25th European Congress of Psychiatry

Plenary

Plenary session: Psychiatry 2017: Acknowledging complexity while avoiding defeatism

PL01

Psychiatry 2017: Acknowledging complexity while avoiding defeatism

M. Maj

Department of Psychiatry, University of Largo Madonna delle Grazie, 80138 Naples, Italy

In the past few years, it has become a sort of cliché to state that psychiatry is in a crisis. In particular, it has been repeatedly argued that: (a) psychiatric diagnoses are invalid; (b) psychiatric research has not progressed significantly (in particular, it has not been able to identify “the cause” of schizophrenia, depression or bipolar disorder); (c) psychiatric treatments are of limited value, and their widespread use has not been able to reduce the incidence of mental disorders. This perception of crisis has been at least in part generated by an identification of mainstream psychiatry with the neo-kraepelinian paradigm, so that the crisis of confidence in that paradigm has expanded into a crisis of confidence in the psychiatric discipline. According to Kuhn, the crisis of confidence in a paradigm is accompanied by a period of “extraordinary science”, marked by a proliferation of competing methodologies, the proposition of a variety of divergent solutions for the problem defining the crisis, and the recourse to philosophy and to debate over fundamentals of the discipline. The crisis of confidence in the neo-kraepelinian paradigm has generated such a period, in which we are all now immersed. In this presentation, I will summarize the main components of the neo-kraepelinian paradigm; I will illustrate why that paradigm has failed, or at least has lost people’s confidence; and will summarize the main elements which are emerging in the current period of “extraordinary science”.

Plenary session: Public mental health and clinical psychiatry: Are they two separate worlds?

PL02

Public mental health and clinical psychiatry: Are they really two separate worlds?

S. Priebe

Queen Mary, University of London, United Kingdom

Public mental health and clinical psychiatry: Are they two separate worlds?

Stefan Priebe, unit for social and community psychiatry, Queen Mary University of London.

Public mental health focuses on health indicators and interventions on population level with an emphasis – although not exclusively – on prevention. In contrast, clinical psychiatry involves treatment of individuals in the setting of a health service and deals with people who usually already have a mental disorder. The theoretical background, the underpinning evidence and the practical approach of public mental health and clinical psychiatry differ from each other and concepts of one of the two cannot easily be transferred to the other.

Nevertheless, the presentation will argue that there are also links between the two. These links may be based on overall applicable values, a common understanding of mental disorders, and social models of overcoming mental distress. These links can have implications for how clinical psychiatrists are engaged in political and societal activities, get involved with local communities, and work in daily practice with their patients.

The public mental health perspective, used in a wide sense of the term, has played a substantial role in the historical development of psychiatry, including its major reforms, and might also open up how clinical psychiatry might be attractive as a career option and relevant as a profession in the future.

25th European Congress of Psychiatry Debate

Debate: Is the concept of schizophrenia useful?

D001

Pro

W. Gaebel

Heinrich-Heine-Universität, Düsseldorf, Germany

The concept of schizophrenia has undergone many changes since its first inception in the early 20th century. Basically, the concept has stood the tests of time, as it provides useful information about the clinical picture, the clinical course and the available treatment modalities. Any alternative concept will need to show that it provides similar information. The concept has also been useful to establish evidence-based guidelines for diagnosis and treatment, and to provide valuable information as regards psychosocial outcomes. In addition, recent genetic and neurophysiological studies have shown that common grounds of aetiopathogenesis can be identified, in that schizophrenia is a mental disorder with some genetic influences and a common pathway in complex disturbances of brain circuits due to altered neurotransmission. Current research focuses on identifying biomarkers for early detection, another area of mental healthcare in which a staging model of schizophrenia proved useful. This presentation will highlight the most pertinent arguments for keeping schizophrenia as a useful diagnostic and therapeutic concept of a mental disorder.

The analysis of the historical development of the currently used diagnosis schizophrenia in DSM or ICD classification indicates that sticking to established terms and methodologies more and more develops to an obstacle in schizophrenia research. The aim of the currently used operational diagnostic approach was to reach reliability of diagnoses between different psychiatrists and researchers as high as possible. This should improve the communication between different research groups and better the comparison of study results. The aim of a high reliability has surely been reached, however, the expected striking progress in research and clinical praxis failed to materialize till today. Reliability, which means agreement, does not simultaneously means validity. Modern brain and genetic research requires more homogenous clinical syndromes or 'diseases' to examine them with scientifically based methodologies and technologies. The prerequisite for doing this, however, is going back to clinical and empirical realities and to integrate these realities into the development of a new generation of classification systems that are free of dogmatic thinking.

Disclosure of interest The author declares that he has no competing interest.

Joint symposium: How long do we have to wait for the antidepressant effect?

JS001

Joint symposium: How long do we have to wait for the antidepressant effect? Mechanisms of action for delay of onset response to antidepressants

F. Artigas

Institut d'investigacions biomèdiques de Barcelona, Spain

Major depressive disorder (MDD) is a severe psychiatric syndrome with very high prevalence and socioeconomic impact. Monoamine-based antidepressant drugs (AD) display slow onset of action and limited efficacy. Preclinical studies show that ADs trigger a series of slow adaptive mechanisms that limit the clinical response. These mechanisms result from the pharmacological blockade of monoamine transporters (SERT, NET) and involve presynaptic, such as autoreceptor desensitization (e.g., 5-HT_{1A} and 5-HT_{1B} for serotonin neurons) as well as postsynaptic mechanisms, such as increased neurogenesis and expression of trophic factors, increased dendritic complexity, etc.

Given the strong homeostasis of serotonin and noradrenaline neurons, a way to improve antidepressant action is to prevent self-inhibitory presynaptic mechanisms mediated by auto- and heteroreceptors after reuptake blockade. This strategy was used in the past with the non-selective 5-HT_{1A} antagonist pindolol and has been incorporated by two recently developed AD (vilazodone and vortioxetine). Likewise, new molecular strategies using RNA interference (RNAi) show that the modulation of gene expression in serotonin neurons offers a great potential. Hence, local or intranasal administration of small interfering RNA (siRNA) molecules targeting SERT or 5-HT_{1A} autoreceptors evokes rapid and robust antidepressant-like effects in rodents.

Moreover, glutamatergic drugs such as the non-competitive NMDA receptor antagonist ketamine, offer a potential for the development of fast-acting AD due to its rapid and persistent antidepressant effects in treatment-resistant unipolar and bipolar patients after single i.v. infusion, an effect that likely involves the activation of AMPA receptors in ventral areas of the cingulate gyrus and the subsequent fast activation of serotonergic function.

Disclosure of interest F.A. has received consulting honoraria on antidepressant drugs from Lundbeck and he has been PI

of grants from Lundbeck. He is also co-author of the patent WO/2011/131693 for the siRNA and ASO (antisense oligonucleotides) molecules.

<http://dx.doi.org/10.1016/j.eurpsy.2017.01.017>

JS002

What do clinical trials tell us about antidepressant delayed onset of action?

J. Rabinowitz

Bar Ilan University, Israel

Response to antidepressants in major depressive disorder is highly variable and determinants are not well understood. Presentation will provide clinical trial data on time to response and determinants of response to antidepressant treatment. Data is from the Innovative Medicines Initiative funded NEWMEDS collaboration, a large public-private collaboration which assembled the largest dataset of individual patient level information from randomized placebo-controlled trials of antidepressant drugs. Studies were conducted by four large pharmaceutical companies. Dataset includes placebo-controlled trials of citalopram, duloxetine, escitalopram, quetiapine and sertraline in adults with MDD. We examined patient and trial-design-related determinants of outcome as measured by change on Hamilton Depression Scale or Montgomery–Asberg Depression Rating Scale in 34 placebo-controlled trials (drug, $n=8260$; placebo, $n=3957$). While it is conventional for trials to be 6–8 weeks long, data presented will show that drug-placebo differences were observable at week 4 with nearly the same sensitivity and lower dropout rates. Having any of these attributes was significantly associated with greater drug vs. placebo differences on symptom improvement: female, patients being middle aged, increasing proportion of patients on placebo, excluding all patients from centers with high placebo response regardless of active treatment response, using active run in periods and including self-report measures. Proof of concept trials can be shorter and efficiency improved by selecting enriched populations based on clinical and demographic variables, ensuring adequate balance of placebo patients, and carefully selecting and monitoring centers. In addition to improving drug discovery, patient exposure to placebo and experimental treatments can be reduced.

Disclosure of interest I have received research grant(s) support and/or travel support and/or speaker fees and/or consultant fees from Takeda, Minerva, Intra-cellular Therapies, Janssen (J&J), Eli

Lilly, Pfizer, BiolineRx, Roche, Abraham Pharmaceuticals, Pierre Fabre, Minerva and Amgen.

Joint symposium: The value of treatment for brain and mental disorders

JS003

Closing the treatment gap: The EPA case study of schizophrenia

W. Gaebel

Heinrich-Heine-universität Düsseldorf, Germany

Introduction Schizophrenia still ranks among the first 10 leading causes of disability worldwide. Recent analyses show that there is a considerable treatment gap in schizophrenia in Europe and worldwide.

Objectives To provide evidence-based information and give a concise overview of what is needed to overcome the treatment gap in schizophrenia.

Methods Using a combined approach of systematic review and health economics was used to assess the socioeconomic impact of medical interventions (or the lack of thereof) for schizophrenia.

Conclusions The case study analysis demonstrates socioeconomic impact and health gains of best practices in specific healthcare interventions for schizophrenia in comparison with the cost burden of current care or non-treatment.

JS004

The cost of non-treatment

M. Knapp

London School of Economics and Political Science, London, United Kingdom

There are large treatment gaps in relation to schizophrenia across all European countries, either because the illness is not recognised or because the response from treatment and care services is inadequate - not evidence-based. This could be because of resource or other constraints. The consequence can be very damaging indeed for individuals with schizophrenia, their families and for the wider society. In this talk I will set out the economic consequences of not identifying or responding appropriately to schizophrenia. Evidence will be drawn from a number of studies, but will be channelled to show new findings in relation to both England and Czech Republic. These figures add to the argument for earlier and better treatment, to benefit everybody including public and private budgets.

Disclosure of interest The author has not supplied his declaration of competing interest.

Joint symposium with the Italian psychiatric association: Early intervention in psychotic disorders: Comparing models and experiences

JS005

Assertive interventions for first episode psychoses: The Danish experience

M. Nordentoft*, N. Albert, C. Hjorthoj, H. Jensen, M. Melau
Mental health services in the capital region of Denmark, university of Copenhagen, Denmark

* Corresponding author.

Early Intervention services with team-based intensive case management and family involvement are superior to standard treatment in reducing psychotic and negative symptoms and comorbid substance abuse and improving social functioning and user satisfaction. The results of the OPUS-trial will be presented together with meta-analyses based on similar trials. The implementation of OPUS all over Denmark will be presented together with the Danish OPUS-fidelity study. Specialized elements are being developed such as inclusion of new methods in CBT for psychotic and negative symptoms, neurocognitive and social cognitive training programs, interventions for supported employment and focus on physical health. Results of long term follow-up studies indicate that the prognosis of first episode psychosis is very diverse with the extremes represented by one group being well functioning and able to quit medication without relapse; and another group having a long term chronic course of illness with a need for support to maintain daily activities. The Danish TAILOR-trial—testing dose reduction versus maintenance therapy will be presented. It will be of immense value to be able to intervene in risk groups identified in the premorbid phase, and there are few examples of ongoing trial for children of parent with schizophrenia and bipolar disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

JS006

Assertive interventions for first episode psychoses: The Italian experience

A. Meneghelli

Solari 19, 20144, Milan, Italy

In Italy, despite the favourable conditions created by the 1978 reform law and the community psychiatry, at the end of the past century there were no culture or initiatives oriented to innovative and evidence-based founded interventions in early psychosis. The watershed was the setting up in the MHD of Niguarda (Milan) of Programma 2000, addressed to FEP and HR mostly inspired by the knowledge of existing studies and experiences and with the recommended characteristics of specificity, multicomponentiality, assertiveness and doctrinal orientation. From the very start, one fundamental aim was to disseminate information, training, supervision, and to raise consensus and initiatives throughout Italy, as well as to improve international links. In many ways, the consequences have been extremely positive. In 2005, Angelo Cocchi and Programma 2000 team founded the AIPP (Italian Association for Early Intervention in Psychosis), now named Italian Association for Prevention and Early Intervention in Mental Health. Over the

years, the Association has organized conferences, scientific days, working network, two national surveys on EIS and produced a document to favour their development. The results of the second survey are the more updated and articulated about the number of early interventions services, their characteristics and distribution in the different Italian regions. The survey conclusion is that EI Services implementation in Italy has been proceeding, albeit slowly. Nevertheless, there is still a great variability of therapeutic

strategies and further efforts are then necessary to stimulate resources allocation as well as to assess and address adherence and fidelity to guidelines recommendations.

State of the art

State of the art: Working together for early detection of psychosis

SOA001

Working together for early detection of psychosis

A. Riecher-Rössler

University of Basel psychiatric hospital, CH-4051, Basel, Switzerland

Introduction In the last decades psychiatry has taken an important and overdue step which other medical disciplines had taken much earlier, i.e. recognizing the chances of early detection and intervention—first in the field of emerging psychosis, in the meantime also in other fields.

Objectives To review new developments in the field of early detection of psychosis and to critically discuss the obstacles still depriving many of our patients of an immediate benefit.

Methods Review and discussion.

Results New developments are very promising. Identification of individuals at risk and prediction of transition to psychosis is possible with an excellent accuracy, comparable to other preventive approaches in medicine. And there is growing evidence how this accuracy can even be more improved by using not only clinical assessments but also additional domains such as neurocognition, neurophysiology, or MRI, as well as new methods for analyses such as pattern recognition. Staged intervention according to the degree of risk seems feasible. However, there are still many obstacles to a broad implementation of this new know-how into clinical practice such as lack of communication, political will and finances, or fears, stigma and prejudices.

Conclusions For the benefit of those concerned - patients and their relatives - a great effort to work together is required from all of us: clinicians, researchers from psychiatry and many other fields, industry, politicians, and last, but not least, patients and their relatives.

Disclosure of interest The author has not supplied his declaration of competing interest.

<http://dx.doi.org/10.1016/j.eurpsy.2017.01.006>

State of the art: psychotherapies vs. pharmacotherapies vs. combination therapies in depressive and anxiety disorders

SOA002

Psychotherapies vs. pharmacotherapies vs. combination therapies in depressive and anxiety disorders

P. Cuijpers

Faculty of Behavioural and Movement Sciences, Vrije Universiteit, Amsterdam, The Netherlands

Both psychological and pharmacological therapies have been found to be effective in the treatment of adult depression and anxiety disorders. Psychological treatments include cognitive behavior therapy, interpersonal therapy, behavioral activation, exposure therapies, and several other types of therapy. Pharmacological treatments include SSRIs, SNRIs TCAs, MAIOs and several other types. In this presentation the results of meta-analyses of trials directly comparing the effects of psychological and pharmacological treatments will be presented, as well as meta-analyses of combined treatments versus either psychotherapy alone or pharmacotherapy alone. Results show that psychological and pharmacological treatments are probably about equally effective at the short term, and combined treatment is more effective than either psychotherapy or pharmacotherapy alone. In the presentation several other issues related to this group of trials will be discussed, like the influence of conflicts of interest and the (lack of) blinding in psychotherapy trials.

Disclosure of interest The author has not supplied his declaration of competing interest.

<http://dx.doi.org/10.1016/j.eurpsy.2017.01.007>

State of the art: identifying and managing mental health needs of homeless individuals

SOA003

Identifying and managing mental health needs of homeless individuals

D. Bhugra

Institute of Psychiatry, Psychology and Ne, London, United Kingdom

The economic downturn worldwide since 2008 has raised many issues, including an increase in homelessness. Individuals who are homeless are visible across the globe. Definitions of homelessness also vary. Living on the streets in all kinds of inclement weather, brings a different set of issues and problems including physical and mental illnesses. Here homelessness is defined as a lack of customary regular access to a conventional dwelling unit. It has been shown in several studies that nearly half were either depressed or had substance use disorders and half had traumatic brain injury. Homelessness is a social issue and the role of the psychiatrist in reaching these vulnerable individuals is a matter of critical importance. In the UK health services are geographically delineated making it more difficult for 'out of area' individuals to get help. The responsibility for looking after people who are homeless, have mental illness or physical co-morbidity, lies with policymakers as well. As clinicians we must advocate for vulnerable patients and psychiatry care needs to be in a joined-up manner. Early interventions and home treatments where and if available are suitable and can be effective but are often linked with secure addresses. Policies must take into account huge variations across cultures and societies and the contributions that unemployment and poverty can play in increasing homelessness. Whether psychiatric disorders lead to homelessness and whether homelessness leads to mental illness is a circular argument and this vicious downward spiral needs to be broken by adequate care and policy support.

Disclosure of interest The author has not supplied his declaration of competing interest.

<http://dx.doi.org/10.1016/j.eurpsy.2017.01.008>

State of the art: social media and e-mental health

SOA004

Social media and e-mental health

M. Krausz

Addiction, West Vancouver, Canada

Mental health services worldwide are only able to serve a minority of patients. Expert advice is in most cases not accessible even in developed countries with a functioning mental health care system. Threshold to care are high and the time between first critical developments and symptoms and first professional interventions is long, sometimes several years.

The evolving communication tools through social media and web-based services may provide new and exciting opportunities to change that. Especially young people have a different approach to interact, learn and access services through the Internet. The momentum there is as crucial as it is in education. Our mental health care system in all its components will most likely very different than today. E mental health will be an integrated component contributing to more capacity, higher quality of care and better accessibility.

What is the key in developing new tools and what can today's clinicians and researchers do to be an active partner in this process? What are the major concerns and how should we address them also as professional organization? This may be an opportunity of a lifetime for a paradigm shift. Its success relates to good integration and implementation of these exciting tools to create a new continuum of tools addressing a continuum of needs.

Disclosure of interest The author has not supplied his declaration of competing interest.

Symposium: Promoting mental health in the health and non-health sectors

S001

Conceptual aspects of mental health in its intersection with human rights and development

S. Galderisi
 University of Campania "Luigi Vanvitelli", Department of Psychiatry, Naples, Italy

Introduction Improving mental health of people is an important goal of the present millennium. Community-based services programs for prevention of mental disorders and promotion of mental health have been implemented in several countries. However, the proportion of people suffering from mental disorders is significantly and persistently high, and psychosocial distress due to migration, natural disasters, and terrorism; in general, feeling of insecurity is unlikely to improve current figures.

Aims To highlight the interrelatedness of mental health, development and human rights, in particular in women and girls.

Methods The presentation will consider conceptual aspects of mental health in its intersection with human rights and development, with particular reference to women and girls.

Results Current definitions of mental health might be misleading and convey the false expectation that mental health coincides with happiness and productivity. An alternative conceptual framework will be presented, in which mental health is a dynamic state of internal equilibrium that enables individuals to use their abilities in harmony with universal values of society. Different factors concur to the dynamic equilibrium, and will be discussed in their intersection with human rights and development, with particular reference to the most frequent violations of human rights (e.g. trafficking, domestic abuse, sexual violence) that contribute to increase the risk of mental disorders in women and girls.

Conclusion Mental health is rooted in personal development and social context in which the person lives. Strategies aimed to address mental health in women and girls will need to consider gender, country and socio-cultural specificities.

Interventions in the health and non-health sectors aimed at promoting mental health

H. Herrman
 Centre for Youth Mental Health, Orygen, The National Centre of Excellence in Youth Mental Health, and The University of Melbourne, Australia
 Orygen, The National Institute of Excellence in Youth Mental Health, Parkville, Australia

The impact of social determinants on women's mental health is becoming clearer worldwide. Poverty, violence and communal insecurity are among the main challenges to women's mental health and the health of their families. Depression is one of the most common mental disorders experienced by women. It typically has an early onset in life and is more frequently found in women made vulnerable by trauma.

Improving mental health for women and girls requires early intervention for depression and other mental disorders; with gender sensitive clinical care and support for recovery in primary health care, and mother, child and reproductive health settings. Early intervention in primary health care and collaboration with patients and family carers encourage integration of mental health with the health care system, in turn protective of human rights.

In addition, gender equity and observance of human rights need to be embedded in policy and practice in health and non-health sectors to ensure that women's mental health is promoted and mental illnesses adequately prevented and treated. Effective promotion of mental health and prevention of mental disorders is possible in countries of all income levels.

S003

The needs of women users of mental health services and their families

M. Amering
 Department of Psychiatry and Psychothera, Waehringer Guertel 18-20, 1090 Viena, Austria

Aim Understand the needs of women users of mental health services and their families and discuss consequences.

Method Non-systematic review of concepts and data regarding the needs of women users of mental health services and their families.

Results inequity and inefficiency of mental health resources affect men and women all around the globe. Some important mental health needs as well as barriers to care are gender-specific. Women have specific needs in specific phases of life, e.g. the perinatal period, as well as specific risk factors, e.g. interpersonal violence and sexual abuse. Developments of women only services as well as the implementation of gender-specific approaches in routine care are underway and need to be evaluated, amended and expanded. Training as well as research requirements are numerous and urgent. Family carers are an essential mental health resource. A majority is female with significant unmet needs. Family advocacy in mental health is prominently supported by female activists as is the psychiatric user movement. Because of the cumulation and the interaction of gender-based and other forms of discrimination, legislations such as those following the UN-Convention on the rights of persons with disabilities include specific provisions for women and girls with psychosocial disabilities.

Conclusions Mental health stigma and discrimination interact with gender inequality and the discrimination of women and girls to their mental health detriment. Clinical and scientific responsibilities in mental health essentially include gender-specific attention to the needs of women and girls and their families.

Women mental health and trafficking

M. Schouler-Ocak

Psychiatric University Clinic of Charité at St. Hedwig Hospital,
Psychiatry and Psychotherapy, Berlin, Germany

“Trafficking in persons,” “human trafficking,” and “modern slavery” have been used as umbrella terms for the act of recruiting, harboring, transporting, providing, or obtaining a person for compelled labor or commercial sex acts through the use of force, fraud, or coercion. Trafficking in persons is an insult to human dignity and an assault on freedom, and robbing basic human rights (US Report, 2015). Reliable data on trafficking are difficult to obtain owing to its illegal nature; the range and severity of trafficking activities; and variations in how trafficking is defined. It is supposed that 49 per cent of the victims are women, 21 per cent girls, 18 per cent men and 12 per cent boys. 53 per cent were involved in sexual exploitation and 40 per cent in forced labor (UN, 2014).

Research findings show that the limitations of current methodologies affect what is known about human trafficking and health. Moreover, findings demonstrate an urgent need for representative and non-purposive recruitment strategies in future investigations of trafficking and health as well as research on risk and protective factors related to human trafficking and health, intervention effectiveness, long-term health outcomes. The psychological impact of victimization may be more severe than the physical violence. Victims who have been rescued from sexual slavery, typically present with various psychological symptoms and mental illnesses, including the following: Post-Traumatic Stress Disorder (PTSD), depression, anxiety, panic disorder, suicidal ideation, Stockholm syndrome, and substance abuse. In this talk current findings will be presented and discussed.

Comorbidity of mental and physical disorders: A major challenge for medicine in the 21st century

N. Sartorius

Action for Mental Health, Geneva, Switzerland

Demographic changes and successes of medicine in preserving and prolonging life are among the main reasons for the significant increase of comorbidity of mental and physical illness. The simultaneous presence of these disorders leads to a worse prognosis of both types of disorder, significant increases of cost of treatment and heightened mortality.

Although these facts are becoming known among members of the profession and among decision makers in the field of health little is done to provide adequate and timely treatment and care for all the diseases from which a person suffers. The fragmentation of medicine into ever finer and more narrow specialties contributes to the decreasing quality of care for people who have the misfortune of having comorbid mental and physical illnesses as does the stigma of mental illness which decreases the probability of timely help and leads to well documented discrimination of those who have mental illness in health services.

The paper will present some information about comorbidity of mental and physical disorders and suggest reforms of health care that might help to resolve the problems which comorbidity produces.

Exercise Interventions for Improving Mental and Physical Health in Schizophrenia

B. Malchow

Ludwig-Maximilians-University, Department of Psychiatry and Psychotherapy, Munich, Germany

Schizophrenia is a severe mental disorder that carries a high personal and socio-economic burden. Especially negative symptoms and cognitive impairments affect the long-term outcome and are the main contributors to disability. An often underestimated aspect of the disease are somatic comorbidities and the very high mortality rates of those with the disorder. The life expectancy is approximately 20 years below that of the general population and there is evidence that persons with schizophrenia may not have seen the same improvement in life expectancy as the general population during the past decades. Among others, lifestyle factors like sedentary behaviour, unhealthy diet, body weight and tobacco smoking are considered modifiable risk factors contributing to this excess mortality. Exercise interventions may be useful not only in attenuating symptoms of the disease but as well in help reducing risk factors for somatic comorbidities.

S007

The impact of the change trial on physical health in people with schizophrenia

M. Nordentoft^{1,*}, H. Speyer², H.C.B. Norgaard³, M. Birk³, O. Mors³

¹ Hellerup, Denmark

² Mental Health Center Copenhagen, Research Department, Hellerup, Denmark

³ Aarhus University Hospital, Research Department P, Aarhus, Denmark

* Corresponding author.

Life expectancy in patients with schizophrenia is reduced by 20 years for men and 15 years for women compared to the general population. About 60% of the excess mortality is due to physical illnesses, with cardiovascular disease being dominant. The aim of this trial was to improve the cardiovascular risk profile.

Methods The CHANGE trial was an investigator-initiated, randomised, parallel-group, superiority, multi-centre trial with blinded outcome assessment. Patients diagnosed with schizophrenia spectrum disorders and increased waist circumference according (>88 cm for women, >102 cm for men), were recruited and centrally randomised 1:1:1 to 12-months of lifestyle coaching plus care coordination versus care coordination alone versus treatment as usual. The primary outcome was 10-year risk of cardiovascular disease assessed post-treatment and standardised to age 60, secondary outcomes included cardiorespiratory fitness and physical activity. ClinicalTrials.gov NCT01585493.

Findings A total of 428 participants were randomly assigned to the CHANGE intervention ($n = 138$); care coordination ($n = 142$); or treatment as usual ($n = 148$). At 12 months, the mean 10 years risk of cardiovascular disease was 8.4% (SD 6.7) in the CHANGE group, 8.5% (SD 7.5) in the care coordination group and 8.0% (SD 6.5) in the treatment as usual group ($P = 0.41$). We found no intervention effects for any secondary or explorative outcomes, including weight, cardiorespiratory fitness, physical activity, diet or smoking.

Interpretation The CHANGE trial did not support individual lifestyle coaching or care coordination as superior compared with treatment as usual in reducing the cardiovascular risk in patients with schizophrenia and increased waist circumference.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Symposium: From prediction errors to disorders of compulsivity: A computational framework

S008

Elucidating the neural circuitry underlying individual differences in response to reward-associated cues

S. Fligel
USA

Stimuli in the environment that have been associated with reward can gain control over behavior and, in some cases, lead to maladaptive behavior. Reward cues acquire inordinate control when they are attributed with incentive salience or transformed into “motivational magnets” (i.e. incentive stimuli). Individuals vary

considerably in the extent to which they attribute incentive motivational value to reward cues, and we can capture this individual variation using an animal model. When rats are exposed to a Pavlovian conditioning paradigm, in which the presentation of a lever-cue is immediately followed by the delivery of a food reward, some rats preferentially approach the lever (sign-trackers, STs) while others approach the food cup (goal-trackers, GTs). Importantly, while the lever is a predictor for both STs and GTs, only for STs does it become an incentive stimulus. Thus, this model allows us to parse the neurobiological mechanisms underlying predictive vs. incentive learning processes. Using this model, we have demonstrated that dopamine is critical for incentive, but not predictive, learning and that the cortico-thalamic-striatal “motive circuit” is engaged only by incentive stimuli. In addition, we have identified the paraventricular nucleus of the thalamus (PVT) as a central node that differentially regulates sign- and goal-tracking behaviors. We have begun to utilize a chemogenetic approach (i.e. DREADDs) in combination with in vivo microdialysis to further elucidate the neural circuitry underlying individual variation in cue-motivated behaviors. Findings suggesting that STs rely primarily on subcortical mechanisms, whereas GTs utilize more “top-down” cortical processes will be presented and discussed.

A reinforcement-learning account of Tourette syndrome

T. Maia

Faculdade de Medicina-Universidade de Lisboa, Instituto de Medicina Molecular, Lisbon, Portugal

Background Tourette syndrome (TS) has long been thought to involve dopaminergic disturbances, given the effectiveness of antipsychotics in diminishing tics. Molecular-imaging studies have, by and large, confirmed that there are specific alterations in the dopaminergic system in TS. In parallel, multiple lines of evidence have implicated the motor cortico-basal ganglia-thalamo-cortical (CBGTC) loop in TS. Finally, several studies demonstrate that patients with TS exhibit exaggerated habit learning. This talk will present a computational theory of TS that ties together these multiple findings.

Methods The computational theory builds on computational reinforcement-learning models, and more specifically on a recent model of the role of the direct and indirect basal-ganglia pathways in learning from positive and negative outcomes, respectively.

Results A model defined by a small set of equations that characterize the role of dopamine in modulating learning and excitability in the direct and indirect pathways explains, in an integrated way: (1) the role of dopamine in the development of tics; (2) the relation between dopaminergic disturbances, involvement of the motor CBGTC loop, and excessive habit learning in TS; (3) the mechanism of action of antipsychotics in TS; and (4) the psychological and neural mechanisms of action of habit-reversal training, the main behavioral therapy for TS.

Conclusions A simple computational model, thoroughly grounded on computational theory and basic-science findings concerning dopamine and the basal ganglia, provides an integrated, rigorous mathematical explanation for a broad range of empirical findings in TS.

⁴ TU Dresden, Universitätsklinikum Carl Gustav Carus, Dresden, Germany
⁵ ETH Zürich and University of Zürich, Translational Neuromodeling Unit, Zurich, Switzerland
 * Corresponding author.

The mesolimbic dopaminergic system has been implicated in two kinds of reward processing, one in reinforcement learning (e.g. prediction error) and another in incentive salience attribution (e.g. cue-reactivity). Both functions have been implicated in alcohol dependence with the former contributing to the persistence of chronic alcohol intake despite severe negative consequences and the latter playing a crucial role in cue-induced craving and relapse. The bicentric study “Learning in alcohol dependence (LeAD)” aims to bridge a gap between these processes by investigating reinforcement learning mechanisms and the influence that Pavlovian cues exert over behavior. We here demonstrate that alcohol dependent subjects show alterations in goal-directed, model-based reinforcement learning (Sebold et al., 2014) and demonstrate that prospective relapsing patients show reductions in the medial prefrontal cortex activation during goal-directed control. Moreover we show that in alcohol dependent patients compared to healthy controls, Pavlovian cues exert pronounced control over behavior (Garbusow et al., 2016). Again, prospective relapsing patients showed increased Nucleus accumbens activation during these cue-induced responses. These findings point to an important role of the mesolimbic dopaminergic system as a predictor of treatment outcome in alcohol dependence.

Symposium: Assisted suicide: An issue for old age psychiatry?

S011

Euthanasia, physician assisted suicide in the Netherlands in dementia and late life psychiatric illness

M. Stek
 The Netherlands

Background Although controversial in many countries, in The Netherlands euthanasia or physician assisted death has increased in patients with early stages of dementia, psychiatric illness and in conditions described as ‘being tired of life’ in the oldest old. There is a strong debate about this practice in the community and among professionals often with exclamation marks ranging from medical murder to providing ultimate care.

Objective To provide figures, describe current practice and debate in The Netherlands with regard to capacity evaluation in older psychiatric patients and end of life questions.

Methods Review of literature, case reports and own experience in the past decade.

Result and conclusion There are few studies on the important issue of capacity making in psychiatric patients. The research that was performed does not show that a high threshold of capacity is required for granting euthanasia. Research on physician-assisted death in early dementia is scarce. With regard to end of life questions the debate in The Netherlands is still ongoing.

Suicide and assisted suicide in Switzerland: Consequences for suicide prevention

G. Stoppe
 MentAge, Basel, Switzerland

As in other countries, in Switzerland, the rate of suicide is highest in the elderly. Assisted suicide is allowed and mostly exerted by private organizations like EXIT. The number of assisted suicide cases has doubled during the last five years and is expected to increase. It is mainly committed by women. In the age group 80+ y the number is higher than the number of suicides. To reduce the number of suicides by 25% by 2030, the federal authorities have issued a national action plan in November 2016. It includes preventive means like reduction of access to methods (weapons, drugs), construction of bridges and buildings, education of lays and professionals and specific treatment of those who have attempted suicide. There has been a position paper of Swiss public health concerning suicide prevention in the elderly. Both papers will be presented and discussed.

Concerning assisted suicide there is a broad discussion on the control of the state and on the role of physicians in the process. A survey of Swiss physicians showed much ambivalence. Position papers of gerontological and geriatric societies focused on the role loneliness and the provision of adequate psychiatric help, e.g. for depression, and the overestimation of autonomy.

Disclosure of interest The author has not supplied his declaration of competing interest.

Mental health and social care providers facing requests of assisted suicide from elderly in nursing homes in Switzerland

D.A. Castelli Dransart^{1,*}, S. Voélin², S. Elena¹
¹ University of Applied Sciences and Arts Western Switzerland-School of Social Work Fribourg, Research and Development, Givisiez, Switzerland

² University of Applied Sciences and Arts Western Switzerland-School of Social Work Geneva, Research, Geneva, Switzerland

* Corresponding author.

Introduction In some Swiss states, right-to-die associations are allowed to assist older people in nursing homes provided that certain requirements are fulfilled.

Objectives To investigate how health and social care providers and their institutions reacted to and dealt with requests of assisted suicide.

Method An exploratory qualitative study was carried out in the States of Fribourg and Vaud among 40 professionals working in nursing homes, home care services or social welfare agencies.

Results The requests of assisted suicide questioned the professional mission, the quality of accompaniment provided to the older people and both professional and personal values. Health and social

care providers were required to ponder over ethical dilemmas or decisions. Several challenges were reported, such as: taking into account and articulating personal freedom or needs with collective functioning or organizational constraints before, during and after the assisted suicide; reconciling self-determination with protection towards vulnerable people (beneficere, non maleficere).

Conclusions Assisted suicide challenges and changes professional end-of-life practices. Education and support should be provided to health and social care providers faced with it.

Symposium: Is it possible to prevent Alzheimer's disease?

S014

Setting the scene: The evidence for pre-clinical change, projections of the impact of intervention, and implications for public health

T.C. Russ^{1,*}, K. Ritchie³, G.M. Terrera², C.W. Ritchie¹

¹ Centre for Dementia Prevention, University of Edinburgh, Edinburgh, United Kingdom

² Inserm, Montpellier, France

³ Department of Psychology, University of Victoria, Canada

Alzheimer's disease has long been considered a neurodegenerative disorder of late life for which there is currently no disease-modifying treatment. This view is now being revised as increasing evidence suggests a long pre-clinical phase extending back into mid-life during which there is exposure to multiple potentially reversible risk factors. Further thought is now being given to the possibility of both early life intervention programs and development of new drug treatments focusing on the pre-dementia period. But how can the impact of such treatments be measured at this early stage since overt dementia may not be diagnosed for decades? In the four talks in this symposium, we will discuss evidence for pre-clinical change, theoretical models which have been used to project the possible impact of risk factor modification in mid-life and their integration into a future public health strategies. The development of new statistical risk models to determine the impact of such prevention measures will be outlined. We will consider the possibilities for drug development targeting the pre-clinical period before presenting the PREVENT Project and EPAD (<http://ep-ad.org/>), a multi-million euro IMI-Horizon 2020 funded project for the development of pre-clinical proof of concept trials. Titles of the four presentations: 1. Setting the scene: the evidence for pre-clinical change, projections of the impact of intervention, and implications for public health (TCR) 2. New statistical risk models for determining the impact of prevention measures in the pre-dementia period (GMT) 3. The PREVENT Study: a prospective cohort study to identify mid-life biomarkers of late-onset Alzheimer's disease (KR) 4. The European Prevention of Alzheimer's Dementia (EPAD) Project: developing interventions for the secondary prevention of Alzheimer's dementia (CWR)

Symposium: Upscaling mental healthcare - Implementing guidance and mental health care recommendations in Europe

S015

How can guidance recommendations contribute to better mental health?

W. Gaebel

Heinrich-Heine-Universität, Düsseldorf, Germany

Introduction In European countries, the quality of mental healthcare services is often limited due to scarce and inequitable distributed resources, and inefficient use of existing resources. Against this background, the EPA Guidance provides recommendations on how to optimize quality of mental healthcare for all European countries.

Objectives Provision of guidance recommendations in order to support optimization and harmonization of mental healthcare services in European countries.

Methods By means of evidence and consensus-based methods EPA guidance papers are developed by experts in psychiatry and related fields [1].

Results As of 2012, five EPA guidance series have been developed and published [2]. They focus on various aspects of mental healthcare and clinical situations that have not been covered by medical guidelines yet but are considered important to deliver high quality mental healthcare. Papers deal amongst others with topics relating to quality assurance of mental health services, as quality of mental health service structures and processes, and building trust in mental health services.

Conclusions EPA guidance recommendations can improve mental healthcare provision and thereby contribute to better mental health of persons receiving mental healthcare. For this purpose, recommendations need to be widely disseminated and implemented in European countries.

Implementation of EPA guidance - One way for all countries?

M.M. Carrasco

Instituto de Investigaciones Psiquiátricas, Spain

The European Psychiatric Association (EPA) guidance project launched in 2008 has the aim of providing European psychiatry with guidance in topics, which are relevant for European mental health care. Guidance from a European perspective can be favorable against the background of a growing sense of Europe and the desirable associated harmonization on all levels of health care policy.

More precisely, the mission of the EPA guidance is defined as 'to improve quality of mental health care in Europe by disseminating written information based on best evidence and psychiatric practice, to facilitate countries learning from each other'.

In consonance with this need of a wider multinational perspective of European psychiatry, EPA adopted in 2012 through a deep change of its statutes a new membership structure that allows National Psychiatric Societies/Associations (NPAs) in Europe the possibility to become full members of EPA. Up to 40 NPAs corresponding to 37 countries and representing over 80.000 psychiatrists have responded positively to the offer and are now part of the Council of National Psychiatric Societies, the body within EPA that integrates them.

The Council of NPAs has become, in this way, a forum for its members to meet, discuss and work on issues concerning European psychiatry. One of the major issues is about the implementation of European guidance in mental health policy, teaching and learning psychiatry, best clinical practice in different areas, and quality indicators. This presentation provides further details on how participating societies could put these policies and recommendations into practice.

Symposium: The natural history of bipolar disorders: from the age of onset to the long-term course

S017

How long is the interval between the onset and the initial management of bipolar disorder? A meta-analysis

G. De Girolamo^{1,*}, G. Signorini², J. Dagani², F. Faustini²

¹ Saint John of God Clinical Research Center, Psychiatric Epidemiology and Evaluation Unit, Brescia, Italy

² IRCCS St John of God Clinical Research Centre, UOPEV, Brescia, Italy

Objective To evaluate the length of the interval between the onset and the initial management of bipolar disorder (BD).

Method We conducted a meta-analysis using the preferred reporting items for systematic reviews and meta-analyses guidelines. Systematic searches located studies reporting estimates of the age of onset (AOO) and indicators of the age at initial management of BD. We calculated a pooled estimate of the interval between AOO and age at management. Factors influencing between-study heterogeneity were investigated using sensitivity analyses, meta-regression, and multiple meta-regression.

Results Twenty-seven studies, reporting 51 samples and a total of 9415 patients, met the inclusion criteria. The pooled estimate for the interval between the onset of BD and its management was 5–8 years (standardized difference, .53; 95% confidence interval, .45 to .62). There was very high between-sample heterogeneity (I^2 ¼ 92.6; Q ¼ 672). A longer interval was found in studies that defined the onset according to the first episode (compared to onset of symptoms or illness) and defined management as age at diagnosis (rather than first treatment or first hospitalization). A longer interval was reported among more recently published studies, among studies that used a systematic method to establish the chronology of illness, among studies with a smaller proportion of bipolar I patients, and among studies with an earlier mean AOO.

Conclusions There is currently little consistency in the way researchers report the AOO and initial management of BD.

However, the large interval between onset and management of BD presents an opportunity for earlier intervention.

Cognitive impairment in bipolar: Neurodevelopmental or neuroprogressive?

A. Young

Institute of Psychiatry, Psychology and Ne, London, United Kingdom

Background Bipolar Disorders (BD) are common and complex diseases. Recent findings have provided evidence that impairments in cognition are evident in the various sub-groups of Bipolar Disorder and persist after resolution of acute episodes.

Method An opinion paper based on a narrative review of the field.

Results Quantifiable cognitive deficits are clearly found in Bipolar 1 and Bipolar 2 Disorders. These persist after recovery from acute episodes. The aetiopathogenesis of these phenomena is likely to be multifactorial. It seems clear that these cognitive impairments are not in general neurodevelopmental and for most are related to repeated episodes of illness [1]. However, the issues of sub-groups with differential profiles of impairment and the trajectory of cognitive change remain to be fully established. The effects of putative treatments (e.g., pharmacological, neurostimulation, cognitive remediation) are at an early stage of evaluation.

Conclusions Future efforts should focus on further integrating the current and emerging research findings into a coherent model, which generates testable hypotheses and allows treatment effects to be tested.

Impact of age at onset on the long-term course of bipolar disorder

R. Kupka

VU University Medical Center, psychiatry, Amsterdam, The Netherlands

Introduction Bipolar disorder (BD) typically starts in adolescence or young adulthood (early-onset; EO-BD), which may have different backgrounds and consequences than late-onset (LO) BD. There are controversies over pre-pubertal age of onset (AoO).

Objectives To give an overview of the various concepts of AoO in BD, the impact of AoO on subsequent illness course, and findings of the Stanley Foundation Bipolar Network (SFBN) with relationship to AoO.

Methods literature review and additional analyses of SFBN database.

Results BD usually begins with a depressive episode. SFBN-data reveal that an earlier AoO is associated with a less favourable prospective illness course (more depression, mood instability and rapid cycling), longer delay to first treatment, past history of suicide attempts, being abused in childhood abuse, more psychiatric and medical comorbidities. Comparison of the US sample with the European sample of SFBN showed an earlier onset in US patients.

Conclusion and early AoF of BD is associated with a poorer long-term outcome, despite adequate current treatment.

Age at the onset of a first episode of psychotic mania: Does it have an impact on outcome?

P. Conus^{1,*}, S.M. Cotton², P.D. McGorry²

¹ Lausanne University, Department of Psychiatry, Prilly, Switzerland

² Orygen Youth Health, Psychiatry, Melbourne, Australia

* Corresponding author.

Purpose Studies conducted in child psychiatry suggest that patients with earlier onset of psychosis have poorer outcome. Similar findings have been published regarding onset of bipolar disorder. However, few studies have been conducted in youth mental health program where these patients may actually receive treatment. Identification of subgroups with distinct need and outcome among first episode mania patients would facilitate the development of specific treatment strategies better suited to the actual needs of patients.

Methods Sixty-seven patients with a first episode of psychotic mania were followed up over 12 months after recovery from this initial episode. Syndromic and symptomatic outcome were determined with the brief psychiatric rating scale, functional outcome with the quality of life scale and premorbid adjustment scale sub items.

Results While 90% of patients achieved syndromic recovery (disappearance of manic syndrome) at 6 and 12 months, 40% had not recovered symptomatically, still presenting with depression and anxiety. Return to previous level of functioning was achieved only by 34% of patients at 6 months and 39% at 12 months. Age at the time of first manic episode with psychotic features was a significant predictor of recovery of functional level.

Conclusions While manic symptoms reduce quickly in most patients after a first episode of psychotic mania, an important number of patients still display symptoms of depression and anxiety after 12 months and 2/3 do not reach functional recovery. Younger age at first episode predicts risk of poorer functional outcome.

Symposium: Negative symptoms: phenomenology, clinical aspects and neuroimaging

S021

Clinical psychopathology of negative symptoms: A phenomenological perspective

A. Raballo

University of Oslo, Norwegian Centre for Mental Disorder Research NORMENT, Oslo, Norway

Negative symptoms encompass a broad constellation of psycho-behavioral phenomena, including affective flattening, poverty of speech, alogia, avolition, social withdrawal, apathy and anhedonia. These phenomena obviously exert a substantial impact on personal autonomy, quality of life and broad functional outcomes, ultimately being an important challenge for clinical decision-making and therapeutic support. In recent years, the attention to negative symptoms in schizophrenia has revamped, boosting the development of new rating tools as well as a broader conceptualization of derivative constructs (e.g. apathy, amotivation, anhedonia). However, despite its behavioral expressivity, the in-depth phenotypic characterization of negative symptoms remains partly unaddressed. Similarly, their clinical intertwining with other non-productive clinical features (e.g. anomalous subjective experiences, cognitive-perceptual basic symptoms and schizotypal features) is generally overlooked. Therefore, the current presentation specifically offers a stratified overview of the phenomenology of negative symptoms filtered through lens of clinical psychopathology.

Disclosure of interest The author has not supplied his declaration of competing interest.

S022

The Evolution of negative symptom constructs

A. Mucci*, S. Galderisi

University of Campania "Luigi Vanvitelli", Department of Psychiatry, Naples, Italy

* Corresponding author.

Introduction Negative symptoms represent a separate dimension of schizophrenia psychopathology, distinct from positive symptoms, disorganization and cognitive impairment. It is increasingly acknowledged that negative symptoms are associated with poor functional outcome and represent an unmet need in schizophrenia treatment. Improvement in definition of their phenomenology, assessment instruments and experimental models are needed in order to improve schizophrenia prognosis.

Aims The presentation will review key aspects of the evolution of negative symptom constructs. In particular, findings concerning phenomenology, clinical assessment, association with functional outcome and brain imaging correlates will be presented.

Methods We searched PubMed for English full-text publications with the keywords

Schizophrenia AND "negative symptoms"/"primary negative symptoms"/"deficit schizophrenia"/"persistent negative symptoms"/"affective flattening"/alogia/"expressive deficit"/apathy/asociality/"social withdrawal"/anhedonia/"anticipatory anhedonia"/avolition/neuroimaging.

Results The distinction between secondary negative symptoms (i.e., those due to identifiable factors, such as drug effects, psychotic symptoms or depression), and primary or persistent negative symptoms (i.e., those etiologically related to the core pathophysiology of schizophrenia) is grounded on solid research evidence and might have major implications for both treatment development and clinical care. The evidence that negative symptoms cluster in motivation- and expressive-related domains is founded on large consensus and empirical evidence and will foster pathophysiological modeling. The motivation-related domain is a stronger predictor of functional outcome than the expressive one.

Conclusions An improved definition and assessment of negative symptoms needs to translate in large-scale studies to advance knowledge. In the short-term, the improved identification of treatable causes of secondary negative symptoms can translate into better care for people with schizophrenia.

Progressive brain changes associated with persistent negative symptoms following a first episode of psychosis

M. Lepage^{1,*}, M. Carolina², B. Michael¹, C. Mallar¹, J. Ridha¹, M. Ashok¹

¹ McGill University, Psychiatry, Montreal, Canada

² McGill University, integrated program in Neuroscience, Montreal, Canada

* Corresponding author.

Early persistent negative symptoms (ePNS) refer to the presence of potentially idiopathic or primary negative symptoms and have been observed following a first episode of psychosis (FEP). There is evidence for cortical changes associated with ePNS and given that a FEP often occurs during a period of ongoing brain development and maturation, neuroanatomical changes may have a specific age related component. The current study examined cortical thickness (CT), hippocampal/amygdala volume and shape as a function of clinical trajectories and age using longitudinal structural imaging in FEP. T1-MRI scans were acquired for early ($n=21$), secondary ($n=30$), non- ($n=44$) PNS patients with a FEP, and controls ($n=44$). Cortical thickness and amygdalar-hippocampal volumes and surface area (SA) metrics were extracted from three time points over a two-year period. Linear mixed models were applied to test for a main effect of group, and age group interactions. Relative to the other groups, ePNS patients showed cortical thinning over time in temporal regions and a thickening with age primarily in prefrontal areas. They also exhibited reduced left amygdalar and right hippocampal volumes. Morphometry revealed decreased surface area in ePNS compared to other groups in left central amygdala. The current study demonstrates that FEP patients with ePNS show significantly different CT trajectories with age. Increased CT may be indicative of disruptions in cortical maturation processes within higher-order brain regions. Amygdalar-hippocampal changes with age are also linked to ePNS with converging results from volumetric and morphometric analyses. Taken together, these results could represent dynamic endophenotypes setting these ePNS patients apart from their non-symptomatic peers.

Symposium: New avenues in the management of bipolar disorder

S024

Mania and depression: What's new?

A. Fagiolini^{1,*}, G. Amodeo²

¹ University of Siena, School of Medicine, Siena, Italy

² University of Siena, Molecular Medicine, Siena, Italy

* Corresponding author.

Despite the high burden of bipolar disorder and the noticeable progress in its treatment, the disorder still goes frequently mis-

diagnosed, unrecognized, or not optimally treated. To date, no medication has been specifically developed on the basis of a precise understanding of the pathophysiology of the disorder, or based on the unique characteristics of several subtypes of bipolar disorder or on the medication mechanism of action. Lithium remains one of the gold standard treatments for bipolar disorder. Its mood-stabilizing properties are thought to occur via specific cellular signaling pathways, such as inhibition of glycogen synthase kinase 3, which is considered to regulate cellular apoptosis. Divalproex, carbamazepine and several atypical antipsychotics are also approved for bipolar disease. Evidence also suggests that antipsychotics show the ability to treat and prevent mania and/or depression but are often burdened by side effects such as sedation, orthostatic hypotension and weight gain. Hence, while it is clear that there still are several unmet needs especially for what pertains tolerability, efficacy for specific subtypes, and predictability. Novel and more effective treatments are needed and researchers are currently engaging in targeted drug development for bipolar illness, aimed at improving pharmacological strategies with marked and sustained effects. A variety of newer medications are being tested. Some of these drugs target pathways that are similar to those targeted by lithium, while others focus on newer targets, such as opiate receptor and N-methyl-D-aspartate (NMDA) receptors. Newer and older treatment strategies for bipolar disorder will be presented and critically reviewed.

The role of long acting antipsychotics in bipolar disorder

E. Vieta

Hospital Clinic de Barcelona, Psychiatry Bipolar Disorders Program, Barcelona, Spain

Antipsychotics are widely used for the short and long-term treatment of bipolar disorder. Depot and long-acting injectable formulations (LAIs) can be particularly useful for certain subgroups of patients. This lecture will discuss the available data from randomized controlled trials of LAIs in bipolar disorder. A recently published meta-analysis and individual studies assessing depot medications, as well as modern LAIs such as risperidone, paliperidone and aripiprazole, will be reviewed, looking carefully into the prevention of either pole of illness and tolerability. Potential indications and patient profile, based on data and clinical experience, will be discussed.

Disclosure of interest The author has not supplied his declaration of competing interest.

S026

Managing cognitive dysfunction in bipolar disorder

K. Miskowiak

University Hospital of Copenhagen, Psychiatric Centre, Copenhagen, Denmark

Cognitive dysfunction, including memory and concentration difficulty, is an emerging treatment target in bipolar disorder. However, a key challenge in the management of these cognitive deficits is the lack of treatments with robust effects on cognition. Further, it is unclear how cognitive dysfunction should be assessed and addressed in the clinical treatment of the disorder. This talk will review the evidence for cognitive impairment in bipolar disorder, including its severity, persistence and impact on patients'

functional recovery. It will then discuss when and how to assess cognition and present some new feasible screening tools for cognitive dysfunction. Finally, it will highlight some novel candidate cognition treatments.

Disclosure of interest I have acted as a consultant and received honoraria from Lundbeck and Allergan.

Symposium: Human based psychiatry: from theory to practice

S027

Evidence-based medicine - A critical review

W. Gaebe

Heinrich-Heine-Universität Düsseldorf, Germany

Evidence-based medicine is a method to establish best practice recommendations based on graded recommendations for diagnostic and therapeutic issues in health care. In mental healthcare, evidence-based medicine has shown that the therapeutic procedures are efficient and can help to not only ameliorate the symptoms of mental disorders, but also to improve the quality of life of those affected by mental disorders. Evidence-based medicine is not, however, cookbook medicine. While evidence is mostly generated in larger group trials and should be applicable to the majority of cases, aspects of the personal situation, social support systems and legal boundaries all affect mental healthcare and may modulate the interpretation of the findings of evidence-based medicine. A human-based psychiatry will therefore need to use the methods of evidence-based medicine as a basis for diagnostic and therapeutic recommendations, but will also need to extend into the acknowledgements of personal accounts, traditions and the cultural framework, in which mental healthcare is provided. This presentation will highlight some of the issues associated with the questions of the roles of evidence-based medicine in mental healthcare, and in a human-based approach towards mental healthcare.

Theoretical background of human based psychiatry

M. Musalek

Anton Proksch Institute, Gräfin Zichy Straße 4–6, 1230 Vienna, Austria

Every medical intervention is embedded in the prevailing spirit of its particular time. The world of modern medicine that is still shaped by positivism is often revered as a world of rational calculation and reason, a world in which mathematical calculation and so-called objectivity are prized above all else. Indeed, today's modern medicine in general and its battlewagon evidence-based medicine is a world of sober number games, reduction and fragmentation, of demystification and de-subjectification. As important and indispensable the achievements of EbM are, it nevertheless

needs to be expanded by a medicine, which focuses not just on illness and its treatment but which places the concrete individual with all his or her sufferings and potentials. Such a human-based medicine (HbM) is no longer indebted to modern positivism, but seeks its foundations in the maxims of post-modernism. Moving away from classical "indication-based medicine" toward a medicine based on human sufferings and potentials necessarily requires a fundamental change in diagnostics and treatment.

