ethical boundaries. It offers relief to caregivers but can be an instrument of abuse. The act of administering a drug without the individual's consent is prima facie wrong but if the context is woven in, a whole new dimension arises.

Microanalysis: The ethical minefield

R. Nagpal (M.D) (Psychiatrist)^{1,*}, A.K. Mital (M.D) (Psychiatrist)²

¹ New Delhi, India

² Mumbai, India

* Corresponding author.

Mental health professionals had always yearned for an intervention, which was restricted to them alone, was safe and had a commercial potential. Narco analysis or chemical hypnosis with or without the supervision of an anesthetist presented such an opportunity in India's largely poorly regulated medical practice. The turning point however was the unrestricted use of narco analysis for forensic reasons often against the will of the recipient that caught the attention of the judiciary. Professionals in candid confessions spoke of the tool replacing normal polite enquiries and unnecessary voyeuristic information being fettered out. Anecdotal evidence suggested police resorting to this tool without client consent or judicial permission. A series of flats after searching enquiry on the statute has led to complete disarray. The legal issues have relegated the ethical issues of consent, the usefulness of "forced" information, the aftermath of "forced" information to the backburner. Currently, the tool is regulated by the judiciary and selectively applied with consent. In the clinical setting, it is fast disappearing.

Informed consent: Pitfalls in a patriarchal & poorly literate society

R. Nagpal (M.D) (Psychiatrist)^{1,*}, E.M.D. Warriar (M.D) (Psychiatrist)²

¹ New Delhi, India

² Kerala, India

* Corresponding author.

The judiciary enquiring *suomotu* into deaths following an oncology trial in central India opened a can of worms. Searching investigation suggested that informed consent was only a cosmetic exercise and the victim was usually illiterate, poor and for a monetary reward and without being informed of the consequences of the intervention, subjected to a drug trial. Further, the process of informed consent was dispensed with and “patient” was asked to sign at the bottom of the document, no questions asked. The ‘patient’ in these trials usually is from the urban poor or deeply patriarchal, poorly literate rural hinterland. This led to a media outcry, a witch-hunt, indictments, penal action and the regulatory body now insisting on a video filmed informed consent. The wheel has truly turned full circle. The regulators while seeking idealistic regulation seem to live in a utopian world. The patriarchal and illiterate populace of rural India is far removed from the rarefied world of videotaped informed consent and presents an ethically quixotic situation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

When it's the time to switch the therapeutic approach on electroconvulsive therapy for residual positive symptoms in schizophrenia?

I. Nechifor (General Psychiatry)*, N. Nita (General Psychiatry), M. Buzut (General Psychiatry)

Socola Institute of Psychiatry, Iasi, Romania

* Corresponding author.

Introduction Schizophrenia is clearly one of the most debilitating diseases. Luckily, in the past 20 years, there has been a wide and good change in symptomatology due to the new atypical antipsychotics. Still, there are patients who are treatment resistant after different adjustments like switching or adding antipsychotics. Most of the clinicians consider Clozapine the “last resort”. But what if it doesn't work so well on some patients?

Objective To determine the point when it's time to try electroconvulsive therapy in schizophrenia treatment-resistant patients or remain on conventional approach.

Aims The aim of this work is to determine whether it's better for those patients who have residual positive symptoms to use oral/depot antipsychotics or to switch on electroconvulsive therapy.

Methods This work presents the case of the patient C.D., 35 years, diagnosed with paranoid schizophrenia since 2008. Risperidone, Olanzapine, Aripiprazole were introduced during time, with some improvement on the positive symptomatology, but the patient developed several side-effects. At his last admission in our hospital, he came after a suicidal attempt caused by high anxiety and depression due to his false beliefs. Clozapine was introduced, but after one month of treatment, the patient still had the belief that his neighbours want to harm him somehow.

Results The patient and his mother definitively refused electroconvulsive therapy because of their personal beliefs. He affirmed that he can live with this “low-dose” of suspiciousness which, unfortunately, had a negative impact on his social life.

Conclusions We still recommend electroconvulsive therapy in these situations, even though, there are many misconceptions regarding this approach.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The effects of personality traits of university students in their romantic relationships

E. Ongun*, G. Unsal Barlas

Marmara University Faculty of Health Sciences, Psychiatry Nursing Department, Istanbul, Turkey

* Corresponding author.

Introduction Most people will have romantic relationship in different periods of their life and sometimes this relationship can contain abuse. The abuse which is perceived in romantic relationships can be an important problem for university students.

Objective This study was conducted to determine the effects of personality traits of university students in the abuse which is perceived in their romantic relationships.

Methods The study was descriptive and analytical. The students of Marmara University Faculties of Law, Pharmacy, Nursing and Midwifery, Cinema and Television department comprised the sample. The measuring instruments consisted of a personal information form, the Basic Personality Traits Instrument (BPTI) and Romantic Relationship Assessment Inventory (RRAI). The data were analyzed with the SPSS 11.5 programme, using the “Mann–Whitney U Test”, “Kruskal–Wallis Test”, “Spearman's Correlation Test”.