S029

Human based psychiatry in clinical practice

L. Küey (Associate Professor of Psychiatry)

World Psychiatric Association

Human based medicine and human based psychiatry are contemporary approaches to the theory and practice of medicine and psychiatry. It is a post-modern way of re-thinking psychiatry enriched by humanities, especially philosophy. In questioning the current research and praxis of psychiatry, it shares the statement by Wittgenstein, "what a curious attitude scientists have": 'We still don't know that; but it is knowable and it is only a matter of time before we get to know it as if that went without saying. So, here, our problematic is not only 'what and how much we do' but also 'how and why we do'. The clinician's main challenge is harmonizing the current available 'scientific universal knowledge' and the 'uniqueness' of that specific person in need of help. In achieving this task, the importance of the synthesis of the clinician's perspective and patient's perspective will be elaborated using depression as a case example. It will be stated that an empathetic understanding of depression, through a subjective, experiential and narrative-centered approach must become a primary concern by building a joint, ongoing, re-construction process of clinical assessment, formulation and treatment. There is no meta-theory explaining "the clinical truth". From the perspective of a human based psychiatric practice, in fact, we do not need such a meta-theory, but instead, we need multi-level/multi-dimensional approaches, also taking the narrative into consideration. We suggest the clinicians to be modest, honest and respectful towards "the clinical truth".

Current hot topics in working with service users and family carers towards a human based psychiatry

M. Amering

Department of Psychiatry and Psychothera, Waehringer Guertel 18-20, 1090 Viena, Austria

Context The significant role of family as a resource for mental health, psychiatric care and recovery and rehabilitation is well documented. However, despite ongoing family advocacy the situation in most settings is still characterized by significant unmet needs and lack of resources and expertise in working with families.

Key messages This presentation will highlight pertinent issues and present data, concepts and experiences towards an improvement of partnership work with users of services and their families in a human based context.

Topics will include the needs of specific types of relatives, such as siblings, children, partners, grandparents, members of the peer group of friends as well as the need for support for families without patient consent. Recent developments with regard to individual

and group therapy as well as multilevel interventions to further family advocacy and the fight against stigma and discrimination will be presented and discussed.

Special attention will be given to new roles and responsibilities arising from the historical challenge of the UN-Convention on the Rights of persons with disabilities for mental health professionals, users of services as well as relatives and friends including changes in national guardianship laws, new rights to patient autonomy as well as new entitlements for support for living in the community including the right to family life, reasonable accommodation and supported decision-making.

Conclusion Current developments with regard to needs and rights of users of services and their families and friends urgently warrant attention and common efforts in Trialogue and other participatory approaches.

Symposium: When forensic-psychiatric care becomes a matter of culture: Challenges of trans-cultural psychiatry in forensic settings

S031

Working with traumatized immigrants with a PTSD diagnosis

I.T. Graef-Calliess

Sehnde/Hannover, Germany

Graef-Calliess Iris (Germany).

Germany has always been an important host country for asylum seekers. Although recently an increasing number of investigations about mental health of specific migrant groups have been published in Germany, there is a paucity of research concerning mental health of traumatized asylum seekers. The aim of the presentation is to present study results which describe socio-demographics, types and frequency of traumatic experiences, psychiatric diagnoses, suicidality and time to access to mental health care in traumatized asylum seekers who applied to an outpatient department of a clinical center with high expertise in transcultural psychiatry and psychotherapy in Hannover, Germany. The study shows that most of the traumatized asylum seekers had experienced multiple pre-migratory traumatic events, had unfavorable post-migratory conditions, had PTSD and depressive disorders as diagnoses, and had high suicidality and late access to mental health care. This is indicative of the mental health situation of asylum seekers in Germany in general. Ways of dealing with this challenge for the mental health care system and options for clinical management will be presented.

Pathways to violent extremism and risk assessment of terror detainees

T. Marquant

CAPRI, forensic psychiatry, Antwerp, Belgium

Introduction Violent extremism has become an important challenge for forensic professionals in prisons. In Belgium, cities like Brussels and Antwerp saw the rise of recruitment hotspots for violent extremism and foreign fighters. Prisons are well-known places

where radicalization occurs. Belgium has the most foreign fighters that left to fight in Syria in Europe. Subsequently, incarcerations of radicalized men and women rose for joining terrorists groups. These events have triggered a need to train psychosocial services in prisons into understanding radicalization and the risk assessment of terror detainees. Mental illness in contrast, is known to be rare amongst violent extremists, and risk assessment as well as advising on reintegration will need specific tools for psychosocial services to advise on reintegration.

Aims The current presentation aims at showing insight into pathways towards violent extremism and introduce risk assessment of terror detainees.

Methods We assembled literature on follow-up and pathways that lead to radicalization and even to violence extremism. Radicalization is not new, whether it stems from religious, political or other motives. This resulted in important literature on different trajectories towards radicalization.

Results We will give an overview of the pathways towards violent extremism (Dean, Moghaddan, Bjorgo) and on risk assessment tools (VERA-2, Pressman)

Conclusions Radicalization happens stepwise in different ways and leads to different types of violent extremists. Pivotal points follow a cognitive opening in the minds of people that might push and pull people towards radicalization and violence. Cases will be used to describe the different types and pathways.

Role of detention in the process of radicalization

N. Verbeeck

Psychiatric Centre St Amandus, Forensic Institute DEviant Sexuality FIDES, Beernem, Belgium

Role of detention in the process of radicalization and opinions about detention regime and approach for the prevention of radicalization in jail.

Following the terrorist attacks in Paris and Brussels, more attention is being paid to the factors, which play a role in the radicalization process of some Western youth. It was found that a large number of radicalized youth have a history of detention and that often this period of detention played a key role in radicalization. As a psychiatrist working in a prison with a high security department where many suspects of terrorism are incarcerated stay, I was asked to advise on the detention regime and on the way of dealing with difficult inmates. In this presentation I would like to elaborate on the elements during detention which determine the process of radicalization of certain prisoners, based on the current knowledge about the radicalization process and on the knowledge about the background of radicalized individuals in combination with own observations and findings about the detention regime in prisons.

Symposium: The role of the telomere-telomerase system in psychiatric disorders and treatments: Underlying mechanisms linking mental illness with cellular aging

S034

Telomere length and depressive and anxiety disorders: Longitudinal associations and underlying mechanisms

B. Penninx*, J. Verhoeven

VU University Medical Center, Psychiatry, Amsterdam, The Netherlands

* Corresponding author.

Many psychiatric disorders have been associated with increased risk of mortality and various aging-related somatic diseases. In addition to unhealthy lifestyles, also various stress-related physiological processes likely play a role in explaining these detrimental health consequences of psychiatric disorders. The impact could be visible at the cellular level, with psychiatric patients presenting more signals of physiological aging for instance as determined by measuring telomere length. In this talk we will first highlight the current state-of-the-art evidence that various psychiatric conditions, including e.g. depression, anxiety and PTSD, are associated with shorter telomere length. Second, we will provide results from the Netherlands Study of depression and anxiety ($n = 2981$) that tested longitudinal associations using 6 year data on psychiatric status and telomere length. These results indicate that the association between depressive and anxiety disorders with telomere length is stable over time, and doesn't show many dynamic associations. Finally, in the same study we have also tested to what extent lifestyle and dysregulations of physiological stress systems such as the immune, HPA-axis and autonomic nervous systems are partly responsible for the observed shorter telomere length in depressed or anxious patients. Results indicate that especially smoking behavior and systemic inflammation partly contribute to the shorter telomere length, but can't completely explain found associations.

In sum, this talk will highlight the current state-of-evidence for an association between various psychiatric conditions with shorter telomere length, and will provide insights into its dynamics and its contributing mechanisms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The role of telomeres and telomerase in the clinical effect and mechanism of action of psychopharmacological interventions

F.S. Bersani

Sapienza University of Rome, Department of Neurology and Psychiatry, Roma, Italy

Originally studied in relation to aging and cancer research, telomeres and telomerase are now also investigated in relation to psychiatric disorders and treatments. Based on findings emerging from clinical and preclinical data, we hypothesize that the telomere-telomerase system represents a novel element mediating the mechanism of action of certain psychopharmacological interventions.

In this symposium I'll present the preliminary evidence on the complex translational relationships between specific psychiatric

medications (i.e. antidepressants, lithium and antipsychotics), the telomere-telomerase system and clinical outcomes. The modulation of intracellular Wnt/b-catenin or PI3 K/Akt signaling pathways, the interaction with BDNF and 5-HT, and the antioxidant properties could represent possible mechanisms by which the different types of psychiatric medications could modulate telomere length and telomerase activity. The potential of the telomere-telomerase system in promoting cellular survival and/or function in the brain and in the periphery could, in turn, represent a neurobiological substrate through which these molecules can mediate the therapeutic effect of such interventions.

Further, in the present symposium I'll show data from our research team on telomere length and telomerase activity in leukocytes predicting clinical response to serotonin-specific reuptake inhibitors (SSRIs) in subjects with major depressive disorder.

Evidence of accelerated biological ageing in post-traumatic stress disorder

D. Lindqvist

Lund, Sweden

Post-traumatic stress disorder (PTSD) is a common and debilitating condition, affecting between 10–20% of soldiers returning from combat zones, and with even higher prevalence rates in Veterans Affairs healthcare settings. PTSD is associated with an increased risk for various medical illnesses, many of which are commonly seen with older age. This raises the possibility that PTSD is associated with accelerated biological aging at the cellular level. Accelerated biological aging occurs when biological age outpaces chronological age, and this process is driven by a number of biological mechanisms including immune activation, oxidative stress, and mitochondrial dysfunction.

In this workshop I will present data from our research group and others pertaining to the biological mechanisms underlying accelerated cellular aging in PTSD. Most, but not all, studies have found that PTSD is associated with shorter mean leukocyte telomere length, an indicator of accelerated cellular aging. Mitochondrial dysfunction has been implicated in PTSD and our research group found evidence of a “u-shaped” relationship between PTSD symptom severity and mitochondrial DNA copy number. For what concerns immunity, we have recently found that PTSD subjects have increased blood levels of pro-inflammatory markers, a more senescent and dysfunctional profile of NK cells and impaired synthesis of nitric oxide. Finally, I will discuss the possibility of accelerated *epigenetic* aging in combat-exposed individuals with and without PTSD, using DNA methylation data.

E-mail address: linda.booij@concordia.ca (L. Booij)

Background Exposure to early life adversity (ELA) has been identified as a major risk factor in the development of major depressive disorder (MDD). It is hypothesized that a mediating mechanism may be environmentally induced alterations in gene function. In our REDEEM (Research in depression: endocrinology, epigenetics and neuroimaging) project we are examining possible epigenetic difference in some previously investigated target genes relevant to depression. To this end, methylation of the following genes were measured: NR3C1 (HPA axis), SLC6A4 (serotonin neurotransmitter function), and CD3ε (T cell receptor gene). We also looked at possible trans-generational transmission of epigenetic markers in a mother-baby sample.

Methods DNA was isolated from depressed patients and controls and babies and a portion of the above genes, encompassing our regions of interest, were amplified by PCR. Percentage methylation levels were measured by pyrosequencing. mRNA was also measured for some gene products to see if function was related to methylation. HPA axis function was measured with serial saliva samples throughout the day.

Results to date: Methylation was increased in the CD3ε promoter in depressed subjects relative to controls. In the total group, those exposed to ELA had significantly increased methylation at this site. Levels of CD3ε mRNA levels were inversely related to methylation. There were some relationships between maternal ELA and baby methylation at the sites examined.

Conclusions Consistent with an allostatic model of ELA damage, our findings suggest an alteration in epigenetic function in acquired

immunity and the HPA axis, mediated by ELA. Findings will be discussed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Stress and the serotonergic system, observations from pet imaging

M. Spies*, R. Lanzenberger

Medical university of Vienna, department of psychiatry and psychotherapy, Vienna, Austria

* Corresponding author.

Introduction Stress response and the neuroendocrinologic factors through which it is mediated are disturbed in anxiety and in affective disorders. While acute stress is thought to result in hypothalamus-pituitary-adrenal- (HPA) axis hyperactivity (Varghese 2001), chronic stress may result in decreased HPA-response (Booij 2013). Antidepressant treatment, on the other hand, is thought to realign HPA-axis activity (Schüle 2007).

On the other hand, dysregulation within the serotonergic neurotransmitter system is understood as a central moderator in the pathophysiology of affective and anxiety disorders. Serotonergic transmission both regulates- and is regulated by- glucocorticoids. Cortisol results in an increase in serotonin synthesis and release while serotonergic transmission is thought to downregulate HPA-axis activity (Lanfumeijer, 2008). Positron emission tomography (PET) studies have demonstrated the link between the serotonergic system and the HPA-axis in humans in vivo. For example, a negative correlation between cortisol and 5HT_{1A} receptor levels in various brain regions has been shown (Lanzenberger, 2010). SERT expression, on the other hand, was shown using PET to be positively related to HPA-axis reactivity (Frokjaer 2013).

Methods n.a.

Aims Available literature on interactions between the HPA-axis and the serotonergic system will be discussed with a focus on data acquired via PET studies.

Results n.a.

Conclusions The interaction between the serotonergic system and the HPA-axis is likely bilateral and may be understood as a neurobiological link by which stress may foster the development of depression and anxiety.

* Corresponding author.

Introduction Major depressive disorder (MDD) is a common psychiatric condition, affecting up to 350 million people worldwide. Its pathogenesis seems to involve dysregulation of the hypothalamic-pituitary (HPA) axis and inflammation as key elements of the condition. Stressful life events and in particular early life adversity seem to play an important role as risk factors for MDD. Epigenetic, which has been found to impact in the transcription of genes, seem to be associated with brain structure and function. Aim of the research was to provide an overview about neuroimaging (epi)-genetics in MDD.

Methods Functional MRI, epigenetic and genetic information was obtained in a cohort of patients with MDD and healthy controls. Associations between, early life adversity, methylation of FKBP5 and SLC6A4, genetic variants and brain function and connectivity have been analysed.

Results Higher methylation of SLC6A4 gene was associated with higher BOLD response during emotion processing and lower BOLD response during higher order cognitive processes. Healthy participants with higher SLC6A4 methylation involved prefrontal cortical regions to a greater extent than the participants with lower SLC6A4 methylation, when trying to switch attention away from negative emotional stimuli (Frodl et al., 2015). Moreover, FKBP5 methylation was association with HPA axis functioning and amygdala brain function in patients with MDD. FKBP5 methylation also was related to grey matter volume.

Conclusions Our study provides further support to the hypothesis that DNA methylation plays a role. Particular peripheral DNA methylation states of MDD candidate genes are associated with brain function during emotion processing in patients with MDD.

Disadvantage of social sensitivity: interaction of oxytocin receptor genotype and child maltreatment on brain structure

U. Dannlowski

University of Münster, department of psychiatry, Münster, Germany

Background Oxytocin has received much attention as a pro-social and anxiolytic neuropeptide. In human studies, the G-allele of a common variant (rs53576) in the oxytocin receptor gene (*OXTR*) has been associated with protective properties such as reduced stress response and higher receptiveness for social support. In contrast, recent studies suggest a detrimental role of the rs53576 G-allele in the context of childhood maltreatment. To further elucidate the role of *OXTR*, gene by maltreatment (G×E) interactions on brain structure and function were investigated.

Methods *n*=309 healthy participants genotyped for *OXTR* rs53576 underwent structural as well as functional MRI during a common emotional face-matching task. Childhood maltreatment was assessed with the Childhood Trauma Questionnaire (CTQ). Gray matter volumes were investigated by means of voxel-based morphometry (VBM) across the entire brain.

Results Structural MRI data revealed a strong interaction of rs53576 genotype and CTQ-scores, mapping specifically to the bilateral ventral striatum. GG homozygotes but not A-allele carriers showed strong gray matter reduction with increasing CTQ-scores. In turn, lower ventral striatum gray matter volumes were associated with lower reward dependence, a pro-social trait. Furthermore, the G-allele was associated with increased amygdala responsiveness to emotional facial expressions.

Conclusions The findings suggest that the G-allele constitutes a vulnerability factor for specific alterations of limbic brain structure in individuals with adverse childhood experiences, complemented by increased limbic responsiveness to emotional interpersonal

stimuli. While oxytocinergic signalling facilitates attachment and bonding in supportive social environments, this attunement for social cues may turn disadvantageous under early adverse conditions.

Symposium: using technology to respond to the mental health needs of refugees in europe: mobile devices, telemedicine, and outcomes management

S042

The use of a telemedicine model and its logistics to reach as many european refugees as possible

D. Mucic

The little Prince psychiatry centre, Copenhagen, Denmark

Current refugee crisis challenges mental health care systems all over the Europe. There is a number of research describing difficulties in dealing with cross-cultural patients. Access to relevant care as well as its availability are often limited due to: a) lack of respective qualified resources b) linguistically, cultural and even racial barriers in addressing of mental health care needs of cross-cultural patient population. By use of various e-Mental health applications, primarily videoconference, we may improve assessment and/or treatment of refugees and asylum seekers on distance e.g. Arabic speaking psychiatrist located in Sweden would be able to assess and/or treat refugees from Syria located in Germany). Specialized centers for treatment of refugees would also be able to get second-opinion service from remote experts and use it in order to confirm or re-consider diagnosis as well as the treatment options. Establishment of international network of cross-cultural experts enables to:

- Improve the mental health care across national boundaries by providing psychiatric consultations to other countries within EU
- Conduct International Treatment Team with Select Skills (e.g. Sign Language and Many Foreign Languages Staff)
- Provide Distance Supervision and Staff Consultation
- Provide Psycho Education of caregivers
- Improve Distance Learning via Case Conferencing and Best Practice Demonstration Across the National Boundaries
- Create Data Base over cross-cultural and other select skills professionals within EU

Preliminary results of USA-European field trial on the use of patient-reported measures in a mobile application and potential uses in refugee populations

W. Narrow^{1,*}, V. Buwalda², J. McIntyre³

¹ *University of New Mexico, psychiatry and behavioral sciences, Albuquerque, USA*

² *Vrije universiteit, psychiatry, Amsterdam, The Netherlands*

³ *University of Rochester medical center, psychiatry, Rochester, USA*

* *Corresponding author.*

Introduction The use of patient-reported outcome measures in psychiatric practices in the United States is still in its beginning phases. More research is needed to determine the usefulness of such measures and the optimal methods to present them to patients and practitioners in routine care settings.

Objectives This presentation will describe the research plan for testing a group of patient-reported outcome measures using digital applications. Potential opportunities for use in underserved refugee populations will be presented.

Methods The outcome measures were selected from those recommended in DSM-5 Section III, including cross-cutting symptom and disability measures. A user-friendly digital application was developed for data collection, synthesis, and presentation. The research plan has three phases: focus groups with patients and clinicians, piloting of methods, and the main study, a pragmatic trial comparing treatment outcomes using outcome measurement versus usual care.

Results Results of the focus group sessions will be presented, along with changes made to the measures and the digital application in response to these results. Current status of the research project will be discussed.

Conclusions The results of this research project will bring greater clarity to questions on the role of outcome measurements in improving quality of care and patient outcomes. With ever greater use of smart phones, tablets, and personal computers, digital technology has the potential to facilitate psychiatric assessment and treatment for underserved, difficult-to-reach populations such as refugees.

Symposium: psychiatric care in Europe for people with intellectual disabilities: how to prevent abusive practices

S044

Mental health and social care regulation in Ireland: New ethical perspectives

P. Dodd

St. Michael's House/university college Dublin, psychiatry, Dublin, Ireland

This talk will outline the regulatory framework (both mental health and social care) currently in place in Ireland for people with intellectual disability (I.D.) and mental health problems, in the context of the varied nature of available mental health services. As not all aspects of service are currently under the regulatory system, potential ethical issues arise, and will be discussed.

In addition new legislation regarding the support of people with vulnerable decision making capacity will be outlined (Assisted Decision Making (Capacity) Act, 2015); potential ethical issues that are currently arising from this legislation will be explored and discussed.

Disclosure of interest The author has not supplied his declaration of competing interest.

Can positive community practice models help prevent abuse?

I. Hall^{1,*}, N. O'Kane²

¹ East London NHS foundation trust, community learning disability service, London, United Kingdom

² Camden and Islington NHS foundation trust, camden learning disability service, London, United Kingdom

* Corresponding author.

All different types of abuse can happen to people with intellectual disabilities living in community setting. This can include physical abuse, including the use of restrictive practices, financial abuse by strangers but also by family and carers. They can also be victim to sexual abuse. Neglect is a relatively common concern, which is perhaps more likely in the community compared to institutional settings.

In this presentation we will discuss the fundamental balancing act between paternalism and autonomy that is so often an issue when supporting people with intellectual disabilities in the community, and how to decide where to draw the line in individual cases. We will consider a range of examples to illustrate this, including unlawful deprivation of liberty, people choosing life partners that others regard as unsuitable, why families might restrict access to services, and whether giving people more control over their care through direct payments and individual budgets can lead to financial exploitation.

Finally we will discuss potential solutions to preventing abuse including robust Safeguarding procedures, integrated working between health and social services, a program of Positive Behavioral Support, maximizing communication, promoting access to health and the recognition of mental health problems, how to disseminate training, and the importance of advocacy and regular review.

Symposium: impulsivity, compulsivity, and behavioural addictions

S046

Common neural networks between ocd and behavioural addictions: Is ocd a behavioral addiction?

G. Grassi^{1,*}, S. Pallanti²

¹ University of Florence, Neurofarba, Florence, Italy

² University of Florence, Neurofarba, Florence, Italy

* Corresponding author.

The stereotypical portrait of an obsessive-compulsive patient is an excessively self-controlled, risk averse individual that acts in order to avoid potential loss or punishments. Although this portrait fits well with several clinical studies showing increased harm-avoidance in obsessive-compulsive disorder (OCD), more recent clinical, neuropsychological and neuroimaging studies challenged this idea and described a different portrait of OCD, showing several commonalities between OCD and addictions such as impulsivity, reward dysfunction and impaired decision-making. The results of these studies conflict with the stereotypical OCD portrait of doubtfulness and risk-aversiveness. In fact, these findings are prototypical for addiction and have led some authors in the last years to view OCD as a behavioral addiction. In our recently published article, we investigated the behavioral addiction model of

obsessive (OCD), by assessing three core dimensions of addiction in patients with OCD and healthy participants. Similar to the common findings in addiction, OCD patients demonstrated increased impulsivity, risky decision-making, and biased probabilistic reasoning compared to healthy controls. During the presentation we will discuss the behavioral addiction model of OCD by focusing on common neuropsychological and neurobiological circuitries.

Pharmacological management of impulsivity and compulsivity

G. Dom

Antwerp university ua and hospital uza, collaborative psychiatric research institute, Boechout, Belgium

Increasingly patients present themselves to psychiatrists and other care providers with a specific request for treatment of one or more behavioral addictions. From a pathogenic point of view impulsivity and compulsivity are important drivers of these behavioral disorders, and as such may represent a target of pharmacological and broader neurobiological, e.g. Neuro-stimulation, treatment. Although currently treatment as usual has a focus on psychosocial and cognitive behavioral interventions, interest is growing toward the pharmacological interventions. In the presentation a state of the art will be presented regarding the pharmacological treatment of behavioral addictions, with a focus on Gambling Disorder and Gaming Disorder.

Disclosure of interest Member Advisory Board Lundbeck - Belgium.

Received funding from Belgian LOTTO for research into Cognitive Behavioral Therapy for Gambling Disorder.

⁶ *Institut of neuropsychiatry and addictions- Parc de Salut Mar, mental health, Barcelona, Spain*

* Corresponding author.

A new computerized CPG for Major Depression (e-CPG-MD) was integrated in electronic medical records of primary care in a 7 million population in Catalonia (Spain). An integrated design allows precise access in each patient visit, improving diagnosis, treatment and follow-up. It facilitates an evaluation of suicide risk in depressed patients.

Objective To evaluate the effects of a multifactor process of implementation of the e-CPG MD, analyzing its use and the key clinical outcomes.

Methods A cluster randomized clinical trial was performed in 10 primary care centers (PCC) in Barcelona. In five of ten centers a multifaceted implementation process of the e-CPG-MD was developed during 6 month. The others five PCCs received only an usual diffusion. The multifaceted process includes an establishment of local implementation teams, an interactive training program, regular feedback audits, educational outreach visits and periodic reminders.

Results At six month, a greater proportion of new MD patients from active PCCs were included in the e-CPG-DEP (4.1% + 3.1% vs. 52.7% + 7.3%, $p < 0.001$); the incidence of MD diagnostics of Major Depression increased significantly (rate quotient = 1.56, $p < 0.001$) and the proportion of cases with moderate and severe MD too (13.6% vs 41.1%, $p = 0.002$).

Conclusions A multifaceted implementation method of an e-CPG-MD increased significantly its uses, the registered incidence of MD and improved the capacity of recognizing severity. Further analysis is necessary in order to determine the impact on clinical outcomes.

Internet based interventions and patient generated bio- and self-monitoring data: How to use them for self-management in affective disorders

U. Hegerl^{1,*}, C. Sander², N. Koburger²

¹ *Universitätsklinikum Leipzig, department of psychiatry and psychotherapy, Leipzig, Germany*

² *German depression foundation, german depression foundation, Leipzig, Germany*

* Corresponding author.

Even in developed countries only a small minority of patients with depression and bipolar disorders receives treatment according to guidelines and the treatment gaps are especially pronounced concerning psychotherapy.

A variety of digital and internet based interventions have been developed mainly building on the principles of Cognitive Behavioral Therapy (CBT). A quite consistent finding is superiority compared to control groups with largest effect sizes when compared to waiting list controls, however the evidence provided by such studies is questionable. More support for efficacy is provided by studies showing a comparable efficacy compared to face-to-face CBT, however sufficiently powered non-inferiority studies compared to antidepressants or face-to-face therapy are needed. Such studies are necessary for deciding whether digital intervention should be integrated in the health care system mainly as a self-management tool or as an alternative to regular treatment with psychotherapy or pharmacotherapy.

A dynamic new area of research explores the value for self-management and treatment decision of longitudinal data generated by the patient via self-ratings, wearables and other biosensors as well as the pattern of smartphone use. Within the BMBF-funded study STEADY a platform will be developed which allows the individual patient to securely store and integrate these data and to analyze them using analytic tools involving time series analyses. An overview will be given of similar approaches started in the last years within mental health.

Disclosure of interest Within the last three years, Prof. Hegerl was an advisory board member for Lundbeck, Takeda Pharmaceuticals, Servier and Otsuka Pharma a consultant for Bayer Pharma and a speaker for Medice Arzneimittel, Novartis and Roche Pharma.

The NYMPHA-MD project: Next generation mobile platforms for health, in mental disorders

M. Faurholt-Jepsen

*Rigshospitalet - Copenhagen university hospital, psychiatric center
Copenhagen, Copenhagen, Denmark*

Bipolar Disorder is a common and complex mental disorder with a prevalence of 1-2% and accounts as one of the most important causes of disability at age 15-44 years worldwide.

Electronic versions of self-monitoring tools and symptom registration using computers, personal digital assistants (PDAs), text messages, and web interfaces have been described in the literature and a large number of commercial Smartphone applications for patients with bipolar disorder are available.

The Next Generation Mobile Platforms for Health, in Mental Disorders project (the NYMPHA-MD project), funded by the European Union's Seventh Framework program for research, technological development and demonstration, focuses on the implementation of a Pre-Commercial Procurement of mobile e-health service for supporting physicians and patients in the treatment of bipolar disorder through continuous patients monitoring in order to dynamically support illness management and potentially identify early warning signs.

The NYMPHA-MD project will define the framework of a Pre-Commercial Procurement for the provisioning of next generation services advocated for mental health treatment with a special focus on bipolar disorder based on the use of new technologies, open standards and open platforms.

The NYMPHA-MD project will focus on identifying requirements involved in the structuring of mental health services with a focus on bipolar disorder treatment including medical, technological, patients, legal, ethical, policy, risk management and business-orientation needs in order to construct a reference model of service provisioning useful in different European contexts.

Neuropersonaltrainer-mh: A new computerized platform for the cognitive remediation in schizophrenia and bipolar disorders

N. Cardoner^{1,*}, A. Cebria², C. Lopez-Sola², M. Serra-Blasco¹, C. Massons², V. Muriel¹, G. Navarra¹, E. Via¹, J. Cobo², X. Golberg¹

¹ *Institut de Recerca Parc Taulí- I3PT, mental health, Sabadell, Spain*

² *Consorti Hospitalari Parc Taulí-I3PT, mental health, Sabadell, Spain*

* *Corresponding author.*

Schizophrenia and mood disorders -including unipolar depression and bipolar disorder-, are severe mental diseases with a highly heterogeneous symptomatology, among which cognitive dysfunction has progressively emerged as a key cornerstone. Patients suffering from these illnesses show significant deficits in different neurocognitive and social cognition domains. These deficits are evident during acute episodes, and in a high percentage of patients persist in periods of recovery, playing a decisive role on functional and clinical outcome. Nowadays, different pharmacological therapies have been tested, obtaining non-conclusive results. In this context, non-pharmacological strategies, such as neurocognitive remediation, have emerged as promising therapeutic intervention. Neurocognitive remediation comprises a program to rehabilitate cognitively impaired subjects, aiming either to restore their

cognitive functioning or to compensate them in specific cognitive domains. One evolving approach, beginning to receive attention for its initial promising results, is computerized cognitive training. This technique employs tasks or games that exercise a particular brain function which target specific neural networks in order to improve cognitive functioning through neuroplasticity in a given neural circuit. In this scenario, we report our recent results with neuropersonaltrainer[®]-MH; a module for neurocognitive remediation consisting in a computerized telerehabilitation platform that enables cognitive remediation programs to be carried out in an intensive and personalized manner. Our group has applied NPTMH[®] in a pilot study treating patients with early onset psychotic disorder with positive and promising results, involving an improvement in functionality, neurocognition, and social cognition performance. Furthermore, new trials in bipolar disorder and major depressive disorder have been recently started.

Symposium: shame and guilt in clinical practice

S052

Shame & guilt: Definitions, antecedents and structure of experience

F. Oyebo

University of Birmingham, Birmingham, United Kingdom

Aims In this lecture I will define and distinguish between shame and guilt. I will then discuss the potential causes of shame and guilt and how these emotions manifest in behavioral and phenomenal terms. I will conclude by introducing a classification that deals with the varieties and nature of the pathologies of shame and guilt that are evident in clinical practice. I will rely on concepts developed by Karl Jaspers, Hans Jonas and Bernhard Schlink. In doing this I will be exploring the role of moral and juridical principles upon the experience of shame and guilt including the place of the imperatives of responsibility upon the experience of shame and guilt. I will argue further that shame and guilt are as important as other secondary emotions such as envy and jealousy but are not as examined and studied in clinical practice. I will make a case for the centrality of these emotions to an understanding of and response to particular clinical conditions in daily practice.

Methods N/A.

Results N/A.

Conclusions Shame and Guilt are both important emotions that are central to our understanding of and response to particular conditions in daily practice. Their antecedents and structure provide a basis for distinguishing between them.

Shame and guilt in mental disorders - diagnostics and treatment

L. Madeira

Faculdade de medicina - universidade de lisboa, psychiatry, Lisbon, Portugal

Guilt and shame are important human emotions, which have been studied by several different disciplines. Seminal and recent inputs in Psychology (particularly Psychoanalysis) and Psychiatry are

briefly reviewed including cross-cultural considerations and developmental psychology studies on these emotions. Yet this keynote focuses in the phenomenology and epistemology of guilt and shame as complex emotions. This includes considering that guilt is experienced in two moments (decompressed into a moment of negligence and another of guilt) while shame only in one moment (prolonged in a “frozen now”). All the inputs have suggested an operationalization of epistemic and phenomenonic differences considering their context, formal object, particular object and action tendency. Lastly it refers to the relation of these experiences with psychopathology and nosology concerning their adaptive and maladaptive nature, their relation with empathy as well as their presence in several disorders such as anxious, depressive and obsessive compulsive sorts.

S054

Shame and guilt inducing drugs

G. DiPetra

Neuropsychiatrist- addiction center consultant, department of mental health, Naples, Italy

The Author in this presentation examines the role of two complex human experiences, the Guilt and the Shame, in the field of the substances addiction. The population of abuser can be divided between users of sedatives and users of stimulants. Sedative drugs and stimulant drug belong to two different way of being-in-the-world. Sedative drugs are able to medicate the internal pain, which is constitutive of the guilt. Stimulant drugs are able to medicate the dysphoria, which is constitutive of the shame. In the realm of psychopathology Tellenbach with the concept of premelancholic personality in the guilty man and Kohut with the concept of narcissism in the tragic man have put the bases for a different typification. In both cases, the common final result, from a psychopathological point of view, is a severe crisis of the temporalization.

Symposium: Challenges in Europe: refugees and asylum seeker patients in mental health

S055

Suicidal behaviour among asylum seekers in the Netherlands; prevalence, background and prevention

C.J. Laban

GGZDrenthe, De Evenaar- North Netherlands centre for transcultural psychiatry, Beilen/Leeuwarden, The Netherlands

Background Problems of asylum seekers are multiple and complex. Having experienced pre migration adversities, they face multiple post-migration living problems in the host country. In clinical practice suicidal ideations and suicidal behavior often occurs.

Objectives/aims To increase knowledge and give directions for preventive measures related to suicidal behavior among asylum seekers.

Method Literature, related to the subject, is summarized.

Results In this presentation the context of the reception of asylum seekers is explained. Data will be shown on suicides and suicidal

attempts among asylum seekers, in comparison with the Dutch population and with international data. Moreover an overview of qualitative and quantitative research findings will be shown on the many risk factors asylum seekers experience: traumatic experiences, loss, mental health problems, poor living conditions, fear to be expelled, uncertain future and post migration living problems. Attention will be given to the situation of imprisoned undocumented migrants in The Netherlands. Hobfoll's theory of the Conservation of Resources will be used to explain the increased risk for suicidal behavior and suicide among asylum seekers and undocumented migrants. Prevention strategies contain cooperation to decrease the risk factors, enhance the protective factors, early detection of signals, and good access to mental health care.

Conclusion Asylum seekers encounter many risk factors for suicidal behavior and suicide. The impossibility to get control over their lives and the lack of resources of resilience needs to be recognized as important risk factors. There is a need for cooperation between all professionals and volunteers to change this situation.

How to deal with growing racism and discrimination against refugees and asylum seekers in Europe?

L. Küey

Associate professor of psychiatry world, psychiatric association, Istanbul, Turkey

The growing number of refugees and asylum seekers pouring in Europe due to wars and armed conflicts constitute a great challenge for psychiatry and the mental health field. This challenge also includes the growing racism and discrimination against refugees and asylum seekers. Discrimination could be defined as the attitudes and behavior based on the group differences. Any group acknowledged and proclaimed as ‘the other’ by prevailing *zeitgeist* and dominant social powers, and further dehumanized may become the subject of discrimination. In a spectrum from dislike and micro-aggression to overt violence towards the other, it exists almost in all societies in varying degrees and forms; all forms involving some practices of exclusion and rejection. Hence, almost all the same specific human physical and psychosocial characteristics that constitute the bases for in-group identities and reference systems could also become the foundations of discrimination towards the humans identified as out-groups. Added to this, othering, rising from imagined and generalized differences and used to distinguish groups of people as separate from the norm reinforces and maintains discrimination.

Albeit the widespread exercise of discrimination against refugees and asylum seekers, peoples and mental health professionals also have a long history of aiming and practicing more inclusive ways of solving conflicts of interests between in-groups and out-groups. This presentation will mainly focus on the psychosocial aspects of the anti-discriminative efforts and search an agenda for the European Psychiatry in this regard.

Disclosure of interest The author has not supplied his declaration of competing interest.

Action plan of the WPA: Action plan which follows the objectives of the association relating to refugees and asylum seekers

D. Bhugra

Institute of psychiatry, psychology & Ne, London, United Kingdom

Recent mass movement of human beings in various parts of the world has brought several challenges. Not only refugees from Syria and Libya to Europe but also refugees, migrants and asylum seekers in Latin America bring specific set of issues with them. It is critical that clinicians are aware of both the vulnerability of individuals to mental ill health as a result of migratory experiences but equally importantly their resilience. The impact on the mental health of those who may be involved directly or indirectly in delivering care along with those new communities who receive these groups need to be taken into account when planning and delivering psychiatric services. It is essential to recognize that experiences of being a refugee or asylum seeker are heterogeneous. Being an asylum seeker carries with it legal definitions and legal imperatives agreed at international levels.

Policymakers and clinicians need to be aware of differential rates of psychiatric disorders in these vulnerable individuals and specific needs related to language, religious values and other cultural factors. Mental health problems may be related to experiencing cultural bereavement where individuals feel that they have lost their cultures, relationships and cultural values. Judicious and careful use of trained culture brokers and mediators should be encouraged as these individuals can inform the team about community needs and inform the community about the team functioning and its principles so that community expectations can be managed appropriately. Such approaches may also help reduce stigma against mental illness.

Symposium: Child maltreatment and unfavourable clinical outcome

S058

Prevalence and consequences of bullying: What could healthcare services do for intervention?

D. Wolke

University of Warwick, department of psychology, Coventry, United Kingdom

Bullying is the systematic abuse of power and defined as aggressive behavior or *intentional harm doing* by peers that is carried out repeatedly, and involves an imbalance of power between the victim and the bully. One in 3 children report having been bullied at some point in their lives, and 10 - 14% experience chronic bullying lasting for more than six months.

Longitudinal research indicates that children who were victims of bullying are at higher risk for common somatic problems, internalizing problems and anxiety or depression disorder, psychotic symptoms and are at highly increased risk to self-harm or think about suicide in adolescence [1]. The mental health problems of victims and bully/victims remain in adulthood. Indeed, we showed that peer bullying in childhood has more adverse effects on diagnosed anxiety and depression disorders than being physically or sexually abused or neglected by parents. Victims also report to have more trouble with making or keeping friends in adulthood and were less likely to live with a partner and have social support. In contrast, bullies had no increased risk for any mental or general health problems, were healthier than their peers, emotionally and physically.

Sadly, many bullied children suffer in silence. To prevent dropping out of school, violence against oneself (e.g. self-harm) and reduce

mental and somatic health problems, it is imperative for health practitioners, families and schools to address bullying.

Adolescent mental health outcomes of early adversities: Not a simple story

A. Oldehinkel

University medical center Groningen, psychiatry, Groningen, The Netherlands

Introduction Living creatures are shaped by their experiences in a constant process of adaptation. These experiences accumulate and so their relative weight diminishes across the lifespan. In children, the relative weight of new experience is high, and children's developing brains are programmed to learn like in no other life phase. Early adversities can thus have a major impact on later mental and physical health outcomes. However, the nature of impact of exposure to adversities early in life on further development is less straightforward than it may seem at first sight.

Objectives In this presentation, I will address and illustrate a couple of issues that manifest the complexity of this association.

Methods The data will come from TRAILS (Tracking Adolescents' Individual Lives Survey), a longitudinal study on the development of mental health from preadolescence into young adulthood, with bi- or triennial assessments from age 11 onwards, for a period of over fifteen years.

Results Results from various analyses indicate that early adversities do not lead to unfavorable outcomes in every person, and that the consequences of early adversities depend on their timing.

Conclusions The experiences that individuals encounter during development are incorporated in a continuous process of adaptation that shapes them and keeps on doing throughout life. Considering the complexity and individuality of these processes, it is inevitable that research findings are often heterogeneous, and effect sizes small.

Disclosure of interest The author has not supplied his declaration of competing interest.

Pathological gambling, impulse control disorder or behavioural addiction: What do the data indicate?

K. Mann^{1,*}, T. Leménager², F. Kiefer², M. Fauth-Bühler²

¹ Central institute of mental health, university of Heidelberg, Mannheim, Germany

² Central institute of mental health, department of addictive behavior & addiction medicine, Mannheim, Germany

* Corresponding author.

Objective The reclassification of PG as an addictive disorder is under debate for ICD-11. Data on psychiatric comorbidity and family history might provide the basis for a well-informed decision.

Methods We compared 515 male pathological gamblers from inpatient treatment units with 269 matched controls. Patients were diagnosed by experienced clinicians. In a random sample of 58 patients clinical diagnoses were validated through SKID 1 interviews [1].

Results 88% had a comorbid diagnosis of substance dependence (nicotine dependence 80%, alcohol dependence 28%). Only 1% of the gamblers had an impulse control disorder diagnosis. Compared with controls first degree relatives were more likely to suffer from alcohol dependence (27.0% vs. 7.4%), PG (8.3% vs. 0.7%) and suicide attempts (2.7% vs. 0.4%).

Conclusions In addition to recent papers on the neurobiology (Fauth-Bühler et al., 2016) and genetics of gambling [2,3], our findings support the classification of PG as behavioural addiction in the ICD-11 [4].

Neurobiological mechanisms of problem gambling and treatment

A. Goudriaan*, R. van Holst, T. van Timmeren

University of Amsterdam- academic medical center, academic medical center, Amsterdam, The Netherlands

* Corresponding author.

Background and aims In the past decade, neurobiological research on pathological gambling has flourished. Based on neurobiological similarities between pathological gambling and substance use disorders and similarities in genetics, diagnostic criteria, and effective treatments, pathological gambling was the first behavioral addiction to be included in the DSM-5 within the revised category Substance-related and addictive disorders.

In this presentation novel findings from gambling research in our research group focusing on the role of impulsivity, anticipation towards monetary outcomes, and the interaction between stress and cue reactivity will be presented, with a focus on new functional MRI results. An overview will be given on the concepts of impulsivity and compulsivity in pathological gambling and relevant neurocognitive and neuroimaging findings. Implications of neurobiological research for novel intervention research, such as in neuromodulation studies and personalized medicine will be highlighted.

Keywords pathological gambling; gambling disorder; impulsivity; compulsivity; neuroimaging; craving

Background Internet gaming disorder appears to be associated with self-concept deficits and increased identification with one's avatar. For increased social network use, the few existing studies suggest striatal-related positive social feedback as an underlying factor. Furthermore, few study findings indicate that internet addicts generally have problems in emotional inhibitory control processing.

Methods Pathological and addicted internet gamers as well as social network users were compared with healthy controls regarding psychometric and neurobiological measures of self-concept-related characteristics, avatar identification and emotional inhibitory control processing.

Results and conclusion Psychometric results indicated that both subgroups showed higher self-concept deficits compared to healthy controls. Neurobiologically, different brain activation patterns were observed in the subgroups during self-knowledge retrieval and inhibition of emotional stimuli. Furthermore, addicted internet gamers showed a higher identification with the own avatar, mirrored in an increased left angular gyrus activation, a region functionally associated with identification processing and feelings of empathy.

These findings provide a starting point for the deduction of specific psychotherapeutic treatment approaches for addicted internet gamers and social network users.

Mobile phone addiction: Evidence from empirical research

D. Kuss

Nottingham Trent university, psychology, Nottingham, United Kingdom

Introduction Recent technological innovations have led to a proliferation of mobile and smartphones, which have become the cornerstone of modern societies in the 21st Century in terms of communication, notifications and entertainment. Latest research however suggests that with the advantages offered by mobile technologies, smartphone use today may have a significant impact on mental health and well being. Overuse has been associated with stress, anxiety, depression and addiction.

Objectives This talk aims to highlight results of current mobile phone addiction research.

Aims To replicate and extend earlier research with regards to psychopathology (depression, anxiety and stress), mobile phone use and age on problematic mobile phone use and addiction.

Methods Individuals aged 16 and above participated in an online study that contained a pool of validated psychometric measures. Data were analyzed using Structural Equation Modeling.

Results Calls per day, time spent on the phone and using social media significantly predicted prohibited and dependent mobile phone use, whereas stress predicted dependent use only. Anxiety and depression did not significantly predict problematic mobile phone use. Findings also revealed that problematic mobile phone use is prevalent across all ages and both genders.

Conclusions The current results have implications for addiction to using mobile phones, and suggest teachers, parents and affected individuals may benefit from awareness and prevention efforts, respectively.

This talk is based on Kuss, D.J. et al. (2016). Problematic mobile phone use and addiction: The roles of psychopathology, mobile phone use and age. Under review, and was funded by the British Academy and NTU.

In the last two decades, both early detection (ED) and early intervention (EI) programs and services have gradually become important and innovative components of contemporary mental health care. However, it is unclear whether ED/EI programs have consistently been implemented throughout Europe.

Here, we report results of the EPA Survey on ED/EI Programs in Europe in 2016.

A 16 item questionnaire was sent to representatives (presidents and secretariats) of 40 EPA National Societies/Associations (NPAs), representing 37 countries. The representatives were also invited to recommend a person for additional information about ED/EI services/programs in the country.

The response rate was 59.4% (22 NPAs). Fifteen out of 28 NPAs were from developed, and 7 out of 8 from economies in transition. ED/EI services have been implemented in 54.5% of the included countries, mean duration 10.0 ± 4.9 yrs. Mostly, neither ED were separated from EI, not the adults from adolescents. National plans to develop ED/EI were reported in four countries. Although national guidelines for schizophrenia exist in most of the countries (73.9%), specific chapters focusing on ED/EI and/or at-risk mental states were not included in the majority of them. Duration of untreated psychosis was unknown in 63.6%. In those who gave the estimation it was 12–100 weeks (median in weeks: 33 developed economies; 44 economies in transition).

The fields of ED/EI have been unequally developed across Europe. Still, many NPAs are without the development plans. EPA and its Sections should address the identified gaps and suggest how to harmonize services for the full range of assessments and interventions.

Diagnostic procedures for prediction of psychosis - Achievements and challenges

A. Raballo

University of Oslo, Norwegian centre for mental disorder research Norment, Oslo, Norway

Individualized prognostic predictions in people at clinical high risk are crucial to tailor suitable interventions and personalized prevention. Furthermore, in recent years, the synergy between fast-pace technical sophistication in neuroscience (e.g. neuroimaging and neurophysiological) and novel bio-statistical tools (e.g. machine learning algorithms) has accelerated the development of more inclusive predictive models and magnified the potential for such individualized risk stratification enriching classical psychopathological tools. However, the clinical translation of such research insights is still circumscribed and, despite incremental optimization of assessment tools, increasingly accepted criteria to characterize at risk mental states and tumultuous advance in the field, the prediction of psychosis at such individual level remains a not fully accomplished target.

Disclosure of interest The author has not supplied his declaration of competing interest.

S066

Intervention in clinical high risk states - Current status and future perspectives

S. Ruhrmann

University of Cologne, department of psychiatry and psychotherapy, Cologne, Germany

Introduction During the last twenty years, international efforts advanced the prevention of psychosis considerably. However, improved predictions as well as well-tolerated and needs-tailored interventions are still required.

Objectives Prediction and Prevention of Psychosis

Aims Presenting the current state and new developments, including the European Union funded multi-center project PRONIA with regard to prediction (www.pronia.eu, 7th Framework Programme grant agreement n° 602152) and the German multi-center trial ESPRIT funded by the Federal Ministry of Education and Research (BMBF grants 01EE1407C and 01EE1407I) with regard to prevention.

Methods Results of meta-analyses will be presented and discussed with regard to achievements and challenges. Possible advances by current projects will be discussed.

Results Pharmacological as well as psychological prevention has been shown to reduce the incidence rate of psychosis in the respective samples considerably. However, particularly social and role functioning, which are prognostically most important, are still an unsolved challenge. Furthermore, new interventions providing an improved tolerability and acceptance by the patients are required. On the level of prediction, a further improvement of predictive validity, particularly with regard to individualized risk estimation is desired.

Conclusions The achievements in the field of prevention of psychosis are impressive, but further progress is needed. This should be achieved by studies like PRONIA, which aims at improving risk estimation by an advanced assessment concept as well as a sophisticated data analysis, and ESPRIT, which compares the effects of N-Acetylcysteine with an innovative, modular psychological

prevention program focusing not only stress and symptom management, but also social cognitive domains.

Intervention in early psychosis - Current status and future perspectives

S. Galderisi*, D. Pietrafesa, D. Palumbo
University of Campania "Luigi Vanvitelli", department of psychiatry, Naples, Italy

* Corresponding author.

Introduction The delay between psychosis onset and initiation of treatment (duration of untreated psychosis, DUP) is associated with a poorer treatment response and overall functional outcome. In Europe several early detection and intervention programs have been developed to reduce the DUP and promote Phase-specific Treatments (PsTs).

Aims To review the evidence of a) the effectiveness of European Early Interventions (EELs) in reducing DUP; b) an impact of PsTs on clinical and social outcomes; and c) EELs cost-effectiveness.

Methods A literature search in PubMed, PsychInfo, Cochrane and individual journals through cross-referencing was performed. All European Randomized Controlled Trials (RCTs) designed to reduce DUP and/or to implement PsTs for people with first-episode psychosis were included in the review.

Results Studies examining early detection programs compared with Standard Care (SC) reported discrepant findings as to their impact on the DUP. PsTs generally reduce hospitalizations and improve service engagement when compared with SC; their impact on other clinical variables, e.g. symptomatology and social functioning, is unclear. Studies assessing EELs cost-effectiveness in comparison with SC consistently report an advantage for EELs in the long run.

Conclusions EELs, as compared to SC, show several advantages that seem to result in an overall reduction in the cost of care. Therefore, the development of EEI is recommended.

On the other hand, some inconsistencies in the reported results suggest that EELs should include psychosocial interventions targeting unmet needs of schizophrenia patients, such as cognitive dysfunction and negative symptoms.

Symposium: Childhood trauma across psychopathology: mediators and outcome in clinical samples and molecular mechanistic correlates

S068

Childhood trauma in bipolar disorders: Familial and individual mediators for predicting occurrence and outcome

B. Etain
University Paris Diderot, psychiatry and addictology, Paris, France

Childhood trauma is highly prevalent in patients with bipolar disorder (BD) and has been associated to a more severe/complex expression of the disorder. Little is known about the familial and individual factors that can mediate the occurrence of trauma within families but also influence the outcomes of BD. We will present data from two independent samples of patients with BD in order to identify the potential mediators for occurrence and severity/complexity. In a first sample of 371 patients with BD, 256 relatives and 157 healthy controls, we will show that there is a familial resemblance for emotional and physical abuses. Patients' level of physical abuse was associated with their parental levels of physical abuse, but also with their father's history of alcohol misuse ($p < 0.05$). Second, in a sub-sample of 270 normothymic patients, we have performed a path-analysis to demonstrate that emotional and physical abuses interacted with cannabis misuse to increase the frequency of psychotic features and delusional beliefs. Finally, in an independent sample of 485 euthymic patients from the FACE-BD cohort we used path-analytic models to show that emotional abuse increased all the assessed affective/impulsive dimensions ($p < 0.001$). In turn, affect intensity and attitudinal hostility were associated with high risk for suicide attempts ($p < 0.001$), whereas impulsivity was associated with a higher risk for presence of substance misuse ($p < 0.001$). These results illustrate that childhood trauma might derive from parental characteristics (own childhood trauma and psychopathology) and increase the severity/complexity of BD through individual dimensions of psychopathology.

S069

Childhood trauma and structural and functional brain mechanisms linked to psychopathology

M. Aas
Oslo university hospital, Norment- KG Jebsen center for psychosis research- division of mental health and addiction, Oslo, Norway

Background Childhood trauma increases the risk of a range of mental disorders including psychosis. Whereas the mechanisms are unclear, previous evidence has implicated atypical processing of emotions among the core cognitive models, in particular suggesting altered attentional allocation towards negative stimuli and an increased negativity bias. Here we tested if childhood trauma was associated with differentiation in brain responses to negative and positive stimuli. We also tested if trauma was associated with emotional ratings of negative and positive faces.

Methods We included 101 patients with a DSM schizophrenia spectrum or bipolar spectrum diagnosis. History of childhood trauma was obtained using the Childhood Trauma Questionnaire (CTQ). Brain activation was measured with functional MRI during presentation of faces with negative or positive emotional expressions. After the scanner session, patients performed emotional ratings of the same faces. Structural MRI was also measured.

Results Higher levels of childhood trauma were associated with stronger differentiation in brain responses to negative compared to positive faces in clusters comprising the right angular gyrus, supramarginal gyrus, middle temporal gyrus, and the lateral occipital cortex (Cohen's $d = 0.72-0.77$). In patients with schizophrenia, childhood trauma was associated with reporting negative faces as more negative, and positive faces as less positive (Cohen's $d > 0.8$).
Conclusions Along with the observed negativity bias in the assessment of emotional valence of faces, our data suggest stronger differentiation in brain responses between negative and positive faces in patients with childhood trauma.

Identification of a long lasting stress signatures associated with enhanced vulnerability for depression by using 'omics and cross species approaches

A. Cattaneo

King's college London, psychological medicine, London, United Kingdom

Depression results from the interplay of vulnerability genes with environmental factors, a phenomenon named as 'gene-environment (GxE) interaction'. To date, GxE interaction studies have been limited to hypothesis-based candidate genes, since genome-wide (GWAS)-based GxE interaction studies would require enormous datasets with genetics, environmental and clinical variables. We used a novel, cross-species and cross-tissues "omics" approaches to identify genes predicting depression in response to stress in GxE interactions. We integrated the transcriptome and miRNome profiles from the hippocampus of adult rats exposed to prenatal stress (PNS) with transcriptome data obtained from blood mRNA of adult humans exposed to early life trauma, using a stringent statistical analyses pathway. Network analysis of the integrated gene lists identified the Forkhead box protein O1 (FOXO1), Alpha-2-Macroglobulin (A2M) and Transforming Growth Factor Beta 1 (TGFβ1) as candidates to be tested for GxE interactions, in two GWAS samples of adults either with a range of childhood traumatic experiences (Grady Study Project, Atlanta, USA) or with childhood emotional abuse only (Helsinki Birth Cohort Study, Finland). Six FOXO1 SNPs showed significant GxE interactions with emotional abuse in the Grady Study that survived stringent permutation analyses and were all replicated in the Helsinki study. In addition, other SNPs in all the three genes showed significant GxE interactions with emotional, physical and sexual abuse in the Grady Study. We therefore provide a successful 'hypothesis-free' approach for the identification and prioritization of candidate genes for GxE interaction studies that can be investigated in GWAS datasets.

S071

Epigenetic signatures of early life adversities in animal models: A role for psychopathology vulnerability

M.A. Riva

University of Milan, Department of Pharmacological and Biomolecular Sciences, Milan, Italy

Stressful experiences early in life (ELS) represent one of the most relevant factors for the vulnerability to psychopathologies. Epigenetic changes, such as DNA methylation, have emerged as a major mechanism through which ELS can alter adult behaviour leading to persistent changes of gene regulation.

We performed DNA methylation analyses in the hippocampus and prefrontal cortex of adult rats exposed to stress during gestation (PNS), a model that is associated with persistent behavioral alterations relevant for psychiatric disorders.

Using an epigenome-wide analysis, an overlap of 893 differentially methylated genes was observed between hippocampus and prefrontal cortex of adult male and female rats exposed to PNS. The list includes several genes previously associated with schizophrenia and other psychiatric conditions, such as calcium and potassium

voltage operated channels as well as GABA and glutamate receptor subunits. By restricting the overlap to genes that were modulated in the same direction, we identified miR-30a as being less methylated in PNS rats. Interestingly one of the targets for this miRNA is the neurotrophin BDNF, whose expression was indeed reduced as a consequence of the prenatal manipulation. Interestingly chronic treatment of PNS rats with the multi-receptor modulator lurasidone during adolescence was able to prevent the changes in miR30a and BDNF expression.

These results highlight the importance for the identification of methylation signatures through which stress exposure early in life could engrave on the outcome of the adult phenotype, and may allow the identification of novel genes and pathways that are affected as a consequence of ELS.

Introduction Maternal mental well being influences offspring development. Research suggests that an interplay between genetic and environmental factors underlies this familial transmission of mental disorders.

Objectives To explore an interaction between genetic and environmental factors to predict trajectories of maternal mental well being, and to examine whether these trajectories are associated with epigenetic modifications in mothers and their offspring.

Method We assessed maternal childhood trauma and rearing experiences, prenatal and postnatal symptoms of depression and stress experience from 6 to 72 months postpartum, and genetic and epigenetic variation in a longitudinal birth-cohort study ($n = 262$) (Maternal adversity, vulnerability and neurodevelopment project). We used latent class modeling to describe trajectories in maternal depressive symptoms, parenting stress, marital stress and general stress, taking polygenetic risk for major depressive disorder (MDD),

a composite score for maternal early life adversities, and prenatal depressive symptoms into account.

Results Genetic risk for MDD associated with trajectories of maternal well being in the postpartum, conditional on the experience of early life adversities and prenatal symptoms of depression. We will explore whether these trajectories are also linked to DNA methylation patterns in mothers and their offspring. Preliminary analyses suggest that maternal early life adversities associate with offspring DNA methylation age estimates, which is mediated through maternal mental well being and maternal DNA methylation age estimates.

Conclusion We found relevant gene-environment interactions associated with trajectories of maternal well being. Our findings inform research on mechanisms underlying familial transmission of vulnerability for psychopathology and might thus be relevant to prevention and early intervention programs.

Introduction Animal and human studies suggest that individual differences in maternal parenting behaviour are transmitted from one generation to the next.

Objective This study aimed to examine potential psychosocial mechanisms underlying an intergenerational transmission of conceptualization of parenting, including affect, cognition, and parental support.

Methods In a subsample of 201 first-time mothers participating in the Maternal Adversity, Vulnerability and Neurodevelopment (MAVAN) project, we assessed maternal childhood rearing experiences, using the Parental Bonding Instrument and the Childhood Trauma Questionnaire. At 6 months postpartum, mothers completed questionnaires on parenting stress, symptoms of depression, internalization of maternal care regulation and current relationship with mother and father.

Results We found significant direct associations of maltreatment and rearing by the grandmother with parenting stress at 6 months. These associations were mediated through distinct psychosocial pathways: the association of maltreatment on higher parenting stress was fully mediated through more maternal symptoms of depression ($z = 2.297$; $P = 0.022$). The association between sub-optimal rearing provided by the mother and higher parenting stress was mediated through lower internalization of maternal care regulation ($z = -2.155$; $P = 0.031$) and to a lesser degree through more symptoms of depression ($z = -1.842$; $P = 0.065$). Finally, higher quality rearing by the grandfather was indirectly related to lower parenting stress through positive current relationship with the father ($z = -2.617$; $P = 0.009$).

Conclusions There are distinct pathways by which early experiences manifest in parenting stress. By understanding the structure of dysregulated parenting, clinicians will have practical information to specifically target maternal motivation, social supports, and

depressed mood to disrupt maladaptive parenting cognitions and practices.

* Corresponding author.

Background There is considerable variation in the prevalence of breastfeeding, which allows for investigation of factors that influence the initiation and duration of breastfeeding and its association with well being of the mother infant dyad.

Aims To better understand factors that influence (1) maternal breastfeeding status and (2) the "effects" of breastfeeding on mothers and infants.

Methods Participants ($n = 170$) derive from a longitudinal Canadian study "Maternal Adversity, Vulnerability and Neurodevelopment (MAVAN)", a project designed to understand the pre- and postnatal influences on maternal health and child social-emotional development. Mothers provided data on breastfeeding status, early life adversity, oxytocin gene and oxytocin gene receptor polymorphisms, depression/anxiety, infant temperament and maternal sensitivity.

Results Early life adversity associated with a shorter breastfeeding duration and higher maternal depression levels. The relation between mothers' early adversity and the duration of breastfeeding was mediated by mothers' depression level, but only in women carrying one variant of the oxytocin rs2740210 gene marker (CC genotype). Mothers who breastfeed at 3 months acted more sensitively towards their infants when they were 6 months old and they in turn had infants who at 18 months showed reduced negative affectivity.

Conclusion Women who have been exposed to early adversity are "living with the past" and they are, to certain extent, protected or more vulnerable to depression, depending on their genotype. Breastfeeding associated with higher maternal sensitivity, which associated with decreased negative emotionality in the infant at 18 months. Our results help to clarify associations between early life experiences, breastfeeding, and the mother-infant relationship.

Perinatal stress, anxiety, and depression: Effects of a MBPCP intervention on mother-infant interaction

S.E. Setterberg*, E. Nissen, W. Jonas, M. Niemi
Karolinska Institute, Department of Reproductive Health, Stockholm, Sweden

* Corresponding author.

Introduction Transition into parenthood is a demanding phase in life and exposes the becoming parents to vulnerability for depression, anxiety and stress. Perinatal mental health problems are a major public health issue and many women suffering from depression during their first year after delivery. High levels of stress during pregnancy are associated with adverse psychological and physiological outcomes for the infant and parents. There seems to be an intergenerational transmission of mental health from parent to infant. The current study evaluated the effectiveness of mindfulness intervention during pregnancy in reducing depression symptoms, anxiety and perceived stress in parents-to-be.

Objectives Assess whether the mindfulness will improve interaction between mother-infant at 12 months.

Methods Perceived stress scale and Edinburgh postnatal depression scale used to measure stress and depression during pregnancy. Parent child early relational assessment assessed mother-infant interaction.

Results Inhibited parent-infant relationships were more common in the control group comparing to the mindfulness intervention group. This is in line with previous research on perinatal depression, anxiety, and stress, showing more dysfunctional dyads. A depressed mother has reduced capability to be alert to her baby's signals, which is necessary for appropriate parent-infant relationship to occur. The cumulative effect of impaired parent-infant relationship is a "depressed dyad" of mother and infant.

Conclusion Mindfulness intervention reduced depressive symptoms, anxiety, and perceived stress in pregnant women. At 12 months mother-infant relationship assessment, the mindfulness intervention group dyads showed a more attuned mother-infant interaction.

Symposium: ICD-11 Classification of mental and behavioural disorders—Recent developments

S076

ICD-11: Example of psychotic disorders

W. Gaebel

Heinrich-Heine-Universität Düsseldorf, Germany

The revision of the current classification criteria for disorders issued by the World Health Organization (WHO) (International Classification of Disorders, ICD-10) is underway and will also include a revision of the classification criteria of the mental and behavioural disorders. Working groups for specific groups of mental disorders had produced suggestions for revised diagnostic criteria and included a working group on schizophrenia and other primary psychotic disorders. This presentation will focus on this group of mental disorders. Major changes suggested were an introduction of symptom and course specifiers, the inclusion of cognitive symptoms and a de-emphasising of the so-called first rank symptoms of schizophrenia, a cross-sectional approach towards the classification of schizoaffective disorder and a reorganization of the acute psychotic disorders. Initial internet-based field trials showed some incremental improvements of diagnostic reliability, but more

crucial for an adjustment of the revised classification criteria will be the expected results of the upcoming clinic-based field trials.

SM-5, ICD-11, RDoC and the future of psychiatric classification

M. Maj

Department of Psychiatry, University of Largo Madonna delle Grazie, 80138 Naples, Italy

The publication of the DSM-III in 1980 was intended to be a reaction to the evidence of the embarrassingly low reliability of psychiatric diagnoses, which was perceived as a major threat to the credibility of the psychiatric profession. The aims of the DSM-III project were actually two. First, the reliable definition of the diagnostic categories was expected to lead to the collection of research data that would validate those diagnostic entities and in particular elucidate their etiopathogenetic underpinnings. Second, there was an expectation that, by increasing reliability, communication among clinicians would be improved and clinical decisions made more rational. Today, one could say that the first aim of the project has not been achieved, while the fulfilment of the second aim has never been tested appropriately. The crisis of confidence in the DSM paradigm, clearly emerging from the debate following the publication of the DSM-5, has led on the one hand to a renewed emphasis on clinical utility, which is featuring prominently in the ongoing process of development of the ICD-11. On the other hand, it has led to a radical attempt to reform psychiatric nosology starting from neurobiological and behavioural phenotypes. This attempt does have its weaknesses, but may also represent a stimulus to reconceptualize some psychopathological constructs, especially in the area of psychoses, in order to reduce the gap between the level of neuroscience and that of clinical phenomenology.

Symposium: Tobacco dependence and smoking cessation in people with mental illness

S078

PA Guidance paper on tobacco dependence and smoking cessation

H.J. Möller

Ludwig Maximilians University, Munich, Germany

Tobacco dependence is the most common substance use disorder in adults with mental illness. The prevalence rates for tobacco dependence are two to four times higher in these patients than in the general population. Smoking has a strong, negative influence on the life expectancy and quality of life of mental health patients, and remains the leading preventable cause of death in this group. Despite these statistics, in some countries smokers

with mental illness are disadvantaged in receiving intervention and support for their tobacco dependence, which is often overlooked or even tolerated. This statement from the European Psychiatric Association (EPA) systematically reviews the current evidence on tobacco dependence and withdrawal in patients with mental illness and their treatment. It provides seven recommendations for the core components of diagnostics and treatment in this patient group. These recommendations concern: (1) the recording process, (2) the timing of the intervention, (3) counselling specificities, (4) proposed treatments, (5) frequency of contact after stopping, (6) follow-up visits and (7) relapse prevention. They aim to help clinicians improve the care, health and well being of patients suffering from mental illness.

Disclosure of interest In the last three years, HJM received honoraria for lectures or for advisory activities by the following pharmaceutical companies: Lilly, Lundbeck, Servier, Schwabe and Bayer.

He was president or in the Executive Board of the following organisations: CINP, ECNP, WFSBP, EPA and chairman of the WPA-section on Pharmacopsychiatry.

Smoking cessation and soft signs of mental disorders

A. Batra^{1*}, S. Eck²

¹ Psychiatry and Psychotherapy, Germany

² University Hospital, Psychiatry and Psychotherapy, Tubingen, Germany

* Corresponding author.

Smoking is associated with major depression, schizophrenia, anxiety and compulsive disorders, personality disorders, or substance abuse disorders [1,2]. More than that, smokers often report higher levels of novelty seeking, anxiety or depressive symptoms without fulfilling full diagnostic criteria for a psychiatric disorder.

In a former study, Batra et al. [3] had shown that smokers reporting higher levels of novelty seeking/hyperactivity, depressivity, and nicotine dependence evince higher relapse rates after completion of a six-weeks behavioural treatment program than smokers reporting low scores on self-report psychological symptom measures.

Another study [4] showed that a modified smoking cessation program matched to at-risk smokers' needs with $n = 268$ adult smokers leads to higher long-term abstinence rates.

All at-risk smokers had been randomly assigned to receive either a standard or modified treatment. Best results were shown for smokers with mild depressive symptoms. The talk reports results of former and recent studies and focuses on the German treatment guidelines for tobacco related disorders.

These [5] recommend to assess tobacco use among patients with mental disorders and should be offered smoking cessation support under consideration of the acuteness and the particularities of the mental disorder using the same psychotherapeutic and pharmaceutical measures as for smokers without additional mental disorders.

Disclosure of interest Financial support by Pfizer, Parexel, SKB, Novartis for smoking cessation studies.

Smoking: A risk factor for suicide

H.J. Aubin

University Hospital Paul Brousse, Addictologie, Villejuif, France

First demonstrated in 1976, the robust association between smoking and suicide mortality has been established and is dose-dependent, with an estimated increase in suicidal deaths risk of 24% for each increment of 10 cigarettes smoked per day. The statistical association has been shown to exist very soon after smoking initiation, during adolescence, and to withstand adjustments for confounding factors, such as demographics, socio-economic status, somatic and psychiatric comorbidity, and substance use. As the underlying mechanism of the greater suicide risk in smokers is not currently elucidated, we will briefly recapitulate the main hypotheses proposed to date: the toxic effects of nicotine, hypoxemia, monoamine oxidase activity inhibition, the high prevalence of psychiatric comorbidity and consequent suicide risk, and smoking-induced serious physical illness with pain and disability resulting in negative mood response. Smoking could also be an inadequate self-medication for psychological symptoms, themselves causing suicide, and finally the association could be due to a third underlying factor associated with both smoking and suicide.

Disclosure of interest Henri-Jean Aubin was member of advisory boards for Pfizer, D&A Pharma, Ethypharm, and Lundbeck, and has received sponsorship to attend scientific meetings, speaker honoraria and consultancy fees from Bioprojet, D&A Pharma, Ethypharm, Lundbeck, Merck-Serono, Novartis, and Pfizer.

S081

Is it feasible and effective to help patients with severe mental disorders to quit smoking?

J. Bobes

University of Oviedo, Oviedo, Spain

Despite the proven association between smoking and high rates of medical morbidity and reduced life expectancy in people with severe mental disorders (SMD), their smoking rates do not decline as they do in the general population. We carried out a non-randomized, open-label, prospective, 9-month follow-up multicentre trial to investigate the clinical efficacy, safety and tolerability of a smoking cessation programme designed for the treatment of patients with SMD in the community under real-world clinical conditions. A total of 82 patients were enrolled. Short-term efficacy: The 12-week 7-day smoking cessation (self-reported cigarettes per day = 0 and breath CO levels ≤ 9 ppm) prevalence was 49.3%, with no statistically significant differences between medications (transdermal nicotine patches 50.0% vs. varenicline 48.6%, chi-square = 0.015, $P = 1.000$). Long-term efficacy: At weeks, 24 and 36, 41.3 and 37.3% of patients were abstinent, with no statistically significant differences between treatments. Safety and tolerability: No patients made suicide attempts or required hospitalization. There was no worsening of the scores on the psychometric scales. In both groups, patients significantly increased weight, without significant changes in vital signs or laboratory results, with the exception of significant decreases in ALP y LDL-cholesterol levels in the varenicline group. Patients under varenicline more frequently presented nausea/vomiting ($P < 0.0005$), patients under TNP experienced skin reactions more frequently ($P = 0.002$). Three patients under varenicline had elevated liver enzymes. In conclusion, we have demonstrated that in real-world clinical settings it is feasible and safe to help patients with stabilized severe mental disorders to quit smoking.

Symposium: Modifying outcomes of ADHD across the lifespan

S082

Continuity of ADHD across the lifespan

P. Asherson

Institute of Psychiatry Psychology and N, King's College London, London, United Kingdom

Introduction For many years ADHD was thought to be a childhood onset disorder that has limited impact on adult psychopathology. However, the symptoms and impairments that define ADHD often affect the adult population, with similar responses to drugs such as methylphenidate, dexamphetamine and atomoxetine to those seen in children and adolescents. As a result, there has been a rapidly increasing awareness of ADHD in adults and an emergence of new clinical practice across the world. Despite this, treatment of adult ADHD in Europe and many other regions of the world is not yet common practice and diagnostic services are often unavailable or restricted to a few specialist centres.

Objective Here we address some of the key conceptual issues surrounding the continuity of ADHD across the lifespan, with a focus relevant to practicing health care professionals working with adult populations.

Conclusions We conclude that ADHD should be recognised within adult mental health in the same way as other common adult mental health disorders. Failure to recognise and treat ADHD will be detrimental to the well being of many patients seeking help for common mental health problems.

Disclosure of interest The author declares that he has no competing interest.

Symposium: Non-Invasive brain stimulation: From mechanisms to applications

S084

Does transcranial electrical stimulation induce changes in peripheral physiology?

S. Lehto

University of Helsinki, Department of Behavioural Sciences, Helsinki, Finland

Transcranial electrical stimulation (tES) is a non-invasive brain stimulation method that has evoked increasing interest during the past years. The most common form of tES, transcranial direct current stimulation (tDCS), is considered to modulate neuronal resting potentials. For example, anodal stimulation over motor cortex appears to lead to increased neuronal excitability under the stimulation electrodes. However, some recent findings suggest that the effects of tDCS extend beyond the cortical areas under the electrodes, to deeper brain structures such as the midbrain. The brain also actively regulates peripheral physiology. Thus, changes in brain activity following tES may lead to modulation of peripheral physiology. For example, tDCS targeting primary motor cortex has been observed to induce changes in peripheral glucose metabolism. Furthermore, stimulation of dorsolateral prefrontal cortex has been shown to lead to alterations in cortisol secretion and the activity of the autonomic nervous system. Unpublished findings from our group corroborate with the above observations. Nevertheless, the evidence regarding peripheral effects of tES remains limited. Investigating such possible effects may be relevant especially from the point of view of tES safety and potential therapeutic discoveries.

Disclosure of interest The author has not supplied his declaration of competing interest.

S085

The effect of prefrontal transcranial direct current stimulation on resting state functional connectivity

D. Keeser

Ludwig-Maximilians-University, Department of Psychiatry and Psychotherapy, Institute for Clinical Radiology, Munich, Germany

Transcranial direct current stimulation (tDCS) of the prefrontal cortex (PFC) is currently investigated as therapeutic non-invasive brain stimulation (NIBS) approach in major depressive (MDD) and other neuropsychiatric disorders. In both conditions, different sub regions of the PFC (e.g. the dorsolateral prefrontal cortex, the dorsomedial prefrontal cortex and others) are critically involved in their respective pathophysiology. Although the neurophysiological properties of tDCS have been extensively investigated at the motor cortex level, the action of PFC tDCS on resting state and functional MRI connectivity of neural networks is largely unexplored. Beyond motor cortex paradigms, we aim to establish a model for PFC tDCS modulating functional connectivity in different conditions to provide tailored tDCS protocols for clinical efficacy studies in major psychiatric disorders such as MDD and schizophrenia. One major obstacle in brain research is that patients represent themselves as individuals not as groups. Recent research has shown that the individual human brain functional MRI connectivity shows different within-variability than the variability found between subjects. Several neuroimaging methods may be useful to find a classifier that can be reliably used to predict NIBS effects. These neuroimaging methods include individual brain properties as well as the evaluation of state-dependency. Anatomical targeted analyses of rTMS

and tDCS in neuropsychiatric patients and healthy subjects have found promising results.

By combining neuroimaging and NIBS new functional models can be developed and compared in different health and pathology states, e.g. in the development of any given psychiatric disorder.

Cognitive enhancement in young healthy subjects using non-invasive brain stimulation and cognitive training

A.K. Brem

Munich, Germany

Transcranial electrical stimulation (tES) is being widely investigated to understand and modulate human brain function. The interest in using tES to enhance cognitive abilities not only in patient populations but also in healthy individuals has grown in recent years. Specifically in combination with cognitive training tES has shown success in enhancing cognition. However, to date, we still know little about the impact of interindividual differences on intervention outcomes. A variety of tES techniques and their effects in combination with cognitive training, interactive effects of tES with baseline cognitive abilities and neurophysiological traits will be presented and following ramifications with regards to the development of individualised stimulation protocols will be discussed.

Corticospinal excitability predicts antidepressant response to rTMS

A. Oliveira-Maia^{1,*}, D. Press², A. Pascual-Leone²

¹ Champalimaud Clinical Centre, Champalimaud Centre for the Unknown, Neuropsychiatry Unit, Lisbon, Portugal

² Beth Israel Deaconess Medical Center-Harvard Medical School, Berenson-Allen Center for Non-invasive Brain Stimulation, Division of Cognitive Neurology, Department of Neurology, Boston, USA

* Corresponding author.

Repetitive transcranial magnetic stimulation (rTMS) targeting the left dorsolateral prefrontal cortex (DLPFC) is a treatment option for patients with medication-resistant major depressive disorder (MDD). However, antidepressant response is variable and there are currently no response predictors with sufficient accuracy for clinical use. Here we report on results of an observational open-label study to determine whether the modulatory effect of 10 Hz motor cortex (MC) rTMS is predictive of the antidepressant effect of 10 Hz DLPFC rTMS. Fifty-one medication-resistant MDD patients were enrolled for a 10-day treatment course of DLPFC rTMS and antidepressant response was assessed according to post-treatment reduction of the 17-item Hamilton Rating Scale for Depression score. Prior to treatment, we assessed the modulation of motor evoked potential (MEP) amplitude by MC rTMS. We measured MEP's to single pulse TMS using surface electromyography, before and after MC rTMS, and calculated MEP modulation as the change of mean MEP amplitude after MC rTMS. MEP modulation proved to be a robust predictor of reduction of clinician-rated depression severity following the course of DLPFC rTMS: larger MC rTMS-induced increase of corticospinal excitability anticipated a better antidepressant response. These findings suggest that MC rTMS-induced

modulation of corticospinal excitability warrants further evaluation as a potential predictive biomarker of antidepressant response to left DLPFC 10 Hz rTMS, and could inform future developments of rTMS to treat depression.

Symposium: Staging of psychiatric disorders: Integrating neurobiological findings

S088

Staging in bipolar disorder: Clinical, biochemical, and functional correlates

I. Grande

Hospital Clinic de Barcelona, Barcelona, Spain

In the field of bipolar disorder, some proposals of a staging model have been suggested considering the progressive features of the disorder. The staging model regards special features of the patients and further draws a route to define the prognosis and treatment as well as the neurobiological background of the disorder. The aim of this model is to identify rational therapeutic targets and provide the most effective and less toxic intervention in a time-sensitive manner. Advocating for a model of staging in bipolar disorder that can group the patients according to quantitative cut-offs of common practice clinical variables as well as defining a biochemical correlation seems to be a further step towards an operative and valid model of staging in bipolar disorder.

Disclosure of interest Dr. I. Grande has received a Juan Rodés Contract (JR15/00012), Instituto de Salud Carlos III, Spanish Ministry of Economy and Competitiveness, Barcelona, Spain and has served as a consultant for Ferrer and as a speaker for AstraZeneca, Ferrer and Janssen-Cilag.

S089

Staging & profiling in addiction, can we cross the gap from bench to bedside?

A. Schellekens

Nijmegen, The Netherlands

Addictive behaviours are highly common (prevalence worldwide about 10%), with major impact on the individual and society (contributing to 5% of overall DALYs and mortality) [1,2]. Though a number of evidence-based treatments are available, relapse rates remain high, up to 50% within one year of treatment [3,4]. Staging of addictive behaviors might contribute to improve this prognosis by indicating which patient could benefit most from which treatment modality.

In DSM-5 clinical staging of addictive disorders is limited to grading the severity of the disorder, based on criterion counts [5]. However, addictive disorders are highly heterogeneous, with distinct clinical profiles and neurobiological underpinnings of the disorder. Reward-processing deficits are considered a hallmark of addiction. Several additional neurobiological deficits have been identified in addicted individuals, such as dysfunction of brain stress systems, anterior cingulate cortex and habenula.

These neurobiological deficits may identify clinical subgroups of patients with distinct pathophysiology (profiling), or be related to progression of the disorder (staging). This presentation will focus

on clinical staging and profiling of addictive behaviors combining neurobiological findings and clinical practice [6].

Clinical staging of psychotic disorders: From dimensions to neurobiology

A. Batalla

Radboudumc, Psychiatry, Nijmegen, The Netherlands

The clinical staging model is an approach used in medicine to define the extent of disease. In psychiatry, this model has recently been applied to psychotic disorders to distinguish the earlier, non-specific features of illness (e.g. ultra-high risk [UHR]; at-risk mental state [ARMS]), from later, more severe features associated with chronic illness. A key element of the staging model is to identify and classify the neurobiological processes underlying the disorder and to define potential interventions in the different stages. With the premise that dysfunctional neural mechanisms underlie symptomatology, the integration of categorical phenotypic classifications (class of disorder) with dimensional criteria (domains of dysfunction) becomes crucial. This approach aims to better classify trans-diagnostic dimensions of disease and discrete symptom-specific subgroup populations within biological frameworks, which may lead to the detection of new biomarkers and the development of more effective treatment and prevention strategies.

Symposium: Mental health care in refugees and asylum seekers

S091

Providing care for migrants and refugees

M. Schouler-Ocak

Psychiatric University Clinic of Charité at St. Hedwig Hospital, Psychiatry and Psychotherapy, Berlin, Germany

With growing globalisation and an increasing number of people on the move across boundaries, it has become vital that service providers, policy makers and mental health professionals are aware of the different needs of the patients they are responsible. One of the most fundamental barriers for migrants, refugees and asylum seekers in accessing health services are inadequate legal entitlement and, mechanisms for ensuring that they are well known and respected in practice. Access to the healthcare system is impeded by language and cultural communication problems. Qualified language and cultural mediators are not widely available, and moreover, are not regularly asked to attend. This can lead to misunderstandings, misdiagnosis and incorrect treatment, with serious consequences for the afflicted. The language barrier represents one of the main barriers to access to the healthcare system for

people who do not speak the local language; indeed, language is the main working tool of psychiatry and psychotherapy, without which successful communication is impossible. Additionally, the lack of health literacy among the staff of institutions, which provide care for refugees and asylum seekers means that there is a lack of knowledge about the main symptoms of common mental health problems among these groups. The healthcare services, which are currently available, are not well prepared for these increasing specific groups. In dealing with ethnic minorities, including asylum seekers and refugees, mental healthcare professionals need to be culturally competent.

In this talk, main models for providing mental health care for migrants and refugees will be presented and discussed.

S092

Cultural competence training and mental health care in refugees and asylum seekers

D. Bhugra

Institute of Psychiatry, Psychology & Ne, London, United Kingdom

Recent mass movement of human beings in various parts of the world has brought several challenges. Not only refugees from Syria and Libya to Europe but also refugees, migrants and asylum seekers in Latin America bring specific set of issues with them. It is critical that clinicians are aware of both the vulnerability of individuals to mental ill health as a result of migratory experiences but equally importantly their resilience. The impact on the mental health of those who may be involved directly or indirectly in delivering care along with those new communities who receive these groups need to be taken into account when planning and delivering psychiatric services. It is essential to recognise that experiences of being a refugee or asylum seeker are heterogeneous. Being an asylum seeker carries with it legal definitions and legal imperatives agreed at international levels.

Policymakers and clinicians need to be aware of differential rates of psychiatric disorders in these vulnerable individuals and specific needs related to language, religious values and other cultural factors. Mental health problems may be related to experiencing cultural bereavement where individuals feel that they have lost their cultures, relationships and cultural values. Judicious and careful use of trained culture brokers and mediators should be encouraged as these individuals can inform the team about community needs and inform the community about the team functioning and its principles so that community expectations can be managed appropriately. Such approaches may also help reduce stigma against mental illness.

Disclosure of interest The author has not supplied his declaration of competing interest.

<http://dx.doi.org/10.1016/j.eurpsy.2017.01.166>

S093

Suicide risk in refugees and asylum seekers

D. Wasserman

Karolinska Institute, National Centre for Suicide Research and Prevention of Mental-Ill Health NASP, Stockholm, Sweden

Increasing numbers of individuals forced to leave their home countries in areas of war, conflict, human rights violations and persecution pose a challenge for host countries to meet the mental-health care needs of these individuals. Refugees and asylum-seekers may face unique risk factors for mental disorder before, during, and after their migration leading to suicidality.

Experiences of family withdrawal, integration difficulties, and perceived lack of care may contribute to suicide within the refugee populations. Identifying effective treatments and support to minimize the risk especially once the individuals arrive in their new country is key to providing appropriate care. Barriers to mental-health care including lack of knowledge about available resources, communication or language barriers, cultural beliefs about origins and treatment of mental disease, as well as a lack of trust in authority, pose a challenge for health care providers and policy makers. Research has been inconsistent in the findings for the prevalence of mental disorders, suicidal behaviours, and suicide ideation among refugees and asylum seekers. Thus far, research has been limited to small scale, non-randomised, often qualitative analysis. Several studies have found higher rates of mental disorder, whereas others have found a similar prevalence as in the general population, although, Post-Traumatic Stress Disorder has more consistently been found to have a higher prevalence among migrants. The lack of early and thorough exploration of suicidal intent in this population requires large-scale quantitative studies to evaluate the effectiveness and feasibility of current practices in mental-health care and suicide prevention.

Symposium: Reward processes in anorexia and bulimia nervosa: a new pathogenetic model and future perspectives for treatment of eating disorders

S094

Functional connectivity of reward circuits in eating disorders

A. Favaro^{1,*}, P. Santonastaso²

¹ University of Padova, general psychology, Padova, Italy

² University of Padova, neurosciences, Padova, Italy

* Corresponding author.

Objective Anorexia nervosa display alterations of reward systems and some authors hypothesize the presence of a “starvation addiction”. The aim of the study is to explore the resting-state functional connectivity of dorsal and ventral striatal nuclei.

Method 51 subjects with lifetime anorexia nervosa (AN) (35 acute and 16 recovered) and 34 healthy controls underwent high resolution and resting-state functional magnetic resonance imaging.

Results The AN group showed a reduced functional connectivity of the putamen in comparison to healthy women and this reduction appeared to be stronger in patients with lifetime binge eating or purging. Both acute and recovered AN groups showed larger left accumbens area in comparison to healthy women. Moreover, the functional connectivity of bilateral nucleus accumbens and putamen showed significant negative correlations with the number of obstetric complications in the AN group.

Discussion the present study supports the hypothesis that AN is associated with structural and functional alterations of striatal networks and unveils a possible role of obstetric complications in the pathogenesis of striatal dysfunction.

Emotional eating in eating disorders and obesity: Sensorial, hormonal and brain factors involved

F. Fernandez-Aranda*, T. Steward, N. Mallorqui-Bague, Z. Agüera, S. Jimenez-Murcia

University hospital Bellvitge-IDIBELL, psychiatry eating disorders unit and CIBERobn, hospitalet del Llobregat, Spain

* Corresponding author.

Obesity (OB) and eating disorders (ED) are two complex weight/eating conditions that share phenotypic traits, including psychopathological variables, specific environmental risk factors and biological vulnerabilities. Both OB and ED are associated with maladaptive eating styles that may be relevant to their development and maintenance. In abnormal/excessive eating behavior, a complex interplay among physiological, sensorial, psychological, social and genetic factors influence appetite, meal timing, and the quantity of food intake and food preferences. Neurobiological functioning has also been found to be altered in extreme weight conditions, namely with regards to reward processing, emotion regulation and decision making. In this presentation we will discuss the relevance of such components as well their interaction using findings from cross-sectional and longitudinal studies conducted in extreme eating/weight conditions, when compared with healthy controls. The development of innovative treatments considering neurobiological factors will also be covered.

Eating disorders and sexuality: A complex relationship

V. Ricca^{1,*}, G. Castellini¹, L. Lelli¹, F. Rotella¹, A.M. Monteleone², M. Maggi³

¹ Florence university school of medicine, department of neurosciences, Firenze, Italy

² University of Naples SUN, psychiatry, Naples, Italy

³ Florence university school of medicine, department of experimental- clinical and biomedical sciences, Firenze, Italy

* Corresponding author.

Introduction The relationships between Eating Disorders (EDs) and sexuality are complex, and of interest for researchers and clinicians.

Objective To identify psychopathological and clinical factors associated with restoration of regular menses and sexual function in EDs patients.

Aims To evaluate the role of sexuality as a moderator of the recovery process after an individual Cognitive Behavioural Therapy (CBT).

Methods 39 Anorexia Nervosa (AN) and 40 Bulimia Nervosa (BN) female patients were evaluated by means of a face-to-face interview, self-reported questionnaires, including Eating Disorder Examination Questionnaire and Female Sexual Function Index, and blood sample for hormonal levels and biomarkers. The assessments were repeated at baseline, at one year follow up, and at three years follow up.

Results After CBT, both AN and BN patients showed a significant improvement of sexual functioning, which was associated with a reduction of core psychopathology. AN patients who recovered regular menses demonstrated a better improvement across time of psychopathological and clinical features, and were more likely to maintain these improvements at follow up. Recovery of regular menses and improvement of sexuality at the end of CBT were

associated with a higher probability to have a full recovery at three years follow up.

Conclusions These results challenge a concept of recovery in EDs exclusively based on weight restoration or behavioral changes. An assessment including sexual functioning and core psychopathology might identify the residual pathological conditions, and it is able to provide information regarding the long term recovery process.

* Corresponding author.

Introduction Nutritional rehabilitation in anorexia nervosa (AN) is impeded by fear of food, eating and change leading to treatment resistance. Oxytocin exerts prosocial effects on anxiety, fear modulation, trust and brain plasticity.

Objective A placebo-controlled RCT examined the effects of self-administered intranasal oxytocin (IN-OT) in AN patients.

Aim To ascertain whether single and repeated doses of IN-OT enhance treatment in AN.

Methods Female AN patients self-administered twice daily 18IU IN-OT ($n=21$) or placebo ($n=21$) for 4–6 weeks during hospital treatment. Weight and BMI were measured at baseline and after treatment. The Eating Disorders Examination (EDE) was the primary outcome measure. Cognitive rigidity was compared between groups after four weeks repeated dosing. The effects of the first and last doses of IN-OT versus placebo, on salivary cortisol before a high-energy afternoon snack, were compared.

Results Weight gain was similar in IN-OT and placebo groups. Only the EDE eating concern subscale score was significantly lower after 4–6 weeks (mean 35 days) of IN-OT ($p=0.006$). Anticipatory levels of salivary cortisol fell from baseline after the initial dose in contrast to the placebo group where levels increased. After four weeks IN-OT, salivary cortisol was significantly lower ($p=0.023$) overall with little anticipatory increase compared to placebo. There were no differences in anxiety scores. Cognitive rigidity was significantly lower in the IN-OT group ($p=0.043$)

Conclusions Self-administered IN-OT might enhance nutritional rehabilitation in AN by reducing eating concern and cognitive rigidity. Lower salivary cortisol before a high-energy snack, suggests reduction of fear rather than anxiety.

Symposium: Role of psychiatry in dementia care

S098

Psychiatrists and legal issues in dementia care

M.M. Carrasco

Instituto de investigaciones, Psiquiátricas, Spain

During more than half a century, Psychiatry has extensively accepted a biomedical model studying mental disorders (including schizophrenia, affective disorders and the large group of stress-related disorders, including anxiety disorder). Thus, the classical dichotomy between functional and organic psychiatric disorders is obsolete and from a theoretical point of view there should be no obstacle for Psychiatry to deal with the study of dementias from gene to clinical levels using empirical methods, including neurotransmitters and scanning techniques. However, in many European countries, the dementias have been claimed as belonging primarily to Neurology, leaving the role of psychiatrists to treat psychotic symptoms and bizarre behavioral disturbances.

However, psychiatrists have a long tradition of detailed psychopathological description and great skill in coping with the many psychological, ethical and social problems that are such important features of mental disorders and particularly the dementias, and so, the specific skills of psychiatrists will certainly be warranted in managing the many significant psychological and social problems of the patient both within the family and in society. The discussion must overcome the sterile debate between specialties to focus on the skills needed to adequately address the needs of patients with dementia and their caregivers.

Role of psychiatrists in memory clinics

F. Verhey

University of Maastricht, The Netherlands

Memory clinics (MCs) are multidisciplinary teams involved with early diagnosis and treatment of people with dementia. In this presentation, we will discuss several trends of the role of psychiatrists over the last twenty years, on the basis of five questionnaires that were sent to MCs every 5 years in the Netherlands.

MCs have developed in Europe using a range of service models but providing similar functions, which include assessment, information, treatment monitoring, education, training and research. MCs may vary among each other, and across countries. Psychiatrists used to play a coordinating role in most MCs, but there is now a tendency that MCs are more frequently led by other specialists, notably neurologists. In 1998 in the Netherlands, only a small minority of the MCs had a structural cooperation with local service providers, but 10 years later, most of them were collaborating with other regional care organizations. In most cases, the collaborating partner was a community mental health team or a long-term care facility.

Symposium: Children of parents with mental disorders: needs assessment and model interventions

S100

The needs of children who have parents suffering from severe mental disorders

G. De Girolamo^{1,*}, G. Signorini², V. Candini²¹ Saint John of god clinical research center, psychiatric epidemiology and evaluation unit, Brescia, Italy² IRCCS St John of God clinical research centre, UOPEV, Brescia, Italy

* Corresponding author.

Abstract

Objective Mental illness in parents is a biological and environmental risk factor to which young people are exposed. Living with a parent suffering from a mental disorder may have a variety of detrimental consequences, including: (a) the reversal of caregiving (“parentification”); (b) the exposure to an adverse environment, where developmental needs of the child (emotional and practical) might be repeatedly neglected (lack of communication, high expressed emotion, etc.); (c) stigma and discrimination. We will provide a review of needs of these children and of possible interventions.

Methods Systematic searches located studies reporting and assessing met and unmet needs of these children.

Results Young people living in such families often have problems of internalizing and externalizing symptoms, cognitions of shame, guilt, and loneliness, perceptions of lacking social support and social acceptance. Children who have mentally ill parents are up to two and a half times more likely to experience poorer mental health outcomes than their peers. Compared to peers, children of parents with mental disorders are also at risk of poorer intellectual and social outcomes, of affect dysregulation, of behavioral problems, of impaired attention and reduced overall adaptive functioning, of higher rates of substance abuse and multiple diagnosis and finally of low occupational status, health risk behaviour and antisocial behavior.

Conclusions Given the high toll paid by children having parents suffering from severe mental disorders, it is urgent to develop, test and implement structured programmes to help these children cope with stressful circumstances and improve their resilience.

Identifying and supporting children of mentally ill parents within adult mental health services

C. Reedtz

Regional centre for child and youth mental health and child welfare, the faculty of health science- UiT The Arctic university of Norway, Tromsø, Norway

Background Studies have shown that implementing a change of practice in adult mental health care to identify and support children of mentally ill parents is challenging, even though the risk of transgenerational transmission of socioemotional problems and psychopathology has been thoroughly demonstrated the last decade.

Aims The current presentation describes the existing practice of identifying and supporting children of mentally ill parents within adult mental health services. The study was conducted after Norwegian health legislation had been changed to make these tasks

mandatory. The effort included implementation of two interventions; Family Assessment, an intervention for practitioners to increase identification of patients who are also parents and their children, and child talks, an intervention designed to provide support for parents and children within the participating hospital.

Method The sample included mental health professionals in a large university hospital in Northern Norway, who responded to a web-based survey on the routines of the services, attitudes within the workforce capacity, worker’s knowledge on the impact of parental mental illness on children, knowledge on legislation concerning children of patients, and demographic variables. Register data from the Electronic Patient Journals (EPJ) was analyzed to assess whether or not the self-reported routines match the reality in the clinic.

Discussion The prospects of clinical change will be discussed in general, as well as to which extent the two implemented interventions have contributed to changes in the clinical practice, workforce knowledge and attitudes in the participating hospital.

Disclosure of interest The author has not supplied his declaration of competing interest.

S102

Dutch intervention programmes for children of mentally ill parents

T. Van Amelsvoort

Department of psychiatry and psychology, Maastricht university, The Netherlands

This presentation reports on the outcomes of a practice-based and science-based enterprise in the Netherlands to develop a comprehensive national prevention program focused on children of parents with a mental illness. An outline of the multicomponent program is presented which includes a wide set of interventions that address evidence-based risk factors and protective factors in multiple domains, including children in different age groups, parents and families, social networks, professionals and the community as a whole.

The 20-year history of this program illustrates the importance of long-term collaborative investments that are required of practitioners, policymakers and scientists to develop and implement a nationwide, comprehensive approach for addressing the prevalent transmission of psychiatric problems from parent to child. The results of recently undertaken controlled efficacy studies of various preventive interventions are presented, as well as findings from process evaluations. Also, strengths and weaknesses of the current program are discussed and recommendations will be offered for the main challenges ahead in terms of program innovation, implementation and research.

Disclosure of interest The author has not supplied his declaration of competing interest.

Toward the development of new strategies to assess the needs of children and adolescents with severely mentally ill parents

K. Abel

University of Manchester- UK, centre for women’s mental health-institute of brain behaviour and mental health- Manchester, Manchester, United Kingdom

Up to 10% of mothers and 5% of fathers in Europe have mental illness. Family, educational and social lives of children and adolescents with parental with mental illness (CAPRI) are disrupted by deprivation & repeated hospitalization. This is an urgent politi-

cal & public health concern: The European Union's CAMHEE report recommends better information on CAPRI risks and resilience and to enable interventions to target the highest risk. This is important because although large numbers of children are in the riskset, most remain resilient. Research needs to support delivery of the CAMHEE initiative by understanding who is at risk and how we can target them early before their life trajectories are fatally disrupted.

To do this, we aim to create groundbreaking cross-national datasets providing robust data on CAPRI prevalence & life trajectories needed to plan future services.

But epidemiology alone cannot expose how risk creates effects at the individual level. We need to know which CAPRI to target with potentially expensive, time-consuming specialist services

Powerful neuroscience techniques such as functional near infrared spectroscopy are now available with which we can link epidemiological risk to elucidate effects of exposure within individual infant brain. This unique interdisciplinary approach yokes robust epidemiological evidence to cutting-edge optical imaging that can be undertaken in very young infants.

This allows us to target developments in clinical interventions for CAPRI to those in greatest need and potentially to those most vulnerable with the future aim to identify early biomarkers of abnormality for targeting intervention in CAPRI.

Big data market analysis of e-health in medical neuroscience

A. Stellbrink*, E. Meisenzahl

Kliniken der Heinrich-Heine-universität Düsseldorf, klinik und poliklinik für psychiatrie und psychotherapie, Düsseldorf, Germany

* Corresponding author.

Depression is associated with more than 100,000 patent applications for its diagnosis and prognosis, the highest number among mental disorders. This is followed by schizophrenia with 47,000, bipolar disorder with 32,110 and hypomania with 11,377. Among diagnostic tools, magnetic resonance imaging is associated with more than 31,000 patent applications. Among recent technologies, biomarkers are associated with more than 12,000 epigenetics with about 970 metabolomics with 515 genome-wide association study (GWAS) with 486 and bionics with 497 patent applications. The patent applications related to diagnosis and prognosis of psychiatric diseases peaked in 2008 and was overall decreasing until 2016, with a local peak in 2013. This trend has been observed despite the value addition of recent technologies like machine learning, big data and internet of things. However, more conservative diagnostic tools from the last decade like magnetic resonance imaging, epigenetics, bionics and neuro-psychological testing are improved by the recent technologies. For example, bionics is improved by sensors of internet of things to collect the data from patients around the world and use the big data analytics to efficiently diagnose the psychiatric diseases. The Regents of the University of California and Human Genome Sciences Incorporation are the respective academic and non-academic institutions leading the innovations related to diagnosis and prognosis of psychiatric diseases.

The ethics of mobile health technology

S. Galderisi*, F. Caputo

University of Campania "Luigi Vanvitelli", department of psychiatry, Naples, Italy

* Corresponding author.

Introduction Mobile health (m-health) technology has been growing rapidly in the last decades. The use of this technology represents an advantage, especially for reaching patients who otherwise would have no access to healthcare. However, many ethical issues arise from the use of m-health. Health equity, privacy policies, adequate informed consent and a competent, safe and high quality healthcare need to be guaranteed; professional standards and quality of doctor-patient relationship in the digital setting should not be lower than those set for in-person practice.

Aims To assess advantages and threats that may arise from the wide use of m-health technologies, in order to guarantee the application of the best medical practices, resulting in the highest quality healthcare.

Methods A literature search has been conducted to highlight the most pressing ethical issues emerging from the spreading of m-health technologies.

Results Few ethical guidelines on the appropriate use of m-health have been developed to help clinicians adopt a professional conduct within digital settings. They focus on the need for professional associations to define ethical guidelines and for physicians to take care of their education and online behavior when using m-health technologies.

Conclusions The rapid spreading of m-health technologies urges us to evaluate all ethical issues related to its use. It would be advisable to produce an ethical code for the use of these new technologies, to guarantee health equity, privacy protection, high quality doctor-patient relationships and to ensure that m-health is not chosen over traditional care for merely economic purposes.

Symposium: Social cognition in schizophrenia: pathophysiology, functional implications and treatment options

S106

Disorganization and social cognition: Data from the italian network of research on psychoses

P. Rocca

Unito, Italy

Social cognition (SC) refers broadly to the domains of cognitive functions that are employed in socially relevant situations. These disturbances have been found to be strongly related to disorganized and negative symptoms in schizophrenia. Each of the disorganization symptoms suggests a diminishment or absence of organization. There seems to be a loss of the ability to be directed toward or committed to a particular focal topic or goal. Such conditions are likely to impact patients' drives or motivations to initiate goal-directed activities that could yield pleasurable opportunities. Moreover, it has been suggested that disorganized

symptoms are an integral link in cognitive pathways, with connections between cognitive processes weakening as disorganized symptoms increase. Thus, it seems that when disorganized symptoms are present, people with schizophrenia are no longer able to effectively utilize the neurocognitive abilities necessary for performing social cognitive or metacognitive tasks. It is also in line with models of disorganization in schizophrenia (Bleuler, 1911) that a “loosening of associations”—similar to current conceptualizations of disorganized symptoms—is at the core of these cognitive disruptions. Previous research has linked disorganization to cognition (neurocognition and SC) and cognition to social functioning, although in separate studies. The present study was conducted to explore a model, where disorganization predicted social functioning both directly both through indirect effects on other determinants (neurocognition, SC and negative symptoms) in a large, and well-characterized sample of patients with schizophrenia recruited in the context of a multi-center study of the Italian Network for Research on Psychoses (NIRP).

Introduction Mentalizing ability is impaired in patients with schizophrenia. Most studies in schizophrenia report hypoactivation of the core-mentalizing network including the medial prefrontal cortex (mPFC) and bilateral temporoparietal junction (TPJ). In our study, in patients with first episode schizophrenia treatment as usual with atypical antipsychotics (TAU) was compared to the add-on effect of a mentalization-based treatment program (MBT) on the mentalizing network in the brain.

Method 12 patients diagnosed with schizophrenia according to DSM-IV-TR criteria participated in the study (6 males, mean age: 30.43, SD = 9.35 years, years of education 13.23, SD = 2.45). A modified treatment program for psychoses was used based on the mentalization-based therapy developed by Bateman and Fonagy (2009). Before and after the treatment fMRI analyses (fixed effects analyses) were carried out (3 Tesla, 5 blocks on/off, 36s, TR = 3.62, SPM) using the n-back task.

Results Preliminary results show single analyses due to the small sample size. Comparing the fMRI scans before and after treatment, increases in the activation patterns were found in first episode patients treated with MBT. In patients with TAU a reduction in the activation patterns was demonstrated (mean changes in the activation clusters in the MBT group was 5.53, SD 12.79, in the TAU group -5.80, SD 6.91).

Discussion Mentalization-based treatment is a promising approach in the treatment of schizophrenia and can have an impact on social networks in the brain. Further studies are needed for a better understanding of social cognition and the related neural mechanisms in schizophrenia.

Introduction Social cognition is a complex construct that refers to the functions required to understand other people's mental states and behavior. In people with schizophrenia, social cognition deficits account for a proportion of variance in functional outcome, independent of symptomatology. However, the relationships among social cognition, neurocognitive functioning and functional outcome are still unclear. Previous investigations had several limitations including small sample size, heterogeneous and limited measures of social cognition and neurocognitive functions.

Aims Within the study of the Italian Network for Research on Psychoses, we investigated factors influencing outcome in patients with schizophrenia and their unaffected relatives. Psychopathology, including depression, neurocognition, social cognition and outcome were assessed using instruments designed to overcome some of the previous limitations.

Methods Structural equation modeling was used to test direct and indirect effects of neurocognition, social cognition and functional capacity on vocational and interpersonal functioning. Tests of facial emotion recognition, emotional intelligence and theory of mind were included to assess social cognition. The MATRICS Consensus Cognitive Battery (MCCB) was used to investigate neurocognition.

Results In both subjects with schizophrenia and their first-degree relatives, social cognition was found to be independent of negative symptoms and to have a direct impact on outcome. Neurocognition was a predictor of functional capacity and social cognition, which both mediated its impact on outcome. Social cognition was independent of functional capacity and negative symptoms.

Conclusions Better understanding of how neurocognitive dysfunction and social cognition deficits relate to one another may guide efforts toward targeted treatment approaches.

Differential neural correlates of dimensions of negative symptoms in Schizophrenia during social-emotional appraisal and effects of treatment

A. Aleman

Department of Neuroscience, Umc, Groningen, The Netherlands

Factor analyses of large datasets have established two dimensions of negative symptoms: expressive deficits and a motivation. This distinction is of relevance as the dimensions differ in their cognitive and clinical correlates (e.g. with regard to functional outcome). Using functional MRI, we examined the neural correlates of the two negative symptom dimensions with brain activation during social-emotional evaluation. Patients with schizophrenia ($n=38$) and healthy controls ($n=20$) performed the Wall of Faces task during fMRI, which measures emotional ambiguity in a social context by presenting an array of faces with varying degrees of consistency in emotional expressions. More specifically, appraisal of facial expressions under uncertainty. We found severity of expressive deficits to be negatively correlated with activation in thalamic, prefrontal, precentral, parietal and temporal brain areas during emotional ambiguity (appraisal of facial expressions in an equivocal versus an unequivocal condition). No association was found for a motivation with these neural correlates, in contrast to a previous fMRI study in which we found a motivation to be associated with neural correlates of executive (planning) performance. We also evaluated the effects of medication and neurostimulation (rTMS treatment over the lateral prefrontal cortex) on activation during the social-emotional ambiguity task. The medication comparison concerned an RCT of aripiprazole versus risperidone. Compared to risperidone, aripiprazole showed differential involvement of frontotemporal and frontostriatal circuits in social-emotional ambiguity. We conclude that deconstruction of negative symptoms into more homogeneous components and investigating underlying neurocognitive mechanisms can potentially shed more light on their nature and may ultimately yield clues for targeted treatment.

Clinical Use of Biomarkers in Suicidal Behaviors

P. Courtet

CHU Lapeyronie, Emergencic Psychiatry, Montpellier, France

The epidemiology, risk factors, and biological basis of suicidal behaviors have been the object of an ever-increasing research in the last three decades. During this period, researchers all over the world have identified potential biomarkers of risk and developed several theories about the mechanisms leading to suicidal behavior. However, the lack of common terminology, instruments, and cooperation has been a major deterrent. Today, the community has established the bases for this collaboration and evidence coming from neuroscientific studies can already be applied to the field of suicidology. We present here a potential semiology based on current evidence coming from biological, clinical, and neuroimaging studies.

The Patient is Suicidal: What Should I Do as a Clinician?

V. Carli

Karolinska Institutet, National Centre for Suicide Research and Prevention of Mental Ill-Health NASP, Stockholm, Sweden

Suicidal behaviour is the most common psychiatric emergency. A large proportion of suicidal behaviour can be prevented, particularly in cases associated with mental disorders. Early recognition of suicidality and reliable evaluation of suicide risk are crucial for the clinical prevention of suicide. Evaluation of suicidal risk involves assessment of suicidal intent, previous suicide attempts, underlying psychiatric disorders, the patients' personality, the social network, and suicide in the family or among acquaintances as well as other well-known risk factors. Suicide risk assessment should take place on several levels and relate to the patient, the family and social network but also to the availability of treatment, rehabilitation and prevention resources in the community. As suicide risk fluctuates within a short period of time, it is important to repeat the suicide risk assessment over time in an emphatic and not mechanistic way. The suicidal person may mislead both family members and hospital staff, giving a false sense of independence and of being able to manage without the help of others. Although extreme ambivalence to living or dying is often strongly expressed by the suicidal individual, it is not seldom missed by others. If observed in the diagnostic and treatment process, dialogue and reflection on such ambivalence can be used to motivate the patient for treatment and to prevent suicide. If ambivalence and suicidal communications go undiscovered, the treatment process and the life of the patient can be endangered. Today, several measurement tools of suicide risk exist, including psychometric and biological measurements. Some of these tools have been extensively studied and measures of their sensitivity and specificity have been estimated. This allows for the formulation of an approximate probability that a suicidal event might happen in the future. However, the low precision of the predictions make these tools insufficient from the clinical perspective and they contribute very little information that is not already gained in a standard clinical interview. Psychiatrists and other mental health professionals have always longed for reliable and precise tools to predict suicidal behavior, which could support their clinical practice, allow them to concentrate resources on patients that really need them, and backup their clinical judgement, in case of eventual legal problems. In order to be useful, however, the approximate probability that a suicidal event might happen in the future is not sufficient to significantly change clinical routines and practices. These should rely on the available evidence base and always consider the safety of the patient as paramount.

Diagnosing and treating suicidal adolescents

J. Balazs^{1,2}

¹ Eotvos Lorand University- Institute of Psychology- Budapest-Hungary, Department of Developmental and Clinical Child Psychology, Budapest, Hungary

² Vadaskert Child Psychiatry Hospital and Outpatient Clinic, Budapest, Hungary

Suicide is the second leading cause of death in Europe among 15–29 year olds. Adolescence is a sensitive period during development with several age specific factors, which can increase suicidal risk.

As it is in all cases, the first step of the diagnostic procedure of suicidal adolescents is creating an appropriate environment for the evaluation and rapport building.

More than 90% of suicidal adolescents has ongoing and usually untreated psychiatric disorder/s and about three-quarters of them has at least one subthreshold diagnosis. Potential common risk factors of adolescence suicide include both internalizing and externalizing disorders, such as major depressive episode, substance use and conduct disorder. The comorbidity of psychiatric disorders—both subthreshold and threshold - has been associated with increased risk for suicide. The careful assessment of subthreshold and full psychiatric disorders of suicidal adolescent is important in suicide prevention and the treatment of suicidal adolescents. The diagnostic procedure includes both clinical assessment and using validated (semi) structured diagnostic interviews. Rating scales can provide information on the severity of the patient's symptoms. Next to the assessment of the symptoms it is important to take the history and to get know about adolescents' possible life events. Clinicians should carefully screen potential suicidal behavior itself, which includes both clinical assessment and validated interviews and tests. Complex treatment of suicidal adolescents can include, if it is necessary hospitalization due to the management of acute suicide risk and the appropriate treatment of subthreshold and threshold psychiatric disorders with the consideration of possible life events.