Results RRAI mean score was 102.41 ± 33.79 ; subscale of BPTI's mean scores were; extraversion 28.60 ± 5.97 ; conscientiousness 28.30 ± 5.91 ; agreeableness 33.73 ± 4.29 ; neuroticism 26.09 ± 6.48 ; openness to experience 21.91 ± 3.83 ; negative valence 9.82 ± 3.36 . There was a low level negative significant relation was obtained between subscale of conscientiousness ($r = -0.196, P = 0.000$), agreeableness ($r = -0.168, P = 0.000$), a low level positive significant relation was found between subdimensions of neuroticism ($r = 0.168, P = 0.000$), negative valence ($r = 0.255, P = 0.000$) and abuse.

Conclusion In conclusion, there is a relation between personality traits and perceived abuse. Therefore, education programmes should be prepared about abusive behaviour and its risk factors and consequences.

Keywords Personality traits; Romantic relationships; Abuse of romantic relationships; Dating violence; Partner abuse

* Corresponding author.

Introduction Mental health care in Bosnia and Herzegovina (BH) is changing and shows the new trends more than 20 years. In last 6 years is established strong network of community mental health centers (CMHC) as a most important service in the prevention, treatment and rehabilitation of mental illnesses.

Objectives Project of mental health in BH (PMH) is the largest reform project, supported by the Swiss Government and it is planned to be implemented in whole BH emphasizing importance of community mental health care and putting patients in the focus of the reform.

Aims and method To show positive trends and practices in BH as well as obstacles in some fields of the reform.

Results For the last six years are made positive national mental health policies, established case management model in work with people with severe mental disorders, broad spectrum of services recognized by health insurance (validation of the work for all team members), user initiatives (organization), active role of primary mental health care, reduction of hospitalization, etc. On the other way, yet are not established protected housing, early interventions services and universal methodology or team structure in all CMHC.

Conclusions Community based mental health care shown as a good choice in the reform of the mental health in BH, confirming positive results from other countries. That is a reason to continue with improvements based on daily practices of the teams in CMHC.

Access to mental health services among internally displaced persons in Ukraine: Results from a nationwide survey

B. Roberts^{1,*}, N. Makhshvili², J. Javakhishvili²

¹ London School of Hygiene and Tropical Medicine, Health Services, London, United Kingdom

² Global Initiative on Psychiatry, Tbilisi, Mental Health, Tbilisi, Georgia

* Corresponding author.

Background There are an estimated 1.4 million internally displaced persons (IDPs) in Ukraine as a result of the armed conflict in Ukraine.

Objectives (i) Measure the burden of key mental disorders (PTSD, depression and anxiety); (ii) examine rates of utilization of health and psychosocial support services; (iii) examine the patterns of utilisation of services.

Methods The study used a cross-sectional survey design and was conducted throughout Ukraine between March and May 2016 with 2203 IDPs aged 18 years and over. Time-location sampling was chosen as a probabilistic sampling method. Outcome measures were the PCL-5 for PTSD, the PHQ-9 for depression and the GAD-7 for anxiety. Descriptive and multivariate regression analyses were used.

Results Of the 2203 respondents, 703 reported experiencing a mental health or emotional problem over the previous 12 months and were also screened positive with PTSD, depression or anxiety. Of these 703, 180 had sought care (with sources of care to be given in the presentation). Therefore, 523 respondents did not seek care, equating to an overall treatment gap of 74%, (74% for PTSD, 71% for depression and 70% for anxiety). Key reasons for not utilising treatment included preferring to use their own medications ($n = 176$); unaffordability of health services ($n = 118$) or medications ($n = 140$); poor understanding by health care providers ($n = 123$); poor quality of services ($n = 78$) and stigma/embarrassment ($n = 41$).

Conclusions The findings support the need for a scaled-up, comprehensive and trauma informed response to provision of the mental health care of IDPs in Ukraine.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Taking care of people suffering from neuropsychiatric illness living at home

T.M. Sæterstrand

Sykepleie og helsefag, Nursing and Health, Bodø, Norway

Content background People suffering from neuropsychiatric illness are often in need of caring and nursing over a long period of time. Research shows that patients suffering from such illness do not very often get enough care in practice.

Aim To gain knowledge about nurses experiences from taking care of older people living at home and suffering from chronic and neuropsychiatric illness.

Method Qualitative analysis: fieldwork and qualitative interviews with 11 nurses who worked in four units in two different municipalities in Norway.

Results Challenges in clinical nursing explain the process nurses work in when they take care of people with neuropsychiatric illnesses living at home. This is caring for patients, taking care of family members, managing complex patient situations and the need for coaching and cooperation.

Conclusion To gain a good cooperation with other health personnel to strengthen the competence is important, especially when the goal is caring. Nurses with education in neuropsychiatric care can strengthen the competence maybe and reach a better patient care. The organization of the community health system needs to be studied.

Introduction Stigma restrains the life opportunities of individuals with serious mental illness. This study aimed at performing a linguistic validation of a battery for measurement of affirming attitudes; a battery that might be used to test the impact of anti-stigma and socially inclusive programs.