When your patient dies by suicide; aftermath and implications

B. Sadock

New York University School of Medicine, New York

Over fifty percent of psychiatrists will have at least one patient die by suicide while in treatment and some will have more than one patient suicide during the course of their career. The impact of patient suicide on the personal and professional lives of those psychiatrists can be profound. Personally, many suffer a grief reaction than can progress to depression in some cases. Almost all experience a sense of shock upon first learning of the event. Feelings of guilt are also common. Professionally, many fear disapproval from peers and may never again treat a suicidal patient. Some psychiatrists leave the field completely or go into administration so that they never have to treat patients again.

Surveys of training programs have found that most provide training in the assessment of suicide risk and in the management of the suicidal patient but there is minimal training in how to deal with the aftermath of a patient suicide. There is a need to teach and to help practicing psychiatrists, at whatever stage in their career, cope with the stress that occurs when one of their patients dies by suicide during the course of therapy. Important issues are how and when to contact family members and other survivors, whether or not to attend a funeral or memorial service and what and what not to do regarding discussing the case with others. The risk of litigation also is influenced by how psychiatrists behave after patient suicide occurs. The case of Ernest Hemingway is used as an example to illustrate some of these concepts.

Symposium: E-Mental Health in Psychiatry—Future Perspectives of an Emerging Field

S114

From Telepsychiatry to eMental Health—Experiences and Prospects in Europe

D. Mucic

The Little Prince Psychiatry Centre, eMental-Health, Copenhagen, Denmark

What started with telepsychiatry (videoconference) has been turned into e-Mental Health (eMH) due to rapid development of IT technology, decreased prices and increased user experiences. Access to mental health care is one of the identified problems within EU mental health services. Increased migration into and within EU cause the increased demands for clinicians with selected skills. Telepsychiatry is the oldest and most common eMH application. The first international telepsychiatry collaboration established between Sweden and Denmark back in 2006 was a success. This model might be used as collaboration prototype while speaking about current refugee crisis in Europe and treatment of mentally ill migrants. The experiences from this pioneer international transcultural telepsychiatry service in combination with various eMH applications may be used as an inspiration for conducting of larger international eMH service capable to provide mental health care toward diversity of patient populations underserved on their mother tongue within EU.

eMH applications could improve quality of care and access to mental health care in rural, remote and under-served as well as in metropolitan areas all around EU.

E-Mental health for mental disorders—focus on psychotic disorders and PTSD

W. Gaebel

Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany

Introduction E- mental health technologies have developed rapidly over the past years and may support finding solutions to challenges like scarce resources or the treatment gap in psychiatry.

Objectives Provision of guidance on eMental health technologies in the treatment of post traumatic stress disorder and psychotic disorders.

Methods Two evidence- and consensus-based EPA Guidance papers on eMental health technologies for the treatment of post-traumatic stress disorder and psychotic disorders were developed.

Conclusions The evidence on the efficacy of e-mental health interventions for the treatment of PTSD and psychotic disorders is promising. However, more research is needed in the field.

Gambling Disorder (GD) is a complex psychopathological phenomenon, characterized by the interaction of multiple etiological factors and a very heterogeneous symptomatological expression. Currently many questions remain concerning the best way of treating GD. Indeed, the traditional used (cognitive) behavioral interventions have at best a modest effect size. In addition, there remains a large treatment gap, i.e. less than 10% of pathological gamblers ever seek help and enter treatment. E-health interventions could potentially help to close this gap. Cognitive bias modification (CBM) refers to a class of cognitive training paradigms that target specific automatic attentional, behavioral or evaluative biases triggered by addiction-related cues. These biases have repeatedly been shown to play an important role in addiction. Recently a number of studies have shown that modifying these biases has been effective in the treatment of different types of addictions, e.g. alcohol use disorders. An online Approach Bias Modification program, testing both Attention Bias Modification (ABM) and Approach Bias Modification (AppBM), is currently tested with Belgian and Dutch problem and disordered gamblers. Personalized motivational feedback has been added to the training program, to increase training adherence and prevent dropout. The same research group is also launching a second web-based study combining online AppBM with an online standard, protocolled, cognitive behavioral Therapy (CBT) program with guidance of a trained therapist. Participants receive nine CBT sessions through online chat with the therapist and, concurrently, nine sessions of AppBM. Preliminary results will be discussed.

E-Mental health in health care systems—a global perspective

J. Wise

CNWL, London, United Kingdom

eMental Health is the use of information technology (ICT) to support and improve mental health; it includes online resources, social media and smartphone applications, as well as videotelephony.

It used to be the new frontier, ungoverned but time has led to a maturity such that the novel is now commonplace and what was once Tomorrow's World is here today. From the experience of the networked Scandinavian countries, to the populations that novel techniques are reaching out to; QR codes in the UK, teens in Australia; from determining levels of Internet Addiction in Poland, to the use of that medium to treat anxiety disorders.

An innovation from Law Enforcement has massive implications for patients recording consultations. Other experiments with risk management led to the failure of 'Radar', but paved the way for social care providers to develop safer systems that can care for large populations with few therapists.

It is this use of Artificial Intelligence that may be the most challenging. Over 90 companies are developing the use of AI in diagnostics and related fields, with 14 US and Canadian hospitals involved

with IBM's Watson. Will Drs become unnecessary? However the most innovative aspect of ICT in medicine is in research whether to greatly accelerate the process, or to ensure that educational tools genuinely answer patients' questions.

eHealth is an expanding field, that holds new promise, and opens question about who we are, what is our role, who do we care for and how; that today, 'No man is an Island', everyone should be connected.

Symposium: European Perspective on Challenges and Opportunities of the Transition from Child & Adolescent to Adult Psychiatric Services

S118

Developing Joint Approaches to Transition Strategy Between Child and Adolescent Psychiatrists and Adult Psychiatrists in the UK

B. Jacobs

United Kingdom

Transition for young people from Child and Adolescent Mental Health Services (CAMHS) to Adult Mental Health Services often creates considerable disquiet for young people and their families in the United Kingdom. There are examples of good services. However, this is a longstanding problem. Professionals know what to do but solutions have been difficult to implement. There is no single solution because services differ across the country. The question becomes how to understand the difficulties of establishing good transition services. What needs to change to achieve this? This presentation will try to address some of these issues.

Introduction Neuroimaging studies have identified several candidate biomarkers of schizophrenia. However, it is unclear whether

the considerable variability in these neurobiological correlates between patients can be translated into the clinical setting.

Objectives We aimed to identify neuroimaging predictors of clinical course in patients with schizophrenia. Combined with the identification of genetically determined markers of schizophrenia risk, our studies aimed to elucidate the biological basis and the clinical relevance of inter-individual variability between patients.

Methods We included over 150 patients with schizophrenia and 279 healthy volunteers across five neuroimaging centers in the framework of the IMAGEMEND project [1]. We performed multiple studies on MRI scans using random forests and ROC curves to predict clinical course. Data from healthy controls served to normalize the data from the clinical population and to provide a benchmark for the findings.

Results We identified ensembles of neuroimaging markers and of genetic variants predictive of clinical course. Results highlight that (i) brain imaging carries significant clinical information, (ii) clinical information at baseline can considerably increase prediction accuracy.

Conclusion The methodological challenges and the results will be discussed in the context of recent findings from other multi-site studies. We conclude that brain imaging data on their own right are relevant to stratify patients in terms of clinical course; however, complementing these data with other modalities such as genetics and clinical information is necessary to further develop the field towards clinical application of the predictions.

Neuroimaging findings in ADHD and the role of genetics

B. Franke

Radboud University Medical Center, Departments of Human Genetics and Psychiatry, Nijmegen, The Netherlands

ADHD is frequently diagnosed in children and adults. The disorder is highly heritable. However, the genetic architecture of ADHD is complex, with multiple genetic variants of individually small effect size contributing to disease in most patients.

In our own studies as well as in the large mega-analyses of the ENIGMA ADHD Working Group, we have investigated the brain substrates of ADHD. We find the disorder to be characterized by delayed sub-cortical and cortical growth of gray matter in childhood, which gradually normalizes in adulthood: sub-cortical volumes as well as cortical thickness and surface area are smaller in children with ADHD, but become indistinguishable from healthy individuals in adulthood. The situation looks different for white matter connectivity: both in childhood and adulthood, widespread differences in the major white matter tracts are found. The pattern of findings suggests that alterations in myelination might lie at the basis of such case-control differences. Since the disorder and many brain structural measures affected in ADHD are highly heritable, we investigated the overlap of genetic risk factors for ADHD with genetic factors involved in brain volume. This resulted in the identification of several genetic variants contributing to disease risk as well as ADHD-related brain phenotype.

In conclusion, we find ADHD to be a disorder of delayed brain maturation in terms of gray matter, but of persistently altered white matter connectivity across the lifespan. Genetic factors influencing both disease risk and brain measures might improve our understanding of disease etiology and persistence.

Cortical and Sub-cortical volumetric abnormalities in bipolar disorder

O. Andreassen

University of Oslo, NORMENT Centre- Dept of Mental Illness and Addiction, Oslo, Norway

Previous MRI studies of bipolar disorder (BD) are often limited by small sample sizes and heterogeneity exists with regard to neuroimaging markers. To address these limitations, the ENIGMA Bipolar Disorder Working Group collected the largest BD neuroimaging data set ever studied ($n=6,500$). Here, we review findings from sub-cortical volume and cortical thickness and area analyses.

ENIGMA harmonized analysis methods were applied to 28 international pooled study samples of MRI data and involved sub-cortical and cortical imaging analyses. We assessed differences between BD and healthy controls (HC) using both mega and meta-analytic multiple linear regression models, adjusting for standard covariates (age, sex, etc.), and correcting for multiple comparisons.

Sub-cortical volume analysis revealed we found consistent volumetric reductions in BD patients for hippocampus and thalamus and enlarged lateral ventricles in patients. In BD, cortical gray matter was thinner in frontal, temporal and parietal regions of both brain hemispheres. BD had large general effects on mean gray matter thickness in both left and right brain hemispheres. Further we found that psychopharmacological treatment showed significant associations with cortical thickness and surface area.

The ENIGMA pipeline allows for identification of brain MRI abnormalities in BD in the largest analysis ever conducted. The results suggest a pattern of brain structure abnormalities, which provide novel insight in pathophysiology of BD, and potential effects of mood stabilizing agents.

Are deficits in social cognition differentiating between schizophrenia and affective disorders

G. Sachs^{1,*}, E. Maihofer², A. Erfurth²

¹ Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria

² Otto Wagner Spital, 6th Psychiatric Department, Vienna, Austria

* Corresponding author.

Over the last decades, in matters of the assessment of psychopathology and its clinical consequences, there has been an increased interest in neurocognitive function including non-social and social cognition.

Classic psychopathology –as represented e.g. by the standardized AMDP system– focuses on pathognomonic signs for the categorization of syndromes [1] and differentiates between disturbances

of perception, concentration, memory retention and long-term memory. A recent short screen for cognitive impairment in psychiatry (SCIP) has addressed five domains of cognitive function: verbal learning–immediate, working memory, verbal fluency, verbal learning–delayed and processing speed [2].

Using the SCIP in admissions from a defined catchment area in the southwest of Vienna we confirm the presence of cognitive deficits in schizophrenic patients and to a lesser degree in bipolar patients. The deficits were present in all five domains and no discriminatory pathognomonic signs could be found between schizophrenia and bipolar disorder.

Recently, possibly selective deficits in social cognition have been described in schizophrenic patients [3]. We review the evidence on the specificity of social impairment to schizophrenia.

From (Psycho) pathology to diagnosis: psychiatry nosology beyond dichotomy

A. Erfurth^{1,*}, G. Sachs²

¹ Otto-Wagner-Spital, 6th Psychiatric Department, Vienna, Austria

² Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria

* Corresponding author.

As in all medical disciplines, diagnosis in clinical psychiatry should be reached in a step-wise approach: after assessing the chief complaint of the patient, a careful examination of the psychopathology follows e.g. by using the AMDP system [1] to preliminarily conclude the process with a syndromal classification [2]. This syndromal classification is of great importance as it guides the initiation of therapy in daily life practice. After gaining additional information (e.g. investigation in the course of the disease, brain imaging, thorough assessment of cognitive function, exclusion of organic causes) a final diagnosis is possible. Unfortunately, a premature jumping to diagnosis is not uncommon (with the potential consequence of incorrect therapies).

In addition to these difficulties, recent neurobiological research has shown that nosologic assignments through conventional diagnostic classifications are far less specific than assumed, revealing a large overlap between diagnostic categories [3,4], e.g. between Schizophrenia and affective disorders. Consequences of this finding are discussed both for the construction of future classification systems and for therapy.

Symposium: Autism spectrum disorders: From the neurobiology to interventions

S124

Psychosis and autism spectrum disorders

M. Kyriakopoulos

London, United Kingdom

Autism spectrum disorders (ASD) and schizophrenia were separated into different diagnostic categories in the late 1970's (DSM-III) having previously been considered as related diagnostic entities. Since then, several lines of evidence have indicated that these disorders show clinical and cognitive overlaps as well as some common neurobiological characteristics. Furthermore, there is a group of patients presenting with ASD and psychotic experiences who pose particular diagnostic and management challenges and may represent a subgroup of ASD more closely linked to psychosis. Evidence from a study of the first empirically derived classification of children with ASD in relation to psychosis based on three underlying symptom dimensions, anxiety, social deficits and thought disorder, will be presented. Further phenomenological, genetic and neuroimaging research on the clinical boundaries and overlapping pathophysiology of ASD and psychosis may help better define their relationship and lead to more effective interventions. Understanding this relationship will also provide a framework of working with patients with mixed clinical presentations.

Autism Spectrum Disorders (ASD) is a group of neurodevelopmental disorders with heterogeneous etiology characterized by deficits in social cognition, communication, and behavioral flexibility. Disturbances on molecular and cellular level in early brain development incl. intercellular communication, an unbalanced ratio between certain neuronal populations and maturation/differentiation process, oxidative stress, happening in embryonal stages, might be promising candidates to explain the development of autistic symptoms.

In order to get a deeper understanding of these processes, valid “disease models” are pivotal. A new cutting edge technique, named brain organoids, has been highlighted as a promising candidate for obtaining a better “disease model”.

Brain organoids derived from patients induced pluripotent stem cells (iPSC) follow in vivo timeline development; they also have the ability to recreate the right complexity of the brains, developmental stages. On the cellular and gene expression level, organoids demonstrate a high similarity to the developing brain in vivo and can therefore recapitulate early stages of the neurogenesis. To date organoids are the most relevant cellular in vitro platform for the understanding of the mechanisms behind ADS pathology. Investigations of “mini brains” at different time points in their development will give a wider and more detailed picture of the disease dynamic and thus the development of therapeutic and prevention strategies. It is a tool that can be used for effective high throughput screening of chemical compounds as potential drugs (“in sphero” drug testing). Organoids are a good modeling system for elucidating the role of epigenetic and environmental factors for development of ASD.

Symposium: Clinical and neurobiological impact of physical exercise interventions in Schizophrenia

S126

The impact of endurance training on brain structure and function in multi-episode Schizophrenia

B. Malchow

Ludwig-Maximilians University, Department of Psychiatry and Psychotherapy, Munich, Germany

Structural and functional brain alterations as well as cognitive deficits are well-documented findings in schizophrenia patients. Cognitive impairments affect the long-term outcome of schizophrenia and are the main contributors to disability. Despite their clinical impact, however, no effective options are available to treat them sufficiently. Aerobic endurance training has been shown to have effects on brain plasticity, gray and white matter volume as well as functional connectivity measures and on cognitive functioning in animal models and healthy humans. However, effects of physical exercise in combination with cognitive remediation are unknown in Schizophrenia. 21 chronic schizophrenia patients and 21 age and gender-matched healthy controls underwent 3 months of aerobic exercise (endurance training, 30 min, 3 times per week). 21 additionally recruited schizophrenia patients played table soccer (known as “foosball” in the USA) over the same period. After 6 weeks of endurance training or table soccer, all participants commenced standardized cognitive training with a computer-assisted training program. We could show that a 3-month endurance-training program combined with CR therapy had positive effects on everyday functioning in multi-episode Schizophrenia patients. Deficits improved from medium to mild as assessed with the GAF. Negative symptoms, short and long-term verbal memory and cognitive flexibility also improved with training. We could demonstrate grey matter volume increase in the left temporal lobe in schizophrenia patients undergoing endurance training. A non-endurance and coordinative training stimulus like

playing table soccer led to a clearly distinct pattern of grey matter alterations in Schizophrenia patients.

Introduction Borderline personality disorder (BPD) is a common and disabling personality disorder associated with difficulties in controlling emotions and impulses, self-injury, feelings of emptiness and abandonment. It is associated with problems in many areas of life, most notably relationships. Psychotherapy is the first-line treatment for people with borderline personality disorder widely used; however, the evidence is not thoroughly investigated. In addition, several specific short-term interventions have been developed during the last decades.

Objectives We are currently updating this cochrane collaboration review on psychological interventions for BPD. First findings on the up-to-date evidence relating to short-term psychological interventions will be presented.

Methods We conducted a cochrane systematic review and meta-analysis of randomized controlled trials (RCTs). Any randomized comparisons of psychological interventions versus unspecific control interventions, waitlist or specific psychotherapeutic interventions in adult BPD patients were eligible. Primary outcomes were BPD core pathology as depicted by DSM criteria. Secondary outcomes included depression, anxiety, general psychopathology, dropouts and adverse events. Two independent researchers selected trials, assessed quality and extracted data independently.

Results The current evidence of short-term psychological interventions in general and the different types of interventions for which RCT evidence is currently available will be evaluated.

Disclosure of interest The authors declare that they have no competing interest.

Introduction Many new approaches have been developed to treat borderline personality disorder (BPD) by means of psychotherapy. Though there is a clear research trend towards short-interventions, the evidence from randomised controlled trials (RCT) on longer-term programmes still accumulates. On the one hand, well-established treatments like Dialectical Behavior Therapy (DBT) or Mentalisation-Based Treatment (MBT) are now subject to real-world effectiveness studies; on the other hand, new dynamic approaches have been studied, lasting longer than 6 months.

Objectives We are currently updating the cochrane Collaboration review on psychological interventions for BPD. First findings on the effects of longer-term psychotherapies will be presented.

Methods We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) according to cochrane collaboration standards. Any randomized comparisons of psychological interventions versus unspecific control interventions, waitlist or specific psychotherapeutic interventions in adult BPD patients were eligible. Primary outcomes were BPD core pathology as depicted by DSM criteria. Secondary outcomes included associated pathology, i.e., depression and anxiety, general psychopathology severity and functioning as well as tolerability and safety. Two researchers selected trials, assessed quality and extracted data independently.

Results The current evidence of longer-term psychological interventions in general, and the types of interventions for which RCT evidence is available will be evaluated and critically discussed.

* Corresponding author.

Background Despite the relatively weak evidence base, individuals with borderline personality disorder are often treated with pharmacological interventions. Amongst the drugs, which have

shown most promise, are mood stabilizers, which were one of the two drug classes with the most beneficial effects in a previous cochrane review though the robustness of findings was described as low (Stoffers et al., 2010). Here we present data on the latest evidence for mood stabilizers based on an updated cochrane review currently underway.

Methods A systematic review and meta-analysis of randomized controlled trials was conducted. All randomized comparisons of drug vs. placebo, drug vs. drug, or drug vs. a combination of drugs in adult BPD patients were eligible for inclusion. Outcomes comprised BPD core pathology as depicted by DSM criteria, associated pathology, i.e., depression and anxiety, general measures of overall psychopathology severity, tolerability, and adverse effects. Two researchers selected trials, assessed quality and extracted data independently.

Results Only a limited number of additional trials using mood stabilizers was identified since the publication of the last cochrane review, mainly utilizing Sodium Valproate. This added to the evidence base for mood stabilizers though the overall evidence remains very limited.

Conclusion Mood stabilizers show some initial evidence for their effectiveness in borderline personality disorder. However, these have to be replicated before wider conclusions can be drawn for clinical practice.

Disclosure of interest The authors declare that they have no competing interest.

Cognitive dysfunctions in the psychoses and their impact on patients' social functioning

A. Mucci*, S. Galderisi

University of Campania "Luigi Vanvitelli", Department of Psychiatry, Naples, Italy

* Corresponding author.

Introduction Impairment of neurocognitive functions, such as attention, memory or executive functions, as well as of social cognition, particularly of affect recognition and theory of mind, are frequently observed in people with Schizophrenia or other psychotic disorders. These dysfunctions are associated with poor real-life functioning. Social cognition deficits mediate in part the impact of neurocognitive dysfunction on functional outcome.

Aims To review literature findings on prevalence, severity and association with functional outcome of neurocognitive and social cognitive deficits in schizophrenia and other psychotic disorders. **Methods** We searched PubMed for English/Italian or French full-text publications with the keywords.

schizophr*/psychosis/psychot*/AND neurocognitive/cognitive/neuropsychological/memory/attention/"executive function"/learning/"social cognition"/"theory of mind"/"affect recognition"/"social emotion recognition"/"emotional intelligence"/"emot* recognition". Furthermore, we manually searched the reference lists of relevant papers, systematic reviews and meta-analyses.

Results In people with schizophrenia, schizoaffective disorder or bipolar disorder with psychotic features, neurocognitive and social cognition deficits were observed in all phases of the disorders, even after symptom remission. Some of these deficits were observed in subjects at high-risk to develop schizophrenia before psychotic onset. In all these subjects, cognitive deficits are associated with worse psychosocial functioning and poor quality of life. Pharmacological treatments do not alleviate cognitive deficits, which can also limit the benefit of other psychological or psychosocial interventions.

Conclusions Neurocognitive and social cognition deficits need to be targeted by specific interventions to improve real-life functioning and quality of life of people with schizophrenia or psychotic disorders.

Biological correlates of the effects of cognitive remediation in the psychoses

R. Penades

Hospital Clinic Barcelona, Department of Psychiatry and Clinical Psychobiology, Barcelona, Spain

Cognitive Remediation Therapy (CRT) deals with the cognitive impairment, which is one of the most disabling symptoms of schizophrenia. Unfortunately, the understanding of its neurobiological correlates is far from complete. Neuroimaging studies have shown that CRT is able to induce neurobiological changes although the results have not always been enough replicated. The most commonly reported changes were those that involved the prefrontal and thalamic regions. Additionally, structural changes were described in both the grey and white matter, suggesting a neuroprotective effect of cognitive remediation. Neuroimaging studies of cognitive remediation in patients with schizophrenia suggest a positive effect on brain functioning in terms of the functional reorganisation of neural networks. From a different perspective, some changes in serum levels of Brain derived neurotrophic factor (BDNF) have been described. However, our replication of this trial has not been able to find any significant differences. So, nowadays the status of BDNF as a biomarker of cognitive recovery is possibly premature. One possible explanation can be the role of genetics and their different polymorphisms. COMT and BDNF polymorphisms could be accounting for the different outcomes of CRT. Moreover, some studies suggested a role of genes affecting dopamine modulation on outcomes of cognitive remediation.

S133

Impact of Cognitive remediation on the use of psychiatric services and patterns of care of patients with psychoses

A. Vita

University of Brescia, Clinical and Experimental Sciences, Brescia, Italy

Cognitive remediation (CR) has proved to be effective in improving cognition, symptoms and psychosocial functioning in schizophrenia and other psychoses, but its impact on the use of psychiatric services and patterns of care of patients suffering from these diseases is still scarcely known. In fact, it would be particularly relevant to know if such intervention may have any modifying effect on use of services and costs of treatments. There is preliminary evidence that such an impact does exist, with possible reduction of number and duration of hospitalizations and of long-term residential stays and consequent reduced costs of inpatient treatment. On the other hand, community treatment costs could be increased as an effect of a shift of psychiatric and psychosocial interventions from inpatient to outpatient activities. A critical review of the existing literature on the issue will be provided, together with a discussion of the impact of this shift towards the attainment of increased functional and social recovery in the individual patient.

Disclosure of interest The author declares that he has no competing interest.

Symposium: Social science and biological findings informing research in suicidal behavior

S134

Electrodermal reactivity and suicide

M. Sarchiapone

University of Molise, Psychiatry, Campobasso, Italy

Electrodermal Activity (EDA) refers to changes in electrical conductance of the skin. Electrodermal hyporeactive individuals are those who show an unusual rapid habituation to identical non-significant stimuli. Previous findings suggested that electrodermal hyporeactivity has a high sensitivity and a high negative predictive value for suicide. The aim of the present study is to test the effectiveness and the usefulness of the EDOR[®] (ElectroDermal Orienting Reactivity) Test as a support in the suicide risk assessment of depressed patients.

One thousand five hundred and seventy three patients with a primary diagnosis of depression, whether currently depressed or in remission, have been recruited at 15 centres in 9 different European countries. Depressive symptomatology was evaluated through the Montgomery-Asberg Depression Scale. Previous suicide attempts were registered and the suicide intent of the worst attempt was rated according to the first eight items of the Beck Suicide Intent Scale. The suicide risk was also assessed. During the EDOR[®] Test two fingers are put on gold electrodes and a moderately strong tone is presented through headphones now and then during the test. The EDOR[®] Test is able to register the electrodermal responses to those tones, along with the blood volume in the fingers. Each patient is followed up for one year in order to assess the occurrence of suicidal behaviors.

Expected results would be that patients realizing a suicide attempt with a strong intent or committing suicide should be electrodermally hyporeactive in most cases and non-hyporeactive patients should show only few indications of death intent or suicides. Preliminary findings will be presented.

Disclosure of interest The participating centres received funding for this study by EMOTRA AB, Sweden.

Neural patterns in ecological momentary assessment of social stressors

P. Courtet^{1,*}, E. Olié², M. Husky³, J. Swendsen⁴¹ CHU Lapeyronie, Emergencic Psychiatry, Montpellier, France² CHU Lapeyronie, Emergency Psychiatry, Montpellier, France³ University of Bordeaux, Laboratoire de Psychologie EA4139, Bordeaux, France⁴ University of Bordeaux, CNRS- UMR 5287 INCIA, Bordeaux, France

* Corresponding author.

Background Suicidal behaviors result from a complex interaction between social stressors and individual vulnerability. Ecological Momentary Assessment (EMA) provides the opportunity to investigate the relationship between social stressors in daily life and the occurrence of negative thoughts leading to suicidal ideation. fMRI showed that a neural network supports the sensitivity to social stressors in suicide attempters.

Objective A joint fMRI/EMA study investigated whether individual differences in brain reactivity to scanner-based social rejection was related to social rejection during real-world social interactions.

Method Sixty women were included: euthymic women with a history of depression with or without suicidal behavior and healthy controls. The Cyberball Game was used as a social exclusion paradigm. Following the fMRI, subjects used EMA for seven

days, providing data on environmental, contextual and emotional factors.

Results In the fMRI study, in comparison to patients without any history of suicide attempt and healthy controls, suicide attempters showed decreased activation in the posterior cingulate cortex, insula and superior temporal gyrus during the exclusion vs. inclusion condition. In the EMA study, social stressors were specific predictors of suicidal ideation in suicide attempters. We will examine here if individuals who show greater activity in specific brain regions during scanner-based social rejection reported a greater social distress during their daily social interactions.

Conclusions this study used a combined technique to assess whether neural reactivity to experimental social rejection in the scanner is related to real-world social experience, and if it may help to understand the sensitivity to social stress in suicidal behavior.

Disclosure of interest The authors declare that they have no competing interest.

A review of advances in social sciences and their application for research in suicidal behavior

J. Lopez Castroman

Nîmes University Hospital, Gard, Nîmes, France

Suicidal behavior and its prevention constitute a major public health issue, and the moderating effect of sociodemographic factors has been studied for more than a century. In the last years it has become evident that the relationship between social factors and suicidal behavior is complex and highly dependent on the context. For instance, minorities suffering marginalization, such as the Inuit in Canada or the aborigines in Australia, present high rates of suicide. However, other minorities, such as immigrants arriving to tightened communities, can be protected from suicide compared to the social majority. Other contradictory effects have been reported concerning income per capita and the evolution of the economy. Unfortunately, the interplay of social factors in suicidal behavior and the social consequences of suicide attempts are rarely represented in theoretical models of suicidal behavior, despite their importance to adapt suicide prevention policies to social groups at risk. In this presentation, recent advances and new and integrative avenues for future research in the social aspects of suicidal behavior will be summarized.

Disclosure of interest The author declares that he has no competing interest.

MicroRNA profiling in postmortem brain and plasma exosomes: Biomarker perspective of suicidality

Y. Dwivedi

University of Alabama at Birmingham, Psychiatry and Behavioral Neurobiology, Birmingham, USA

Introduction Suicide is a leading cause of death. Although research on the biological aspects of suicide is accumulating, there is no testable biomarker to assess suicidality. miRNAs, small non-coding RNAs, have been implicated in synaptic plasticity, genetic susceptibility to stress and coping to stress response. Because of the presence of microRNAs in circulating body fluids, miRNAs can not only be used as regulators of disease pathologies but also in prognosis and treatment response.

Objectives Whether miRNAs can be used as biomarker for suicidality.

Aims To examine miRNA expression in brain of suicide victims and in plasma exosomes of suicidal individuals.

Methods microRNA expression was studied in prefrontal cortex of depressed suicide subjects and healthy normal controls. Role of microRNAs in synaptic plasticity was studied by examining total and synaptosomes. microRNA expression was also studied in plasma exosomes of depressed non-suicide and depressed suicide subjects and healthy normal controls.

Results We found a global down-regulation of miRNAs in depressed subjects (21 miRNAs significantly down-regulated). Many of them were synaptically enriched and encoded at nearby chromosomal loci, shared motifs within the 5'-seeds, and shared putative mRNA targets. In addition, we found a dramatic reorganization of microRNAs in a coordinated and cohesive fashion in depressed subjects. We also detected changes in miRNAs in plasma exosomes of depressed suicide subjects that corresponded to microRNA changes in prefrontal cortex.

Conclusion Our study provides critical evidence that microRNAs play a major role in suicide pathophysiology and that these microRNAs can be reliably used as peripheral biomarker.

Symposium: Driving ability and psychotropic drugs

S138

Driving ability and psychotropic drugs: Introduction, epidemiology and general aspects

A. Brunbauer

kbo-Inn-Salzach-Klinikum gemeinnützige GmbH, Wasserburg am Inn, Germany

Psychiatric illness, psychotropic drugs and driving ability. For most people driving is an important activity in daily life affecting physical, social, and economic well-being. Driving mobility is also an important part of one's self-identity that may influence health status. It could be demonstrated that 67% of psychiatric patients reported to have a valid driver's license and 77% of them referred to regularly use their cars. Closer inspection of data reveals, that road mobility is largely linked to psycho-functional status. In this context a significant issue is the impact of medical conditions and/or psychoactive medicines on road safety. Psychiatric patients, considered as a group, seem to have a moderately elevated risk of being involved in a road traffic accident with high-risk rates especially for organic mental disorders. With respect to pharmacotherapy, within psychotropic medicines an increased road traffic crash risk for benzodiazepines, z-hypnotics and some antidepressants has been well documented. The combination of psychoactive drugs additionally increases risk that is highest when combined with alcohol. However, therapeutic drug use may also lower risk, as the illness itself constitutes a higher risk of road traffic accidents. As many studies did not adequately control for confounding factors, results of epidemiological studies must be interpreted cautiously.

S139

Antipsychotics and driving ability

C. De las Cuevas

University of La Laguna, Psychiatry, San Cristóbal de La Laguna, Spain

Driving a vehicle is an important everyday life skill associated to a psychiatric patient's autonomy and identity. Nevertheless, the right to drive is not a right at all, it is a privilege granted and regulated by rules and restrictions from the States that have also the duty to pull this privilege and deny the ability to legally drive in potentially unsafe drivers. The decision about for whom and when to forbid driving is a difficult matter of judgment that must remain a clinical and professional judgment within the medical encounter. Both antipsychotics as the psychiatric disorders target of these psychoactive drugs produce changes of psychomotor performance that can interfere with the ability to drive safely. Moreover, it is really hard to distinguish between the effects of the disease itself as opposed to the effects of the medication when studying the interaction between antipsychotics and driving ability. Previous results of our research in the field indicate that psychiatric patients who improved clinically after drug treatment also showed improvements in driving ability. So, adequate psychotropic treatment causes a positive effect on driving performance that outweighs the possible deleterious effect of medication. However, it remains essential to supply mental health professionals with new information, which is quantitatively and qualitatively valid, on the role of antipsychotics in driving ability. The purpose of the present lecture is to review research undertaken to-date on the effects of antipsychotic medications on driving ability. A search of various databases, including Medline, Embase and PsycInfo, will be conducted.

S140

Antidepressants and driving ability

J. Ramaekers

Department Neuropsychol, Psychopharmacol. Maastricht University, The Netherlands

Depression is a mental disorder that is likely to affect daily functions, including driving ability. However, driving performance of depressed patients remains poorly investigated. We will present 2 studies designed to assess driving performance of patients receiving long-term antidepressant treatment. The first study compared driving performance of untreated depressed patients, depressed patients receiving SSRI or SNRI treatment for 6–52 weeks and matched healthy controls. The second study compared driving performance of long-term users of sedative antidepressants to that of matched healthy controls. A standardized on-the-road driving test was used to assess standard deviation of lateral position (SDLP), a measure of weaving. In the first study, mean SDLP of untreated and treated patients were significantly higher as compared to SDLP of matched controls. Driving impairment in the treated group was significantly less as compared to the untreated group. SDLP was positively correlated to severity of depression across both groups of patients. In the second study, SDLP of patients receiving sedative antidepressants (e.g. mirtazapine) during 0.5–3 yrs was significantly higher as compared to matched controls. Driving performance of patients receiving sedative antidepressants for more than 3 yrs did not differ from matched controls. Severity of depression in these patients groups was low. It is concluded that symptoms of depression are a major cause of driving impairment. Reductions in severity of depression through antidepressant treatment reduce severity of driving impairment. Sedative antidepressants such as mirtazapine however can still induce driving impairment in patients with remission for up to 3 yrs of use.

Driving ability and psychotropic drugs: Legal framework, forensic aspects

M. Graf

University Psychiatric Hospitals, Basel, Switzerland

Although the rate of victims of road traffic accidents is already relatively low in Switzerland compared to other western countries, still 253 people died in 2015. The Swiss parliament therefore issued in 2012 already a program called “Via sicura” to increase road traffic security by means of a package of measures, ranging from immobilizing systems for the car in case of drunken drivers to stricter rules for medical assessment of ability to drive a car and better training for doctors in such assessment to finally stricter laws regarding lower tolerance for alcohol levels and zero tolerance for drug consumption when driving a car. The presentation will focus on changes in legal regulation for both medical assessment as well as rules for alcohol or drug consumption when driving a car. Positive and negative consequences for the field of forensic psychiatry are discussed.

Symposium: Ethics and aesthetics in psychiatry—Tasks and goals

S142

Ethics and aesthetics—Philosophical perspectives

M. Poltrum

Anton Proksch Institute, Vienna, Austria

European intellectual history teaches us that beauty is not just an adornment to life but is also a major source of strength for our life. Moreover, the positive aesthetic experience also has healing power. That beauty is a highly effective antidote to life's suffering, i.e. acts as an anti-depressant, has been documented in the tradition of philosophical aesthetics from Plato to Bloch. Beauty reveals truth and goodness (Plato), it shows the harmonious order and the glory of things (Pseudo-Dionysius the Areopagite), it is one of the transcendental names of God (Thomas of Aquinas), in beauty the world appears in its perfection (Baumgarten), beauty is the daughter of freedom (Schiller), it offers a temporary escape from the suffering of existence (Schopenhauer), aesthetic values are the only values that withstand nihilism and the meaninglessness of existence and are thus the actual stimulus of life (Nietzsche), the beautiful is the sensual appearance of the idea (Hegel), beauty is an anti-depressant and Weckamin of being, it tears people out of their forgetfulness of Being (Heidegger), there is a close relationship between the shining forth of the Beautiful and the evidentness of the Understandable (Gadamer), in an artwork and through the aesthetic attitude the Other, foreign, the non-identical that is mangled and mutilated

in the administered world is preserved and saved (Adorno). Many more positive affirmative descriptions from the tradition of philosophical aesthetics demonstrate that beauty and the aesthetic have a therapeutic dimension.

Ethics in transcultural psychiatry

M. Schouler-Ocak

Psychiatric University Clinic of Charité at St. Hedwig Hospital, Psychiatry and Psychotherapy, Berlin, Germany

Global migration and the increasing number of minority groups, including immigrants, asylum seekers, refugees and ethnic minorities, mean that increasingly, psychiatrists and patients may come from different cultural backgrounds. Therefore, cultural differences between patients and clinicians have become a matter of growing importance to mental health care as western societies have become increasingly diverse. This talk will attempt to illustrate how attention to these cultural differences enriches the discussion of ethics in mental health care. This talk will also attempt to underline that cultural competence is able to enhance the ethical treatment of mental health of patients from different cultural backgrounds. Consequently, to be culturally competent, a clinician must be sensitive, knowledgeable, and empathetic about cultural differences. Therefore, cultural competence is a concrete, practical expression of bioethics ideals. According to Hoop et al. in 2008, it is a practical, concrete demonstration of the ethical principles of respect for persons, beneficence (doing good), nonmaleficence (not doing harm), and justice (treating people fairly), the cornerstones of ethical codes for the health professions.

In this talk the complex relationship between culture, values, and ethics in mental health care will be analyzed and discussed.

Disclosure of interest The author declares that he has no competing interest.

S144

Social aesthetics and mental health—Theory and practice

M. Musalek

Anton Proksch Institute, Vienna, Austria

The Hows of dealing with life and with our fellow human beings is the main focus of scientific endeavor of social aesthetics as a multidisciplinary research domain. This knowledge about the Hows of our social coexistence in general and in preventative and curative medicine in particular provides the indispensable social aesthetics foundation for therapeutic interventions in which the individual once more becomes the measure of all things and activities. European intellectual history teaches us that beauty is not just an adornment to life but is also a major source of strength for our life. Moreover, the positive aesthetic experience also has healing power. Social aesthetics that wishes also to be understood as the science of beauty in interpersonal relationships provides us with knowledge that in medical-therapeutic practice becomes a key pillar of human-centred approaches to prevention and treatment.

Symposium: Subtypes of schizophrenia

S145

Characterization of different subtypes of schizophrenia: Premorbid functioning, neurophysiological differences, functional outcomes

S. Galderisi*, A. Mucci, P. Bucci, M. Maj

University of Campania "Luigi Vanvitelli", Department of Psychiatry, Naples, Italy

* Corresponding author.

Introduction Although not included in current diagnostic systems, deficit versus non-deficit and resistant versus non-resistant schizophrenia subtypes look more promising than traditional schizophrenia subtypes in terms of stability across time, clinical utility and interest for research.

Aims To critically analyze evidence supporting the validity of two schizophrenia subtypes: Deficit Schizophrenia (DS) and Treatment Resistant Schizophrenia (TRS).

Methods Empirical data supporting the validity of DS and TRS subtypes will be critically reviewed.

Results DS, in comparison with non-deficit schizophrenia, is characterized by poorer premorbid functioning, more insidious onset, lower prevalence of dysphoria, hostility, suicidal ideation, depressive symptoms and substance abuse, different neurobiological abnormalities, and poorer response to treatment. The diagnosis of DS shows high reliability and stability across time. However, research based on this approach has proven difficult, especially in first-episode schizophrenia, and findings have not been as homogeneous as expected.

TRS patients, as compared to non-TRS ones, show persisting psychotic symptoms, greater severity of negative symptoms, more severe cognitive dysfunctions, poorer premorbid functioning, longer duration of untreated psychosis, more frequent co-morbidity with personality disorders, earlier illness onset and poorer social functioning.

Conclusions Future research should consider a) refining diagnostic criteria for DS and identifying valid DS endophenotypes; b) dissecting TRS based on psychopathological characteristics (e.g. presence of primary and persistent negative symptoms or persistently severe positive symptoms), and underlying neurobiological mechanisms (e.g. dopamine synthesis capacity and glutamatergic transmission).

Genetics and neurophysiological characterization of first episode and deficit schizophrenia

J. Samochowiec^{1,*}, P. Bienkowski², D. Frydecka³, B. Misiak³, J. Kucharska-Mazur¹, J. Pelka Wysiacka¹¹ Pomeranian Medical University, Psychiatry, Szczecin, Poland² Department of Psychiatry, Warsaw Medical University, Warsaw, Poland³ Department of Psychiatry, Medical University of Wrocław, Wrocław, Poland

* Corresponding author.

The deficit subtype of schizophrenia (DS) is hypothesized to constitute a pathophysiologically distinct subgroup of schizophrenia patients suffering from enduring, idiopathic negative symptoms. The aim of the present study was to assess a relationship between the deficit/non-deficit dichotomy and various markers. We tested a hypothesis that stem cells and factors that modulate their trafficking may be biological markers of acute psychosis.

Methods The DS was identified using the SDS. The MMP-9, BDNF, and COMT gene polymorphisms were genotyped. DNA methylation of the human endogenous retrovirus type K (HERV-K) sequences was determined. Smell identification test was performed using the Sniffin' Sticks test. For the assessment of executive function we used the Wisconsin Card Sorting Test, the Trail Making Test, Verbal Fluency Test Phonemic, Stroop Color Word Test and Go/No Go task.

Results and Discussion There was no association between the examined functional gene polymorphisms, methylation levels and DS. Similarly, there was no relationship between overall odor identification abilities and the deficit/non-deficit dichotomy. The results tended to indicate specific problems in the identification of few odors in DS. DS, compared with the non-deficit group, obtained lower scores in the WCST and TMT and exhibited greater interference within concept formation and non-verbal cognitive flexibility. Furthermore, in patients with the first schizophrenia-like episode, the number of circulating Lin (-)/CD45 (-)/CD34 (+) very small embryonic like stem cells (VSELs) and the S1P plasma level were the best predictors of risk and are proposed as novel markers for the first "schizophrenic" episode of psychosis.

S147

From identification of neurofunctional systems to individualization of treatment for schizophrenic disorders

P. Falkai

Medical University, Munich, Germany

Schizophrenia is a severe brain disorder characterized by positive, negative, affective and cognitive symptoms and can be viewed as a disorder of impaired neural plasticity. Schizophrenia leads to long-term disability in a substantial proportion of the sufferers and it is still connected with an unfavorable outcome. Therefore, it is inevitable to find and apply interventions to reduce the risk of psychosis and/or prevent a further chronification of the illness. There are two major obstacles translational schizophrenia research has to face: One is the introduction of easy to measure and reliable biomarkers; the second are add-on treatments to improve the residual symptoms of this illness. To reach the first goal, subgroups must be identified utilizing biomarkers in order to induce specifically targeted treatments. For the long-term prognosis and outcome it is necessary for biomarkers to constitute easy measurable clinical routine parameters. Studies will be summarized using clinical (GAF, PANSS, CGI) and imaging data in order to accurately predict the outcome in the first week, for 4 and for 52 weeks. This will help to subdivide these groups into a good, an intermediate and a fair outcome group. Future clinical studies will benefit enormously if it was possible to focus on the intermediate group, where recovery could be reached by targeted treatment as most of those subjects are showing partial recovery or remission.

Workshop: To screen or not to screen?

W001

Problems of screening for psychiatric comorbidity in the medically ill: What can be recommended?

A. Diefenbacher

Evangelisches Krankenhaus Königin Elisabeth, Berlin, Germany

CL-psychiatrists have to work under severe time pressure in acute care setting. Hence, it is necessary to have an armamentarium of screening tools for disorders most frequently met in the general hospital. This presentation will discuss such tools for delirium, alcohol abuse, depression, personality disorders (“how to manage difficult patients”), attachment styles. On a conceptual level, the so-called “situational approach” in cl-psychiatry will be discussed.

The impact of screening psychiatric comorbidity and high-risk feedback on liaison psychiatric consultation rates and clinicians' attitudes on a neurology ward

R. Van Damme^{1,*}, G. Portzky¹, P. Boon², G.M.D. Lemmens¹

¹ *Department of Psychiatry, Ghent University Hospital, Ghent, Belgium*

² *Department of Neurology, Ghent University Hospital, Ghent, Belgium*

* *Corresponding author.*

Introduction Lifetime prevalence of psychiatric comorbidity in neurological patients is as high as 55%, but it remains often undetected and therefore untreated in hospital settings. Further, clinicians tend to make little use of the consultative and liaison psychiatric team for detection and treatment of anxiety and mood disorders in neurological patients. The current study aimed to investigate whether the implementation of a stepped screening protocol with high risk feedback to the clinician had an influence on the use of consultative and liaison psychiatric services.
Method All patients admitted to the neurological ward were assessed using a stepped screening protocol for depression, anxiety

<http://dx.doi.org/10.1016/j.eurpsy.2017.01.025>

and substance use during 15 months. Positive screening resulted in feedback to the clinicians depending on the study phase (e.g. feedback vs. no feedback).

Results No differences were found in the use of consultative and liaison psychiatric services during the non-feedback and feedback phase.

Conclusion Screening and high risk feedback of psychiatric comorbidity in neurological patients does not increase psychiatric referral rates. It points to the necessity of a more integrated collaborative care model for detection and treatment of psychiatric comorbidity.

The screening for depression and neurocognitive disorders in subjects newly diagnosed with HIV

S. Ferrari^{1,*}, C. Piemonte¹, L. Feltri¹, F. Ottolini¹, S. Maffei², M.G. Nanni³, S. Alboni⁴

¹ *University of Modena & Reggio Emilia, Department of Diagnostic-Clinical Medicine and Public Health, Modena, Italy*

² *University of Parma, Department of Neurosciences, Parma, Italy*

³ *University of Ferrara, Department of Mental Health, Ferrara, Italy*

⁴ *University of Modena & Reggio Emilia, Department of Life Sciences, Modena, Italy*

* *Corresponding author.*

Background Inflammatory mediators may be relevant to explain the frequent comorbidity between depression, neurocognitive disorders and HIV. HIV induces activation of inflammatory mediators, mainly cytokines, that have been involved in the onset of depression and response to antidepressant treatment.

Aim To identify recurring profiles of inflammatory biomarkers subtending depression, effectiveness of antidepressants and neurocognitive disorders among HIV-infected individuals.

Methods All adult newly HIV-diagnosed out-patients attending HIV clinics in three towns of Northern Italy were screened, assessed for depression and studied immunologically and for neurocognitive disorders.

Results Twenty-five patients have been enrolled so far: of these, 35% were positive to PHQ-9 screening, of which 6 were positive to the diagnostic assessment for depression. No neurocognitive disorders were found among the patients. As the project will develop, it

is expected that frequency of depression, neurocognitive disorders and effective antidepressant treatment will be found to correlate to the profile of immune biomarkers. These findings might help to understand the etiology of depression in HIV, and specifically the role of inflammation and immunological changes.

Psychosocial screening of alcohol liver disease patients before liver transplantation

D. Telles-correia

Faculty of Medicine, University of Lisbon, Psychiatry, Lisbon, Portugal

In Europe, 30% to 50% of liver transplantations are currently due to alcoholic liver disease (ALD). In the United States, this percentage is 17.2%. Post-transplant survival and other predictors of clinical course do not differ significantly from those in other types of transplanted patients, as long as there is no relapse of drinking. However, 20%–25% of these patients lapse or relapse to heavy drinking post-operatively, which has been associated with an increased risk of liver damage and mortality. It is therefore crucial to design specific selection and follow-up strategies aimed at this particular type of patient. Several good and poor prognosis factors that could help to predict a relapse have been suggested, among them the duration of abstinence, social support, a family history of alcoholism, abuse diagnosis versus alcohol dependence, non-acceptance of diagnosis related to alcohol use, presence of severe mental illness, non-adherence in a broad sense, number of years of alcoholism, and daily quantity of alcohol consumption. In this article, we discuss these and other, more controversial factors in selecting ALD patients for liver transplantation. Abstinence should be the main goal after transplantation in an ALD patient. In this article, we review the several definitions of post-transplant relapse, its monitoring and the psychopharmacological and psychotherapeutic treatment.

Workshop: Women in psychiatry: Mind the gender gap

W005

The current status of women in psychiatry in Europe

S. Frangou

Icahn School of Medicine at Mount Sinai, Psychiatry, New York, USA

For more than two decades, psychiatry has retained its position amongst the medical specialties with the highest proportion of women entering residency programs. The percentage of women in junior academic positions in psychiatry is also high and consistently higher than that of men. However, the number of women in positions of leadership remains disproportionately low at around 5% with no evidence of improvement over time. The phenomenon of female under-representation is not unique to psychiatry or academia. Women are under-represented in all fields of leadership and this is a matter of wider societal concern. In this presentation, I will discuss external and internal barriers that women face and detail positive actions that can help women succeed in their careers.

Disclosure of interest The author has edited and co-authored a book on “Women in Academic Psychiatry: A mind to Succeed”

Barriers to gender equality in career advancement and leadership

D. Wasserman

Karolinska Institute, Stockholm, Sweden

Life as a researcher includes a large amount of competition and a heavy workload. Professor's tasks comprise, besides their own research, to lead your research team, to have the responsibility for higher education, expertise in diverse contexts, review of scientific articles, to seek financial support, to work with national and international committees, to serve in administrative posts at the university and in international associations, to write articles, books and book chapters, to attend meetings and conferences, and to address the many other tasks that may arise throughout one's career. This makes one dependent on skillful co-workers, which should not be taken for granted. Given the constant flow of incoming requests, one has to think and choose before agreeing to commit to a task at hand, in order to not set aside your own research. This demands a high capability to prioritize. The choice of a life partner who can share both professional and private interests, a partner who understands, encourages and supports, while at the same time gives the necessary critical feedback, is a treasure. Freud said “love and work are the cornerstones of our humanness”, but work must be pleasurable thus try to combine work, love, and play.

Workshop: Mental health impact of SUDS on neurodevelopmental mental disorders

W007

Neuroimage studies: The effect of methylphenidate in cocaine users with ADHD

C. Crunelle

Overijse, Belgium

Background Attention deficit/hyperactivity disorder (ADHD) is an important contributing factor in the pathophysiology of substance use disorders (SUD), and ADHD occurs more often in populations with SUD compared to the general population. This high prevalence rate and comorbidity may relate to a shared neurobiological vulnerability, including a deregulation of the brain's dopamine system. This comorbidity directly impacts the treatment of ADHD: treatment with methylphenidate is less effective in patients with ADHD and SUD compared to ADHD patients without SUD.

Methods We investigate the underlying neurobiological background of reduced treatment effectiveness for adult ADHD patients with comorbid SUD.

Results We observed lower available dopamine transporters, as well as a reduced binding of methylphenidate to these transporters, and more neurocognitive dysfunction in adults ADHD patients with SUD compared to ADHD patients without SUD.

Conclusion Comorbid ADHD and SUD has a high prevalence rate and reduces ADHD treatment effectiveness, which makes it necessary to screen for the presence of ADHD in patients

seeking SUD treatment. Neurobiological and neurocognitive differences are present between ADHD patients with and without SUD, which together may partially explain the reduced effectiveness of methylphenidate in adult ADHD patients with SUD.

Treatment of ADHD with cannabinoids

P. Asherson^{1,*}, R. Cooper²

¹ London, United Kingdom

² King's College London, Social Genetic and Developmental Psychiatry, London, United Kingdom

* Corresponding author.

Introduction Adults with ADHD describe self-medicating with cannabis, with some reporting a preference for cannabis over ADHD medications.

Objectives The experimental medicine in ADHD-cannabinoids study was a pilot randomised placebo-controlled experimental study of a cannabinoid medication, Sativex oromucosal spray, in 30 adults with ADHD.

Methods The primary outcome was cognitive performance and activity level using QbTest. Secondary outcomes included ADHD and emotional lability (EL) symptoms.

Results Thirty participants were randomly assigned to the active ($n=15$) or placebo ($n=15$) group. For the primary outcome, no significant difference was found in the ITT analysis although the overall pattern of scores was such that the active group usually had scores that were better than the placebo group (Est = -0.17, 95%CI -0.40 to 0.07, $P=0.16$, $n=15/11$ active/placebo). For secondary outcomes, Sativex was associated with non-significant improvements in hyperactivity/impulsivity ($P=0.03$), a cognitive measure of inhibition ($P=0.05$), inattention ($P=0.10$) and emotional lability. Per-protocol effects were higher.

Conclusion Results did not meet significance following adjustment for multiple testing. One serious (muscular seizures/spasms) and three mild adverse events occurred in the active group and one serious (cardiovascular problems) adverse event in the placebo group. Adults with ADHD may represent a subgroup of individuals who experience a reduction of symptoms and no cognitive impairments following cannabinoid use. This provides some preliminary evidence in support of the self-medication theory of cannabis use in ADHD. A larger trial is warranted.

Disclosure of interest Kings College London research support account for Asherson received honoraria for consultancy to Shire, Eli-Lilly and Novartis educational/research awards from Shire, Lilly, Novartis, Vifor Pharma, GW Pharma and QbTech speaker at sponsored events for Shire, Lilly and Novartis.

Guidelines for managing ADHD and substance use disorders

F. Matthys

Department of Psychiatry, University Hospital Brussels (UZ Jette) & Vrije Universiteit Brussels (VUB), Belgium

Guideline for managing ADHD and substance use disorders (SUD) Frieda Matthys, MD, PhD.

Background Despite the high prevalence of ADHD in adults with SUD and the availability of an approved guideline, under diagnosis and inadequate treatment still persist. This comorbidity associates with reduced treatment effectiveness, making successful treatment in adults with ADHD and SUD a challenge.

Methods The guideline of 2010 for recognizing and treating adult ADHD in patients with SUD is updated in 2016, in cooperation

with caregivers, of the addiction centers in Belgium and based on research literature and clinical experience. The English translation is discussed by an international group of clinicians and experts to result in a consensus statement via ICASA (International Collaboration on ADHD and Substance Abuse).

Results This consensus presents a useful guide for the diagnosis and treatment of ADHD and SUD. Due to the lack of scientific evidence on some of the topics, the guide is a combination of evidence based and practice based recommendations.

Conclusion The management of ADHD in patients with SUD remains a challenge. Diagnosis is complicated by SUD symptoms and by the skepticism associated with the recognition of ADHD in adults. The treatment is hampered by high relapse rates and reduced effectiveness of the currently available pharmacotherapies. Combining psycho- and pharmacotherapy in an integrated treatment that covers both ADHD and SUD, may help to keep these patients in treatment.

A Dutch manual for the integrated treatment of ADHD and SUD is being developed.

Disclosure of interest Honorarium Lilly.

Workshop: big data in psychiatry. unprecedented opportunities, new strategies

W010

Permutations and computational power: A molecular cascade analysis to approach big data in psychiatry

A. Drago

Aarhus university- Denmark, department of clinical medicine- Psykiatrisk Forskningsenhed Vest, Herning, Denmark

In the last few years, we conducted a number of molecular pathway analyses on the genetic samples provided by the NIMH. The molecular pathway approach accounts for the polygenic nature of the most part of psychiatric disorders. Nevertheless, the limits of this approach including the limited knowledge about the function of the genes, the fact that longer genes have higher probability to harbour variations significantly associated with the phenotype under analysis and the false positive associations for single variations, demand statistical control and bio-statistical knowledge. Permutations are a methodology to control for false positive associations, but their implementation requires that a number of criteria are taken into account: 1) the same number of genes and the same number of variations of the index pathway must be simulated in order to limit the bias of selecting significantly longer or shorter genes; 2) a sufficient number of permuted pathways is created ($10E5$ to $10E6$ depending on computational resources) which demands higher computational power; 3) the correct statistical thresholds are identified and discussed; 4) some pathways might be over-represented and the source of information must be constantly updated. The tools for running a molecular pathway analysis (R Foundation for Statistical Computing, 2013) when interacting with a supercluster PC and the international bioinformatic datasets (Embase, NIMH and others), together with the critical steps of bioinformatics scripting (bash language) are described and discussed.

Inflammation and pruning may inform risk to psychiatric disorders. Lessons from large genetic data

C. Crisafulli

University of Messina, department of biomedical and dental science and morphofunctional images, Messina, Italy

Background It's known that psychiatric disorders are caused to either environmental and genetics factors. Through the years several hypotheses were tested and many genes were screened for association, resulting in a huge amount of data available for the scientific community. Despite that, the molecular mechanics behind psychiatric disorders remains largely unknown. Traditional association studies may be not enough to pinpoint the molecular underpinnings of psychiatric disorder. We tried to applying a methodology that investigates molecular-pathway-analysis that takes into account several genes per time, clustered in consistent molecular groups and may successfully capture the signal of a number of genetic variations with a small single effect on the disease. This approach might reveal more of the molecular basis of psychiatric disorders.

Methods i)We collected data on studies available in literature for the studied disorder (e.g. Schizophrenia, Bipolar Disorder);ii)We extracted a pool of genes that are likely involved with the disease;iii)We used these genes as starting point to map molecular cascades function-linked. The molecular cascades are then analyzed and pathways and sub-pathways, possibly involved with them, are identified and tested for association.

Results/discussion We obtained interesting results. In particular, signals of enrichment (association) were obtained multiple times on the molecular pathway associated with the pruning activity and inflammation. Molecular mechanics related to neuronal pruning were focused as a major and new hypothesis for the pathophysiology of psychiatric disorders and the role of inflammatory events has been extensively investigated in psychiatry. interesting, inflammatory mechanics in the brain may also play a role in neuronal pruning during the early development of CNS.

Introduction Cognitive dysfunction is recognized as a core feature of schizophrenia and is considered an important predictor of functional outcomes. Despite this, current treatment strategies largely fail to ameliorate these cognitive impairments. In order to develop more efficient treatment strategies, a better understanding of the pathogenesis of cognitive dysfunction is needed. Accumulating evidence indicates that genetic risk of schizophrenia contributes to cognitive dysfunction. However, the precise genetic variants jointly influencing schizophrenia and cognitive function remain to be determined.

Aims Here, we aimed to identify gene loci shared between schizophrenia and general cognitive function, a phenotype that

captures the shared variation in performance across several cognitive domains.

Methods Using a Bayesian statistical framework, we compared genome-wide association study (GWAS) data on schizophrenia from the Psychiatric Genomics Consortium cohort ($n = 79,757$) with GWAS data on general cognitive function from the CHARGE Consortium ($n = 53,949$). By conditioning the false discovery rate (FDR) on shared associations, this statistical approach increases power to detect gene loci.

Results We observed substantial polygenetic overlap between schizophrenia and general cognitive function, which replicated across independent schizophrenia sub-studies. Using the conditional FDR approach we increased discovery of gene loci and identified 13 loci shared between schizophrenia and general cognitive function. The majority of these loci (11/13) shows opposite directions of allelic effects in the phenotypes, in line with previous genetic studies and the observed cognitive dysfunction in schizophrenia.

Conclusions Our study extends the current understanding of the genetic etiology influencing schizophrenia and general cognitive function by identifying shared gene loci between the phenotypes.

Bipolar disorder (BPD) is a highly debilitating psychiatric disorder. The underlying molecular mechanisms of BPD remain largely unknown. Studies targeting postmortem brain tissues of BPD patients have identified very few consistently replicated differences in the expression levels of protein-coding RNAs across different areas of the brain. Since differential expression of the human genome produces a wide spectrum of protein-coding and noncoding RNAs, we hypothesized that major molecular deficits associated with BPD could reflect dysregulation of multiple classes of RNA. To test this hypothesis, we obtained postmortem human medial frontal gyrus tissue from BPD patients and healthy controls ($n = 16$). To survey the implication of both protein-coding and long non-coding RNAs (lncRNAs) in BPD, we then performed RNA sequencing, PCR validation and replication experiments adopting a case-control design. Thirty-six genes and fifteen lncRNA transcripts not previously implicated in BPD were detected as differentially expressed (FDR < 0.1). Functional analyses identified enrichments of angiogenesis, vascular system development and histone H3-K4 demethylation. In addition, we report extensive alternative splicing defects in the brains of BPD subjects compared to controls. Finally, we describe for the first time a large reservoir of circular RNAs (circRNAs) that populate the medial frontal gyrus and report significantly altered levels of two circular transcripts (cNEBL and cEPA3) from the NEBL and EPA3 loci in BPD. Our findings may not only contribute to gain insight into the pathophysiology of BPD but may be tested in the near future as potential biomarkers for diagnostics.

Workshop: love, sex and psychiatry: the case of gender dysphoria

W014

A Dimensional perspective on sexual orientation and gender

G. Castellini

University of Florence, department of neuroscience- psychology- drug research and child health, Florence, Italy

Gender identity - the subjective experience of membership to a gender - is generally taken for granted by most of the persons. It is part of our general identity, and provides a sense of continuity of the self, and interrogative on this aspect of our life are barely present in our consciousness. Exceptions are represented by stages of development such as adolescence or some categories of persons who do not identify themselves into the dichotomous world of men/female. The debate on gender identity recently has broken into the consciousness for Psychopathology, rising interrogatives from different perspectives, including Medicine, Psychology, Anthropology, and Ethic.

In the present symposium we resume the historical trajectory of gender definition, emphasizing the importance of a different perspective on gender than the common definition provided by western culture. We propose a phenomenological perspective on the components of sexual identity, which includes anatomical sex, gender identity, sexual orientation, and gender role. The phenomenological approach is coherent with the dimensional view on sexual identity proposed by the DSM board, as well as by LGBT movements. This position considers Gender Dysphoria and transsexualism as a pole of gender variants continuum. Phenomenology looks at the comprehension of subjective gender heterogeneity, and the subjective world of gender dysphoric persons as the only way to take care of them; every psychological medical or surgical treatment should come as consequences. The phenomenological perspective on gender dysphoria may be useful to understand and partially explain the different subjective satisfaction to common hormonal and surgical treatment.

Gender identity issues in children and adolescents

T.D. Steensma

VU university medical center, center of expertise on gender dysphoria- medical psychology, Amsterdam, The Netherlands

Gender identity issues in children and adolescents. Gender dysphoria (GD) refers to the significant distress due to the incongruence between assigned gender at birth and experienced gender. Over the last decade, the care for prepubescent children and adolescents with GD is rapidly changing and there is a growing number of specialized gender clinics for youth. However, the offered care between countries is very different and the best clinical practice in this population is still controversial and under debate among dedicated professionals.

The current presentation will focus on providing a clinical picture of children and adolescents referred to gender identity clinics. For prepubescent children the focus will be on the present knowledge about the psychosexual development of these children and treatment & counseling approaches are presented and discussed. With regard to the adolescents, medical treatment approaches are presented and discussed, followed by the results from the only follow-up study on medical treatment in adolescents with GD.

Disclosure of interest The author has not supplied his declaration of competing interest.

Introduction Avolition represents an important domain of negative symptoms in schizophrenia with a strong impact on functional outcome. Primary and persistent avolition is refractory to available pharmacological and psychological treatments. A better understanding of its pathophysiological mechanisms is fundamental to promote development of new treatments. Recent models of avolition converge on dopaminergic circuits involved in motivation and its translation in goal-directed behavior. Deficits in task-related activation or connectivity within mesolimbic and mesocortical dopamine circuits were reported in schizophrenia but the relationship with avolition was not fully established.

Aims The present study aimed to investigate resting-state functional connectivity (RS-FC) within the motivation circuits in schizophrenia patients and its relationships with primary and persistent avolition.

Methods RS-FC, using VTA as a seed region, was investigated in 22 healthy controls (HC) and in 26 schizophrenia patients (SCZ) divided in high (HA) and low avolition (LA) subgroups. Avolition was assessed using the Schedule for the Deficit Syndrome.

Results HA, in comparison to LA and HC, showed significantly reduced RS-FC with the right ventrolateral prefrontal cortex (R-VLPFC), right insula (R-INS) and right lateral occipital cortex (R-LOC). The RS-FC of these regions was negatively correlated to avolition.

Conclusions Our findings demonstrate that avolition in schizophrenia is linked to dysconnection of VTA from key cortical regions involved in retrieval of outcome values of instrumental actions to motivate behavior.

Reward circuits and apathy in schizophrenia: neuroimaging and treatment strategies

A. Aleman

Department of neuroscience, university of Groningen, university medical center Groningen, Groningen, The Netherlands

Approximately 50% of patients with schizophrenia shows deficits in motivation and initiation of goal-directed behavior, which are suggestive of reward system dysfunction. We conducted a meta-analysis of neuroimaging studies reporting on the neural correlates of reward processing and negative symptoms in schizophrenia. A significant mean weighted correlation was observed, revealing deficits in activation of reward neurocircuitry. A more specific finding is comprised activation of the ventral striatum, involved in anticipation of reward, and structures that play a critical role in the ability to represent the value of outcomes and plans. In a study of VTA connectivity in the resting state in a large group of patients with schizophrenia, we found reduced connectivity with lateral prefrontal, temporal and parietal regions to be associated with higher degrees of apathy. Apathy belongs to the most debilitating symptoms of schizophrenia and represents a significant unmet need in its treatment. Quantitative integration of published findings suggests that treatment with noninvasive magnetic brain stimulation can improve negative symptoms. Previous PET-studies have shown that such stimulation may target circuits with dopaminergic innervation. A behavioral treatment approach that may also target reward-related circuits will also be discussed briefly. It can be concluded that recent results regarding reward and motivated behavior in schizophrenia have clinical implications and may help develop novel treatment strategies.

Disclosure of interest AA received speaker fees from Lundbeck.

Self-regulation of the dopaminergic reward system via real time fmri neurofeedback in schizophrenia

M. Kirschner

Department of psychiatry- psychotherapy and psychosomatics, Switzerland

Introduction Alterations in the mesolimbic dopamine system play a crucial role in the pathophysiology of schizophrenia. However, little is known about potential disturbance in endogenous regulation of neural activity due to cognitive control. Recent research on real-time fMRI (rtfMRI) revealed a novel method to stimulate the substantia nigra and ventral tegmental area (SN/VTA), using positive mental imagery. Importantly, this self-regulation ability could be improved with rtfMRI neurofeedback. For the first time, we applied this innovative method in patients with schizophrenia (SZ) to investigate potential alterations in endogenous regulation of the reward system.

Methods 14 (SZ) and 14 healthy controls (HC) were included in this ongoing study. Participants performed a rtfMRI task with abstract visual feedback of neural activity in the SN/VTA. In the active condition, we instructed participants to voluntarily up-regulate SN/VTA activity by recalling rewarding scenes. Neurofeedback learning was correlated with the self-reported negative symptoms.

Results In contrast to HC, SZ were not able to actively self-regulate SN/VTA activity. Furthermore, they failed to improve self-regulation with rtfMRI neurofeedback. Importantly, impaired neurofeedback learning was associated with negative symptoms, in particular diminished expression.

Discussion Our preliminary results show that self-regulation of SN/VTA activity is impaired in SZ. Although neurofeedback train-

ing improves self-regulation using positive mental imagery in HC, this method might not be suitable as a potential treatment strategy in SZ. The present findings provide new insights to the association between negative symptoms and dopaminergic dysfunction and highlight the strengths and limitation for the use of rtfMRI neurofeedback in schizophrenia.

Introduction The world is becoming increasingly globalised and this has a major impact on the delivery of healthcare. Issues such as conflict, migration, climate change and technological advances all contribute to this. But are we equipped to deal with the challenges of Global Health?

Objectives To discuss the core competencies that health professionals should have in Global Health.

Methods The UK's Global Health Curriculum Group (GHCG), a group of healthcare professionals, was commissioned by the Academy of Medical Royal Colleges to lead a consultation on global health competencies. The consultation took the form of a modified Policy Delphi which involved an online survey and face-to-face and telephone interviews over three rounds. Over 250 stakeholders participated, including doctors, other health professionals, policy-makers and members of the public from all continents of the world. *Results* This study demonstrated broad agreement that global health competence is essential for postgraduate doctors and other health professionals. It identified five core competencies, relevant to the UK and applicable to other parts of the world: (1) diversity, human rights and ethics; (2) environmental, social and economic determinants of health; (3) global epidemiology; (4) global health governance; and (5) health systems and health professionals.

Conclusions This framework of five core competencies aims to equip psychiatrists and other doctors with the skills, knowledge and attitudes necessary to practice in a globalised world.

In the workshop we will harness the international nature of the delegates attending the congress to enable a lively debate about the meaning of global mental health and the skills psychiatrists need.

* Corresponding author.

Introduction Cortical brain abnormalities are frequently observed in adults with psychotic disorders, but few studies have investigated adolescents with early-onset psychosis (EOP). A previous magnetic resonance imaging (MRI) study from the NORMENT group in Norway, found widespread cortical thinning and smaller subcortical volumes in adult patients with psychotic disorders, particularly schizophrenia, compared to healthy controls.

Methods Participants from the ongoing NORMENT adolescent EOP-study, 30 patients (age: 13.3–18.3 years, mean age: 16.5, 66% female) and 45 healthy adolescents (age: 13.6–18.8 years, mean age: 16.2, 58% female), underwent 3T MRI on the same scanner. Surface-based morphometric analyses were performed using FreeSurfer version 5.3.0. Group differences in vertex-wise cortical volume, thickness and surface area were investigated by fitting general linear models at each vertex on the surface. Age, sex and group were entered as covariates, and a non-parametric cluster-wise correction method for multiple comparisons was applied and cluster-forming and cluster-wise threshold set at 0.05.

Results Preliminary results show thinner cortex in the left medial frontal lobe and smaller surface area in the left temporoparietal junction in EOP patients compared to healthy controls after correction for multiple comparisons.

Conclusion Surface-based analysis is sensitive to alterations in cortical morphology in an adolescent EOP sample. The regions exhibiting reduced cortical thickness and area in EOP overlap with findings in an adult psychosis sample. Large-scale studies are warranted to better identify the pattern of abnormalities and clarify effects of age, diagnosis and medication.

Background Adolescent-onset schizophrenia (AOS) is associated with cognitive impairment and poor clinical outcome. Cognitive dysfunction is thought to reflect functional dysconnectivity between the frontal cortex and the striatum. Previous work [1] has shown frontostriatal dysconnectivity in large WM tracts explain

core cognitive deficits, with processing speed, which is affected by alterations in WM connectivity, being an intermediary variable.

Objective To undertake a follow-up MRI study using whole-brain structural connectomics to track topological changes in the follow-up (1st episode versus follow-up), in order to characterize the early stages (evolution of the first two years) of the disorder.

Design A follow-up study of 25 AOS subjects and 25 age and sex-matched healthy subjects.

Outcome Network theory will be applied to identify topological alterations in structural networks, including frontostriatal white matter (WM) tracts in relation to cognition and outcome measures.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Auditory cortex characteristics in early onset psychosis and its associations with auditory hallucinations: A structural MRI Study

R.E. Smelror¹, V. Lonning^{1,*}, L. Mørch-Johnsen¹, S. Nerland¹, T. Gurholt², I. Agartz¹

¹ NORMENT and K.G. Jebsen Centre for Psychosis Research, Institute of Clinical Medicine, University of Oslo, Department of Psychiatric Research, Diakonhjemmet Hospital, Oslo, Norway

² NORMENT and K.G. Jebsen Centre for Psychosis Research, Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway

* Corresponding author.

Introduction Smaller auditory cortex volume in schizophrenia patients with auditory hallucinations (AH) may be a result of reduced cortical surface area and/or cortical thickness. A neuro-imaging study from our group demonstrated that adult schizophrenia spectrum patients with AH had significantly thinner cortex in the left side Heschl's gyrus (HG), compared to patients without AH, and healthy controls (HC).

Objectives This study aims to investigate if adolescents with early-onset psychosis (EOP) and AH demonstrate thinner cortices in HG, as found in Mørch-Johnsen et al. in 2016, compared to EOP patients without AH, and HC.

Methods EOP patients (schizophrenia spectrum, psychotic disorder not otherwise specified) ($n = 29$) underwent MRI. Mean volume, cortical thickness and surface area in auditory cortex regions (HG, superior temporal gyrus [STG]) were compared between patients with AH ($n = 20$) and without AH ($n = 9$), measured with item P3 from the Positive And Negative Syndrome Scale (PANSS), and 48 HC.

Results Preliminary results show no significant differences between patients with and without AH and HC in mean volume, cortical thickness, or surface area in HG or STG. There were no significant side differences across hemispheres for these structures. **Conclusions** AH in EOP were not related to smaller volume, thinner cortex or reduced surface area in auditory cortex regions. To overcome the limitation of having a relatively small sample size, the sample will be expanded with other EOP cohorts. Investigations into HG structure variation in relation to AH in EOP will also be conducted.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Progressive frontal dysconnectivity during working memory in eos patients: A longitudinal functional MRI study

S. Frangou¹, M. Kyriakopoulos^{2,*}, D. Danai³

¹ New York, USA

² King's College London, Child and Adolescent Psychiatry, London, United Kingdom

³ City University, Psychology, London, United Kingdom

* Corresponding author.

Working memory (WM) dysfunction is considered a cardinal feature of schizophrenia. Typically developing adolescents show significant gains in WM performance, which have been attributed to increased "frontalisation" within the fronto-cingulate-parietal network that underpins WM. We used functional magnetic resonance imaging and psycho-physiological interaction to measure blood oxygenation level-dependent signal and functional connectivity in response to the 2-back WM task from 25 youths with EOS and 25 yoked healthy adolescents that were assessed twice with a mean interval of 4 years between assessments. Patients showed reduced prefrontal connectivity at baseline and the magnitude of this effect increased over the follow-up period. Our results suggest on-going functional connectivity abnormalities in EOS patients' post-disease onset that are linked to prefrontal dysfunction and contribute to worsening WM despite anti-psychotic treatment.

* Corresponding author.

Background Early-onset first-episode psychosis (FEP) and high functioning autism spectrum disorders (ASD) are complex neuro-developmental disorders that share symptomatology but it is not clear if they also share neurobiological abnormalities (Chisholm et al., 2015). We examined thickness, surface area and volume in a direct comparison of children and adolescents with FEP (onset before 18 years), high-functioning ASD, and healthy subjects.

Methods Magnetic resonance imaging scans of 85 participants (30 ASD, 29 FEP, 26 healthy controls, age range 10–18 years) were obtained from the same MR scanner using the same acquisition protocol. The FreeSurfer analysis suite was used to quantify vertex-wise estimates of the metrics thickness, surface area, and volume.

Results ASD and FEP had spatially overlapping insular deficits for each metric. The transdiagnostic overlap of deficits was greatest for volume (55% of all insular vertices) and smallest for thickness (18%). Insular thickness and surface area deficits did not overlap in ASD and overlapped only in 8% of all insular vertices in FEP.

Conclusions Morphological insular deficits are common to FEP and high functioning ASD when compared to healthy participants. The pattern of deficits was similar in both disorders, i.e. a largely non-overlap of insular thickness and surface area. The non-overlap provides further evidence that these metrics represent two independent outcomes of corticogenesis, both of which are affected in FEP and ASD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Enigma-collaborative analyses of neuroimaging eop data: What have we achieved?

I. Agartz^{1,*}, V. Lonnig¹, R. Smelror¹, M. Lundberg², T. Edbom², T.P. Gurholt¹

¹ University of Oslo, Clinical Medicine, Oslo, Norway

² Karolinska Institutet, Clinical Neuroscience, Stockholm, Sweden

* Corresponding author.

Introduction The ENIGMA-EOP collaboration aims to identify structural phenotypic markers that robustly discriminate adolescents with early-onset psychosis (EOP) from healthy controls through mega- or meta-analysis of magnetic resonance imaging (MR) data. Through larger samples we will obtain sufficient power to detect the brain structural correlates, overcome some of the clinical heterogeneity and characterize the developmental trajectories.

Methods Multiple linear regression was used to investigate structural brain differences in two Scandinavian adolescent EOP cohorts (altogether 50 patients; ages 12.1–18.3 years (mean 16.4 years), 60% female; 68 controls; ages 12.0–18.8 years (mean 16.2 years), 62% female) acquired on two different 3T GE MRI scanners. The statistical analysis included site as a covariate in addition to age, sex and intracranial volume (ICV). The results are presented by p-values, Cohens's-d effect size and with an indication of directionality. MRI scans were processed following the ENIGMA (<http://enigma.ini.usc.edu/>) structural image processing protocols using FreeSurfer (Fischl 2012) version 5.3.0 to measure subcortical brain volumes.

Results Preliminary results show significant or trend-significant group effects on right amygdala ($P=0.001$, $d=0.33$, patients < controls), total grey matter volume ($P=0.037$, $d=0.21$, patients < controls), ICV ($P=0.028$, $d=0.22$, patients < controls) and third ventricle ($P=0.067$, $d=0.19$, patients > controls). Sub-analyses in the two individual groups show overlapping findings in right amygdala. Previously reported enlarged lateral and 4th ventricles, and caudate, from a similar Scandinavian adolescent EOP cohort (Juuhl-Langseth, 2012) were not replicated.

Conclusion There is a need for larger subject samples in EOP to better capture disease mechanisms. Research groups interested in participating can join ENIGMA-EOP through: <http://enigma.ini.usc.edu/ongoing/enigma-eop-working-group/>.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Workshop: Forensic psychiatry in Europe in 2017: Discussing similarities and differences of five national systems

W026

Forensic care in Italy: Changes, illusions and realities

G. De Girolamo*, V. Bulgari

Saint John of God Clinical Research Center, Psychiatric Epidemiology and Evaluation Unit, Brescia, Italy

* Corresponding author.

Violence and the risk of violence posed by patients with severe mental illness is a major public health problem for many reasons. Firstly there is the obvious harm to victims, secondly the counter-therapeutic effect on patients of the violence itself, thirdly the restrictive measures typically deployed by services to manage the violence, and finally the significant additional financial cost of these specialist services. Within mental health services the sometimes inaccurate estimate of risk of violence posed by patients can lead to the frequent use of a variety of coercive measures including involuntary hospitalization, enforced medication, restraint and seclusion. These restrictive and costly interventions are almost unanimously perceived as traumatic by the patients and can, in turn, trigger frustration, therapeutic resistance and even aggression instead of treatment adherence and cooperation.

Services for the treatment of psychiatric patients who pose a risk of violence are developing and maturing across Europe. New models of care for this extremely complicated multiple needs clinical population exist. However across Europe intervention strategies and service organization and delivery for these patients are very different, and have never been comparatively evaluated. The lack of reliable comparative data has prevented many European countries benefiting from innovative strategies already tested in those countries which have made the greatest efforts in research and service innovation. In this workshop we will compare the organization and functioning of forensic mental health services in different countries; in particular this presentation will inform about the recent changes in forensic mental health services occurred in Italy.

Forensic care in France

T. Fovet*, P. Thomas

CHRU de Lille, Nord, Lille, France

* Corresponding author.

In France, the number of inmates with psychiatric disorders has grown substantially during the last two decades. In this context, significant changes occurred in France's forensic psychiatry service provision in recent years. Especially, full-time inpatient units for inmates (called unités d'hospitalisation spécialement aménagées, UHSA) have been created in 2010. These changes clearly improved access to mental health care for inmates. Moreover, some recent trends in indicators such as the suicide rate in French prison, which has fallen slightly, are promising [1]. However, the practice of psychiatry in prisons is a subject of debate between the proponents of the development of a specific care system for inmates and those considering that psychiatric teams must stay out of prison. One should insist on the dichotomy between the justice system and the health system, which appears constitutional in France. Indeed, the professional independence of caregivers from the judiciary system and the medical confidentiality are fundamental values on which French model has been built. Furthermore, the improvement of the

quality of health care in prisons could alarmingly lead the judges to preferentially choose imprisonment for patients suffering from mental disorders committing offences while prison should in no way be considered as a patient care setting. This trend is evidenced by the low rate of individuals judged irresponsible for their crime because of mental health status currently observed in France.

Forensic care in Germany

H. Dressing^{1,*}, H.J. Salize²

¹ Germany

² Central Institute of Mental Health, Psychiatry, Mannheim, Germany

* Corresponding author.

Although the idea that offenders suffering from a mental disorder must primarily be considered as ill and should therefore be exempted from punishment is of considerable antiquity legal frameworks and key concepts, which are applied in this field, differ widely in European Union member States. The respective legal regulations and epidemiological data of Germany will be presented. In German penal law the question of the guilt of an offender is of central significance. Legal regulations on the placement and treatment of mentally ill offenders in a forensic psychiatric hospital are subsumed under the section "Measures on improvement and safety". Section 63 of the German penal law provides for the temporarily unlimited commitment to a forensic- psychiatric hospital. In accordance with section 64 of the German penal law addicted offenders can be committed to a detoxification center for a period of up to two years. The available epidemiological data show a clear increase in the admissions to forensic psychiatric hospitals and to detoxification centers since beginnings of the 1990s. Recently the German parliament passed a new law. The aim of the new law is to strengthen patients' rights and to diminish the number of forensic patients.

Insulin resistance and markers of Allostatic load in depression

Introduction Among patients with major depression, increased inflammatory markers at baseline may predict an anti-depressant response. Reducing inflammation may augment response to psychotropic medications. Few studies have investigated an association between Leukocyte Telomere Length (LTL) and therapeutic response in depression, reporting mixed results. No studies assessed LTL and treatment response with PPAR- γ agonists.

Objectives (1) LTL as a predictor of anti-depressant response to PPAR- γ agonist in patients with unremitted depression.

(2) the correlation between LTL and insulin resistance (IR) status.

Aims We aimed to assess LTL as a predictor of antidepressant response to Pioglitazone in groups of insulin resistant and insulin-sensitive subjects using surrogate markers of IR.

Methods Medically stable men and women ($n=42$) ages 23–71 with non-remitted depression participated in double-blind placebo controlled add-on of Pioglitazone to treatment-as-usual. Oral glucose tolerance tests were administered at baseline and at 12 weeks.

Results At baseline, no differences in LTL were detected by depression severity, duration or chronicity. LTL was also not significantly different between insulin-resistant and insulin-sensitive subjects. Subjects with longer telomeres exhibited greater declines in depression severity in the active arm, but not in a placebo arm. LTL also predicted improvement in insulin sensitivity in the group overall and did not differ between the active and placebo arm.

Conclusions LTL may emerge as a viable predictor of antidepressant response. An association between insulin sensitization and LTL regardless of the baseline IR status points to potential role of LTL as a non-specific moderator of metabolic improvement in these patients.

Elevated body mass index (BMI) is associated with increased morbidity and mortality. The investigation of the relationship between BMI and brain organization has the potential to provide new insights relevant to clinical and policy strategies for weight control. Here, we quantified the effect of BMI on the functional connectivity of the Default-Mode (DMN), Central Executive (CEN), Sensorimotor (SMN) and Visual (VN) networks in 496 healthy individuals that were studied as part of the Human Connectome Project. We found that elevated BMI was associated with disrupted functional integration of sensory-guided (SMN, VN) with internally controlled (DMN, CEN) networks, implicating increased attention to sensory stimuli as a possible mechanism underpinning overeating and weight gain. Our results suggest that weight control strategies should expand to include wider societal policies that incorporate modifications to eating environments and to the visual presentation and branding of food products.

Comorbidity of depression and diabetes: Questions recently answered and raised

N. Sartorius

Action for mental health, Geneva, Switzerland

This paper will present information about a multicentric international collaborative study, which explored the frequency of depressive disorders in people with diabetes Type 2. The study was carried out in 14 countries—5 in Asia (Bangladesh, China, India, Pakistan and Thailand), two in Africa (Kenya and Uganda), two in Latin America (Argentina and Mexico) and five in Europe (Germany, Poland, Russia, Serbia and Ukraine). The study found that depressive disorders and sub threshold depression are frequent in people with diabetes: one tenth of all the nearly 3000 patients examined had major depression and another 15% sub threshold depressive disorders. Depression was only rarely recognized by the physicians dealing with diabetes and those few who were recognized were not provided treatment of their depressive disorders. The presentation will draw attention to the need to improve skills of diagnosis and treatment of psychiatric disorders of physicians who are not psychiatrists.

Depression and its somatic consequences: Allostatic load as the connecting link

B. Penninx

VU university medical center/GGZ inGeest, department of psychiatry/PI NESDA study, Amsterdam, The Netherlands

Stress-related psychiatric disorders, such as depressive and anxiety disorders, have been associated with increased risk of overall mortality as well as with the onset of various aging-related somatic diseases. In addition to unhealthy lifestyles and poorer (self) care, various stress-related physiological processes likely contribute to these detrimental health consequences of psychiatric disorders. Considering the fact that the impact of stress-related disorders is visible on many different somatic health outcomes, it is unlikely that contributing biological systems are very specific. In fact, it is likely that multiple dysregulations of stress systems, including the immune, HPA-axis and autonomic nervous systems, but also various general proteomic or metabolomic pathways are involved. The concept of Allostatic Load (AL) emphasizes the presence of a multi-system physiological dysregulation.

In this talk I will summarize what the evidence is for somatic health consequences of psychiatric conditions, with depression as an important example. Subsequently, I will provide an overview of the various stress systems that are dysregulated in depressed patients. In addition, I will provide empirical data from the Netherlands Study of Depression and Anxiety ($n=2981$) that illustrate that there is evidence that depressed patients are especially at risk for a dysregulation in multiple physiological stress systems. I will also illustrate how such a state of AL can impact on basis cellular aging indicators like telomere length and epigenetic age.

In sum, this talk will highlight the current state-of-evidence for an association between depressions with the onset of many adverse somatic health outcomes, and will provide insight into the contributing role of a multisystem physiological dysregulation.

Stay foolish, stay fit: An excursus on strategies to prevent burnout of mental health professionals

S. Ferrari^{1,*}, G. Rioli²

¹ Modena, Italy

² University of Modena & Reggio Emilia, Department of Diagnostic-Clinical Medicine and Public Health, Modena, Italy

* Corresponding author.

Burn-Out (BO) is commonly described as a growing situation of work stress and conceptualized as a combination of emotional exhaustion, depersonalization/cynicism and reduced personal efficacy. Some professionals are exposed to a higher risk, depending on their specific work mansions (most typically the so called helping professions) and on personal and contextual conditions. Evidence from scientific literature has confirmed that being younger and working in the field of mental health are very significant risk factors for BO. Furthermore, BO is an essential target for preventive strategies: prevention of BO, rather than treatment of potential psychopathological consequences, has been proved to be more effective and cost-effective, though unfortunately very often disregarded or left to individual initiatives.

Physical activity, diet, and other features of a healthy lifestyle are core targets of interventions aimed at prevention of BO. Increasing evidence is collected on the effectiveness of mindfulness-based techniques and yoga. Supervision, and more specifically Balint-inspired models of group case discussions. Scientific and professional associationism is also effective as a strategy to avoid isolation. Finally, interventions aimed at improving work organization, targeting logistic aspects (eg. Time schedules), infrastructures (eg. Parking places) or dynamics and human interactions, are also essential and effective.

Suicidal behavior among Portuguese psychiatry trainees: Comparison with the European situation

J. Gama Marques

Faculdade de Medicina da Universidade de Lisboa, Clínica Universitária de Psiquiatria e Psicologia Médica, Lisboa, Portugal

Introduction The aim of this paper was to assess the prevalence of suicide ideation and attempts in Portuguese psychiatry trainees (adult, child and adolescence), and compare the data with the general population and other European countries.

Material and Methods A structured and anonymous questionnaire was sent by email to 159 Portuguese trainees of adult psychiatry, child and adolescence psychiatry with questions about personal history of suicidal ideation and suicide attempts, as well as family history of suicide attempts and completed suicides. This is part of the BoSS Study (Burnout Syndrome Study) performed in 21 countries worldwide. Data was analyzed in SPSS v.19.

Results From the inquired population, 62 trainees (40.3%) partially responded, and 46 (29%) were complete responders - these entered the final analysis. There was a ratio of 2:1 (female: male) and a mean age of 29 years. The suicidal ideation was present in passive form in 44% and in active form in 33%; also,

4.3% of respondents had previous suicide attempts. In first-degree relatives, 22% had attempted suicide and 13% completed suicide.

Discussion The results are worrying and may be associated with some factors to which this population is exposed.

Conclusion It is necessary further research to better understand this phenomenon, its causes and potential modifiers.

W035

Workplace stress among non-doctor trainees in psychiatric rehabilitation

U. Volpe

University of Naples SUN, department of psychiatry, Naples, Italy

Mental health care settings have long been associated to a specific and long-standing emotional involvement, eventually determining professional stress and burnout in psychiatrists. However, recent evidence demonstrated that also non-doctor mental health workers may be at high risk of developing job dissatisfaction. Previous studies also suggested that the longer exposure to psychiatric settings the higher the levels of burnout. We report here data from a survey conducted among first-year students of rehabilitation courses in psychiatry ($n=44$) and logopedics ($n=39$), before and after the first exposure to an health care environment over a 6-month term. We investigated their psychological wellbeing and risk of psychiatric morbidity (by means of GHQ-12), levels of burnout (with the Maslach Burnout Inventory) and knowledge about mental health (by means of the MAKs schedule). The two groups were comparable as for the main socio-demographic characteristics as well as for their knowledge about mental health before training. We found a significant difference between students in mental and general health care, with significantly higher emotional exhaustion and depersonalization and lower personal accomplishment levels in the former group, after 6-month training. Such changes were significantly correlated to variations in knowledge about mental health issues and risk of psychiatric morbidity. The implementation of a specific peer support group was perceived as extremely useful by the majority of the students (96%) and had a positive impact on their burnout levels and psychological wellbeing.

Workshop: Mothers with major mental illness and their young infants: Can we meet the challenges?

W037

Risks and challenges in perinatal mental health

A. Wieck

Laureate House, Wythenshawe Hospital, Manchester, United Kingdom

Mental illness affects 1 in 5 women during pregnancy and the first year postnatal and in about 1 in 20 women the condition is serious. When a woman with major mental illness becomes pregnant she and her child face a number of risks. These include poor pregnancy and neonatal outcomes and a sharp rise of psychiatric admissions after childbirth. Mental illness is also one of the leading causes of maternal death. Risks to children are impaired parenting and developmental disadvantage in emotional, behavioral and cognitive domains. Parental mental illness also has a significant role in infanticide and abuse-related serious harm to children, with infants <1 year old being most at risk.

A recent analysis has shown that the resulting economic costs to public services and the wider society are extremely high. In view of the wide-ranging consequences, a number of European countries have set up specialized perinatal mental health services. These consist of specialized inpatient units and community teams. The essential components of their service are preconception counselling, expert advice on the use of medication during pregnancy and breastfeeding, joint inpatient admissions of mothers and babies, interventions to improve parenting, and advice to children's social services. None of these countries, however, are yet offering universal access.

In order to improve service provision and outcomes it is important that perinatal mental health is acknowledged more widely as a public health priority. The workshop will provide an opportunity for participants to discuss approaches to raise awareness and promote perinatal service developments.

* Corresponding author.

During the perinatal period, women may experience severe mental health problems. Research has shown the potential negative impact of mother-baby's separation and of parental psychiatric illness, on the child. MBUs care requires different staff's expertise in order to: treat women with psychiatric disorders, ensure child care and development, and support appropriate mother-infant interaction with "good enough" mothering. For this, a multidisciplinary team is needed. Specific attention is also given to the child's father. Most

MBUs may admit women with infants from birth till one year old and during several weeks or months.

More than two third of admitted women are discharged either symptom-free or greatly improved. An efficient follow up at discharge should be prepared with the women, the child's father, when presents, and linked to familial, social and medical resources. Moreover, MBUs staff should collaborate with other psychiatrists, obstetricians, midwives, pediatricians, and social workers. Mother-baby units should be part of a local health perinatal network including maternity unit, neonatal care, and community resources.

Referral for admission in MBUs may be required for women with a first acute episode, or a relapse, of a severe psychiatric disorder such as postpartum psychosis, manic disorder, major depressive episodes, schizophrenia, personality or behavior disorders. Moreover for prevention purposes, referral of women with known chronic mental health problems may start already during pregnancy.

Challenge of beneficence and limit of MBUs' care will be discussed with participants.

Disclosure of interest Florence Gressier has given talks for Lundbeck and Servier and received a grant from Servier for a post-doctoral degree (2011-2012).

W039

Maternal mental illness and early parenting interventions

A.L. Sutter-Dallay

Bordeaux University, Bordeaux Population Health, Bordeaux cedex, France

The importance of the "1001 critical days" (conception to age 2) underlies the need to act early in life to enhance children's developmental outcomes. Lack of intervention is likely to affect the children of today but also the generations to come. For adults, transition to parenthood is a major stressful life event. The strong emotional load of this experience can make this transitional period much more challenging for adults with psychological, social and economic vulnerabilities, and lead to unadjusted interactions.

Then, applying the "transactional model of development" (Sameroff, 2009) to the early perinatal period helps us to understand how the needs of infants can easily affect a parent's mental state and induce inadequate parenting behaviors. These in turn make the infant's interactions more difficult and the infant's development more likely to be impaired. Perinatal mental health is thus an important public health challenge for it is essential to provide services to enhance maternal and infant emotional well-being at a moment that is simultaneously when the mother's social and emotional vulnerabilities are at their height and a critical time in the child's development.

Perinatal mental health policies, including joint care of parents and infants, must provide positive support for the potential virtuous circle between the skills and vulnerabilities of the infant and the parents.

This presentation will explore the different types of joined perinatal care for parents and infants that cover a range of services, from parent-infant psychotherapies to joint mother-baby hospitalizations.

⁹ University of Antwerp, Collaborative Antwerp Psychiatric Research Unit, Antwerp, Belgium

* Corresponding author.

Introduction The aim of postgraduate psychiatric training is to prepare psychiatrists to practice independently. The quality of care provided will depend on the training they received. Pregnancy and childbirth (usually called the perinatal period) are a high-risk period for many women with psychiatric problems. An illness episode at that time can have a devastating effect on women and the whole family, including the child's development.

Objectives To understand how perinatal mental health training is organized within Europe and how it fits in the training curricula.

Methods The European Federation of Psychiatric Trainees conducts an annual survey of all member country organizations. We have asked respondents if they received training in perinatal psychiatry, whether that was optional or mandatory and what was its duration. Where training in perinatal psychiatry was not available we asked if they felt it should be.

Results Data will be presented from the 35 countries that responded in the 2016 survey. Six countries reported that training in perinatal mental health is available. But it is mandatory in only one, with the others offering a mix of theoretical and practical optional training. Of the 29 countries that do not offer perinatal psychiatry training, the majority reported it should be offered and mandatory.

Conclusion There is a gap in the expectations of psychiatrists treating women in pregnancy and after birth, and a widespread lack of training for them to be able to do so effectively.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Approaching and offering treatment to a patient in perinatal period might be complicated. Often, it is regarded as one of the most difficult aspects in psychiatry. Given the increasing trends in the number of female patients of childbearing age consulting to psychiatric services, it has become an issue that specialists of today and tomorrow need to be well aware of.

Objectives To better understand the impact of perinatal mental health training on psychiatric trainees from different countries in Europe who receive such training.

Methods The European Federation of Psychiatric Trainees conducts annual surveys, directing questions to national trainee representatives, to assess the situation of psychiatric training. EFPT representatives of the countries where perinatal mental health training was reported to be included in psychiatry and/or child and adolescent psychiatry training programmes, namely Germany, France, Malta, Finland and Ireland, were contacted. Qualitative interviews focusing on the confidence (or in confidence) trainees feel when a patient who is planning pregnancy, pregnant or breastfeeding consults to them and the impact of training in perinatal mental health on their attitudes as clinicians were explored.

Results Although theoretical training in perinatal mental health is considered as an important aspect of psychiatry training in general, practical training or rotations are not found as essential. However, being able to benefit to more than one generation was perceived as a source of motivation.

Conclusions Perinatal mental health is appreciated as a critical part of theoretical education by trainees and in countries where a clinical rotation is available, it enhances making more use of resources and consultation possibilities.

Evidence indicates that migrant and ethnic minority groups have an elevated risk of psychosis in a number of countries. Social disadvantage is one of the hypotheses put forward to explain these findings. The aim of this study is to investigate main effects, association and synergism between social disadvantage and migration on odds of psychotic experiences. We collected information on social disadvantage and migration from 332 patients and from 301 controls recruited from the local population in South London. Two indicators of social disadvantage in childhood and six indicators of social disadvantage in adulthood were analyzed. We found evidence that the odds of reporting psychotic experience were higher in those who experienced social disadvantage in childhood (OR= 2.88, 95% CI 2.03–4.06), social disadvantage in adulthood (OR= 9.06, 95% CI 5.21–15.74) and migration (OR= 1.46, 95% CI 1.05–2.02). When both social disadvantage and migration were considered together, the association with psychosis was slightly higher for social disadvantage in childhood and migration (OR 3.46, 95% CI 2.12–5.62) and social disadvantage in adulthood and migration (OR 9.10, 95% CI 4.63–17.86). Migrant cases were not more likely than non-migrant cases to report social disadvantage ($p=0.71$) and no evidence of an additive interaction between migration and social disadvantage was found (ICR 0.32 95% CI –4.04–4.69). Preliminary results support the hypothesis that the association between social disadvantage and psychosis is independent of migration status.

* Corresponding author.

Introduction Researches show that the period of migration, or the migration process itself, may confer an increased risk for psychosis. Some studies have addressed whether the high rates of psychosis found in migrants could be due to higher genetic or environmental risk factors. Facing severe or chronic stress such as trauma, social isolation, low socio-economic status, late-life social adversity may result in long term, sometimes permanent, alterations of the biological stress response system, leading to the onset of psychosis.

Objectives This study aims to examine, in a large sample of first episode psychosis patients, whether negative social experiences like stressful life events and difficulties, trauma and isolation have significantly higher frequencies in migrants with respect to natives.

Methods The present study is conducted within the framework of the EUGEI (European Network of National Schizophrenia Networks Studying Gene Environment Interactions) study, a Europe-wide

incidence and case-control study of psychosis conducted in 12 centers chosen to include areas with large first and subsequent generation migrant populations.

Data about age, gender, migration history, trauma, life events, ethnicity, social class and family history of mental disorders have been collected.

Results Preliminary data on the relationship between trauma and migration in first episode psychosis will be presented.

Conclusions Since migration is an important stressful life event, and difficulties in integration in host countries may remain chronic, it is important to identify in each context the most vulnerable minority groups in order to implement targeted prevention interventions.

The social defeat hypothesis of schizophrenia: an update

E. Van der Ven

Leiden, The Netherlands

Research provides strong evidence of an elevated risk for developing psychotic symptoms and psychotic disorder among various ethnic and other minority groups. Furthermore, ethnicity may modify the risk for autism-spectrum disorder, but the evidence of this is still thin. Misdiagnosis, selective migration and other methodological artefacts are implausible explanations for the findings on psychotic disorder. Instead, we propose that 'social defeat', defined as the chronic experience of being excluded from the majority group, may increase the risk for psychotic disorder by sensitizing the mesolimbic dopamine system. Future challenges lie in connecting the underlying biological mechanisms to behavioral expression in socially excluded groups, as well as in bridging the gap with the clinical field and the wider society by stimulating the implementation of strategies that strengthen the position of minority populations.

Introduction Research has established that there are high rates of first episode psychosis (FEP) in immigrant populations. These findings could indicate that socio-environmental risk factors, such as individual social class, social capital, early trauma, life events, neighborhood deprivation could be relevant in explaining the differences in incidence rates observed between migrants and natives, following the socio-developmental model of Morgan et al. (2010). Some preliminary results also indicate that migration history itself versus ethnicity could implicate higher risk of the onset of psychotic disorders.

Aims To present preliminary findings from the EUGEI European Network of National Schizophrenia Networks Studying Gene Environment Interactions study.

Methods Population based FEP incidence/case control study. Comparison of the incidence rate of FEP and of the distribution of several risk factors (e.g. substance abuse, neighborhood deprivation, urbanicity and trauma) in natives and migrants in different countries across Europe.

Results Preliminary results of the EUGEI study will be discussed in comparison with previous evidences.

Conclusion The EUGEI study allows a deeper understanding of the excess of FEP found among migrants in Europe.

Based on a systematic review on TRS 285 studies were included regarding definitions of TRS ($n = 11$), genetics (18), brain structure and functioning (18), cognition (8), other neurobiological studies (16), medication (158), psychotherapy and cognitive rehabilitation (12), electroconvulsive therapy (ECT) and repetitive transcranial magnetic stimulation (rTMS) (15), prognosis (21), and other miscellaneous studies (8). Definitions of TRS varied notably. TRS was associated with 3 to 11-fold higher healthcare costs than schizophrenia in general. One-fifth to one-third of all patients with

schizophrenia were considered to be resistant to treatment. Based on limited evidence of genetics, brain structure and functioning and cognition, TRS may present as a different disorder with different etiology compared to non-TRS. Clozapine, olanzapine, risperidone, ECT and cognitive-behavioral therapy have shown effectiveness, although the number of studies and quality of research on interventions is limited. About 40% to 70% of TRS patients had an unfavorable prognosis. Younger age, living in a rural or less urban area, primary education level, more psychiatric hospital treatment days in the year before first schizophrenia diagnosis, inpatient at first schizophrenia diagnosis, paranoid subtype, comorbid personality disorder and previous suicide attempt may be risk factors associated with TRS.

TRS is a poorly defined, studied and understood condition. To create a framework of knowledge for TRS, as a basis to develop innovative studies on treatment, there is a need for a consensus on the definition of TRS. Prospective long-term prognostic and novel treatment intervention studies are needed [1].

Emerging sensor-based m-health interventions in the assessment of psychotic symptoms

M. Bulgheroni

Ab.Acus srl, R&D, Milan, Italy

This speech aims to overview ongoing research trends on the integration of mobile health and sensors based behavioral analysis in therapeutics programs for subjects with mental health symptoms or disorders. The variety of easily acquirable personal data by smartphones and wearables in a transparent and unobtrusive way, offers the opportunity to describe the person in terms of his/her lifestyle and behavior at physical, cognitive and environmental level. An appropriate management of these data may initiate a new line in healthcare management characterized by tailored and timely interventions. However, despite the huge amount of data that could be acquired, an effective contribution of such information to the improvement of the quality of care in mental health is still not sufficiently explored. The sensors and data which have been used in studies on mental status include accelerometer, gyroscope, GPS, microphone, calls, messages, screen, apps usage, environmental light, heart rate, skin conductance, and temperature. The primary outcomes build on correlations between sensor data and mental health status/severity of symptoms. These data are provided from studies on bipolar disorders and depression, using validated clinical scales (Patient Health Questionnaire-9; Hamilton Rating Scale for Depression; Young Mania Rating Scale; Center for Epidemiologic Studies Depression Scale; etc.).

m-RESIST consortium is fully aware of the importance to describe behavioral patterns of patients with schizophrenia that could be used to setup remotely based therapeutic tool. m-RESIST is setting up a framework for the creation of a Clinical Decision Support System based on a mobile therapeutic intervention for treatment-resistant schizophrenia.

Identifying service and care needs from the users' perspective in treatment-resistant schizophrenia

K. Rubinstein^{1,2,3}

¹ *The Gertner Institute of Epidemiology and Health Policy Research, Israel*

² *Psychiatric Division, Sheba Medical Center, Israel*

³ *Tel-Aviv University, The Sackler School of Medicine, Israel*

Exploring service and care needs of patients with treatment-resistant schizophrenia is necessary for a better understanding of their psychosocial functioning, in order to develop rehabilitation goals as well as to provide them with better care.

m-RESIST is an innovative project aimed to empower patients with resistant schizophrenia, to personalize treatment by integrating pharmacological and psycho-social approaches, and to develop knowledge related to the illness using predictive models designed to exploit historical and real-time data, based on environmental factors and treatment outcomes.

m-RESIST is a system based on computer and cellular applications and wearable computing devices. The system will serve patients, caregivers and clinicians, and include the following functions: Information, Assessment, Monitoring, Communication, and Intervention.

The first step in the development process included definition of the end user needs and preferences, in order to involve users in the design of the system. Outpatients with treatment-resistant schizophrenia, informal carers (relatives), and clinicians were included in the sample. There were a total of 9 focus groups, 3 in each pilot country. Each group was composed of one of the participant profiles. Additionally, 35 individual interviews were performed, which were unevenly distributed throughout the 3 institutions.

The current workshop section will present the outcomes of this process: perceived advantages and disadvantages of the technological solution, as well as conclusions for further development. In addition, methodological issues, future challenges, relevant for the evolution of the m-RESIST project, in particular, as well as technological developments in the field of mental health, in general, will be discussed.

m-RESIST project as an example of m-health approach in schizophrenia: Content, aims and realization

I. Corripio

Barcelona, Spain

This communication aims to present m-RESIST, the first mHealth program for patients with treatment resistant schizophrenia (TRS). The main objective of this European project is to develop an intervention programme to allow TRS patients to self-manage their condition, which is associated with persistent positive symptomatology, extensive periods of hospital care, and a greater risk of excess mortality and multi-morbidity.

m-RESIST could offer a new tool for mental health professionals to better monitor TRS patients, providing a tailored and optimized therapeutic intervention. In this sense, m-RESIST will develop and validate a mHealth tool aimed to reduce the severity of episodes and further complications. Moreover, this tool will involve and promote a proactive role of patients and caregivers in the therapeutic process, promoting an active and collaborative role with the medical team in the treatment decision-making procedure.

m-RESIST intervention, will integrate: (1) a sensor data analysis module, which will process data coming from smart phone and wearable devices, providing passive information such as movement or social activity; (2) a predictive modeling engine, which will enable prediction of clinically significant events, such as hospitalization, risk behaviors and social isolation; and (3) a clinical decision support system (CDSS), which will provide the users with necessary information to support health-related and clinical decision-making.

The pilots of this project will take place in Tel-Aviv, Budapest and Barcelona during May, June and July of 2017. Although cost-effectiveness variables will also be measured, the main assessment will be focused on acceptability, usability, satisfaction, empowerment and quality of life outcomes.

Disclosure of interest The author has not supplied his declaration of competing interest.

* Corresponding author.

Objective To investigate the impact of childhood trauma on the clinical course of panic disorder.

Method Longitudinal data of 539 participants with a current panic disorder were collected from the Netherlands Study of Depression and Anxiety (NESDA). Childhood trauma was assessed with a structured interview and clinical course after two years with a DSM-IV-based diagnostic interview and the Life Chart Interview.

Results At baseline, 56.3% reported childhood trauma, but this was not predictive of persistence of panic disorder. Emotional neglect and psychological abuse were associated with higher occurrence of anxiety disorders other than panic disorder (social phobia) and with higher chronicity of general anxiety symptoms (anxiety attacks or episodes and avoidance). Baseline clinical features (duration and severity of anxiety and depressive symptoms) and personality traits (neuroticism and extraversion) accounted for roughly 30 to 60% of the total effect of childhood trauma on chronicity of anxiety symptoms and on occurrence of other anxiety disorders.

Conclusion After two years, childhood trauma is associated with chronicity of anxiety symptoms and occurrence of social phobia, rather than persistence of panic disorder. These relationships are

partially accounted for by duration and severity of anxiety and depressive symptoms, and neuroticism and extraversion.

Pharmacological and psychotherapeutic interventions for management of post-stroke depression: A Bayesian network meta-analysis of 27 randomized controlled trials

L. Deng

West China Hospital Of Sichuan University, Stroke Clinical Research Unit, Department of Neurology, Chengdu, China

Background Post-stroke depression (PSD) constitutes an important complication of stroke, leading to great disability as well as increased mortality. Since which treatment for PSD should be preferred are still matters of controversy, we aimed to compare and rank these treatments.

Methods We did a network meta-analysis to incorporate both direct and indirect evidence from relevant trials by Bayesian random effects model. We searched PubMed, the Cochrane Library Central Register of Controlled Trials, Scopus, Embase for randomized controlled trials of different PSD treatments. The primary outcomes were efficacy and tolerability. We assessed the quality of evidence using the GRADE framework.

Result From 1347 citations, 27 randomised trials with a total of 1620 participants were included in this network meta-analysis. In terms of primary outcome, only for reboxetone (standardised mean difference [SMD] –12.84, 95% credible interval [CrI] –23.13 to –2.65) and nortriptyline (SMD –7.95, 95% CrI –14.85 to –1.75) enough evidence existed to support superiority compared with placebo. No significant difference was observed in terms tolerability. Considering patient response rate, repetitive transcranial magnetic stimulation (rTMS) was statistically more effective than sertraline plus nimodipine (Relative risk [RR] 5.53, 95% CrI 1.36 to 23.86) and fluoxetine (RR 10.74, 95% CrI 3.55 to 35.97)

Conclusion Compared with placebo, reboxetone and nortriptyline offered a clear advantage for PSD patients. rTMS is probably the best option to consider in addition of pharmacological treatment. Nevertheless, doctors need to consider our results together

with all known safety and economy information when selecting the strategy for individual patients.

* Corresponding author.

Introduction Self-report instruments are useful tools for the assessment of psychopathological symptoms such as obsessive-compulsive symptoms. The Padua Inventory (PI) is a measure that has been widely used in clinical and research settings and studied in several countries.

Objectives This study explores the psychometric properties and factor structure of the Portuguese version of the PI.