Methods Three measures were considered: the Recovery Scale, Empowerment Scale and Self-Determination Scale. Two native Arabic speakers, bilingual in English, independently translated the original measures into Arabic. A collaborative pooled version of the questionnaires was then obtained from the two translations. The pooled version was back-translated into English by a professional translator. A draft Arabic version of the battery was obtained from the comparison between the original questionnaires and the back-translation and was tested on 30 Arabic-speaking medical students. We also discussed the existence of other wording that enables the meaning of statements to be expressed clearly.

Results The test of the different items allowed the detection of three typing errors. It also highlighted mistranslating two terms to one term that does not distinguish between them in term of the meaning: "Goal" and "Purpose". Comments were reported on the wording of certain items in the questionnaire. These comments referred to the problems related to the grammatical and syntactical construction of certain expressions. The translation from English into Tunisian dialect is different from our dialect.

Conclusion We proposed an Arabic version of a battery of measures that reflect affirming attitudes. This is a step for reliable measures that assess stigma in Arabic countries.

Introduction Drama therapy is a useful therapy method for improving the life quality of psychiatric patients. Drama therapy is a rehearsal of everyday life. In this therapy method, clients actively join the creative process in order to better understand their life experiences.

Objectives Drama therapy may improve patients' ego functions, psycho-social and self-expression abilities, problem-solving skills, real-life adaptations and contribute to patient's psychiatric treatment.

Aim The main aims were to examine the curative effects of drama group therapy and the effects of drama therapy on functionality in psychiatric patients.

Method The study was performed at the Istanbul University Faculty of Medicine. Patients were referred from the Psychiatry Polyclinic of this university to Art Therapy and Rehabilitation Program. Drama therapy is an applied drama-based art group therapy. The 10 subjects in our study, ranged from 20 to 50 years old. This therapy group gathered once a week for a ninety minute session. Subjects continued their medical care and received psychotherapy throughout the 24-week study. The therapy plan included an introduction, a warm-up session, a drama therapy work and a sharing session. Patients were assessed in pre and post-treatment with Global Assessment of Functioning and Wilcoxon Signed Ranks Test was used for statistical analysis. Yalom's Group Curative Factors Scale was applied.

Result There was a significant decrease in loss of functioning ($P < .05$). In Group Curative Factors, the means of hope, identification, group cohesion and altruism were determined high.

Conclusion Our study demonstrates that drama therapy has positive effects on patients with severe psychiatric patients.

² Psychiatric Hospital N° 3 named after VA Hilyarovsky, Administration, Moscow, Russia

* Corresponding author.

Introduction Over the past 20 years, considerable progress was made in understanding the multiple and complex needs of patients with mental disorders and ways to organize comprehensive care. However, organizing care in inpatient, pathology-focused settings,

where patients were seen increasingly as consumers of 'inpatient psychiatric' services is challenging.

Objectives and aims Inspired by modern trends, we are more able to integrate recent developments in psychosocial treatments, broadly defined, into progressive treatment framework within inpatient setting.

Methods Results of an audit of our service (psychosocial treatments) over the previous 5 years will be compared to published results of other services with a range of service delivery methods.

Results Excerpts from mental health care practice in Moscow based Psychiatric Hospital N° 3 named after VA Hilyarovsky – are provided. The pathways of care as well as the basic principles governing the treatment (careful attention to referral sources; optimal patient-treatment matching; and psychosocial, rather than medical supremacy) are outlined. Training and development is central to the effective and efficient working of any staff group. As part of the service developments, a number of inductions (on psychosocial treatments) were provided on regular basis to all staff joining the service.

Conclusions Though the opportunity for future reform remains on the horizon, some of the strengths and weaknesses of our current health care practice will be presented.

Documenting the decision-making process for initiation of pharmacological VTE prophylaxis in patients admitted to an adult psychiatry ward background

G. Sikka^{1,*}, N. Mistry²

¹ Tameside General Hospital, Psychiatry, Ashton-Under-Lyne, United Kingdom

² Macclesfield General Hospital, Psychiatry, Macclesfield, United Kingdom

* Corresponding author.

Background Venous thromboembolism (VTE) is a condition that causes a blood clot to form within the venous blood system. If this blood clot forms in the peripheral venous system, it can cause symptoms such as calf pain and swelling. If this clot becomes dislodged, it may travel through the vessels into the pulmonary artery which can have much more severe consequences.

Objectives There has been a great deal of effort in recent years to increase the percentage of in-patients receiving a VTE assessment; and for those patients to receive appropriate VTE prophylaxis. VTE is a significant cause of inpatient deaths. This audit aims to compare current working practice to local standards and identify learning points.

Method VTE assessment data were collected from two acute psychiatric in-patient wards within a specified, random date range in 2016. Data was collected by checking paper admission documentation. NICE guidelines also state that all patients should be assessed for VTE on admission, with a standard of 100%.

Results Overall, 6.25% of general adult psychiatry patients had a VTE assessment done within 24 hours of admission.

Conclusion This audit shows that the necessary standards are not met. Importance of these assessments will be communicated during induction programmes for all staff and the results of this audit communicated to current staff on all in-patient psychiatry wards.