Methods Translation and translation-back of the original version were executed. A total of 847 participants (468 women and 379 men) from the general population was recruited through a snowball procedure and completed the PI and other mental health measures. The data set was randomly split in order to conduct principal component analysis (PCA) and confirmatory factor (CFA) analysis in two different samples. Moreover, internal consistency, convergent and discriminant validity and test-retest reliability analyses were conducted.

Results From the PCA analysis four factors emerged, comprising clusters of items related to doubting/impaired control over mental activities, contamination/washing/cleaning, checking and worries about losing control over motor behaviors. CFA results revealed that the model presented a poor fit to the data and indicated that the model would benefit from the establishment of correlations between pairs of error terms of items with identical contents. The PI exhibited excellent internal consistency, good test-retest reliability and good convergent and discriminant validity.

Conclusions The PI Portuguese version showed a similar factor structure to the one presented in other studies and revealed good psychometric properties. Nevertheless, results from the CFA suggest that shortening the PI may be advantageous.

Anti-basal ganglia antibodies (ABGA) and excitatory neurotransmitters in obsessive-compulsive disorder (OCD)

S. Gnanavel^{1,*}, A. Parmar², P. Sharan², V. Subbiah³, U. Sharma⁴, J. Nr⁴

¹ Northgate hospital, CYPS Child psychiatry, Morpeth, United Kingdom

² All India Institute of Medical Sciences, Psychiatry, New Delhi, India

³ AIIMS, Neurobiochemistry, New Delhi, India

⁴ AIIMS, NMR, New Delhi, India

* Corresponding author.

Introduction OCD is a complex disorder with multiple aetiological theories. Recent research points to role of autoimmunity as well as hyperactivity of glutaminergic pathways in aetiopathogenesis of the disorder. It is possible that autoimmune mechanisms may modulate excitatory neurotransmission resulting in OCD.

Aims/objectives This study aimed to study the association between serum anti-basal ganglia autoantibodies (ABGA) and Glx (glutamate+glutamine) levels in caudate nucleus and anterior cingulate cortex as demonstrated by ¹H-MRS (proton magnetic resonance spectroscopy).

Methods Thirty psychotropic-naïve OCD patients and an equal number of age, gender matched healthy controls were studied using ¹H-MRS and levels of Glx were obtained. ABGA was measured using ELISA (enzyme linked immunosorbent assay) technique and categorised as present or absent in the serum.

Results ABGA was present in significantly higher proportion of patients as compared to controls ($P < 0.05$). Glx level was significantly higher (as measured by ¹H-MRS) in patients with ABGA as compared to those without ABGA ($P = 0.02$). The study results did not differ based on age, gender, disease severity and illness duration.

Conclusions The study demonstrates presence of ABGA in at least a subset of OCD population. The significant correlation between brain Glx levels and presence of ABGA provides a putative neurobiological framework for OCD. The strengths of the study include psychotropic-naïve patients, blinded investigators and use of standardized instruments. The limitations include small sample size, use of Glx as proxy measure of glutamate and lack of other disorder controls. Similar studies on a larger sample are warranted for a better understanding.

Reaching out to patients with antisocial personality disorder with brief psychoeducation

M. Hesse*, B. Thylstrup

Aarhus University, Department of Psychology, Aarhus, Denmark

* Corresponding author.

Introduction Patients with antisocial personality disorder incur high costs on society, and are at high risk of dropping out of treatment and are often excluded from treatment, yet very little research has been conducted on how to best help these patients.

Objectives To test a six-session psychoeducation program, Impulsive Lifestyle Counselling, in outpatients with substance use disorders and antisocial personality disorder.

Aims To test the efficacy of the intervention versus treatment as usual in community outpatient treatment for substance use disorders.

Methods Pragmatic randomized trial in 13 outpatient community substance abuse treatment uptake areas. Patients were interviewed by blinded interviewers 3, 9 and 15 months post-randomization and tracked through a national substance abuse treatment register. Mixed effects regression were used to assess substance use and self-reported aggression and Cox regression was used to assess risk of dropout.

Results A total of 175 patients was randomized. At 3-month follow-up, patients randomized to intervention reported more days abstinent and less drug use severity than patients randomized to treatment as usual. In addition, patients randomized to intervention were at lower risk of dropout after intervention. In addition, patients randomized to intervention were more likely to report having received help for antisocial personality disorder at follow-up interviews.

Conclusions A brief psychoeducational intervention may improve outcomes for outpatients with antisocial personality disorder.

Childhood parental childrearing differently influences on adulthood fears, agoraphobia and navigation strategy selection in females and males

J. Kállai^{1,*}, S. Rózsa², G. Vincze³, L. Martin⁴, Á. Csathó¹, K. Dorn⁵, I. Török⁶

⁴ Kaposvár University, Department of Pedagogy and Psychology, Kaposvár, Hungary

⁵ University of Pécs, Pediatric Clinic, Pécs, Hungary

⁶ Semmelweis University, Department of Applied Psychology, Budapest, Hungary

* Corresponding author.

Introduction Using self-report assessment methods, the present study examined affective factors that influenced the gender specific use of a survey-based orientation strategy and landmark-based route-finding strategy in an unfamiliar environment. First, we analyzed the role of early navigation experiences and the influence of early parental attachment (emotional warmth, overprotection and rejection) on way finding strategy. Second, the study analyzed the intercorrelations between way finding strategies and fear-related avoidance behavior and anxiousness.

Methods Three hundred and sixteen male and female students were recruited in a study to analyze the relationships between navigation strategies, fears, early parental childrearing behavior and navigation experiences. We proposed that use of navigation strategy depends on not only the physical features of the current environment and the participants' gender, but also fears of closed and opened spaces and types of perceived parental childrearing behavior.

Results We found that when exploring strange places, females used a route-finding strategy in contrast to males who used an orientation strategy for exploring a strange environment. Fear enhanced the preference for a route-finding strategy in both females and males. A route-finding strategy was associated with agoraphobic scores in females and with social fears in males. Perceived rejection from father and emotional warmth from mother together induces usage of route-finding navigation strategy.

Conclusion The family background influence on the capability to have personal experiences in unfamiliar environment and to cope with fears and behavioral avoidance in strange opened and closed places.

Reasons for acute psychiatric admissions and psychological interventions for patients with borderline personality disorder

N.P. Lekka*, G. Carr, T. Gilpin, B. Eyo

Sheffield Health and Social Care Foundation Trust, Acute Inpatient Service, Sheffield, United Kingdom

* Corresponding author.

Introduction NICE guidelines advise to consider admission for patients with borderline personality disorder (BPD) for the management of crises involving significant risk to self or others. Furthermore, to consider structured psychological interventions of greater than three months' duration and twice-weekly sessions according to patients' needs and wishes.

Objectives We aimed to assess reasons for admission and access to psychological interventions in an acute inpatient BPD population.

Methods Case notes of patients with a diagnosis of BPD (ICD-10 F60.3 and F60.31), discharged from four acute general adult wards in Sheffield during a period of twelve months were studied retrospectively, using a structured questionnaire based on BPD NICE guidance.

Results Of the 83 identified BPD patients, seventy-eight percent were female and 82% between 16–45 years old. Eleven patients had four or more admissions. Eighty percent reported suicidal ideation at admission, with 50% having acted on it (70% by overdose, 50% cutting, 10% hanging). Of this cohort, 58% reported they intended to die. Psychosocial factors at admission were identified in 59 cases, including relationship breakdown (47.5%), alcohol/drug use (30.5%) and accommodation issues (17%). Disturbed/aggressive behaviour was documented in 27.1% of these cases. Sixty-eight percent of patients had psychology input in the 5 years preadmission: 38% (21 patients) received structured therapy, whilst 62% received only one assessment or advise to teams.

Conclusions Patients were mainly admitted for risk management. A high proportion received unstructured psychological interventions. Services offering structured psychological interventions should be supported, as hospitalisations only temporarily address BPD patients' suicidality and psychosocial difficulties.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Assessing the role of weight suppression (WS) and weight loss rate (WLR) in eating disorders

G. Miotto*, I. Chiappini, A. Favaro, P. Santonastaso, D. Gallicchio

Università degli Studi di Padova, Clinica Psichiatrica, Padova, Italy

* Corresponding author.

Introduction and aims In this study, we aim to assess the role of weight suppression (WS) in eating disorders, not only from a quantitative point of view but also assessing the speed of the weight loss by using a new parameter: the weight loss rate (WLR). We analysed the role of these two indexes in different eating disorders domains, considering both eating behaviours and outcome profiles.

Methods The sample consisted of 414 patients, including 62 with AN binge purge subtype (ANBP), 146 with AN restrictive subtype (ANR) and 206 with bulimia nervosa (BN). Data about response to treatment were available for a subsample of 201 patients. A cross-sectional design was used for the clinical symptoms detected during the initial assessment and a longitudinal design was adopted for the response to treatment analysis.

Results No significant relationship emerged between both WS and WLR and variables collected at baseline assessment. We

observed, on the contrary, a significant association between WS and weight gain at the end of treatment. High WLR predicted remission of binge eating and compensatory behavior in BN patients. We further analyzed our data to identify threshold values of both WS and WLR of clinical utility.

Conclusions The role of WS and WLR as predictive factors in the outcome of eating disorders is of great interest and these initial results remark the usefulness of collecting these data during the initial assessment in order to plan a tailored therapeutic intervention.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Interaction between oxytocin gene variants and perceived parenting in relation to social anxiety in adolescents: Evidence for differential susceptibility effects

S. Olofsdotter^{1,*}, C. Åslund¹, T. Furmark², E. Comasco³, K. Nilsson¹

¹ Uppsala University, Centre for Clinical Research, Västerås, Sweden

² Uppsala University, Department of Psychology, Uppsala, Sweden

³ Uppsala University, Department of Neuroscience, Uppsala, Sweden

* Corresponding author.

Introduction Adolescence is a period of increasing demands in independent social functioning where parenting style may have an impact on social anxiety. A context-dependent effect of oxytocin on human social behavior has been suggested, however research on the gene coding for oxytocin (OXT) has mostly been reported without considering contextual factors.

Aim This study investigated interactions between parenting style and polymorphic variations in the OXT gene in association with social anxiety symptoms in a community sample of adolescents.

Methods The study group consisted of 1359 adolescents. Two single nucleotide polymorphisms located near OXT, rs4813625 and rs2770378, were genotyped. Social anxiety and perceived parenting style were assessed by behavioral questionnaires.

Results Significant joint effects in line with the differential susceptibility framework were observed for rs4813625 with parenting style. The levels of social anxiety among C allele carriers were conditional on the level of supportive parenting style whereas homozygote G carriers' levels of social anxiety were unaffected by supportive parenting style. The nature of the interactions between rs2770378 and parenting style was in line with the diatheses-stress model. However, associations of rs2770378 and parenting style with social anxiety became nonsignificant in nonlinear models.

Conclusions The study provides preliminary evidence for a modifying effect of supportive parenting style on the relationship between rs4813625 and social anxiety symptoms in adolescents, independent of sex. The findings may be interpreted from the perspective of the social salience hypotheses of oxytocin, with rs4813625 affecting social anxiety levels along a perceived unsafe-safe social context dimension.

Disclosure of interest The authors have not supplied their declaration of competing interest.

An investigation of the coupling of temperament traits with major depression

W. Sulis^{1,*}, I. Trofimova²

¹ McMaster University, Psychiatry, Hamilton, Canada

² McMaster University, Psychiatry and Behavioral Neuroscience, Hamilton, Canada

* Corresponding author.

A diversity of neurochemical hypotheses related to major depression (MD) suggests that further investigation is needed for uncovering the neurophysiological nature of MD. Since both temperament and mental illness have been linked to varying degrees of the same neurotransmitter imbalances in neurophysiological systems of behavioral regulation, the analysis of temperament traits as weak forms of neurochemical imbalances might give new insights into symptoms and nature of MD. This study analyzed the predictions of the opioid receptor hypothesis within the neurochemical model of functional ensemble of temperament proposing that a dysregulation of the opioid receptors acting on monoaminergic systems gives rise to the symptoms of major depression (MD). The study investigated the coupling of sex, age and temperament traits with MD across four age groups (17–24, 25–45, 46–65, 66–85) by reviewing the records of testing in 423 patients and volunteers with (210) and without (213) the MD. The records included testing with the personality assessment inventory, structure of temperament questionnaire, structured clinical interview and other diagnostic measures. In line with the hypothesis, patients with MD had significantly lower physical endurance, social-verbal endurance, mental endurance, plasticity, physical tempo, sensation seeking and self-confidence, and higher impulsivity and neuroticism than non-depressed individuals. Other sex- and age-related effects are reported. The results suggest that new versions of the DSM should consider an increase of impulsivity and a decrease in plasticity of behavior as criteria symptoms of MD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

An investigation of the coupling of temperament traits with anxiety

W. Sulis^{1,*}, I. Trofimova²

¹ McMaster University, Psychiatry, Hamilton, Canada

² McMaster University, Psychiatry and Behavioral Neuroscience, Hamilton, Canada

* Corresponding author.

Temperament traits and anxiety have been linked to varying degrees of neurotransmitter imbalances in neurophysiological systems of regulating behaviour. The diversity of neurotransmitters implicated in anxiety symptoms raises questions as to whether the multiple neurotransmitter systems secondarily express dysfunction in a higher-level system, which modulates their activity. This study analyzed the predictions of the neurochemical functional ensemble of temperament (FET) model that proposes that a dysregulation of the opioid receptors acting on monoaminergic and GABA systems gives rise to the symptoms of GAD. The study investigated the coupling of sex, age and temperament traits with generalized anxiety disorder (GAD) across three age groups

(17–24, 25–45, 46–65 years). The records of patients aged 65–85 years old were also examined but showed significantly less presence of GAD in comparison to other age groups. Temperament was assessed using the activity specific 12-trait structure of temperament questionnaire. Consistent with the hypotheses of the FET, patients with GAD reported lower mean scores on the traits of social-verbal endurance, mental endurance, plasticity and sensation seeking and higher mean scores in the trait of impulsivity, than healthy individuals. GAD was associated with significantly lower self-confidence in women than in men. The results suggest that new versions of the DSM should consider an increase of impulsivity and a decrease in plasticity of behavior as criteria symptoms of anxiety. Moreover, the results suggest that the current criterion of fatigue should be specified as more related to social-verbal and mental aspects and less to physical aspects of endurance.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Predictors of remission at 1-year follow-up among ocd patients: Findings from The Netherlands obsessive-compulsive disorder association (NOCDA) study

L. Tibi^{1,*}, P. van Oppen², A. van Balkom², M. Eikelenboom², G. Anholt¹

¹ Ben Gurion University, Psychology, Be'er Sheva, Israel

² VU University Medical Center, Psychiatry, Amsterdam, The Netherlands

* Corresponding author.

Introduction Obsessive-compulsive disorder (OCD) is described as a chronic condition. However, relatively little is known about predictors affecting its long-term outcome.

Objective To examine the contribution of clinical and interpersonal determinants in predicting remission status of 254 OCD patients at one-year follow-up (FU1).

Methods We used the baseline and FU1 data of The Netherlands obsessive-compulsive disorder association (NOCDA) study. Clinical predictors were chronicity level, depressive and obsessive-compulsive symptom severity. Suspected interpersonal factors included attachment style, social support and expressed emotion. Remission status was defined using the Yale-Brown obsessive-compulsive symptom (Y-BOCS) scale. χ^2 tests and ANOVAs were used for bivariate analyses, followed by multivariate multinomial logistic regression analyses to assess main effects and interactions in predicting remission status at FU1.

Results Bivariate tests demonstrated significant differences in remission status as a function of chronicity level, depressive and obsessive-compulsive symptom severity and social support. Regression analyses revealed that increased baseline OCD severity reduced the odds for both partial and full remission at FU1 (OR = .87, 95%CI = .82–.93, $P < 0.001$). Increased depressive severity at baseline reduced the odds for partial remission at FU1 (OR = .95, 95%CI = .91–.98, $P < 0.01$). Interactions analyses demonstrated that the adverse effects of OCD severity on partial remission disappeared at the presence of secure attachment (IOR = 1.11, 95%CI = 1.05–1.24, $P < 0.05$) and high social support (IOR = .88, 95%CI = .78–.98, $P < 0.05$).

Conclusions The contribution of clinical severity is critical for understanding the prognosis of OCD. The interpersonal context of OCD patients may mitigate the unfavorable effect of severity on outcome, thus should be addressed in treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The effectiveness of the inference based approach to treating obsessive-compulsive disorder with poor insight; a randomized controlled multicentre trial

H. Visser^{1,*}, H. van Megen¹, T. van Balkom²

¹ GGZ centraal, psychiatry, Amersfoort, The Netherlands

² GGZ ingeest, psychiatry, Amsterdam, The Netherlands

* Corresponding author.

Background There is an urgent need for an effective psychological treatment for patients with obsessive compulsive disorder (OCD) with poor insight, since this disorder is associated with severe suffering and a low quality of life. The inference based approach (IBA), a new psychotherapy for OCD specifically targets insight in OCD. In a randomized controlled multicentre trial, the effectiveness of IBA was compared to the effectiveness of CBT for treating patients with OCD with poor insight. In this study, 24 sessions of IBA were tested versus 24 sessions of CBT. Ninety patients with a main diagnosis of OCD with poor insight according to the DSM-IV criteria participated in the study. The primary outcome was reduction of the obsessive-compulsive symptoms.

Results In both conditions, a significant OCD symptom reduction was reached, but no condition effects were established. Post hoc, in a small subgroup of patients with the worst insight ($n = 23$), it was found that the patients treated with the IBA reached a significantly higher OCD symptom reduction than patients treated with CBT [estimated marginal mean = -7.77 , $t(219.45) = -2.4$, $P = 0.017$]. Of patients treated with IBA, 41.9% were responder and 20.9% completely recovered. Of the patients treated with CBT, 42.6% were responder and 12.8% recovered.

Conclusion Patients with OCD with poor insight improve significantly after psychological treatment. The results of this study suggest that both CBT and the IBA are effective treatments for OCD with poor insight. The IBA might be more promising than CBT for patients with more extreme poor insight.

Thyroid profile and its relationship with response to treatment with lithium in bipolar mood disorder patients

P. Avinash^{1,*}, K. Pathak²

¹ Himalayan Institute Of Medical Sciences, Psychiatry, Motihari, India

² Lgb Regional Institute Of Mental Health, Psychiatry, Tezpur, India

* Corresponding author.

Introduction There is substantial evidence that even minor perturbation of thyroid function plays a significant role in clinical course and treatment outcome in depressive disorder; however the same is not yet clear in bipolar disorders.

Aims and objectives To study the relationship between pretreatment thyroid profile and response to treatment with lithium along with other predictors of response to treatment with lithium in cases of bipolar mood disorder.

Methods This study was conducted in the indoor facilities of a regional Institute of Mental Health, Tezpur, India in the year of

2012. Forty-five consecutive indoor patients diagnosed with bipolar mood disorder using DSM-IV-TR criteria were selected. On day 1, blood was collected for thyroid profile and BPRS 24 item scale version 4.0 was applied. They were started on lithium monotherapy and only lorazepam was used on S.O.S basis. On day 30, the BPRS was applied again to check the response to treatment, statistical analysis was done using SPSS version 16.

Results The mean percentage fall of the BPRS score was 40%, with the maximum fall in the subscale of grandiosity and minimum for depression. Age, illness duration, substance use, family history second or later episodes were negatively correlated with treatment response. Pretreatment T4 level was positively correlated, while pretreatment TSH level was negatively correlated with the treatment response.

Conclusion Lithium monotherapy proved to be a good agent for first episode of bipolar Mood disorder patients with manic symptoms and pretreatment T4 and TSH level were predictors of treatment response.

* Corresponding author.

Introduction The study gathered information in order to draw useful conclusions to describe bipolar patients and their clinical management. The data collection was conducted as part of RENDiBi epidemiological study.

Objectives The statistical analysis of the collected data will be essential to understand the possible changes in drug treatment, through the help offered by a parameter, Polarity Index (PI), the numerical expression of the efficacy profile of a drug, very useful especially in the long-term management.

Methods Administration of a first detection card (demographic data, medical history) and five scales (CGI-BP, Mood Insight Scale, YMRS, HDRS) and a structured interview (MINI). The parameters analyzed were: polarity prevalence, ratios efficiency (IE) (values indicating the effectiveness of treatment compared to manic components and/or depressive), treatment and PI.

Results The degree of correlation between PI and IETot is positive and statistically significant. The correlation between PI and IEm is statistically significant; the correlation is however not significant between PI and IEd; treatment with antipsychotics alone has increased PI, while the one with mood stabilizers has lesser; treatment with antipsychotics has increased PI in patients with predominantly polarity than those with manic depressive prevailing polarity.

Conclusions There is a correlation between PI and effectiveness on manic symptoms and it is statistically significant (as already evident in the literature). The PI is numerically higher in the treatment of the subject with manic polarity, in agreement with previous studies that associate to the more effective drugs used for the management of manic recurrences a higher PI.

Obesity and obstetric complications are associated with rapid-cycling in Italian patients with bipolar disorder

A. Caldiroli^{1,*}, M. Buoli¹, B. Dell'Osso¹, G.S. Carnevali¹, M. Serati¹, T. Suppes², T.A. Ketter², A.C. Altamura¹

¹ IRCCS Foundation Ca' Granda Ospedale Maggiore Policlinico, Psychiatry, Milan, Italy

² Stanford University- School of Medicine, Psychiatry and Behavioral Sciences, Stanford, CA, USA

* Corresponding author.

Introduction Rapid cycling (RC) worsens the course of bipolar disorder (BD) being associated with poor response to pharmacotherapy. Previous results about clinical variables potentially associated with RCBD were discordant or unreplicated.

Objectives An early diagnosis should be the goal to properly treat RCBD patients.

Aims To compare clinical variables between RC and non-RC bipolar patients and to identify related risk factors.

Methods A sample of 238 bipolar patients was enrolled from three different community mental health centers. Descriptive analyses were performed on total sample and patients were compared in terms of sociodemographic and clinical variables according to the presence of RC by multivariate analyses of variance (MANOVAs, continuous variables) or χ^2 tests (qualitative variables). Binary logistic regression was performed to calculate odds ratios.

Results Overall, 28 patients (11.8%) had RC. The two groups were not different in terms of age, age at onset, gender distribution, type of family history, type of substance use disorder, history of antidepressant therapy, main antidepressant, psychotic symptoms, comorbid anxiety disorders, suicide attempts, thyroid diseases, diabetes, type of BD, duration of untreated illness, illness duration, duration of antidepressant treatment and GAF scores. In contrast, RC patients had more often a history of obstetric complications ($P < 0.05$), obesity ($P < 0.05$) and a trend to hypercholesterolemia ($P = 0.08$). In addition, RC bipolar patients presented more frequently lifetime MDMA misuse ($P < 0.05$) than patients without RC.

Conclusions Obesity and obstetric complications are risk factors for the development of RC in BD. Lifetime MDMA misuse may be more frequent in RC bipolar patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Epidemiology of bipolar spectrum disorder: Results from the general population survey of South Korea

S. Chang^{1,*}, C. Tae Young², J. Sung-Won³

¹ Kyungpook National University Hospital, Psychiatry, Daegu, Republic of Korea

² Catholic University of Daegu School of Medicine, Psychiatry, Daegu, Republic of Korea

³ Keimyung University-DongSan Medical Center, Department of Psychiatry, Daegu, Republic of Korea

* Corresponding author.

Introduction Patients with subthreshold bipolar disorder (sub-BP) experience severe clinical courses and functional impairments, which are comparable to those with bipolar I and II disorders (BP-I and -II). Nevertheless, lifetime prevalence, socioeconomic correlates and diagnostic overlaps of bipolar spectrum disorder (BPS) have not yet been estimated in the general population of South Korean adults.

Aims This study aimed to estimate the lifetime prevalence, correlates and diagnostic comorbidities of BPS using a validated

screening instrument in the nationwide general population of South Korea.

Methods A total of 3013 adults among the 2011 Korean Epidemiologic Catchment Area survey (KECA-2011) completed face-to-face interviews using the Korean versions of the composite international diagnostic interview 2.1 and mood disorder questionnaire (K-CIDI and K-MDQ).

Results The lifetime prevalence of BPS in the South Korean adults was measured to be 4.3% (95% CI 2.6–6.9). Nearly 80% of the subjects with BPS were codiagnosed with other DSM-IV nonpsychotic mental disorders: 35.4% (95% CI 24.2–48.5) for major depression and dysthymic disorder, 35.1% (95% CI 27.7–43.3) for anxiety disorders and 51.9% (95% CI 40.5–63.1) for alcohol and nicotine use disorders. Younger age (18–34 years) was the only sociodemographic predictor of BPS positivity ($P=0.014$) and the diagnostic overlap patterns were different between men and women.

Conclusions Positivity for BPS was estimated to be much greater than the prevalence of DSM-IV BP in South Korea. Most of the respondents with BPS were diagnosed with other major mental disorders and this might be related with mis and/or underdiagnosis of clinically relevant Sub-BP.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Many hypotheses have been proposed about development of bipolar disorder including inflammatory processes due to the external and endogenous factors. There are strong evidences that immunological dysfunction is present in bipolar disorder. In the pathophysiology of bipolar disorder, there are many data that support the inflammatory hypothesis.

Objectives In this study, to clarify the etiology of bipolar disorder, based on the inflammatory process hypothesis, it is aimed to measure and evaluate serum 15d-PGJ2 and PPAR γ , anti-inflammatory cytokine IL-4 levels in patients with bipolar disorder.

Methods This study was performed at Ankara Numune Training and Research Hospital. Ninety-five patients are included in the study that were in their mania or remission periods and meet the DSM-V criteria for bipolar disorder. Forty-four healthy volunteers are included in the study as well. Serum IL-4, 15d-PGJ2, PPAR γ levels are measured in both groups. Young Mania Scale, Hamilton Depression Scale, demographic data form were given to patient group.

Results In our study, 15d-PGJ2, PPAR γ levels were found statistically significantly lower in patients with bipolar disorder compared to healthy controls.

Conclusion There are differences in anti-inflammatory prostaglandin levels in patients with bipolar disorder who are in their mania period when compared to healthy controls and patients in their remission period. This does not show any significance according to smoking and gender. This implies that inflammation markers could be a good candidate to determine trait markers, which will provide an insight for preventing patient

from mania period or prognosis after the diagnosis of bipolar disorder.

Impulsivity and brain volume in patients with bipolar disorder type I and bipolar disorder type II

D. Janiri^{*}, G. Giuseppin, E. Spinazzola, M. Maggiora, G. Sani Sapienza University of Rome- Faculty of Medicine and Psychology, NESMOS Department Neurosciences- Mental Health and Sensory Functions, Rome, Italy

* Corresponding author.

Introduction Impulsivity is a key feature of both bipolar disorder (BD) type I (BDI) and type II (BDII).

Objective Structural neuroimaging studies help clarifying brain mechanisms underpinning the regulation of impulsivity in BDI and BDII.

Aims To address the question whether grey matter (GM) alterations relate differently with impulsivity in BDI and BDII.

Methods We assessed 54 euthymic outpatients, diagnosed with BDI ($n=28$) or BDII ($n=26$) according to DSM-IV-TR criteria. They underwent a 3 T magnetic resonance imaging (MRI) investigation. GM brain volumes were analyzed on a voxel-by-voxel basis using Statistical Parametric Mapping 8. The Barratt Impulsiveness Scale (BIS), version 11A, was used to assess trait impulsivity.

Results BDI and BDII patients present an inverse relationship between impulsivity and GM volume in two cerebral areas: the right cerebellum (right crus I) and the interface between the left angular gyrus and the left inferior parietal cortex (Brodmann Area 39, 7, 40). More specifically, a negative relationship for BPI and a positive relationship for BPII were found in both areas.

Conclusions Results suggest that the different diagnosis between BDI and BDII could have a significant effect on GM changes according to impulsivity severity and point up the importance of considering the BP subtype distinction in neuroimaging studies on this topic.

Inflammation and neurodegeneration findings in early stage bipolar disorder

S. Karabulut^{1,*}, U. Akcan², İ.C. Küçükali², E. Tüzün², S. Çakır¹

¹ İstanbul Medical Faculty, Psychiatry Department, İstanbul, Turkey

² Institute of Experimental Medicine, Neuroscience, İstanbul, Turkey

* Corresponding author.

Introduction There is growing evidence about neuroinflammation in the aetiopathogenesis of bipolar disorder. Early diagnosis and intervention strategies are thought to be excessively important lately.

Objectives To check neuroinflammation levels in early stage bipolar disorder and explore the associations with clinical variables.

Aims We aimed to evaluate inflammation and neurodegeneration findings in early stage bipolar disorder.

Methods Serum interleukin 1-receptor antagonist (IL-1Ra), interleukin 6 (IL-6), tumor necrosis factor-alpha (TNF- α), high sensitive C reactive protein (hs-CRP), S100B and neuron specific enolase (NSE) levels were assessed by enzyme-linked immunosorbent assays in a total of 30 patients with bipolar disorder in the early stage and compared with 30 matched healthy controls. The clinical symptoms were rated using Montgomery Asberg Depression Scale,

Young Mania Rating Scale, Positive and Negative Syndrome Scale and Clinical Global Impression Scale.

Results Among the patients with bipolar disorder, 14 (% 46.6) were in a manic/hypomanic state and 12 (% 40) were in a euthymic state. Serum IL-6 levels were significantly higher ($P=0.018$), TNF- α and S100B levels were significantly lower in the early stage group ($P<0.001$ and $P=0.03$, respectively). After repeated analysis with only drug-naïve patients, the results showed no difference. There was a positive and significant correlation between TNF- α levels and CGI, MADRS scores (all $P<0.05$); NSE levels and MADRS scores ($P<0.05$).

Conclusions This study supported the association of early stage bipolar disorder with inflammation and neurodegeneration. IL-6 may be a potential biomarker. Thus, early diagnosis and intervention may be crucial to prevent progressive neuroinflammation and neurodegeneration in early stages of disorder.

The correlation between plasma brain-derived neurotrophic factor and cognitive function in bipolar disorder is modulated by the BDNF Val66Met polymorphism

S.Y. Lee

Kaohsiung Veterans General Hospital, Psychiatry, Kaohsiung, Taiwan ROC

Objectives Brain-derived neurotrophic factor (BDNF) may be involved in the pathogenesis of bipolar disorder (BD). The functional BDNF Val66Met polymorphism (rs6265) is associated with secretion of BDNF. The current study aimed to explore the correlation between changes of plasma BDNF and cognitive function after 12 week of treatment, considering the influence of the BDNF val66Met polymorphism. The correlation of changes of plasma BDNF with quality of life (QOL) was explored.

Methods First diagnosed patients with BD were recruited. Symptom severity, plasma BDNF levels were examined during weeks 0, 1, 2, 4, 8, and 12. QOL, Wisconsin Card Sorting Test (WCST) and the Conners' Continuous Performance Test (CPT) were assessed at baseline and endpoint. The genotype of the BDNF Val66Met polymorphism was determined. The change of cognitive function and QOL measures over 12 weeks were reduced by factor analysis. Pearson's correlation was used to investigate the association between change of plasma BDNF levels with cognitive function and QOL.

Results Five hundred and forty-one BP patients were recruited. Three hundred and fifty-five (65.6%) patients completed the 12-week follow-up. A significant negative correlation was found between changes of plasma BDNF level with factor 1 (WCST) ($r=-0.25$, $P<0.001$). After further stratification according to subtypes of BD and the BDNF genotypes, above significant correlation was found only in those with BP-I and the BDNF Val66Met Val/Met genotype ($r=-0.54$, $P<0.008$).

Conclusion We conclude that changes in plasma BDNF significantly correlated with changes in WCST in patients with BD; such correlation is moderated by the BDNF Val66Met polymorphism and subtype of BD.

Cortical inhibition in symptomatic and remitted mania compared to healthy subjects: A paired-pulse TMS study

N. Sanjay*, R. Basavaraju, S. Biradar, U. Mehta, M. Kesavan, J. Thirthalli, V. Ganesan

Nation Institute of Mental Health and Neuro Sciences NIMHANS, Department of Psychiatry, Bangalore, India

* Corresponding author.

Introduction Cortical inhibition (CI) is a neurophysiological outcome of the interaction between GABA inhibitory interneurons and other excitatory neurons. Transcranial magnetic stimulation (TMS) measures of CI deficits have been documented in both symptomatic and remitted bipolar disorder (BD) suggesting it could be a trait marker. The effects of medications and duration of illness may contribute to these findings.

Objective To study CI in BD.

Aims To compare CI across early-course medication-naïve BD-manía, remitted first episode mania (FEM) and healthy subjects (HS).

Methods Symptomatic BD subjects having < 3 episodes, currently in mania and medication-naïve ($n=27$), remitted FEM ($n=27$; YMRS < 12 and HDRS < 8) and 45 HS, matched for age and gender, were investigated. Resting motor threshold (RMT) and 1-millivolt motor threshold (MT1) were estimated from the right first dorsal interosseous muscle. Paired-pulse TMS measures of short (SICI; 3ms) and long interval intracortical inhibition (LICI; 100ms) were acquired. Group differences in measures of CI were examined using ANOVA.

Results Table 1.

Conclusions Symptomatic mania patients had the highest motor thresholds and the maximum LICI indicating a state of an excessive GABA-B neurotransmitter tone. Remitted mania patients had deficits in SICI indicating reduced GABA-A neurotransmitter tone. Putative changes in GABA-A neurotransmitter system activity with treatment may be investigated in future studies. CI has received less attention in BD as compared to schizophrenia and is a potential avenue for future research in this area.

Table 1 Measures of motor threshold and CI across the three groups.

	Symptomatic mania (n=27)	Remitted mania (n=27)	HS (n=45)	F ^a	p ^b	Posthoc LSD
RMT Mean(SD)	37.93 (8.85)	32.63 (6.19)	37.09 (7.12)	4.161	0.019	BD > FEM HS > FEM
MT1 Mean(SD)	50.97 (12.15)	41.48 (8.27)	49.00 (11.34)	5.964	0.004	BD > FEM HS > FEM
SICI (%) Mean(SD)	27.47 (33.14)	9.05 (58.65)	35.34(28.39)	3.578	0.032	FEM<HS
LICI (%) Mean(SD)	76.93 (19.52)	71.52(27.48)	56.32 (45.87)	3.215	0.045	BD > HS

Clinical and sociodemographic correlates of suicidality in bipolar patients

U. Ouali

Razi Hospital, Psychiatry A, Mannouba, Tunisia

Introduction A major concern in patients with BIPOLAR Disorder (BD) is the high frequency of suicidality. It is important to determine the subgroup of patients particularly exposed to this risk.

Objectives To explore sociodemographic and clinical characteristics of BD patients with a history of suicide attempts and compare them to those who never attempted suicide.

Methods This is a retrospective, cross-sectional, descriptive and comparative study on 100 patients followed in our department and diagnosed with BD type I according to DSM 5. Demographic and clinical data was compared across the groups: suicide+ (S+) and suicide–(S–).

Results Overall, 77 patients never attempted suicide (S–), whereas 23 had made at least one suicide attempt (S+). Females represented 61,9% of the S+ group. S+ patients had more relatives with psychiatric illness (82,6% vs. 57,1%) and affective illness (43,5% vs. 33,8%). The mean diagnostic delay was 6,61 years in the S+ group vs. 4,58 in the S– group, with 78,3% of S+ patients first receiving another diagnosis than BD. S+ patients had significantly more depressive episodes and manic episodes with mixed features. Quality of intervals was worse in S+ patients. Anxiety comorbidity was significantly higher in the S+ group (52,2% vs. 13%; $P=0,000$). Hyperthymic temperament was significantly associated with the S– group.

Conclusions Depressive polarity, anxiety comorbidity, as well as diagnostic delay seem to elevate the risk for suicidality in bipolar patients. Suicidality should be closely monitored in patients with these characteristics.

* Corresponding author.

Background Euthymic patients with bipolar disorder (BD) experience residual symptoms. Interestingly, residual symptoms appear to impact the natural course of BD and represent potential predictors of recurrence and functional impairment.

Objectives The study aimed to analyse the relationship between residual depressive symptoms, sleep disturbances and cognitive impairment as determinants of psychosocial functioning in a large sample of euthymic BD patients.

Methods We performed a cross-sectional study of 468 BD outpatients in clinical remission for at least 6 months. Bipolar Depression Rating Scale (BDRS), Pittsburgh Sleep Quality Index (PSQI) scale, Visual Analogic Scales (VAS) evaluated cognitive impairment and functioning assessment short test were used to assess residual symptomatology and functioning of patients. We evaluated functioning with. Structural equation modelling (SEM) was used to describe the relationships among the residual depressive symptoms, sleep disturbances, perceived cognitive performance and functioning.

Results SEM showed good fit. This model revealed that residual depressive symptoms (path coefficient = 0.37) and perceived cognitive performance (path coefficient = 0.27) were the most important features significantly related to psychosocial functioning. Sleep disturbances were indirectly associated with functioning via residual depressive symptoms and perceived cognitive performance (path coefficient = 0.23).

Conclusions This study contributes to a better understanding of the determinants of psychosocial functioning during the interepisodic periods of BD patients. These findings should have implications for the improvement of functioning of BD patients in a personalized approach to treatment.

Subcortical structures in suicide attempters with bipolar disorder, type I

G. Sani^{*}, A. Simonetti, E. Ambrosi, D. Janiri, G. Kotzalidis
Sapienza University of Rome, NeSMOS, Rome, Italy

* Corresponding author.

Introduction Suicidality is a major health concern with as yet unclear neurobiology.

Objectives To identify emotional correlates of suicidality in bipolar disorder I (BD-I).

Aims To detect subcortical structural morphology changes associated with suicide attempts.

Methods We enrolled 30 patients with BD-I of which 15 had history of suicide attempts, and 15 healthy controls (HCs) with no such history. Groups were defined according to suicide attempt history and psychopathology. Subcortical gray matter volumes were obtained from 3 T structural MRI scans using FreeSurfer. Intergroup differences were investigated through ANOVAs followed by post hoc Fischer's least significant difference.

Results HCs had larger left hippocampal and left accumbens volumes than both BD-I attempters and nonattempters. BD-I attempters had smaller left hippocampi and larger left amygdala than both nonattempters and HCs.

Conclusions Differences were observed in emotional processing mediating neural circuitries, with BD-I attempters showing opposite patterns to nonattempters between amygdala and hippocampus.

Effectiveness of psychoeducational family intervention on coping strategies of relatives of patients with bipolar I disorder

M. Savorani*, G. Borriello, V. Del Vecchio, G. Sampogna, C. De Rosa, C. Malangone, M. Luciano, B. Poci, V. Giallonardo, A. Fiorillo

University of Naples SUN, Psychiatry, Naples, Italy

* Corresponding author.

Background Relatives' coping strategies – an essential element for the recovery of patients with severe mental disorders – are grouped in problem-oriented and emotion-focused. The former include practical strategies to deal with the stressful situation and are associated with a better long-term outcome of patients and relatives; the latter are psychologically driven and are associated with a worse outcome. It has been reported that psychoeducational family intervention (PFI) can improve problem-oriented coping strategies, while few data are available on relatives of patients with bipolar disorder.

Objectives To assess the impact of the PFI on promotion of problem-oriented coping strategies adopted by relatives of patients with bipolar I disorder.

Methods This study was conducted in 11 Italian mental health centers. Patients and their relatives were allocated to the experimental group receiving PFI or to the control group (waiting list). Before starting the intervention and at the end of the PFI, coping strategies were assessed using the family coping questionnaire.

Results Of the 139 recruited families, 72 families were allocated to the experimental group and 67 to the control group. Relatives from the experimental group reported a significant improvement in problem-oriented coping strategies, such as positive communication ($P < .01$) and searching for information ($P < .05$). On the other hand, a reduction in collusion ($P < .0001$), avoidance ($P < .01$) and resignation ($P < .001$) were found at the end of the intervention.

Conclusions PFI is effective in promoting the coping strategies in relatives of patients with bipolar I disorder and it should be given routinely in mental health centers.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Integrating the findings from boundary sciences for development of the DSM/ICD classifications

I. Trofimova

McMaster University, Psychiatry and Behavioral Neurosciences, CILab, Hamilton, Canada

Introduction Temperament and mental illnesses are considered to be varying degrees along the same continuum of imbalance in the neurophysiological regulation of behavior. Mental disorders are linked to specific patterns in the relationships between neurotransmitters and between brain structures. Similar links were found for temperament traits. Development of DSM and ICD classifications

might benefit therefore from an integration between psychiatry, functional neurochemistry and differential psychology.

Objectives To describe the neurochemical systems underlying mental disorders and temperament traits in healthy adults.

Methods Findings in neurochemistry, neuropsychology, differential psychology and psychopathology are compared to the traits described in various temperament models. This analysis is summarized in the perspective of the neurochemical functional ensemble of temperament (FET) model.

Results Neurochemical correlates for 12 main dynamical aspects of behavior are presented as a systemic framework that follows a universal functional structure of human actions described in kinesiology, neuroanatomy, neurochemistry and clinical neuropsychology. The role of monoamine systems (serotonin, dopamine, noradrenalin), acetylcholine, GABA/glutamate, neuropeptide and opioid receptor systems are linked to regulation of specific dynamical properties of behavior in a systematic way. Several insights for the structure of the classification of mental disorders from the perspective of the FET model are proposed.

Conclusions An integration of research in neurochemistry and psychopathology of behavior with differential psychology based on healthy samples can bring new insights for future versions of DSM and ICD classifications of mental disorders. Such integration does not follow either dimensionality or categorical approach but instead is based on functional ecology of human behavior.

Disclosure of interest The author has not supplied his declaration of competing interest.

Substance use disorder among admitted patients with bipolar disorder in a psychiatric service during a three-year period

M. Fernandes*, S. Silva, D. Mota, A. Oliveira, J. Ribeiro, V. Santos, N. Madeira, C. Pissarra, Z. Santos
Centro Hospitalar e Universitário de Coimbra, Centro de Responsabilidade Integrada em Psiquiatria e Saúde Mental, Coimbra, Portugal

* Corresponding author.

Introduction Bipolar disorder has the highest rates of comorbid substance use disorders. Approximately 60% of patients with bipolar I disorder have a lifetime diagnosis of a substance use disorder (SUD). Excluding tobacco, alcohol is the substance most often abused, followed by cannabis, amphetamines and cocaine.

Objectives Determine the prevalence and compare sociodemographic and clinical variables in patients with SUD comorbid diagnoses and patients without this comorbidity.

Methods Charts of all patients with a diagnosis of bipolar disorder admitted in the Coimbra Hospital and University Center over a three-year period (2013–2015) were reviewed to gather data on sociodemographic and clinical data.

Results During a three-year period, 189 patients were admitted with bipolar disorder, almost half of patients (47,6%) had a SUD comorbid diagnosis. Comorbidity of BD and SUD is characterized by a complicated course with multiple recurrences of bipolar episodes and increased hospitalizations. The risk of suicide attempt is significantly higher when associated with SUD. In addition, BD is associated with pervasive social, family, and employment dysfunction. Poor treatment adherence in this population is also a serious clinical challenge that significantly impacts treatment response and outcome. The authors will analyze all this variables in the population admitted.

Conclusion According to the most recent literature on SUD and BD, these two problems occur together so frequently that all patients with a bipolar diagnosis should also be assessed for drug and alcohol problems. BD complicated by SUD represents a seri-

ous public health problem and a major challenge to treatment providers.

* Corresponding author.

Background Both major depressive disorder (MDD) and alcohol use disorder are highly prevalent, often comorbid and cause significant socioeconomic burden. At CAMH, we have developed and integrated care pathway (ICP) to treat these disorders and evaluated its effectiveness in comparison to treatment as usual (TAU).

Methods Chart review; descriptive statistics, χ^2 and t -tests, linear mixed effects models, Kaplan–Meier and log-rank analyses.

Results Overall, 81 patients were enrolled into ICP. Comparisons of treatment retention rates between ICP patients and matched historical controls ($n=81$) showed significantly lower dropout rate in ICP cohort (18.5% vs. 69.1%, $P<0.001$, Fig. 1). The ICP patients demonstrated significant reduction in depressive symptoms severity (QIDS: 14.6 vs. 10.0, $P<0.001$; BDI 26.3 vs. 16.2, $P<0.001$), reduction in the amount of alcohol consumed weekly from 44.6 standard drinks at baseline to 12.6 ($P<0.001$) by the end of treatment, which was significantly better compared to controls (56.9 vs. 25.2, $P<0.001$), $P=0.014$ (Fig. 2).

Conclusions The ICP is a feasible approach to treatment of concurrent AUD and MDD with significantly higher retention rates than TAU. Patients demonstrate improvements on several levels including depressive symptoms, and changes in alcohol drinking patterns.

* Corresponding author.

Introduction Illicit drug use is well known as an important contributor to the global burden of diseases, but the physical and psychopathological risks of recreational drugs misuse are often underestimated and drug-related fatalities in specific settings are under-investigated.

Objectives and methods In the framework of the EU-funded project “EU-Madness”, we collected and analysed all the reports of drug-related fatalities in Ibiza from January 2010 to September 2016, with the aim of characterising the sample, and identifying the involved substances and the nature of deaths associated with their consumption.

Results Overall, 58 drug-related fatalities were registered from 2010 to September 2016 (87.9% males, 12.1% females, mean age 33.16; females were significantly younger than males). Most of the deceased were Britons (36.2%), followed by Spanish (22.4%), Italians (6.9%) and Germans (5.2%). In half the cases, the substance identified in post-mortem analyses was a stimulant; in 24.1% of the sample it was a depressor a prescription drug or more than two substances in 22.4%. Most of the fatalities were due to cardiovascular accidents (62%); 22.4% were deaths by drowning, 12% by fall from heights and 3.4% were due to mechanical asphyxia.

Conclusions According to the results from our sample, stimulants (mainly MDMA and cocaine) are the substances of abuse involved in most drug-caused fatalities. The number of fatalities per year has been steadily increasing, but the growing diffusion of novel psychoactive substances (NPS) does not seem to be a direct cause (although better methods of their analysis in post-mortem samples should be designed).

Validation of the Italian version of the “abnormal bodily phenomena questionnaire” in a sample of patients with schizophrenia: Preliminary data

M. Chieffi*, D. Palumbo, S. Patriarca, G. Plescia, V. Montefusco, D. Pietrafesa, A. Mucci, S. Galderisi

University of Naples SUN, Psychiatry, Naples, Italy

* Corresponding author.

Introduction The abnormal bodily phenomena questionnaire (ABPq) originates from the analysis of clinical files of more than 350 patients with schizophrenia. It consists in a semi-structured interview created to evaluate the subjective anomalies in feelings, sensations, perceptions and cognition in the domain of the lived body.

Objectives The present study is aimed at providing preliminary data for the validation of the Italian version of the ABPq.

Methods The ABPq was translated and adapted into Italian. ABPq scores were correlated to those obtained by the schizophrenia proneness instrument, Adult version–body perception disturbances (SPI-A E, body) that evaluates the same kind of phenomena, in order to examine its convergent validity. Moreover, ABPq was correlated to psychopathological domains assessed by the Positive and Negative Syndrome Scale (PANSS) and by the Brief Negative Symptom Scale (BNSS).

Results The experimental sample included 40 clinically stable patients. Our findings showed a strong correlation between ABPq and SPI-A E, body. An association of ABPq total score with the positive and disorganized dimensions was also observed.

Conclusions Our preliminary data suggest that the Italian version of ABPq has a good convergent validity. The presence of abnormal bodily phenomena resulted to be associated to a greater severity of the disease and therefore it could be hypothesized that they represent an indicator of clinical severity.

The longitudinal effects of experiential avoidance on depression symptoms in patients with inflammatory bowel disease

I.A. Trindade*, C. Ferreira, J. Pinto-Gouveia

Faculty of Psychology and Education Sciences - University of Coimbra, CINEICC - Cognitive Behavioural Centre for Research and Intervention, Coimbra, Portugal

* Corresponding author.

Inflammatory bowel disease (IBD) has been vastly associated with the development of depression and it is thus considered that the mechanisms that underlie this link should be explored. The present study aimed to examine the longitudinal effects of IBD symptoms and a maladaptive emotion regulation process, experiential avoidance (defined as the tendency to attempt to control internal experiences), on depression symptoms. The sample comprised 116 IBD patients of both sexes that completed validated self-report measures on an online platform in three different times (equally spaced 9 months apart) during an 18-month period. Results demonstrated that IBD symptomatology at baseline was linked to experiential avoidance and depressed mood 9 and 18 months later. The level of experiential avoidance at baseline was also correlated with the subsequent experience of depression symptoms, 9 and 18 months later. Results also revealed that, although IBD symptomatology at baseline predicted depressive symptomatology 18 months later ($\beta = 0.24$; $P = 0.008$), when experiential avoidance at baseline was added to this model, this process became the only predictor of the outcome ($\beta = 0.60$; $P < 0.001$; $R^2 = 0.41$). These results corroborate previous literature by indicating that IBD symptomatology may lead to depression symptomatology. Nevertheless, the current study additionally revealed that the engagement in experiential avoidance – that is, in attempts at controlling the frequency, form or intensity of internal experiences – might have a greater role on the determination of patients' depressed mood than the experience of adverse physical symptomatology. Maladaptive forms of emotion regulation in IBD patients should be targeted to prevent depression symptoms.

* Corresponding author.

Introduction The Maudsley obsessional-compulsive inventory (MOCI) is a widely used self-report measure of obsessive-compulsive symptoms in clinical and non-clinical populations, both in research and clinical settings. Nogueira et al. confirmed in 2011 that the MOCI Portuguese version has good psychometric properties, having a factorial structure that is in accordance with those reported by other groups.

Aims Based on the previous results of exploratory factor analysis with a Portuguese students sample, the present study aimed to

perform a confirmatory factor analyses (using Mplus software) to verify if the three dimensions' structure fitted the data.

Methods The sample comprised 234 students on their first three years of college education (78.2% female), between 18–26 years old ($M=20.55$; $SD=1.66$). Participants filled the Portuguese version of the MOCI.

Results Our results showed that the MOCI Portuguese version with original 3-factor structure has a good fit ($\chi^2_{(227)}=386.987$, $P<.05$; $RMSEA=0.053$, $90\%CI=0.044-0.062$; $CFI=0.928$; $TLI=0.920$; $WRMR=1.089$). Good reliability was found for all subscales (Cronbach alpha $<.80$).

Conclusions The MOCI Portuguese version reliably and validly assesses three OC symptom dimensions in young adults. Further research is needed to confirm this structure in Portuguese clinical samples.

* Corresponding author.

Introduction Early stages after a first psychotic episode (FEP) are crucial for the prognosis of the disease. Those patients who drop out of treatment after a FEP show a significant increase in their vulnerability to relapse. Relapses associated a greater risk of neurotoxicity, chronicity, hospitalization, decrease of response to the treatment, increase of burden and functional decline.

Objectives To determine what antipsychotic is more effective in the prevention of relapse after a first psychotic episode.

Material and methods PAFIP is an assistance program focused on early intervention in psychosis. Between January 2001 and January 2011, 255 patients were recruited and randomly assigned to treatment with haloperidol ($n=48$), olanzapine ($n=41$), risperidone ($n=44$), quetiapine ($n=34$), ziprasidone ($n=38$) and aripiprazole ($n=50$). We compared the rates of relapse and remission reached by haloperidol, olanzapine, risperidone, aripiprazole, ziprasidone and quetiapine during a 3-year follow-up. All of the patients were antipsychotic naives at the beginning of the treatment.

Results There were no statistically significant differences in regard to the rate of clinical remission. Patients assigned to the groups of aripiprazole, olanzapine and risperidone presented a solid trend to a significantly inferior rate of discontinuation for any reason since the beginning of the treatment.

Conclusions These data point to a greater protection against relapse and a likely better prognosis related to the use of aripiprazole, Olanzapine and risperidone.

³ Faculty of Philosophy and Social Sciences - Catholic University of Portugal, Braga Regional Centre, Braga, Portugal

* Corresponding author. Faculty of Medicine, University of Coimbra, Psychological Medicine, Coimbra, Portugal.

Introduction College students are known for their variable sleep schedules. Such schedules, along with other common student practices are associated with poor sleep hygiene. The persistence of the precipitating stressor is one of the factors involved in the persistence of insomnia.

Aims To examine the role of the perceived stress, perseverative thinking, strategies of cognitive emotion regulation and negative affect as predictors of sleep difficulties.

Methods The sample comprises 549 college students.

Measures PSS-10, PTQ, CERQ and POMS-58. Three questions were used to access difficulties in initiating sleep (DIS), maintaining sleep (DMS) and early morning wakening (EMA). A Sleep Difficulties Index (SDI) was calculated by summing DIS, DMS and EMA scores.

Results In total sample, the multiple linear regression explained 27.7% of the SDI total variance ($R^2=.277$, $F(9, 375)=15,942$, $P<.0001$). The significant predictors of the total variance of SDI were perceived distress ($B=.246$, $P=.0001$), repetitive thought ($B=.189$, $P=.005$), cognitive interference and unproductiveness ($B=-.188$, $P=.006$), rumination ($B=.130$, $P=.044$) and negative affect ($B=.156$, $P=.018$).

Conclusions Preventive interventions focused on predictor factors (perceived stress, perseverative thinking, rumination and negative affect) should be considered in order to promote better mental health in college students.

* Corresponding author.

The 22q11.2 deletion syndrome (22q11DS) is characterized by high rates of psychotic symptoms and schizophrenia, making this condition a promising human model for studying risk factors for psychosis. We explored the predictive value of ultra high-risk (UHR) criteria in a sample of patients with 22q11DS. We also examined the additional contribution of sociodemographic, clinical and cognitive variables to predict transition to psychosis within a mean interval of 32.56176 months after initial assessment.

Eighty-nine participants with 22q11DS (age range: 8–30 years; mean: 16.1647) were assessed using the structured interview for psychosis-risk syndromes. Information on axis I diagnoses, internalizing and externalizing symptoms, level of functioning and IQ was also collected. At baseline, 22 (24.7%) participants met UHR criteria. Compared to those without a UHR condition, they had a significantly lower functioning, more frequent anxiety disorders and more severe psychopathology. Transition rate to psychosis was 27.3% in UHR and 4.5% in non-UHR participants. Cox regression analyses revealed that UHR status significantly predicted conversion to psychosis. Baseline level of functioning was the only other additional predictor. This is the first study investigating the predictive value of UHR criteria in 22q11DS. It indicates that the clinical path leading to psychosis is broadly comparable to that observed in other clinical high-risk samples. Nevertheless, the relatively high transition rate in non-UHR individuals suggests that other risk markers should be explored in this population. The role of low functioning as a predictor of transition to psychosis should also be investigated more in depth.

Family environment as predictor of adolescents' loneliness

M. Balážová*, I. Gallová, J. Praško, M. Šlepecký, A. Kotianová
University of Constantinus the Philosopher in Nitra, Department of Psychological Sciences, Nitra, Slovak Republic
* Corresponding author.

Introduction At the present time, adolescents are in particular vulnerable to feelings of loneliness. They are gradually emancipating from their family and establish relationships with peers. Among the important predictors of loneliness belong genetic and personal variables and factors of social environment.

Objectives and aims To examine predictors of adolescents' loneliness which are located in family environment. To find out how empathy, emotional relationship and control by both of parents contribute to loneliness of adolescent boys and girls.

Methods We examined 206 adolescents in the age from 10 to 18 years through Basic Empathy Scale, Parenting Style Scale and UCLA Loneliness Scale. Stepwise multiple linear regression analysis was used for data analysis.

Results The significant predictors of boys' loneliness in family environment are emotional relationship of mother and affective empathy of father. The significant predictors of girls' loneliness include emotional relationship and cognitive empathy of father. Parental control is not a significant predictor of adolescents' loneliness.

Conclusion Adolescents' loneliness is largely influenced by factors of family environment. Our study highlights the role of emotional relationship provided by the opposite sex parent. Cold behavior of the opposite sex parent could reduce self-esteem and self-confidence of adolescents. Both could help them establish relationships with peers and people outside family, thus protecting them against loneliness. A significant predictor of boys' and girls' loneliness is also empathy of father. We recommend to make use of our findings in clinical practice with adolescents, in family therapy as well as in context of attachment.

⁵ Institute of Health and Society, Newcastle University, Newcastle, United Kingdom

* Corresponding author.

Aims To describe the mental disorders and social function of the hard to reach young people (HTRYP) from the innovations project (IP) and compare to a matched sample from a community mental health team (CMHT).

Background IP was a new multidisciplinary team based within an inner city, walk-in health centre, North East England (throughout 2011).

Methods Phase 1 and 2: retrospective review of clinical case notes of YP who attended the IP and CMHT. Phase 3: 24-months follow-up evaluation of the mental state and social function, using Health of the Nation Outcome Scales for Child and Adolescent Mental Health (HoNOSCA) and Children's Global Assessment Scale (CGAS).

Results Overall, 36 referrals accepted by the IP, 31 met criteria for HTRYP, 15 were offered individually tailored therapy. IP group experienced more deprivation compared to the CMHT matched sample ($n=115$). At baseline, the HTRYP had more mental disorders, higher severity scores and lower levels of social function (HTRYP HoNOSCA mean: 19.1 and CMHT mean: 11.2 $P<0.001$ and HTRYP CGAS mean: 51.0, CMHT mean: 58.9, $P=0.05$). The HTRYP made significantly greater improvement compared to CMHTYP; (HoNOSCA $P<0.001$ and CGAS $P<0.002$). Thirteen HTRYP attended the follow-up review at 24 months compared with nine of CMHTYP. There was great variability in terms of social function between the YP within each sample.

Conclusion The term "HTR" describes a state, which the YP may be at a particular point their lives. A service, which utilises a developmental theoretical framework, offers regular reviews and an individualised care plan, could reduce longer-term morbidity and mortality suffered by HTRYP.

Implications of COMT and subclinical psychiatric symptoms on the phenotypic variability of 22q11.2 deletion syndrome: A transversal and longitudinal approach

S. Guerrero^{1,*}, M. Armando¹, M. Pontillo¹, F. Papaleo², S. Vicari¹

¹ Child Psychiatry Unit- Bambino Gesù Children's Hospital- IRCCS, Department of Neuroscience, Roma, Italy

² Istituto Italiano di Tecnologia, Department of Neuroscience and Brain Technologies, Genova, Italy

* Corresponding author.

Introduction 22q11.2 deletion syndrome (22q11.2DS) results from a hemizygous microdeletion on chromosome 22 and is characterized by phenotypic variability. Several studies have been

conducted on the impact of COMT functional polymorphism in 22q11DS, suggesting that attenuated psychotic manifestations are frequent in children and adolescents and represent one of the strongest predictors for the onset of psychotic disorder.

Objectives We explored possible interaction between COMT polymorphism and subclinical psychiatric symptoms in a 22q11.2DS cohort of 42 participants aged 6 to 26 years: 17 hemizyosity for COMT-Met and 25 hemizyosity for COMT-Val.

Aims To analyse impact of COMT gene in 22q11DS and its related psychiatric correlates.

Method Each participant, genotyped for the catechol O-methyltransferase (COMT) Met/Val polymorphism, underwent structured psychiatric and cognitive assessment. Analysis of positive and negative symptoms was performed by the structured interview for prodromal syndromes (SIPS). Finally, longitudinal data available in a subsample of 24 individuals were used to explore the developmental trajectories of psychotic symptoms one year later.

Results There was a significant positive correlation between COMT Val polymorphism and positive symptoms; at follow-up, no significant correlation were found between COMT polymorphism and psychiatric symptoms. No other significant differences were found between groups (Comt/Met-Comt/Val) on any other CBCL or QI score.

Conclusions COMT and additional genes microdeleted might interact in the susceptibility to schizophrenia in 22q11.2DS: psychotic symptoms might result from an epistatic interaction with other genes. Moreover, gene-environment, in presence of genetic vulnerability could increase the risk of schizophrenia in 22q11DS.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Coping victimization among peers in Spain

E. Magallón-Neri^{1,*}, S. Vanneste-Morales², M. Fornis¹, T. Kirchner¹

¹ University of Barcelona, Faculty of Psychology. IR3c, Clinical Psychology and Psychobiology, Barcelona, Spain

² University of Barcelona, Clinical Psychology and Psychobiology, Barcelona, Spain

* Corresponding author.

Background Bullying at school and victimization problems in adolescence have a negative impact in personal identity development specifically in mental health field.

Objective To analyze coping profiles used in a communitarian adolescents sample in relation to victimization among peers and controlling the other victimization subtypes.

Method From Barcelona Metropolitan area, 1031 adolescents between 12 and 20 years old participated (37.5% boys; 15.7% foreigners). The different coping strategies were assessed with adolescent coping orientation for problem experiences test and the victimization types with juvenile victimization questionnaire.

Results A 46.2% of adolescents suffered a victimization event by peers in the last year. As victimization level by peers advance, it presents an increase of unproductive coping strategies ($P < .001$; d -Cohen = 0.92). Regularly women score higher than men in low and moderate victimization groups ($P < .05$). However, when it reaches the highest expression (higher risk profile), unproductive strategies use in both genders is very similar and significant differences disappear. The results show that avoidant coping type is associated with a higher rate of victimization by peers. Positive relationship between previous victimization in other areas and peer victimization rate was found.

Conclusions It is of high importance to develop and strengthen coping psychoeducation programs centered in solving this prob-

lem and struggling against victimization consequences by peers in adolescence. Due to that, increase of this victimization type is very related to the use of unproductive strategies use and therefore a coping by avoiding the problem.

Early childcare and trajectories of behavioral difficulties in children: The EDEN mother-child cohort study

M. Melchior

Inserm, Pierre Louis Institute of Epidemiology and Public Health, Paris, France

Background There is no consensus of the relationship between early childcare and later psychological development.

Methods We studied 1428 children participating in the French EDEN cohort. Childcare was reported prospectively between ages 4 months and 3 years: childminder, collective care, informal care. Children's behavior was assessed by mother-reported strength and difficulty questionnaire (SDQ) scores at ages 3.5, 5.5 and 8 years. Trajectories of children's behavioral difficulties (emotional difficulties, behavioral problems, peer-relations difficulties, symptoms of hyperactivity and inattention, prosocial behavior) were identified using group-based trajectory modelling (PROC TRAJ, SAS). To control for selection and confounding factors, we used propensity scores based on over 30 covariates, included in multinomial regression models as inverse probability weights of exposure.

Results Compared to children in informal care, those who were cared for by a childminder or in collective care were less likely to have peer problems (respectively, ORs for the intermediate level trajectory = 0.67 [95% IC: 0.47–0.95] and 0.49 [95% IC: 0.34–0.72]; ORs for the high level trajectory = 0.47 [0.27–0.82] and 0.33 [0.17–0.62]). Collective care was also associated with a reduced likelihood of intermediate ($OR = 0.71$ [0.52–0.98]) and high trajectories of hyperactivity and inattention ($OR = 0.50$ [0.35–0.81]), intermediate ($OR = 0.58$ [0.39–0.88]) and high trajectories of emotional symptoms ($OR = 0.54$ [0.32–0.92]) and intermediate ($OR = 0.72$ [0.51–1.01]) and high behavioral problems trajectories ($OR = 0.54$ [0.34–0.85]).

Conclusion Childcare attendance prior to school entry – particularly collective childcare – may have beneficial effects for children's psychological development and peer relations.

Predicting secondary mental health care use in adolescence using self-, parent- and teacher-reported problem behavior in a community-based record-linkage study

D. Raven^{1,2,*}, F. Jörg^{1,2}, E. Visser¹, R.A. Schoevers¹, A.J. Oldehinkel¹

² Friesland Mental Health Services, Research and Education, Leeuwarden, The Netherlands

* Corresponding author.

Introduction In adolescence, help-seeking is affected by different actors. The influence of each actor on help-seeking is often studied in isolation, or, if multiple informants are included, using only few assessments of adolescents' mental health.

Objectives The aim of this study is to determine the extent to which self-, parent- and teacher-reported problem behavior predict secondary care in adolescence and to what extent the informants' relative importance changes over time.

Methods Data from the Dutch community-based cohort study tracking adolescents' individual lives survey (TRAILS) were linked to administrative records of secondary care from 2000 (age 9) to 2011 (age 21). Internalizing and externalizing problems were assessed using the youth self-report, child behavior checklist and teacher checklist of psychopathology at ages 11, 13 and 16, and the adult self-report at age 19.

Results The annual incidence of secondary care fluctuated between 1.3% and 2.4%. In Cox regression analyses that adjusted for sociodemographic covariates and problem behavior, internalizing problems but not externalizing problems predicted secondary care. Secondary care between the ages 11 to 13 years was predicted best by teachers, between the ages 13 to 16 by parents, and between the ages 16 to 21 by adolescents.

Conclusions The relative importance of informants for predicting secondary care shifts over time, which suggests that each informant is the driving force behind secondary care at a different phase of adolescence. The treatment gap may be reduced by improving problem recognition of teachers in secondary education and by educating young adults about mental health problems.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Mental disorders are increasing among children and adolescents in Sweden – a nationwide study with focus on gender differences

P. Salmi*, M. Berlin

National Board of Health and Welfare, Epidemiology, Stockholm, Sweden

* Corresponding author.

Introduction An increasing number of young people in Sweden are diagnosed with mental disorders and there appears to be significant gender differences in disease pattern.

Objective To more thoroughly characterize the increase in mental disorders among young people with focus on gender differences.

Aim To increase the knowledge of age and sex-specific trends in incidence and prevalence rates of mental disorders among children and adolescents.

Method Data on psychiatric diagnoses for the last 10 years were obtained from Swedish national registers held by the National Board of Health and Welfare in Sweden.

Results Neuropsychiatric, depressive and anxiety disorders have increased markedly among young people the last decade. In addition, men are increasingly diagnosed with substance-related disorders whereas women with borderline personality disorder.

Conclusion The increase in mental disorders among young people is marked and disease affects men and women differently. Because of greater awareness today, some conditions like ADHD are more frequently diagnosed. However, the increase in depressive and anxiety disorders appears genuine and represents an additional challenge.

The impact of age on the prevalence and clinical relevance of attenuated psychotic symptoms in patients of an early detection service

F. Schultze-Lutter^{1,*}, C. Michel¹, B.G. Schimmelmann¹, D. Hubl²

¹ University of Bern, University Hospital of Child and Adolescent Psychiatry and Psychotherapy, Bern 60, Switzerland

² University of Bern, University Hospital of Psychiatry and Psychotherapy, Bern 60, Switzerland

* Corresponding author.

Introduction Compared to 16–40-year-olds, 8–15-year-olds of the community reported higher frequencies of perceptual and lesser clinical significance of non-perceptual attenuated psychotic symptoms (APS).

Objectives/aims We examined if a similar age effect is present in a clinical never-psychotic sample ($n = 133$) referred to a specialized service for clinical suspicion of developing psychosis.

Methods APS and brief intermittent psychotic symptoms (BIPS) were assessed using items P1-3 and P5 (non-perceptual) and P4 (perceptual) of the structured interview for psychosis-risk syndromes, current axis-I disorders with the mini-international neuropsychiatric interview and psychosocial functioning with the Social and Occupational Functioning Assessment Scale (score < 71 indicative of at least some difficulty in social, occupational, or school functioning).

Results Overall, 64% reported APS (61%) or BIPS (7%); any perceptual APS/BIPS was reported by 43% and any non-perceptual APS/BIPS by 44%. In correspondence to the results of the community study, perceptual but not non-perceptual APS/BIPS were significantly more frequent in younger age groups below the age of 16 (8–12 yrs: $OR = 4.7$ (1.1–19.5); 13–15 yrs: $OR = 2.7$ (0.9–7.7)); 20–24-year-olds as reference group). An age effect of APS/BIPS on presence of any current axis-I disorder (59%) or functional difficulties (67%) could not be detected. Yet, when APS onset requirements were met, the likelihood of a psychiatric diagnosis increased significantly with advancing age.

Conclusion Overall, the replicated age effect on perceptual APS in this clinical sample highlights the need to examine ways to distinguish clinically relevant perceptual APS from perceptual aberrations likely remitting over the course of adolescence.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Basic symptoms in the community and their association with age

F. Schultze-Lutter^{1,*}, C. Michel¹, B.G. Schimmelmann¹,

S. Ruhrmann², J. Kindler¹, S.J. Schmidt¹

¹ University of Bern, University Hospital of Child and Adolescent Psychiatry and Psychotherapy, Bern 60, Switzerland

² University of Cologne, Department of Psychiatry and Psychotherapy, Cologne, Germany

* Corresponding author.

Introduction Limited clinical relevance of attenuated psychotic symptoms before the turn from early to late adolescence, i.e., age 15/16, was reported.

Objective This emphasizes the potentially important role of neurodevelopmental aspects in the early detection of psychoses.

Aims We examined the age effect on prevalence and clinical relevance of 14 cognitive and perceptual basic symptoms (BS) included in risk criteria of psychosis in a random representative 8–40-year-old community sample ($n = 689$).

Methods Participants underwent clinical interviews for BS, psychosocial functioning and current mental disorder on the telephone.

Results BS were reported by 18% of participants, mainly cognitive BS (15%). Age seemed to affect perceptible and cognitive BS differently, indicating an age threshold for perceptible BS in late adolescence (around age 18) and for cognitive BS in young adulthood (early twenties) – with higher prevalence, but a lesser association with functional deficits and the presence of mental disorder in the below-threshold groups. Thereby, effects of the interaction between age and BS on functioning and mental disorder were commonly stronger than individual effects of age and BS.

Conclusion Differential age effects of perceptual and cognitive BS seem to follow normal brain maturation processes, in which they might occur as infrequent and temporary nonpathological disturbances. Their persistence or occurrence after the conclusion of main brain maturation processes, however, might signify aberrant maturation processes. Thus, BS might provide important insight into the pathogenesis of psychosis and into potential neuroprotective targets.

Risk factors for suicide attempt: A retrospective study

L. Castaldo*, L. Mazzone, G. Serra, S. Vicari
Pediatric Hospital Bambino Gesù, Department of Neuroscience,
Roma, Italy

* Corresponding author.

Introduction Suicide is a leading cause of death among adolescents.

Objectives To investigate suicidal behaviors among Italian adolescents.

Aims To assess the rates of suicidal ideation (SI) and suicide attempts (SA) and the associated risk factors in patients admitted to emergency department (ED) of the Bambino Gesù Children's Hospital.

Methods Retrospective study based on data of patients admitted to the ED from 1 January 2011 to 30 May 2016 who required a neuropsychiatric (NPI) consultation. We analyzed:

- outcome of the NPI consultation (hospitalization or discharge);
- risk factors for SA and SI;
- methods employed for SA.

Results The number of NPI consultations for SI and SA increased from 6.45% in 2011 to 13.3% in 2015. More than 90% of consultations recommended hospitalization in the psychiatric unit (137 patient [66% female]; mean age of 15.5 ± 1.6 years) with average length of stay of 13.64 ± 10.63 days. Risk factors for SI and SA were non-suicidal self-injury, family conflicts and previous suicide attempts. Subjects evaluated for a SA reported a significantly higher frequency of family history of mood disorder ($\chi^2 = 5.94$; $P = 0.02$) and a comorbid substance abuse ($\chi^2 = 4.49$; $P = 0.03$) when compared with SI group. The method most frequently used to attempt suicide was ingestion of medications (52.83%).

Conclusions There was an increasing demand of NPI consultation of SA and SI in the last years. A family history of mood disorder and a history of substance abuse are risk factors able to differentiate between SI and SA.

² National Institute of Health and Welfare, Department of Health-Mental Health Unit, Helsinki, Finland

³ University of Helsinki, Institute of Behavioural Sciences, Helsinki, Finland

⁴ City of Helsinki, Department of Social Services and Health Care, Helsinki, Finland

* Corresponding author.

Introduction Substantial evidence supports association between childhood maltreatment and suicidal behaviour, however, a limited number of studies have examined psychological mechanisms mediating the relationship among patients with mood disorders.

Objective To investigate directly the potential intermediating mechanisms between childhood maltreatment and suicidal behaviour among patients with mood disorders.

Aims We examine by formal mediation analyses, if:

- the effect of childhood maltreatment on suicidal behaviour is mediated through borderline personality disorder traits;
- the mediation effect differs between lifetime suicidal ideation and lifetime suicide attempts.

Methods Depressive disorder and bipolar disorder (ICD-10-DCR) patients ($n = 287$) from the Helsinki university psychiatric consortium (HUPC) Study were surveyed on self-reported childhood experiences, current depressive symptoms, borderline personality disorder traits and lifetime suicidal behaviour. Psychiatric records served to complement the information on suicide attempts.

Results The influence of childhood maltreatment on lifetime suicidal ideation and lifetime suicide attempts showed comparable total effects. In formal mediation analyses, borderline personality disorder traits mediated all of the total effect of childhood maltreatment on lifetime suicide attempts, but only 21% of the total effect on lifetime suicide ideation. The mediation effect was stronger for lifetime suicide attempts compared to ideation ($P = 0.002$) and independent of current depressive symptoms.

Conclusions The mechanisms of the effect of childhood maltreatment on suicidal ideation and attempts may diverge among psychiatric patients with mood disorders. Borderline personality disorder traits may contribute to these mechanisms, although the influence appears considerably stronger for suicide attempts than for suicide ideation.

The role of maladaptive psychological strategies in the association between shame and psychological quality of life

C. Ferreira*, A.L. Mendes, J. Marta-Simões
 Faculty of Psychology and Education Sciences - University of Coimbra, CINEICC, Cognitive Behavioural Centre for Research and Intervention, Coimbra, Portugal

* Corresponding author.

Shame experiences have been highly associated with the engagement in maladaptive strategies (such as experiential avoidance and cognitive fusion) to cope with unwanted thoughts and feelings. Furthermore, these maladaptive processes have been linked to different psychopathological conditions.

The current study aimed to test the mediational effect of two different emotional regulation processes, cognitive fusion (i.e., the entanglement with unwanted inner events) and experiential avoidance (i.e., the unwillingness to be in contact with these inner experiences and the tendency to avoid and control them), on the association between external shame and psychological quality of life.

Participants were 421 (131 males and 290 females), aged between 18 and 34 years old.

The tested path model explained 40% of the variance of psychological quality of life and showed excellent model fit indices. Results demonstrated that external shame presented a significant direct effect on psychological quality of life and, in turn, an indirect effect, through the mechanisms of cognitive fusion and experiential avoidance. In fact, these findings seem to suggest that higher levels of external shame are linked to a higher tendency to engage in cognitive fusion and to lower acceptance abilities, which appear to explain decreased levels of psychological quality of life.

The present findings seem to offer significant clinical implications, emphasizing the importance of targeting maladaptive emotion strategies through the development of acceptance and decentering abilities.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Interaction between previous attempts and diagnosed psychiatric disorder as a risk marker of repeated suicide attempts among adolescents: Results from a prospective hospital-based study

G. Martínez-Ales*, E. Jiménez, E. Roman, P. Sánchez, I. Louzao, A. Cano, A. Orosa, I. Rubio, A. Fraga, A. De Diego, M. Coll, L. Nocete, V. Baena, R. Gallego, B. Rodríguez, M.F. Bravo
 Hospital Universitario La Paz, Psychiatry, Madrid, Spain

* Corresponding author.

Suicide is the second most frequent cause of death among the youth and its rates among adolescents have recently risen. Up to 30% of adolescents who attempt suicide will try it again within a year. Our objective is to analyze how previous attempts and diagnosed psychiatric disorder behave as markers of risk of reattempts and their statistical interaction. We include every underage patient treated by an emergency room psychiatrist after a suicide attempt in a General Hospital between years 2010 and 2015. Patients free of relapse after 1000 days are censored. We obtain Kaplan–Meier estimates for the risk of a new attempt as a time-dependant variable, dividing them by the presence of previous suicide attempts, diagnosed psychiatric disorder or both at a time, checking the differences by

using log-rank tests. Then, we perform Cox proportional risk models including both variables and a factor of their interaction and adjust them by sex and age in a non-automatically driven multivariate analysis, thus obtaining HR estimates. We present 150 cases (118 female; mean[SD] age in years: 15.8 [1.6]). Overall, 22.6% of them relapse during follow-up time. Multivariate models show interaction of previous attempts and diagnosed psychiatric disorder is associated with relapse with an HR of 1.27×10^8 (95% CI: $5.51 \times 10^7 - 2.9 \times 10^8$). Interaction of both factors is an outstanding risk marker of relapse after an attempted suicide and should thus be given clinical importance in tertiary prevention.

Personality and spirituality as predictors of suicidality in depressed patients

S. Mihaljevic^{1,*}, B. Aukst-Margetic², S. Karnicnik¹, B. Vuksan-Cusa²

¹ General Hospital Virovitica, Psychiatry department, Virovitica, Croatia

² Clinical Hospital Centre Zagreb, Psychiatry Department, Zagreb, Croatia

* Corresponding author.

Introduction Some studies show that more expressed spirituality and some dimensions of personality have protective role from suicidality.

Aim The aim of our study is to examine the influence of the spiritual quality of life (QoL) and dimensions of personality on course of suicidality in patients with depression.

Methods Ninety-nine patients were assessed with self-report measures of suicidality (BHS), personality (TCI), spirituality (WHOQOL-SRPB) during a yearlong follow-up.

Results Spirituality was inversely linked with suicidality at baseline and during follow-up and more expressed spirituality influenced faster recovery from suicidality. Dimensions of temperament harm avoidance and self-directedness show as significant predictors of recovery from suicidality.

Conclusion In our sample, spirituality, harm avoidance and self directedness are significant predictors of recovery from suicidality. This finding is stimulus for further researching of protective factors from suicidality.

Are volunteering and caregiving associated with suicide risk? A census-based longitudinal study

D. O'Reilly^{1,*}, M. Rosato², A. Maguire¹¹ Queen's University Belfast, Centre for Public Health, Belfast, United Kingdom² Ulster University, Bamford Centre, Belfast, United Kingdom

* Corresponding author.

Background This record linkage study explores the suicide risk of people engaged in caregiving and volunteering. Theory suggests opposing risks as volunteering is associated with better mental health and caregiving with a higher prevalence and incidence of depression.

Methods A 2011 census-based study of 1,018,000 people aged 25–74 years (130,816 caregivers and 110,467 volunteers; 42,099 engaged in both). All attributes were based on census records. Caregiving was categorised as either light (1–19 hours/week) or more intense (20+ hours/week). Suicide risk was based on 45 months of death records and assessed using Cox proportional hazards models with adjustment for and stratification by mental health status at census.

Results More intense caregiving was associated with worse mental health (OR_{adj} = 1.15; 95%CI = 1.12, 1.18); volunteering with better mental health (OR 0.87; 95%CI 0.84, 0.89). The cohort experienced 528 suicides during follow-up. Both volunteering and caregiving were associated with a lower risk of suicide though this was modified by baseline mental ill-health ($P=0.003$), HR 0.66; 95%CI 0.49, 0.88 for those engaged in either activity and with good mental health at baseline and HR 1.02; 95%CI 0.69, 1.51 for their peers with poor mental health. There was some indication that those engaged in both activities had the lowest suicide risk (HR 0.34; 95%CI 0.14, 0.84).

Conclusions Despite the poorer mental health amongst caregivers they are not at increased risk of suicide. The significant overlap between caregiving and volunteering and the lower risk of suicide for those engaged in both activities may indicate a synergism of action.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Incidence and predictors of suicide attempts in bipolar I and II disorders: A five-year follow-up

S. Pallaskorpi^{1,*}, K. Suominen², M. Ketokivi³, H. Valtonen², P. Arvilommi², O. Mantere⁴, S. Leppämäki⁵, E. Isometsä⁶¹ Finnish National Institute for Health and Welfare - THL, Psychiatric and Substance Abuse Services, Helsinki, Finland² Helsinki City Department of Social Services and Healthcare, Psychiatric and Substance Abuse Services, Helsinki, Finland³ IE Business School, Operations and Technology Department, Madrid, Spain⁴ McGill University, Department of Psychiatry, Montreal, Canada⁵ Helsinki University Central Hospital, Department of Psychiatry, Helsinki, Finland⁶ University of Helsinki, Department of Psychiatry, Helsinki, Finland

* Corresponding author.

Introduction Although suicidal behavior is very common in bipolar disorder (BD), few long-term studies have investigated incidence and risk factors of suicide attempts (SAs) specifically related to illness phases of BD.

Objectives We examined incidence of SAs during different phases of BD in a long-term prospective cohort of bipolar I (BD-I) and II

(BD-II) patients and risk factors specifically for SAs during major depressive episodes (MDEs).

Methods In the Jorvi bipolar study (JoBS), 191 BD-I and BD-II patients were followed using life-chart methodology. Prospective information on SAs of 177 patients (92.7%) during different illness phases was available up to five years. Incidence of SAs and their predictors were investigated using logistic and Poisson regression models. Analyses of risk factors for SAs occurring during MDEs were conducted using two-level random-intercept logistic regression models.

Results During the five-year follow-up, 90 SAs per 718 patient-years occurred. Compared with euthymia the incidence was highest, over 120-fold, during mixed states (765/1000 person-years [95% confidence interval (CI) 461–1269]) and also very high in MDEs, almost 60-fold (354/1000 [95%CI 277–451]). For risk of SAs during MDEs, the duration of MDEs, severity of depression and cluster C personality disorders were significant predictors.

Conclusions In this long-term study, the highest incidences of SAs occurred in mixed phases and MDEs. The variations in incidence rates between euthymia and illness phases were remarkably large, suggesting that the question “when” rather than “who” may be more relevant for suicide risk in BD. However, risk during MDEs is likely also influenced by personality factors.

Cost-effectiveness of a specialised medium secure personality disorder service

R. Woodward*, R. Lingam, F. Papouli

Bamburgh Clinic-Northumberland Tyne and Wear-Newcastle upon Tyne-UK, Forensic Personality Disorder Services, Newcastle upon Tyne, United Kingdom

* Corresponding author.

Introduction The Oswin unit located in the North East of England is commissioned primarily for offenders screened on the offender personality disorder (OPD) pathway based on measures of personality disorder being linked to moderate to high risks to other persons.

Objectives The Oswin Unit was re-designed in early 2014 meeting commissioning specifications to meet objectives based on access, measuring quality and reducing. The primary objective of this pathway is to ensure personality Disorder offenders have access to “community-to-community”, joint-up care and monitoring of risks. The Oswin unit implemented a re-designed service offering individuals formulation based assessments and risk management embedded in the OPD pathway. The overall objective of this project is to evaluate the effectiveness and risk amelioration of this hospital-based service.

Aim As part of a broader service development and evaluation project, the cost-effectiveness of the current model of the unit was compared to that of the unit prior to the redesign of the service.

Method Collection of data on number of admission and length of stay and calculation of expenses per capita. Retrospective analysis of costs of care.

Results Analysis of comparative figures post-implementation of this new model of care found 41% more episodes of care. Cost-analysis indicated a saving of £200,000.

Conclusion The new Oswin Model meets commissioning objectives in offering access to hospital-based care and focused treatments for prisoners ‘stuck’ in prison pathways. This finding led to further investigation using thematic measures of quality of care to evaluate the effectiveness of this service and risk amelioration.

Psychoeducational family intervention: Benefits and obstacles reported by mental health professionals

B. Pocal*, M. Savorani, G. Borriello, V. Del Vecchio, G. Sampogna, C. De Rosa, C. Malangone, M. Luciano, V. Giallonardo, A. Fiorillo

University of Naples SUN, Psychiatry, Napoli, Italy

* Corresponding author.

Introduction Despite several guidelines recommend the use of psychoeducational family interventions (PFIs) as add-on in the treatment of patients with bipolar I disorder (a), their implementation on a large scale remains limited (b).

Objectives To identify benefits and obstacles in implementing a PFI in the clinical routine care.

Methods This was a multicentre, real-world, controlled, outpatient trial, carried out in 11 randomly recruited Italian mental health centres. Mental health professionals received a training on PFI and provided the intervention to patients with bipolar I disorder and their relatives. Difficulties and benefits in performing PFI were collected through an ad-hoc schedule, which was administered at baseline and 5 times during the different stages of the intervention.

Results Mental health professionals report significant improvements in the intervention-related benefits over time ($T_0 = 5.3 \pm 2.0$ vs. $T_5 = 7.9 \pm 0.9$; $P < .0001$), in particular in their professional skills ($T_0 = 6.5 \pm 2.3$ vs. $T_5 = 8.0 \pm 0.8$; $P < .01$). They also report to be more satisfied with their own work ($T_0 = 6.6 \pm 2.3$ vs. $T_5 = 8.0 \pm 1.3$; $P < .05$). The most relevant difficulties were related to the need to integrate the PFI with other work responsibilities and to the lack of time, which did not decrease overtime.

Conclusions PFIs are feasible in routine care for the treatment of patients with bipolar I disorder and their relatives, and main obstacles are related to the organization of mental health centres, and not to the characteristics of the intervention itself.

Aberrant salience and alexithymia in subthreshold psychotic experiences among adolescent migrants in Italy: A comparison with native Italian adolescents

A. Pozza^{1,*}, D. Dèttore²

¹ University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy

² University of Florence, Department of Health Sciences, Florence, Italy

* Corresponding author.

Introduction In this decade in the Italian context, there has been a significant increase of the immigration phenomenon. Consistent data indicated higher risk of psychotic experiences among migrants. Poor work investigated clinical variables associated with stronger subthreshold psychotic experiences among this population of adolescents. Aberrant salience, the biased assignment of significance to otherwise innocuous stimuli, and alexithymia, the difficulty identifying/describing feelings are believed to have a role in the onset and maintenance of psychotic symptoms. No

study evaluated whether they could moderate the relation between migrant status and psychotic experiences among in adolescence.

Objectives The current study investigated whether salience and alexithymia predicted more intense subthreshold psychotic experiences and moderated the effect of migrant status among migrant and native Italian adolescents.

Methods Seventy-three adolescents born in other countries than Italy and 75 native Italian adolescents (mean age = 17.57, SD = 2.08, 47.30% females) completed the aberrant salience inventory, the Toronto Alexithymia Scale-20 and the screening for psychotic experiences.

Results Migrant adolescents had higher levels of subthreshold psychotic experiences ($F = 10.65$, $P < 0.01$), alexithymia ($F = 8.93$, $P < 0.01$) and salience ($F = 4.38$, $P < 0.05$) than native Italian adolescents. A main effect of aberrant salience and alexithymia on subthreshold psychotic experiences emerged. An interaction effect between migrant status and alexithymia was found: migrant adolescents with stronger alexithymia had more intense subthreshold psychotic experiences.

Conclusions Public health policies should consider migrant adolescents as a group at risk for stronger subthreshold psychotic experiences. Prevention programs could take into account alexithymia as a target of intervention for this population of adolescents.

⁴ Icahn School of Medicine at Mount Sinai, Department of Psychiatry, NY, USA

⁵ Levanger Hospital, Department of Research and Development, Levanger, Norway

* Corresponding author.

Introduction Suicide takes a great toll on both individuals and societies. Successful preventive measures would require a careful understanding of the scope of suicidal ideation as well as its associated factors. Amongst mental disorders, anorexia nervosa has the highest mortality rate due to suicide.

Objective and aims Studying the prevalence of suicidal ideation and its associated factors in adolescents (13–19 years old) affected by disordered eating (DE).

Methods Logistic regression was employed to study associations between suicidal ideation and age, gender and disordered eating in adolescents from a population-based prospective study, The Young-HUNT 3 cohort, 2006–8. DE cases were defined using the self-reported questionnaire (Eating Attitude Test-7) and then grouped into two subscales, poor appetite/under-eating and uncontrolled appetite/overeating.

Results A total of 3933 (boys 49% and 51% girls) were included. In total, 177 poor appetite/under-eating and 365 uncontrolled appetite/overeating cases were identified. Prevalence of suicidal ideation was 24.5% in total sample with girls being more affected (27.1%). Prevalence of suicidal ideation amongst poor appetite/under-eating case group and uncontrolled appetite/overeating cases was respectively 43.5 and 39.2%. The odds-ratio of suicidal ideation amongst poor appetite/under-eating

cases compared to control group was 2.56 (95% CI, 1.85 to 3.42, P -value < 0.001) whilst the odds-ratio of suicidal ideation amongst uncontrolled appetite/overeating cases compared to control group was 2.19 (95% CI, 1.75 to 2.74, P -value < 0.001). Results remained significant after adjusting for anxiety and depression symptoms.

Conclusion Focus on high risk groups such as DE seems important in taking suicide preventive measures.

Are social networks useful to challenge stigma attached to mental disorders? Findings from the time to change social marketing campaign 2009–2014

G. Sampogna^{1,*}, C. Henderson², G. Thornicroft², S. Evans-Lacko², I. Bakolis², E. Robinson², M. Luciano¹, V. Del Vecchio¹, A. Fiorillo¹

¹ University of Naples SUN, Department of Psychiatry, Naples, Italy

² Institute of Psychiatry- Psychology and Neuroscience–King's College London, Health Services and Population Research Department, London, United Kingdom

* Corresponding author.

Introduction The new channels of communication as social media (e.g. Facebook and Twitter) and the social marketing campaign (i.e. campaign focused on enabling, encouraging and supporting behavioural changes among target audiences) can represent useful strategies to challenge stigma attached to mental disorders.

Objectives To evaluate the efficacy of the social marketing campaign of the time to change (SMC-TTC) anti-stigma programme on the target population in England during 2009–2014.

Aims To assess the impact of the SMC-TTC anti-stigma programme in terms of:

- use of the social media channels;
- levels of awareness of the SMC-TTC;
- changes in knowledge, attitude, and behaviour related to mental disorders.

Methods Participants completed the mental health knowledge schedule (MAKS), the community attitudes toward mental illness (CAMI) and the reported and intended behaviour scale (RIBS), together with an ad-hoc schedule on socio-demographic characteristics.

Results In total, 10526 people were interviewed, it was found a growing usage of the SMC-TTC media channels and of the level of awareness of the campaign (P < 0.001). Being aware of the SMC-TTC was found to be associated with higher score at MAKS (OR = .95, CI = .68 to 1.21; P < .001), at “tolerance and support” CAMI subscale (OR = .12, CI = .09 to .16; P < .001) and RIBS (OR = .71, CI = .51 to .92; P < .001), controlling for confounders.

Discussion In the general population, SMC-TTC has been found to be effective in improving attitudes and behaviours towards people with mental disorders.

Conclusions Considering these promising results obtained in England, social media can represent the possible way forward for challenging stigma. The future on-going evaluation of the SMC-TTC may further shed light on the essential role of social media in reducing of stigma and discrimination.

* Corresponding author.

Introduction People seeking information and news regarding suicide are likely to use the Internet. There is contrasting evidence about the relationship between the cyclicity of suicide-related search volumes and national suicide-rates in different countries.

Objectives The objectives were to investigate first the cyclicity of Italian suicides and online suicide-related searches carried out by the Italian population in the same time frame (2008–2012) and analyze the correlation between the two cyclicities.

Aims The study aimed to gain further insights on suicide-related internet use and its relationships to completed suicides.

Methods Italian mortality database provided monthly national data concerning suicides (2008–2012). Google trends provided data of online monthly search-volumes of the term “suicide”; “commit suicide”; “how to commit suicide” in Google search (2008–2014).

Results Seasonal AR model suits the trend of Italian suicides with a periodic 1-year cycle. No specific cyclicity for Google search volumes for “how to commit suicide” and “to commit suicide” was found (ARIMA [0,1,1] and ARIMA [1,0,1] respectively). Google search time series for “suicide” performed with ARIMA (1,1,1) and the cross correlation analysis showed that it lags national suicides of three months (ρ = 0.482, P -value < 0.001).

Conclusions Online searches for suicide-related terms in Italy are more linked to factors other than suicidality such as personal interest and bereavement. To our knowledge, no previous study reported a lag of three months between online searches for “suicide” and national suicides. This may shed further light on the grieving process being of help in organizing effective supportive strategies for the survivors.

In the framework of biopsychosocial model of health and pathology that is nowadays widely recognized in the different fields of modern medicine the mind, building the core of personality and the brain as the central regulatory organ play an essential role in the interdisciplinary approach to somatic illnesses. It is a common knowledge that comorbid anxiety and depression disorders can influence the course of various somatic illnesses and worsen their prognosis. We

also have evidence-based studies that depression for example is an independent risk factor of heart infarct onset. On the other hand, we observe the somatization of clinical picture of mental disorders, the increase of atypical forms manifesting through pain or other somatic syndromes that leads to the increase of mental illnesses in the primary care. The research of common pathways of mental and somatic pathology should be the subject of further interdisciplinary research programs. The other issue is the patient's compliance that plays in important role in the success of every kind of treatment. Personality traits and status of mental health can influence ones attitude to illness as well as motivation to therapy. We cannot assess the population state of health without taking into consideration the evaluation of mental status as well as such definitions like subjective well being, life quality and stigmatization.

Personality disorders and perinatal psychiatry: Food for thoughts from perinatal psychiatric department experience

E. Di Giacomo^{1,*}, F. Colmegna², M. Clerici³

¹ PhD program in Neuroscience–Doctorate School of the University of Milano–Bicocca, Psychiatric Department–S. Gerardo Health Care Trust–Italy, Milan, Italy

² S. Gerardo Health Care Trust, Psychiatric Department, Monza, Italy

³ University of Milano Bicocca, School of Medicine and Surgery, Milan, Italy

* Corresponding author.

Background Pregnancy and postpartum are sensitive unique moments in women's life. Perinatal psychiatry is focused on depression and psychosis, but personality issues is often neglected as well as risk factors for personality disorders instead of being considered causative of onset or recrudescence of psychiatric symptoms in perinatal.

Methods In total, 129 women were referred to perinatal psychiatric department during their pregnancy or postpartum in the last three years. They were administered SCID II, Childhood Trauma Questionnaire (CTQ), Beck Depression and Anxiety Inventories (BDI and BAI), Edinburgh Postnatal Depression Scale (EPDS) and World Health Organization Quality of Life (WHOQOL). Their interaction with babies was monitored at birth and during follow up. Children's behavioral development is under evaluation through structured tests.

Results BDI and BAI scored moderate or severe in 31 and 27% of women, EPDS was significant in 36%, while SCID II highlighted 24% of borderline, 17% narcissistic, 4% schizoid, 4% paranoid and 9% obsessive/compulsive PD. Nineteen of them suffered physical abuse during childhood, 26 sexual abuse, 89 emotional neglect and only 15 out of 129 were negative to any kind of abuse during childhood.

Conclusion Personality disorders appears to influence maternal adjustment to pregnancy and motherhood. Abuses suffered during childhood confirm their role as potential risk factor in personality issues which clearly express their effect in adaptation to change in personal role and in emphatic interactions.

What do patients want? Correlates of patient satisfaction and treatment engagement

R. Gearing*, A. Webb

University of Houston, GCSW, Houston, USA

* Corresponding author.

Introduction Motivation and ability to engage with treatment may deteriorate or falter if a patient is not satisfied with their protocols or provider. Improving patient satisfaction may more effectively strengthen treatment engagement.

Objectives 1) Determining what patients want from their provider relationship; and 2) identifying means for a provider to effectively assess and evaluate patient satisfaction in relation to treatment engagement.

Methods A systematic review of published meta-analyses, systematic reviews, and literature reviews between 1996 and 2016 was conducted across three databases (Medline, PsycINFO, CINAHL). Using variations of the search terms patient; satisfaction; medication, medical and psychiatric treatment; and engagement/adherence, a total of 1667 articles were identified. After removing duplications, 1582 articles were independently screened for eligibility (e.g. conceptual focus, methodological limitations) by two research assistants, resulting in the final inclusion of 50 meta-analysis, systematic review, or literature review articles that focused on predictors or barriers to patient satisfaction and/or predictors or barriers affecting engagement/adherence.

Results Barriers and predictors of patient satisfaction centered on two fundamental domains:

– relationship with Provider (sub-factors: multicultural competence, shared decision making, communication skills, continuity of care, empathy) and;

– outcomes (sub-factors: therapeutic outcome, patient expectations).

Eight treatment engagement/adherence barrier and predictor domains were identified, specifically treatment regimens; illness beliefs, emotional/cognitive factors; financial and logistic; social support; symptom/illness characteristics; demographics and patient-provider relationship.

Conclusions Key findings highlight actions psychiatrists and other clinical providers may consider in addressing barriers and highlighting promoters to improve patient satisfaction and overall engagement and adherence.

* Corresponding author.

Introduction Lurasidone is an atypical antipsychotic that demonstrated efficacy in the treatment of adults with schizophrenia in the dose range of 37–148 mg/day.

Objective/Aims The objective of this analysis was to evaluate the efficacy of lurasidone in adolescent patients with schizophrenia.

Methods Adolescents (13–17 years old) diagnosed with schizophrenia were randomly assigned to six weeks of double-blind treatment with lurasidone 37 mg/day, 74 mg/day or placebo. Changes from baseline to week 6 in PANSS total and subscale (positive, negative, general psychopathology, excitability) scores were evaluated using mixed-model repeated-measures analysis.

Results A total of 326 patients (mean age, 15.4 years) were randomized and received lurasidone 37 mg/day ($n=108$), 74 mg/day ($n=106$), or placebo ($n=112$). The PANSS total score at week 6 demonstrated a placebo-adjusted, least-squares (LS) mean improvement of -8.0 ($P<0.001$; effect size [ES], 0.51) for the 37 mg/day group and -7.7 ($P<0.001$; ES=0.48) for the 74 mg/day group. Placebo-adjusted LS mean change for lurasidone 37 mg/day and 74 mg/day, respectively, was -3.2 ($P<0.001$; ES=0.62) and -3.2 ($P<0.001$; ES=0.60) on the PANSS positive subscale, -1.7 ($P=0.011$; ES=0.41) and -1.6 ($P=0.022$; ES=0.35) on the PANSS negative subscale, -2.8 ($P=0.012$; ES=0.38) and -2.8 ($P=0.011$; ES=0.37) on the PANSS general psychopathology subscale, and -1.1 ($P=0.016$; ES=0.36) and -1.8 ($P<0.001$; ES=0.53) on the PANSS excitability subscale.

Conclusions In adolescent patients with schizophrenia, lurasidone (37 mg/day and 74 mg/day) demonstrated statistically significant efficacy and clinically meaningful improvement across a wide spectrum of symptoms associated with schizophrenia. Efficacy and safety of clozapine in patients with intellectual disability

P. Ifteni*, A. Teodorescu

Universitatea Transilvania din Brasov, Facultatea de Medicina, Brasov, Romania

* Corresponding author.

Introduction Aggression is common and a major behavioral problem in patients with intellectual disability (ID). Antipsychotics are frequently used for psychosis or challenging behavior. There is little literature regarding utilization of clozapine in patients with ID for aggressive behavior.

Aims and objectives The aims of the study were the evaluation of efficacy and safety of clozapine in treatment of aggression in patients with ID.

Methods A longitudinal naturalistic study including a cohort of 225 consecutive patients with intellectual disability admitted to an acute psychiatric unit between 1 January 2014 and 31 December 2015. Severity of symptoms was assessed at admission with Modified Overt Aggression Scale (MOAS) and Global Assessment of Functioning Scale (GAFS). The data included: demographics, main psychiatric diagnosis, IQ, alcohol/smoking, institutionalization,

antipsychotics and another psychotropics, restraint, readiness to discharge (RDQ), side-effects and length of stay.

Results Of 225 potentially eligible individuals, 205 (92.7%) were treated with antipsychotics and 110 male (53.56%) with mean age 32.37 (SD=9.9). Thirty-seven patients (18%), 18 male (48.65%) were treated with clozapine, mean dose 309.45 mg/day (range 100–450 mg/day). Clozapine reduced need for restraint and duration of hospitalization compared with haloperidol ($P<0.05$).

Conclusions Clozapine was efficient and safety for treating persistent aggression in patients with intellectual disability. There were no seizures, myocarditis or agranulocytosis during study. Larger and randomized trials are needed to fully explore the anti-aggressive benefit of clozapine.

Childhood trauma and cortisol response to the Trier Social Stress Test in symptomatic patients with eating disorders

F. Marciello^{1,*}, V.-M. Buonomenna¹, V. Caivano¹, G. Cascino¹, G. D'Agostino¹, D. Nunziata¹, P. Monteleone²

¹ Second University of Naples, Department of Psychiatry, Naples, Italy

² University of Salerno, Department of Medicine–Surgery and Dentistry “Scuola Medica Salernitana”–Section of Neurosciences, Salerno, Italy

* Corresponding author.

Introduction Childhood trauma exposure is associated with the risk of eating disorders (EDs) in adulthood. The biological basis of this link may involve a persistent dysregulation of the endogenous stress response system, in particular the hypothalamic-pituitary-adrenal (HPA) axis, as a consequence of early life maltreatment.

Objective Adult patients with EDs and history of childhood trauma may have a dysregulation of the HPA axis that could be different from EDs patients without childhood trauma exposure.

Aims In order to assess the effects of childhood trauma experiences on HPA-axis activity in EDs, we compared the salivary cortisol response to the Trier Social Stress Test (TSST) of adult patients with EDs according to their history of childhood trauma.

Method Twenty-seven EDs patients and 13 healthy women participated in the study. Salivary cortisol responses during exposure to the TSST was measured. Participants also completed the childhood trauma questionnaire (CTQ) and eating-related psychopathological rating scales.

Results According to CTQ, 15 individuals with EDs reported childhood maltreatment whereas 12 EDs patients and all the healthy women did not experience childhood maltreatment. Compared with the control group, non-maltreated EDs patient group exhibited a slightly enhanced cortisol response to TSST, whereas the group of non-maltreated EDs patients showed a normal cortisol response. Moreover, EDs patients with childhood maltreatment exhibited statistically significant blunting of cortisol compared to non-maltreated ones.

Conclusions The present findings support the evidence that, in patients with EDs, there is a dysregulation of HPA-axis activity and that childhood trauma exposure may contribute to this dysregulation.

⁴ Medical University of Graz, Institute of Pathophysiology and Immunology, Graz, Austria

* Corresponding author.

Introduction Anorexia nervosa (AN) is a lethal psychiatric disease with only narrow treatment possibilities. Recent study results point out, that gut microbiota might be a contributing factor in the development and persistence of AN through effects on the gut-brain-axis.

Methods We used 16S rRNA sequencing to characterize the composition and diversity of the gut microbiota of 18 AN patients, 19 normal weight controls and 19 athletes matched by age using stool samples. The QIIME-pipeline was used to assess the sequencing result. All participants completed an activity-questionnaire (IPAQ) and inventories to measure depression (BDI, HAMD).

Results Kruskal-Wallis test identified significant differences in alpha-diversity (Chao-1-estimator [$P=0.013$], number of observed species [$P=0.027$]) between groups. Spearman-Correlation revealed a significant correlation of number of observed species ($r=0.366$, $P=0.006$) Chao-1-estimator ($r=0.352$, $P=0.008$) and BMI (Fig. 1). Furthermore, a higher BMI was related to lower depression scores ($r=0.351$, $P<0.001$). Although there was a tendency of a negative correlation of BDI-scores and alpha-diversity ($r=-0.180$, $P=0.059$), correlations with depression scores and IPAQ-scores did not reach significance level (Fig. 1).

Conclusions Our preliminary data demonstrate correlations of alpha-diversity and BMI. Further studies are needed to provide further insights in AN gut microbiota and its influence factors.

Scatterplot of BMI vs. No of observed species

The different effect of childhood trauma on amygdala and hippocampus in patients with bipolar disorder and healthy controls

D. Janiri¹, P. De Rossi¹, A. Simonetti¹, G. Spalletta², G. Sani^{1,*}

¹ Sapienza University of Rome, NeSMOS, Rome, Italy

² IRCCS Santa Lucia Foundation, Department of Clinical and Behavioral Neurology, Rome, Italy

* Corresponding author.

Introduction Childhood trauma (CT) is a relevant environmental stressor for bipolar disorder (BP). Amygdala and hippocampus are key areas involved both in the pathophysiology of BP and in mediating the biological response to stress.

Objectives Structural neuroimaging studies help clarifying neural correlates of the relationship between BP diagnosis and CT.

Aims To verify the impact of CT on amygdala and hippocampus and hippocampal subfields volumes in BP patients and healthy control (HC).

Methods We assessed 105 outpatients, diagnosed with BPI or BPII according to DSM-IV-TR criteria, and 113 HC subjects. History of CT was obtained using the childhood trauma questionnaire (CTQ). High-resolution magnetic resonance imaging was performed on all subjects and volumes of amygdala, hippocampus, nucleus accumbens, caudate, pallidum, putamen, thalamus and hippocampal subfields were measured through FreeSurfer.

Results All deep gray matter structures were smaller in BP than HC. CT modulated the impact of the diagnosis on bilateral amygdala and hippocampus, in particular on subiculum, presubiculum and cornu ammonis CA1. It was associated with bilateral decreased volumes in HC and increased volumes in patients with BP.

Conclusions Childhood trauma impacts on the amygdala and hippocampus, brain areas involved in response to stress and emotion processing, and specifically on the hippocampal subfields most implicated in learning through positive/negative reinforcement.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Prevalence of psychopathological features in intellectual disability: The Italian SPAID-G multicentric study

D. Scuticchio^{1,*}, M.O. Bertelli¹, G. Chiodelli², R. Cavagnola², F. Manna³

¹ CREA Research and Clinical Center–San Sebastiano Foundation, Misericordia di Firenze, Florence, Italy

² Fondazione Istituto Ospedaliero di Sospiro Onlus, Fondazione Istituto Ospedaliero di Sospiro Onlus, Cremona, Italy

³ Istituto Opera Don Guanella, Istituto Opera Don Guanella, Roma, Italy

* Corresponding author.

Introduction Despite increasing awareness of high prevalence of psychiatric disorders in people with intellectual disability (ID), diagnostic tools are few and scarcely used in daily practice. SPAID-G (psychiatric instrument for the intellectually disabled adult-general version) is the first Italian for carrying out psychiatric diagnostic orientations in adults with ID. It was designed to be easy and quick instrument for daily clinical practice.

Objectives/Aims The present study was aimed at evaluating psychometric and psychodiagnostic characteristics of the SPAID-G and at supplying new data on the prevalence rate of psychiatric disorders in a multicentric Italian sample of people with ID living in different settings.

Methods The SPAID-G was consecutively administered to more than 800 persons with ID attending residential, rehabilitative or

clinical services across Italy. A part of the sample was also assessed for psychopathology through the use of DASH-II, PDD-MRS and clinically diagnosed in accordance to DSM-IV-TR and DSM-5 criteria.

Results SPAID internal consistency, inter-rater reliability and concordance with DASH-II and PDD-MRS resulted to be good. Around 40% of the sample was assessed to have a cluster of psychopathological symptoms that could be consistent with a psychiatric diagnosis. Autism, impulse control disorder and personality disorder resulted to be the most frequent over threshold scores.

Conclusions The SPAID-G seems to be a valid and cost-effective screening tool for the psychiatric assessment within the Italian population with ID.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ National Health Trust, Department of Mental Health, Chieti, Italy

* Corresponding author.

Introduction Patients affected by bipolar disorder type I (BD-I) show a significant emotional impairment during both acute and euthymic phases of the illness, but the influence of negative life experiences is not yet fully understood.

Objectives Aim of the present study was to investigate the role of previous traumatic events on negative emotion processing in euthymic BD-I patients.

Methods Eighteen euthymic BD-I patients, 7 reporting past traumatic events (T-BD-I), but free of post-traumatic stress disorder (PTSD) symptoms at the moment of the evaluation and 11 never exposed to traumas (NT-BD-I), were compared to 24 not traumatized controls (NC). All participants performed a IAPS-based emotional task: they were required to identify vegetable items (targets) among neutral or negative pictures. Accuracy (percentage of correct responses) and mean reaction times (RT) were recorded.

Results T-BD-I performed similarly to NC and significantly better than NT-BD-I in terms of accuracy (Fig. 1). No significant between-group effects were observed for mean RT.

Conclusions A previous history of traumatic events, without current PTSD symptoms, may significantly impact the negative emotion processing in euthymic BD-I. Interestingly, traumatized patients showed a better accuracy when processing both neutral and negative images, thus suggesting that paying more attention to external stimuli may be a successful compensatory mechanism to cope with potential environmental threats.

A simple composite dynamic digital tool to communicate complex physical and mental health needs and measure outcomes: The Cornwall health radar

R. Shankar*, C. Quick, J. Dawson, P. Annal
Cornwall Foundation NHS Trust, ID neuropsychiatry, Truro, United Kingdom

* Corresponding author.

Introduction Clinician-patient communication is a major factor in influencing outcomes of healthcare. Complexity increases if an individual has multiple health needs requiring support of different clinicians or agencies.

Aim To develop and evidence a simple dynamic computerised tool to capture and communicate outcomes of intervention or alteration in clinical need in patients with multiple chronic health needs.

Method A MS Excel algorithm was designed for swift capture of clinical information discussed in an appointment using pre-designed set of evidenced based domains. An instant personalized single screen visual is produced to facilitate information sharing and decision-making. The display is responsive to compare changes across time. A prototype was conceptually tested in an epilepsy clinic for people with Intellectual disability (ID) due to the unique challenges posed in this population.

Results Evidence across 300 patients with ID and epilepsy showed the tool works by enhancing reflective communication, compliance and therapeutic relationship. Medication and appointment compliance was 95% and patient satisfaction over 90%.

Conclusion To discuss all influencing health factors in a consultation is a communication challenge esp. if the patient has multiple health needs. A picture equals 1000 words and helps address the cognitive complexity of verbal information. The radar offers an evidenced based common framework to host care plans of different health conditions. It provides individualised easy view person centred care plans to allow patients to gain insight on how the dif-

ferent conditions impact on their overall well being and be active participants. The tool will be practically demonstrated.

* Corresponding author.

Introduction Lurasidone, an atypical antipsychotic, demonstrated efficacy and safety in adults with schizophrenia.

Objective/Aims To evaluate the efficacy and safety of lurasidone in adolescent patients with schizophrenia.

Methods Adolescents (13–17 years old) with schizophrenia were randomly assigned to six weeks of double-blind treatment with lurasidone 37 mg/day, 74 mg/day or placebo. An ANCOVA using an LOCF approach was performed to assess change from baseline on secondary study endpoints: Pediatric Quality of Life Enjoyment and Satisfaction Questionnaire (PQ-LES-Q) and Children's Global Assessment Scale (CGAS).

Results Patients were randomized to lurasidone 37 mg/d ($n=108$), 74 mg/day ($n=106$), or placebo ($n=112$). Placebo-adjusted LS mean improvement at week 6 on the PQ-LES-Q was 5.3 ($P=0.001$) and 5.8 ($P<0.001$) for the 37 mg/day and 74 mg/day groups, respectively; and, on the CGAS was 4.6 ($P=0.002$) and 4.9 ($P<0.001$) for the 37 mg/day and 74 mg/d groups, respectively. The most common adverse events occurring at $\geq 5\%$ in either lurasidone group and at least twice the rate of placebo were: nausea, somnolence, akathisia, vomiting and sedation. Mean change in weight at week 6 for placebo, 37 mg/day, and 74 mg/day groups was 0.05 kg, 0.17 kg, and 0.49 kg, respectively. Lurasidone treated patients did not show clinically meaningful differences from placebo on laboratory measures of cholesterol, triglycerides, glucose, and prolactin.

Conclusions Adolescent patients with schizophrenia treated with lurasidone demonstrated significant improvement in quality of life and function. Lurasidone was generally well-tolerated and associated with minimal changes in weight and metabolic parameters. Sponsored by Sunovion Pharmaceuticals Inc. ClinicalTrials.gov identifier: NCT01911429.

Clinical characteristics associated with suicide attempt in patients with bipolar disorder

M.-E.-M. Vismara^{*}, B. Dell'Osso, C. Dobrea, L. Cremaschi, G. Benedetta, C. Arici, B. Benatti, L. Oldani, A.-C. Altamura
Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Psychiatry-University of Milan, Milan, Italy

* Corresponding author.

Introduction Bipolar disorder (BD) is a chronic, highly disabling condition, associated with a high burden of morbidity and mortality, often secondary to suicidal behaviors. In previous reports, different variables have been associated with a higher risk of suicidal acts, with variable effect.

Objectives To evaluate which socio-demographic and clinical variables correlate with suicide attempts in bipolar patients.

Aims To enrich literature data about suicidal behaviour in BD.

Methods A sample of 362 BD patients (DSM IV-TR) was retrospectively collected and divided in two subgroups, in relation to the presence of a previous suicide attempt. Socio-demographic and clinical variables were compared between attempters and non-attempters using Corrected multivariate analysis of covariance (MANCOVA).

Results A total of 26.2% of analyzed patients attempted suicide in their lifespan, and approximately one third of them had multiple suicide attempts (i.e. ≥ 2 ; 31%). Depressive polarity at index mood episode, higher number of psychiatric hospitalizations, comorbidity with alcohol abuse, eating disorders and psychiatric poly-comorbidity were significantly associated with suicide attempt. Additionally, treatment with lithium, poly-pharmacotherapy (≥ 4 current drugs) and higher recurrence of psychosocial rehabilitation were significantly more frequent in patients who attempted suicide.

Conclusions The present paper reported a correlation with some specific clinical variables and the lifetime presence of suicide attempt in patients with BD. Although these retrospective findings did not address the causality issue, they may be of clinical relevance in order to better understand suicidal behavior in BD and to adopt proper strategies to prevent suicide in higher risk patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

What is the relationship between the levels of work-stress and burnout?

R. Ptacek^{1,*}, J. Raboch¹, M. Vnukova¹, D. Dubacova²

¹ First Faculty of Medicine–Charles University, Department of Psychiatry, Prague 2, Czech Republic

² University of New York in Prague, Psychology, Prague, Czech Republic

* Corresponding author.

Objective Burnout is constantly becoming more exhaustively researched topic. It is assumed there is strong relationship between burnout and work-stress. The aim of this study was to investigate the relationship between burnout and work-stress in order to test the hypothesis that there is an association between these two variables.

Method The study sample comprised of economically active Czech population, that was a representative sample. Data was gained through combination of interviews and questionnaires

depending on the age of the participants. Data was then analyzed using multiple linear regressions.

Results The total sample comprised of 1027 participants; 675 persons aged 25–50 years and 352 persons aged 51–65 years. The sample contained roughly equal number of men (52.8%) and women (47.2%). The full model explained 59.79% variance and was highly significant $F(18,1008) = 85.76, P = 0.01$. Some factors that participants feel like could help them reduce the stress in workplace and subsequently reduce the burnout are longer holidays, lowering the administration burden, better work place conditions and lastly increasing the authority a person has in a given work place.

Conclusion The study has shown an association between work-stress and burnout and thus in order to prevent burnout with it related job absence certain precaution steps should be made. The reoccurring theme that would seem to improve the situation is decreasing the administrative work that is unrelated to the profession as well as increasing the powers the employees have in their position.

Influence of gender in patients attended in emergency rooms for suicidal tendencies

B. Mata Saenz*, E. Segura Escobar, E. Lopez Lavela, L.-M. Asensio Aguerri, L. Nuevo Fernandez, T. Rodriguez Cano, L. Beato Fernández

Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain

* Corresponding author.

Introduction The first time when people attempt suicide first contact is critical. Psychiatrists must decide to hospitalize them or follow-up in mental health units and the bases of a doctor-patient relationship are formed.

Objectives An analysis of referrals to psychiatry from the emergency room (ER) was developed. Our objective was to discover if there was a statistical correlation between gender and other variables, especially repeated visits and admissions.

Methods Our sample was composed of patients who visited the ER for suicidal tendencies for 20 months. We carried out an observational retrospective study. The variables collected were: age, gender, cause, repeated visit (visit to the ER in the following two months), previous attempts, previous follow-up, method used, use of toxic substances during the attempt, intentionality, referral from the ER, later follow-up and diagnostic impression at the ER.

Results A total of 620 patients were sampled. The relationship between gender and repeated visit, previous attempts, dysfunctional personality traits, use of substances and later follow-up was found (χ^2). Although the relationship between admissions and gender were not statistically significant, influence by gender (over all in males) can be observed in logistic regression models. As well as, in patients who visited the ER several times, dysfunctional personality traits seem to be the most common but gender marks significant differences between groups.

Conclusions The data obtained is consistent with those reported in previous studies. To know who the riskier groups are can allow professionals to plan protocols and unify admission criteria.

Risk of mental disorders and difficulties or conflict in relationships in young adults

S. Gorbeña, P. Penas*, E. Calvete, I. Crespo, I. Iraurgi

University of Deusto, Department of Personality–Assessment and Psychological Treatment, Bilbao, Spain

* Corresponding author.

Introduction Higher risk of mental health problems has been linked with problems in relationships, including the experience of relational conflict with significant others and peers. Conversely, positive relations with others have been established as a key factor of psychological well being.

Objectives We hypothesized that psychological maladjustment will be related to the number, nature and severity of relational stressors. Furthermore, there would be a higher likelihood of risk of mental disorders for those who experience more relational hardships and of greater severity. Positive relations with others will protect from risk of mental health problems.

Method A total of 4461 university students completed a health and well-being survey, including the GHQ-12 (centesimal and 3-point cut-off scores), Ryff psychological well-being scale and a scale of 25 life stressors. Indexes of number and severity of difficulties in relationships were calculated with 10 items including romantic partners, friends, family, and classmates.

Results Correlations were significant. Logistic regression showed a risk effect for all stressors with OR values above 1.32. Overall perceived severity had the highest value (OR=2.38, 95% CI=2.16–2.61) and amongst the 10 stressors, gender related abuse/violence was also the highest (OR=1.90, 95% CI=1.73–2.09). Positive relations showed a protective effect (OR=0.60, 95% CI=0.56–0.54).

Conclusions Findings can inform health promotion, prevention and therapeutic interventions so as to improve the quality of personal relationship and conflict management skills, and to strengthen well-being associated with positive relations with others. Academic institutions committed to student welfare and the promotion of healthy environments should play a major role in young adults' mental health.

Clinical prediction of suicide attempt in schizophrenia using a machine learning approach

V. De Luc*, A. Bani Fatemi, N. Hettige

CAMH, psychiatry, Toronto, Canada

* Corresponding author.

Objective Suicide is a major concern for those afflicted by schizophrenia. Identifying patients at the highest risk for future suicide attempts remains a complex problem for psychiatric intervention. Machine learning models allow for the integration of many risk factors in order to build an algorithm that predicts which patients are likely to attempt suicide. Currently, it is unclear how to integrate previously identified risk factors into a clinically relevant predictive tool to estimate the probability of a patient with schizophrenia for attempting suicide.

Methods We conducted a cross-sectional assessment on a sample of 345 participants diagnosed with schizophrenia spectrum disorders. Suicide attempters and non-attempters were clearly identified using the Columbia Suicide Severity Rating Scale (C-SSRS) and the Beck Suicide Ideation Scale (BSS). We developed two classification algorithms using a regularized regression and random

forest model with sociocultural and clinical variables as features to train the models.

Results Both classification models performed similarly in identifying suicide attempters and non-attempters. Our regularized logistic regression model demonstrated an accuracy of 66% and an area under the curve (AUC) of 0.71, while the random forest model demonstrated 65% accuracy and an AUC of 0.67.

Conclusion Machine learning algorithms offer a relatively successful method for incorporating many clinical features to predict individuals at risk for future suicide attempts. Increased performance of these models using clinically relevant variables offers the potential to facilitate early treatment and intervention to prevent future suicide attempts.

Introduction Wellness self-management is an adaptation and expansion of the illness management and recovery, an internationally recognized best practice. WSM is a recovery-oriented, curriculum-based practice designed to help adults with severe mental health problems make decisions and take action to manage symptoms and improve their quality of life.

Objectives In the present study, the Italian translation of the WSM was implemented and validated. Moreover, the impact of its application in a day hospital setting on cognitive functions, psychopathology, personal resources and real-life functioning with respect to treatment as usual (TAU) was investigated.

Aims The study was aimed at assessing the effectiveness of a semi-structured version of WSM in a day hospital setting in patients with severe mental illness.

Methods Fourteen patients with a diagnosis of severe mental illness were recruited and randomly assigned to either WSM or TAU. WSM participants attended four 2-hour sessions per week for 1 month, including lessons selected on the basis of the goals of participants. Both groups received weekly planned treatment in the day-hospital setting and continued their pharmacotherapy.

Results The two groups of patients were comparable for age, education, cognitive functioning and psychopathological severity.

WSM produced a significantly greater improvement in neurocognition, psychopathology, personal resources and real-life functioning with respect to TAU.

Conclusions Our results offer promising preliminary evidence that the use of WSM provides an effective complement to current mental health treatment.

* Corresponding author.

Introduction An impairment of premorbid adjustment (PA) has been regarded among poor prognostic indicators of schizophrenia. Some discrepancies in the literature suggest the usefulness of further characterizations of its impact on different aspects of the disease.

Aims The present study aimed to investigate the association of poor PA with psychopathology, neurocognition and real-life functioning in patients with schizophrenia recruited within the multicenter study of the Italian network for research on psychoses. functioning during childhood and adolescence (early adjustment) was assessed also in a group of healthy controls (HC) and one of unaffected relatives of patients (UR).

Methods Group comparisons were performed between patients with poor and those with good PA. Differences in frequency of poor early adjustment were investigated among patients, HC and UR.

Results Patients with poor PA, as compared to those with good PA, showed earlier age of onset, more severe negative symptoms and disorganization, greater impairment on all cognitive domains with the exception of attention/vigilance and worse real-life functioning in the considered areas (interpersonal relationships, community activities and work abilities). The pattern of poor early adjustment was more frequent in patients with respect to UR and HC and, to a less degree, in UR with respect to HC.

Conclusions Our findings confirm that poor PA in schizophrenia is associated with poorer illness outcome, and offer a further characterization of PA impact on different psychopathological and cognitive domains. They also suggest that poor early adjustment is a candidate endophenotype of schizophrenia, occurring in patients and their unaffected relatives.

Introduction Negative symptoms are a core feature of schizophrenia but their pathophysiology remains elusive. They cluster in a motivation-related domain, including apathy, anhedonia, asociality and in an expression-related domain, including avolition and blunted affect.

Aim Our aim was to investigate the different neurobiological underpinnings of the two domains using the brain electrical microstates (MS), which reflect global patterns of functional connectivity with high temporal resolution.

Method We recorded multichannel resting EEGs in 142 schizophrenia patients (SCZ) and in 64 healthy controls (HC), recruited to the Italian network for research on psychoses study. Four microstates (MS) classes were computed from resting EEG data using the K-Mean clustering algorithm. Pearson's coefficient was used to investigate correlations of microstates measures with negative symptom domains, assessed by the Brief Negative Symptoms Scale (BNSS).

Results SCZ, in comparison to HC, showed increased contribution and duration of MS-C. Only the avolition domain of BNSS correlated with the contribution and occurrence of MS-A. Within the same domain, anticipatory anhedonia, apathy and asociality, but not consummatory anhedonia, were positively correlated with contribution and occurrence of microstate A. Asociality was also negatively correlated with contribution and occurrence of MS-D.

Conclusion Our findings support different neurobiological underpinnings of the negative symptom domains, avolition and expressive deficit. Furthermore, our results lend support to the hypothesis that only anticipatory anhedonia is linked to the avolition domain of the negative symptoms. Mixed results in the literature concerning the presence of MS-A and D abnormalities in schizophrenia might be related to the syndrome heterogeneity.

* Corresponding author.

Introduction Relapse prevention during early stages after psychosis onset is a key factor for long term outcome. While factors associated with first relapse have been widely studied, factors associated with subsequent relapses are poorly described.

Objectives To determine predictive factors of first and subsequent relapses among patients recruited from a cohort of PAFIP Early Intervention Program.

Material and methods We analyzed socio-demographic and clinical data of a cohort of 393 first episode psychosis (FEP) patients that were recruited since February 2001 to May 2011. Of these, 341

achieved clinical remission and were, therefore, considered to be at risk of relapse. They were followed-up for 3 years. A wide range of potential factors were included as possible predictors of relapse. Test univariate, analysis logistics of regression, regression of Cox and analysis of survival of Kaplan-Meier were carried out.

Results Poor adherence to medication was the main predictor associated to first relapse (ExpB: 2.979; $P < 0.001$). After the first relapse, only 56 patients (33.9%) underwent a second relapse, being the diagnosis (ExpB: 1.975; $P = 0.074$), the age of onset (ExpB: 1.078; $P = 0.003$) and a low level of positive symptomatology (ExpB: 0.863; $P = 0.03$) the predictors of associated with a second relapse.

Conclusions After a FEP, non-adherence to medication is the main predictor of first relapse. Second and subsequent relapses relate with non-modifiable factors such as age of onset or schizophrenia diagnosis. This subgroup of patients could have greater predisposition to relapse related with the severity of the disease itself.

For the first time in Spain, a large scale survey (5205 people) was carried out to establish the real needs of those directly affected by the illness. Patients and caregivers responded to a 9-question survey concerning dimensions: personal, social, medical treatment, psychotherapy and rehabilitation. For patients, the most important need (an average score of 3.5 on a scale of importance from 1 to 4) was to feel their emotional needs covered. The following average scores were also obtained: feel well physically (3.42), improve autonomy (3.41), have leisure activities (3.21) and work/study (3.1). A total of 42% of patients indicated having little or no freedom over their lives. Thirty-six percent indicated that medical treatment did not start soon enough, 35% that psychotherapy started too late and 13% saying they had received no psychotherapy at all. The help from professionals most valued was provide information about the illness (3.4), dedicating more time (3.4) investigating new treatments (3.3) paying attention to secondary effects (3.3) and incorporating the patient in decision making (3.3). Most patients reported a state of health “regular to good” but 10% indicated not being understood at all in their social environment since onset of illness and 25% being little understood. The anti-stigma initiative most valued was to increase investment in schizophrenia in health planning. Integral health planning should incorporate patient insights concerning basic needs and treatment preferences.

⁵ Hospital Louis-Mourier–University Paris diderot, AP–HP and Inserm U894 and Fondation FondaMental, Department of Psychiatry, Colombes, France

* Corresponding author.

Background Tobacco smoking is common in schizophrenia. Some characteristics are usually associated to tobacco smoking in schizophrenia, such as younger age, earlier onset of the disease, number of hospitalizations or higher treatment doses. However, little is known about positive symptoms or aggressiveness, as well as trauma history.

Objectives to study the relationship between smoking status and clinical characteristics in patients with schizophrenia.

Method A total of 474 patients with were consecutively included in the network of FondaMental Expert Center (FACE) for schizophrenia and assessed with the structural clinical interview for DSM-IV axis 1 disorders (SCID), validated scales for psychotic symptomatology and childhood trauma questionnaire. Tobacco abuse or dependence was defined according to the SCID. Ongoing antipsychotic treatment was recorded. Aggressiveness was measured with Buss-Perry Aggression Questionnaire (BPAQ).

Results A sample of 474 patients with schizophrenia was included in this study (non-smokers, $n=215$; non-smokers, $n=259$). Mean age at tobacco onset was 17.19 years old ($SD=3.93$). In multivariate analysis, smoking was associated with SGA use ($P=0.028$), with higher scores of physical aggressiveness ($P=0.042$), with current alcohol-dependence ($P=0.002$). However, no association was observed with sex, age of onset, trauma history, global functioning, observance or psychotic symptomatology.

Conclusions Tobacco smoking was associated with physical aggressiveness, but not with earlier onset of the disease nor traumas or psychotic symptomatology. Besides, the results of the present study are in favor of a superior efficacy of second-generation antipsychotics in the treatment of comorbid tobacco use. These results need further investigation in longitudinal studies.

How could affect stress, PEP and sex in working memory?

C.-R. Maria Isabel^{1,*}, C.-R. Manuel², M. Andrea¹, R.-V. Miguel¹

¹ Hospital Virgen del Rocío, Psychiatry, Sevilla, Spain

² Hospital Virgen del Rocío, Mental Health, Sevilla, Spain

* Corresponding author.

Background The first episode of psychosis is a crucial period when early intervention can alter the trajectory of the young person’s ongoing mental health and general functioning. Cognitive abilities are nuclear for the social recovery. Stress impairs

higher cognitive processes, dependent on the prefrontal cortex (PFC) and that involve maintenance and integration of information over extended periods, including working memory and attention. Different mechanism are involved such as HPA-Axis hyperactivity, affecting PFC. Recently, investigations show the different evolution of cognitive abilities between different sex in WM.

Methods A sample of 41 FEPs and 39 healthy subjects were evaluated. The variables assessed were verbal and visual memory, attention, working memory, processing speed, mental flexibility, verbal fluency, motor coordination, planning ability and intelligence.

Results We found an interaction between age (<16 years and >16 years) and group (psychosis vs. controls) in working memory ($P=0.04$). There were no difference in men <16 years old control group and men with same age plus psychosis (5.87 ± 1.57 vs. 5.83 ± 1 ; $P=0.1$) in WM. However, this work was found to be significantly different in the univariate analysis of working memory in the group <16 years old women control (7.30 ± 1.56) and women psychosis group (5.61 ± 1.91).

Conclusion Social cognition and stress seem to be directly relation. Some studies show that stress enhance cognition performance in men while impairing it in women. Stress affect a variety of cognitive processes such attention and working memory. Deficit in social cognition are present in the prodromal phases of psychosis.

⁴ Hospital Universitario Son Espases, Servicio de Psiquiatría, Palma de Mallorca, Illes Balear, Spain

* Corresponding author.

Introduction The identification of new genetic variants underlying psychosis is crucial to improve its molecular diagnosis and to determine the disease etiology, which is necessary to develop new therapeutic targets.

Aim To identify novel rare genetic variants associated to mental disorders, using whole exome sequencing (WES).

Methods Two families with high prevalence of mental disease were genotyped using WES. The first family has 5 members affected, the mother with a bipolar disorder, three sons, two with schizophrenia and one with schizoaffective disorder, and a cousin with major depression and psychotic symptoms. The second family is constituted by 38 members affected by major mental diseases in three generations. Key affected members of each family were genotyped by WES. Shared rare variants, with allelic frequencies below 0.5% in general population, were identified among the affected members of the family. The segregation of those variants was confirmed by Sanger sequencing.

Results In family 1, thirty-seven genetic variants related to neurodevelopment were identified. Two of those variants in the genes *TRIP12* and *RNF25* segregated with psychosis. In family 2, seven rare genetic variants contained in genes related to neurodevelopment were identified. A mutation in the gene *ARHGAP19* segregated with psychosis.

Conclusions Three new genes have been found to be associated with psychosis. *TRIP12* and *RNF25* encode two E3-ubiquitin ligases which modulate the Wnt pathway, mutations in which lead to neurodevelopmental defects. *ARHGAP19* encodes a GTPase which regulates the RhoA protein, involved in the regulation of the cytoskeleton.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction According to the dopamine hypothesis functional brain abnormalities and neurochemical alterations may converge to cause psychosis through aberrant salience attribution. Indeed, resting-state functional magnetic resonance imaging (rs-fMRI) has revealed widespread brain disconnectivity across the psychotic spectrum.

Objectives To advance the understanding of the dopaminergic involvement in intrinsic functional connectivity (iFC) and its putative relationship to the development of psychotic disorders we aimed to investigate the link between L-Dopa, a dopamine precursor, and its modulation of striatal iFC in subthreshold psychosis, i.e. non-clinical psychosis.

Methods We used a randomized, double-blind placebo controlled study design including in our sample 56 healthy, male, right-handed, subjects with no familiar risk factors for psychosis who were assessed with the Schizotypal Personality Questionnaire (SPQ) and underwent 10 minutes of rs-fMRI scanning. All subjects received either 250 mg of Madopar DR[®] (200 mg L-Dopa plus 50 mg benserazid, dual release form) or a placebo. We analysed resting-state iFC of 6 striatal seeds, known to evoke dopamine related networks.

Results The main effect of L-Dopa presented itself (FWE-corrected) as a significant decrease in iFC from the right ventral striatum to the cerebellum and the precuneus cortex, and an increase in iFC to the occipital cortex. Subjects with high SPQ positive symptom sub-scores showed a significant increase of L-Dopa induced connectivity.

Conclusion We identified striatal functional connectivity being modulated by augmented dopamine availability, and in support of the dopamine hypothesis, we found that those iFC patterns are associated to high scores of psychotic like experiences.

5-years follow-up of antipsychotic medication and hospitalizations after first episode hospital-treated psychosis in a Swedish nation-wide cohort

P. Strålin^{1,*}, J. Hetta²

¹ Karolinska University hospital, Psychiatry, Stockholm, Sweden

² Karolinska Institutet, Clinical Neuroscience/Psychiatry, Stockholm, Sweden

* Corresponding author.

Introduction Outcome after first episode psychosis is heterogeneous, but knowledge about the distribution and predictive factors is limited.

Objective To investigate medication and rehospitalizations for five years after first episode hospital treated psychosis.

Method Swedish population registers were used to select a nation-wide cohort of 962 cases (589 or 61% men) with a first hospitalization for psychosis at ages between 16–25 years. Cases were categorized year by year for 5 years after the initial hospitalization with regard to rehospitalizations and dispensations of antipsychotics and other medications.

Results The 5-years mortality was 4% ($n=39$) with suicides in 16 cases (1.6%, 11 of which were men). Additionally, 139 cases (23% of women and 10% of men) had hospitalizations for suicide attempts within 5 years. A bimodal distribution of years with medication was found indicating two different trajectories of outcome. One peak was seen for cases with dispensations of antipsychotics 5 of 5 years (40% of the cohort). Another peak was seen at dispensations during at most 1 of 5 year (30%). During year 5, 514 (56% of 923 cases surviving 5 years) had dispensations of neuroleptics and 257 (28%) were hospitalized, whereas 356 cases (39%) had no dispensation of neuroleptics or hospitalization.

Conclusions The population of young cases with first episode psychosis is heterogeneous with at least two clearly separable trajectories based on medication and hospitalizations. The high mortality and high incidence of suicide attempts during a five-year period demonstrate a need for careful monitoring of these patients.

Cognitive screening scale for schizophrenia (CSSS): The development and the structure of the scale

A. Szulc^{*}, J. Gierus, T. Koweszeko, A. Mosiolek

Medical University of Warsaw, Department of Psychiatry, Pruszkow, Poland

* Corresponding author.

Objectives The study presents the construction of CSSS: a short screening scale intended for diagnosis of cognitive deficits among people with schizophrenia. The final version of the scale consist of 6 subscales which measure basic cognitive functions.

Methods A total of 160 persons (124 with schizophrenia and 36 healthy controls) were tested using the initial version of the CSSS scale consisting of 11 subscales. Correlation analysis between the subscale results was carried out, as well as confirmatory factor analysis, internal consistency analysis of the scale, IRT (item response theory) analysis of the item's difficulty, and analysis of the scale's accuracy as a classifier.

Results One factor explains 37% of the variance of the subscales' results. The scale has satisfactory internal consistency (0,83). Subjects with schizophrenia achieved significantly lower scores than

healthy subjects. The area under the ROC curve (AUC) for discriminating between subjects with schizophrenia and healthy subjects was 0.83. Cut point of 16 raw points is 86% sensitive and has 70% specificity.

Conclusions The form of the tool that has been achieved as a result of presented analyses suggests that this scale has a potential to fulfill the assumed goals, which will be tested during continuing validation studies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Disorganization in schizophrenia: A resting EEG study

A. Vignapiano^{1,*}, T. Koenig², A. Mucci¹, G.-M. Giordano¹, A. Amodio¹, G. Di Lorenzo³, C. Niolu³, M. Altamura⁴, A. Bellomo⁴, S. Galderisi¹

¹ University of Naples SUN, Department of Psychiatry, Naples, Italy

² University Hospital of Psychiatry and Psychotherapy, Translational Research Center, Bern, Switzerland

³ University of Rome "Tor Vergata", Department of Systems Medicine, Rome, Italy

⁴ University of Foggia, Department of Clinical and Experimental Medicine–Psychiatry Unit, Foggia, Italy

* Corresponding author.

Introduction In subjects with schizophrenia (SCZ), the disorganization factor was found to be a strong predictor of real-life functioning. "Conceptual disorganization" (P2), "difficulties in abstract thinking" (N5) and "poor attention" (G11) are considered core aspects of the disorganization factor, as assessed by PANSS. The overlap of these items with neurocognitive functions is debated and should be further investigated.

Aims Within the Italian network for research on psychoses study, electrophysiological and neurocognitive correlates of the disorganization factor and its component items were investigated.

Methods Resting state EEGs were recorded in 145 stabilized SCZ and 69 matched healthy controls (HC). Spectral amplitude (Samp) was averaged in nine frequency bands. MATRICS consensus cognitive battery (MCCB) was used for neurocognitive assessment. Band Samp differences and correlations with psychopathology and MCCB scores were explored by global randomization statistics.

Results SCZ showed increased delta, theta, and beta1 and decreased alpha2 Samp. A negative correlation between alpha1 and disorganization was observed in SCZ. At the item level, only N5 showed this correlation. MCCB neurocognitive composite was associated with P2 and N5 but not with alpha1 Samp.

Conclusions Our findings suggest an heterogeneity of the disorganization dimension and a partial overlap with neurocognitive domains. The N5, "difficulties in abstract thinking", had a unique association with alpha1 Samp, which is thought to be involved in the formation of conceptual maps.

Autistic traits in patients with anorexia nervosa, bulimia nervosa or binge eating disorder: A pilot study

C. Gesi^{*}, C. Carmassi, M. Luciano, L. Bossini, V. Ricca, A. Fagiolini, M. Maj, L. Dell'Osso

Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

* Corresponding author.

Introduction Previous data showed higher autistic traits in individuals with anorexia nervosa (AN) compared to healthy controls (CTL). It is not known, however, whether this characteristic is shared by other feeding and eating disorders (FEDs) or it is uniquely associated to AN.

Objectives To compare autistic traits among individuals with AN, bulimia nervosa (BN), binge eating disorder (BED) and CTL and to investigate which specific dimensions differentiate one group from another.

Methods A total of 241 FED patients (53 AN, 41 BN, 42 BED) and 105 CTL were administered the autism-spectrum quotient (AQ), the adult autism subthreshold spectrum (AdAS Spectrum), the Ritvo autism and Asperger diagnostic scale 14-item (RAADS-14 Screen).

Results FED subjects reported higher AQ, AdAS spectrum and RAADS-14 total and subscales scores compared to CTL (all $P < .001$). No differences were found amongst AN, BN and BED subjects in questionnaires' total scores. BN group scored higher than AN in the hyper-/hyporeactivity to sensory input domain of the AdAS spectrum ($P < .001$); AN group scored higher than BED in the attention switching domain of the AQ ($P < .001$), and BED group scored lower than both AN and BN in the mentalizing deficit domain of the RAADS-14 (all $P < .001$).

Conclusions We reported for the first time that not only AN but also BN and BED patients show greater autistic traits compared to CTL. Longitudinal studies are needed to confirm this preliminary report and to elucidate whether autistic traits either precede, co-occur or follow FEDs.

Resilient coping and social networks in old age

F. Daniel¹, A. Antunes², S. Guadalupe², I. Massano-Cardoso^{3,*}, H. Vicente²

¹ Miguel Torga Institute, University of Coimbra Centre for Health Studies and Research, Coimbra, Portugal

² Miguel Torga Institute, Coimbra, Portugal

³ Miguel Torga Institute, Faculty of Medicine of the University of Coimbra, Coimbra, Portugal

* Corresponding author.

Introduction Both resilient coping strategies and the structural/functional characteristics of personal social networks are considered important factors when facing adversity and the challenges inherent to the aging process.

Objectives To analyze the association between the configurations of ego-centred networks and different levels of resilient coping in a sample of elderly people.

Methods Quantitative, cross-sectional study comparing groups, with 512 participants, mostly women ($n = 325$; 63.5%), married ($n = 264$; 51.5%), with 76 years old in average ($SD \pm 7.6$), and with basic education ($n = 261$; 51%). We used a socio-demographic questionnaire, the IARSP-Elderly (personal social network assessment tool) and the Brief Resilient Coping Scale for data collection.

Results We found different levels of resilient coping in our sample: low (50.4%); medium (38.7%); strong (10.9%). These three levels of coping were associated with the composition of ego-centred networks, namely the proportion of friends and colleagues ($P < 0.05$), different perceived emotional support, reciprocity and satisfaction with the network ($P < 0.05$), frequency of contacts and relationships' durability ($P < 0.05$).

Conclusions Higher levels of coping are associated with a larger proportion of friends in the network, whereas the familiar networks are associated with low coping. Although participants in our study revealed mainly kin comprised networks, these results

reflect the relevance of resilient coping in the activation of non-kin relationships in old age.

Keywords Personal social networks; Ego-centred networks; Resilient coping; Elderly

Being afraid of compassion: Fears of compassion as mediators between early emotional memories and psychopathological symptoms in adulthood

M. Matos*, J. Duarte, J. Pinto-Gouveia

University of Coimbra, Cognitive and Behavioral Centre for Research and Intervention CINEICC University of Coimbra, Coimbra, Portugal

* Corresponding author.

Introduction There is evidence suggesting that for some individuals self-generating compassion and being open to compassion from others can be difficult or aversive. To date, however, no study has explored how these fears of compassion are associated with early emotional memories, such as shame or safeness memories, and to symptoms of depression and anxiety in adulthood. The current study set out to investigate the mediator effect of fears of compassion on the relationship between the traumatic and centrality features of shame memories, early memories of warmth and safeness, and symptoms of depression and anxiety.

Method In this cross-sectional study, participants were 302 individuals (171 women; age $M = 36.28$; $SD = 11.45$) recruited from the general community population, who completed self-report measures of fears of compassion (for self, for others and from others), shame memories, safeness memories, depression and anxiety.

Results Path analysis showed that fears of compassion for self and of receiving compassion from others mediated the effects of shame traumatic memory, centrality of shame memory and early memories of warmth and safeness on depressive and anxiety symptoms. Fear of compassion for self was the best predictor of depression and anxiety.

Conclusions Fears of compassion may render an individual more vulnerable to defeat and threat responses when faced with stressful life events, which can manifest as symptoms of depression or anxiety. Clinical implications might be derived from these findings as these fears, as well as the negative emotional memories fuelling them, may need to be addressed in therapy to assist patients in self-generating and receiving compassion.

Genetic counselling in psychiatric disorder with high suicide risk

D. Cozman^{1,*}, R. Moldovan², B. Nemes¹

¹ Iuliu Hatieganu University of Medicine and Pharmacy Cluj-Napoca, Department of Medical Psychology, Cluj-Napoca, Romania

² Babes-Bolyai University Cluj-Napoca, Psychology, Cluj-Napoca, Romania

* Corresponding author.

Introduction A better understanding of the genomics of mental illnesses allowed genetic counselling to be provided to individuals with severe mental illness and their families.

Aim The present study was aimed at assessing the efficacy of genetic counselling for severe mental illnesses with high suicide risk.

Method Assessment was performed before and after genetic counselling session. Measures used were evaluation of traumatic events in childhood, multidimensional scale for perception of social support (SMSSP), positive and negative affect schedule (PANAS-X), Brief Psychiatric Rating Scale (BPRS), Paykel questionnaire and Genetic Counselling Outcome Scale (GCOS). Paykel's questionnaire consists of five questions about suicidal thoughts and attempts, including: life-weariness, death wishes, suicidal ideation, suicidal plans and suicide attempts. Intervention and assessment lasted approximately one and a half hour. Data from 48 patients was analysed.

Results Mean age of participants was $M = 38.4$, $SD = 9.7$, and the group was better represented by females (57%). The participants had various diagnoses, 22% had schizophrenia, 36% bipolar disorder and 42% recurrent depressive disorder. Forty percent of participants reported suicidal ideation and 22,5% had a past history of suicide attempt. Genetic counselling had a direct positive influence upon GCOS specific items and reduced the Paykel scores among participants presenting with suicidal ideation.

Conclusion Genetic counselling offers information about the disorder, the role of genetics and the impact of environmental factors. Preliminary data suggest that providing genetic counselling decreases the suicidal ideation frequency.

Analysing CYP2D6*4 Allele frequency in patients with schizophrenia

V. Djordjevic^{1,*}, T. Jevtovic Stoimenov²

¹ Clinical center Nis, Daily hospital, Nis, Serbia

² Medical Faculty, Institute of Biochemistry, Nis, Serbia

* Corresponding author.

Introduction Schizophrenia is treated with antipsychotics and other psychotropic medications, many of which are substrates for the highly polymorphic CYP2D6 enzyme. The most frequent variant allele is CYP2D6*4- leading cause of poor metabolism (PM) phenotype. PM causes the reduction of therapeutic response, increase the risk of adverse drug reactions and increase the plasma concentration of both drug and its metabolites above the levels of toxicity.

The Aim Analysing CYP2D6*4 allele frequency among schizophrenic patients for further individualisation and rationalisation of therapy.

Patients and methods Research was conducted on 38 schizophrenic patients and 110 healthy individuals. CYP2D6*4 allele was detected with allele specific PCR.

Results Both wild type allele carriers are 55% of the schizophrenic patients, 45% are wild type/*4heterozygous, and *4/*4 homozygous are not identified. There is a statistically significant difference in the genotype distribution ($P < 0.05$) between schizophrenic patients and healthy individuals. Significantly higher *4 allele frequency (37%) comparing to healthy individuals ($P < 0.0001$) indicates the necessary caution in administration of CYP2D6 substrates. A lower frequency of PMs in schizophrenic patients than in healthy individuals could be explained with CYP2D6 neuroactive substrate metabolism. Forty-five percent of the schizophrenic patients are intermediate metabolisers carrying the higher risk of adverse

response to CYP2D6 substrates comparing to wild type homozygous. As none of the analyzed patients was PM, exceeded plasma concentrations of medications above toxic levels are not expected when administrating the right dosage.

Conclusion Altered CYP2D6 metabolism may contribute to the vulnerability, clinical severity and treatment outcome of schizophrenia.

Differential susceptibility properties of the *5HTTLPR* gene in relation to depressive symptoms and delinquency

K.-W. Nilsson*, C. Åslund

Uppsala University, Centre for clinical research, Västerås, Sweden

* Corresponding author.

Introduction The candidate gene-environment interaction (cG × E) research field in psychiatry has traditionally been dominated by the diathesis-stress framework, where certain genotypes are assumed to confer increased risk for adverse outcomes in a stressful environment. In later years, theories of differential susceptibility or biological sensitivity have been presented, suggesting that cGs that interact with environmental events do not exclusively confer a risk for behavioural or psychiatric disorders but rather seem to alter the sensitivity to both positive and negative environmental influences.

Aims The present study investigates the susceptibility properties of the *5HTTLPR* gene in relation to depressive symptoms and delinquency in two separate adolescent community samples: $n = 1457$, collected in 2006; and $n = 191$, collected in 2001.

Results Two-, three- and four-way interactions between the *5HTTLPR*, positive family environment, negative family environment, and sex were found in relation to both depressive symptoms and delinquency. However, the susceptibility properties of the *5HTTLPR* gene were distinctly less pronounced in relation to depressive symptoms.

Conclusions If the assumption that the *5HTTLPR* gene induces differential susceptibility to both positive and negative environmental influences is correct, the previous failures to measure and control for positive environmental factors might be a possible explanation for former inconsistent findings within the research field.

⁴ Hôpital Sainte-Anne, CMME, Paris, France

* Corresponding author.

Introduction Anorexia nervosa (AN) is a severe psychiatric disorder. The epigenetic regulations are strongly suggested in AN. We and other groups have performed a whole-genome methylation study (methylome) in AN. We found that the differentially methylated CpG sites are located around genes involved in biological processes in link with embryonic morphogenesis, brain develop-

ment and its plasticity, in particular adhesion and axon guidance. Here, we study an independent group of 40 AN patients. Furthermore, we have done a follow-up during more than one year, to compare the methylation profiles in subjects that evolve to the remission.

Objectives Our work is to replicate the methylome study in an independent AN cohort and to characterize profiles of methylation at two times for the same subjects to compare the AN patients that convert to remitters.

Aims Our goal is to identify diagnostic and prognostic epigenetic signatures for AN.

Methods Of the 40 AN patients, 18 evolved to remission. Furthermore, the blood samples of the subjects from the 2 times will be investigated, like this, each subject is its own control. Methylation of DNA is measured by using the Infinium HumanMethylation450 BeadChip technology.

Results Comparisons of AN to controls showed similar profiles of methylation involving the same biological processes as previously identified. We are comparing now the difference of methylation between the 18 remitters and the 18 actual AN, taking into account of the two times of samples.

Conclusions We expect to characterize specific methylation signature of the prognostic of the AN remission.

⁴ University Hospital of Cagliari, Unit of Clinical Pharmacology, Cagliari, Italy

* Corresponding author.

Introduction Bipolar disorder (BD) is characterized by unusual shifts in mood and energy and affects 1 to 3% of the general population. Lithium (Li) can prevent patients from depression and mania, as well as reduce the risk of suicide. Unfortunately, a high rate of patients do not respond positively to Li treatment. In line with various studies, Li treatment is also associated with potentially severe adverse reactions, including renal dysfunctions. Specifically, it has been reported that Li may induce reduction of glomerular filtration rate (GFR) in long-term treated BD patients.

Aims The aim of our study was to evaluate the contribution of genetic variants in Li-induced reduction of the estimated GFR (eGFR) in bipolar patients, under long term Li therapy.

Objectives We screened the literature to identify genes previously shown to be associated with kidney function or Li mechanism of action and genotyped tag SNPs covering these genes.

Methods The sample comprised 70 Sardinian bipolar patients genotyped for 46 SNPs, located in 33 genes, with Invader assay and Sanger sequencing.

Results Our results showed that a SNP (rs378448) located in Acid Sensing Ion Channel Neurona-1 (*ACCN1*) gene, significantly interacted with years of Li treatment in reducing eGFR ($F = 4.166$, $P = 0.046$).

Conclusions Our preliminary findings suggest that *ACCN1* (*ASIC2*) gene could be involved in modulating the susceptibility of BD patients to develop renal dysfunctions induced by chronic Li treatment.

Association between two single-nucleotide polymorphisms of *TAAR1* gene and suicide attempts

A. Zdanowicz^{1,*}, A. Sakowicz², E. Kusidel³, P. Wierzbinski⁴

¹ Medical University, Department of Adult Psychiatry, Lodz, Poland

² Medical University, Department of Medical Biotechnology, Lodz, Poland

³ University of Lodz, Department of Spatial Econometrics, Lodz, Poland

⁴ Medsolver- Psychological and Psychiatric Clinic, Lodz, Poland

* Corresponding author.

Introduction *TAAR1* is a G protein-coupled receptor expressed broadly throughout the brain. Recently, *TAAR1* has been demonstrated to be an important modulator of the dopaminergic, serotonergic and glutamatergic activity.

Aims Assessment of the relation between two single-nucleotide polymorphisms of *TAAR1* gene, suicide attempts and alcohol abuse.

Methods A total of 150 Polish patients were included, 59 subjects after suicide attempt vs. 91 controls. The chosen SNPs (rs759733834 and rs9402439) were studied using RFLP-PCR methods. The Hardy-Weinberg equilibrium was tested in control group. **Statistical tests** Chi² or Yeates Chi² Test were used.

Results The mean age of study subjects and controls was: 38 ± 12.3 and 42 ± 12.8 respectively; 49% study males vs. 54% male controls. We did not observe the association between the carriage of the genotypes GG, GA and AA of rs759733834 polymorphisms in either of the groups. The distribution of genotypes in respect to rs9402439 polymorphism (CC, CG, GG) was also insignificant. Among patients with alcohol dependence, the frequency G allele of rs9402439 polymorphism was lower compared to non-addicted ones (27 vs. 47%) *P* < 0.01.

Conclusions *TAAR1* polymorphisms rs759733834 and rs9402439 are not related to suicide attempts. The carriage of allele G of rs9402439 polymorphism is related to lower risk of alcohol addiction OR 0.40 95%CI 0.20–0.81. To our knowledge, this is the first study on the *TAAR1* receptor and the risk of suicide and it might offer a new insight into genetic etiology of *TAAR1* receptor.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Verbal learning and memory in at-risk mental state and first episode psychosis patients and their correlates to brain structural alterations

L. Egloff*, C. Lenz, E. Studerus, U. Heitz, S. Menghini-Müller,

F. Harrisberger, S. Ittig, K. Beck, L. Leanza, C. Andreou,

A. Riecher-Rössler, S. Borgwardt

University of Basel Psychiatric Hospital, Department of Psychiatry, Basel, Switzerland

* Corresponding author.

Introduction Patients with a first episode psychosis (FEP) have repeatedly been shown to have gray matter (GM) volume alterations. Some of these neuroanatomical abnormalities are already evident in the at-risk mental state (ARMS) for psychosis. Not only

GM alterations but also neurocognitive impairments predate the onset of frank psychosis with verbal learning and memory (VLM) being among the most impaired domains. Yet, their interconnection with alterations in GM volumes remains ambiguous.

Objective To evaluate associations of different subcortical GM volumes in the medial temporal lobe with VLM performance in ARMS and FEP patients.

Methods Data were collected within the prospective Früherkennung von Psychosen (FePsy) study, which aims to improve the early detection of psychosis. VLM was assessed using the California Verbal Learning Test (CVLT) and its latent variables Attention Span (AS), Learning Efficiency (LE), Delayed Memory (DM) and Inaccurate Memory (IM). Structural images were acquired using a 3 Tesla magnetic resonance imaging scanner.

Results Data from 59 ARMS and 47 FEP patients were analysed. Structural equation models revealed significant associations between the amygdala and AS, LE and IM; thalamus and LE and IM; and the caudate, hippocampus and putamen with IM. However, none of these significant results withstood correction for multiple testing.

Conclusions Although VLM is among the most impaired cognitive domains in emerging psychosis, we could not find an association between low performance in this domain and reductions in subcortical GM volumes. Our results suggest that deficits in this domain may not stem from alterations in subcortical structures.

⁴ Xinxiang Medical University, Department of Psychology, Xinxiang, China

* Corresponding author.

Deep-brain magnetic stimulation (DMS) is an effective therapy for various neuropsychiatric disorders including major depression disorder. The molecular and cellular mechanisms underlying the impacts of DMS on the brain remain unclear. Studies have reported abnormalities in the white matter of depressive brains, suggesting the involvement of myelin and oligodendrocyte pathologies in the development of major depressive disorder. In this study, we use a cuprizone induced demyelination animal model to generate depressive like behaviours and white matter and oligodendrocyte damages. Meanwhile, we treated the animal with DMS 20 minutes daily during the cuprizone challenge or recovery period. Behavioural tests, including nesting, new objective recognition, working memory and depression-like behaviours were tested periodically. Histological staining and western blotting were used to examine the underlying mechanism of DMS. We found that DMS reverse cuprizone induced behavioural deficits in acute demyelination but not during the recovery period. DMS alleviated demyelination and inflammation induced by cuprizone. During the recovery period, DMS had no impacts on overall neural progenitor cell proliferation, but enhanced the maturation of oligodendrocyte. This data suggest that DMS may be a promising treatment option for improving white matter function in psychiatric disorders and neurological diseases in future.

Objectives Socially-assistive robots have been used with older adults with cognitive impairment in residential care, and found to improve mood and well-being. However, there is little known about the potential benefits in adults with other neuropsychiatric symptoms.

Aims The aim of this project was explore the utility and acceptability of a socially-assistive robot in engaging adults with a variety of neuropsychiatric symptoms.

Methods Betty, a socially-assistive robot was installed in a unit which specialises in the assessment and diagnosis of adults presenting with neuropsychiatric symptoms. She is 39 cm tall, has a baby-face appearance and has the ability to engage individuals through personalised services which can be programmed according to individuals' preferences. These include singing songs and playing games. Training for the nursing staff who were responsible for incorporating Betty into the unit activities was provided. The frequency, duration and type of activity which Betty was involved in was recorded. Patients admitted who could provide informed consent were able to be included in the project. These participants completed pre- and post-questionnaires.

Results Eight patients (mean age 54.4 years, SD 13.6) who had diagnoses ranging from depression and schizophrenia participated. Types of activities included singing songs, playing Bingo and reading the news. Participants reported that they were comfortable with Betty and did not feel concerned in her presence. They enjoyed interacting with her.

Conclusions This pilot project demonstrated that participants found Betty to be acceptable and she was useful in engaging them in activities. Future directions would involve larger sample sizes and different settings.

Introduction Behavioral disorders, such as conduct disorder, influence choice of treatment and its outcome. Less is known about other variables that may have an influence.

Objectives/Aims We aimed to measure the parent drug and metabolite plasma levels in risperidone-treated children and adolescents with behavioral disorders and investigate the role of drug dose and patients' gender and age.

Methods We recruited 115 children/adolescents with DSM-5 behavioral disorders (females=24; age range: 5–18 years) at the Departments of Psychiatry of the Hospitals of Bolzano, Italy, and Innsbruck, Austria. We measured risperidone and its metabolite 9-hydroxyrisperidone plasma levels and the parent drug-to-metabolite ratio in the plasma of all patients by using LC-MS/MS. A subsample of 15 patients had their risperidone doses measured daily. We compared risperidone and 9-hydroxyrisperidone plasma levels, as well as risperidone/9-hydroxyrisperidone ratio, in males vs. females and in younger (≤ 14 years) vs. older (15–18 years) patients by using Mann-Whitney U test. We fitted linear models for the variables "age" and "daily risperidone dose" by using log-transformation, regression analysis and applying the R2 statistic.

Results Females had significantly higher median 9-hydroxyrisperidone plasma levels ($P=0.000$). Younger patients had a slightly lower median risperidone/9-hydroxyrisperidone ratio ($P=0.052$). At the regression analysis, daily risperidone doses and metabolite, rather than parent drug-plasma levels were correlated ($R^2=0.35$).

Conclusions Gender is significantly associated with plasma levels, with females being slower metabolizers than males. Concerning age, younger patients seem to be rapid metabolizers, possibly due to a higher activity of CYP2D6. R2 suggests a clear-cut elimination of the metabolite.

Grey matter volume patterns in thalamic nuclei are associated with schizotypy in healthy subjects

P. Di Carlo^{1,*}, G. Pergola¹, M. Cariello¹, A. Bonvino¹, M. Mancini¹, P. Taurisano¹, G. Caforio², A. Bertolino¹, G. Blasi¹

¹ University of Bari "Aldo Moro", Department of Basic Medical Science, Neuroscience and Sense Organs, Bari, Italy

² Bari University Hospital, Psychiatry Unit, Bari, Italy

* Corresponding author.

Introduction Schizotypy refers to a set of temporally stable traits that are observed in the general population and that resemble, in attenuated form, the symptoms of schizophrenia. In a previous work, we identified volumetric patterns in thalamic subregions which were associated with disease status, and trained a random forests classifier, accounting for such thalamic volumetric patterns, that discriminated healthy controls (HC) from patients with schizophrenia (SCZ) (81% accuracy) [1].

Objectives i) to assess performance of random forests classifier developed by Pergola and coworkers [1], in an independent sample of healthy subjects; ii) to test whether false positives (FP), i.e. HC classified as SCZ based on such classifier would be associated with greater schizotypy compared with true negatives (TN), i.e. HC classified as such.

Methods A total of 167 HC participated in the MRI study and filled the Schizotypal Personality Questionnaire (SPQ). We pre-processed MRI data with SPM8 and DARTEL. Then, we used thalamic grey matter volumes (GMV) as features in the random forests prediction of disease status at the single subject level. Finally, we tested SPQ scores differences between FP and TN with Mann-Whitney test.

Results The classification accuracy was 71%. FP had greater SPQ scores compared to TN ($P=0.007$).

Conclusions Classification accuracy of our classifier in an independent sample suggests that thalamic GMV patterns are reproducible markers of disease status. Furthermore, the present results also suggest that variability of thalamic GMV patterns in HC may have relevance for subclinical phenotypes related to schizophrenia spectrum.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The impact of relapses in acute schizophrenia's clinical outcome:

A descriptive cross-sectional analysis

I. Carreira Figueiredo^{1,*}, D. Pereira¹, I. Cargaleiro¹, P. Aguiar²

¹ Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisboa, Portugal

² Escola Nacional de Saúde Pública, Statistics and Statistical Methods in Clinical Epidemiology, Lisboa, Portugal

* Corresponding author.

Introduction Recent studies suggest that most of schizophrenia's first-episode patients have the potential for long-term remission. Conversely, some meta-analysis estimate the actual median recovery rate to be 13.5% [1]. Relapses may contribute to the emergence of increased morbidity and treatment resistance.

Objectives To evaluate possible relationships between the numbers of previous admissions, years of diagnosed disease and hospitalization length.

Methods A cross-sectional retrospective study on all patients ($n=202$, 150 men and 52 women) admitted at an acute inpatient unit throughout the year of 2015, diagnosed with schizophrenia (ICD-9, 295). Collection of socio-demographic data, number of previous admissions (PA), years of diagnosed disease (YDD) and hospitalization length (HL). Descriptive statistical analysis, Spearman rank correlation and Mann-Whitney U test.

Results Overall, the sample's mean age was 44.3 years old (std 12.7), being lower in men (42.5 versus 49.7). The average of admissions was 1.2 per year. PA and YDD were significantly associated ($P<0.0001$). Contrarily, there was no statistical association between the number of PA and HL ($P>0.1$), as well as between YDD and HL ($P>0.1$) was found.

Conclusion This study provides additional evidence for schizophrenia's early onset in men. There seems to be no association between relapses and treatment resistance, considering PA, YDD and HL as valuable soft outcomes. Future understanding of

relapses' pathophysiological mechanisms is warranted in order to explain schizophrenia's low median recovery rate.

Introduction In 2001, the World Health Organization (WHO) created the International Classification of Functioning, Disability and Health (ICF) to offer a comprehensive and universally accepted framework to describe functioning, disability and health. The ICF Core Sets (ICF-CS) are a selection of categories that serve as a minimal standard for the assessment of functioning and disability in a specific health condition. The ICF-CS for schizophrenia was created in 2015 based on four preliminary studies that intend to capture different perspectives.

Objectives The aim of this study is to describe the similarities (i.e. overlap) and discrepancies (i.e. unique contribution) between the clinical, patient and expert perspectives on the most relevant problems in functioning of individuals with schizophrenia, being focused on the European WHO region.

Methods Forty-four experts from 14 European countries participated in an expert survey, patients with schizophrenia were involved in four focus groups, and health professionals assessed 127 patients in relation to daily life functioning. Information gathered from these three preliminary studies was linked to the ICF.

Results Data showed that although a considerable number of second-level ICF categories agreed on the three preparatory studies ($n=54$, 27.7%), each perspective provided a unique set of ICF categories. Specifically, experts reported 65 unique ICF categories, patients 23 and health professionals 11.

Conclusions Even though there were similarities between perspectives, each one underlined different areas of functioning, showing the importance of including different perspectives in order to get a complete view of functioning and disability in individuals with schizophrenia.

The prevalence of mental disorders in Portugal is 23%. Of these, anxiety disorders are most prevalent. Given these data, the development and implementation of remediate programs in general takes urgent character, especially in the younger population, where it is estimated that one in every five children suffer from some mental disorder. Given the lack of intervention programs in performance anxiety, we propose the development and implementation of a group program for elementary school children, targeting both the improvement and possible recovery of this condition as a means of reducing school failure in these children. In this program the following aspects will be addressed: the study and regulation of emotions; perceptions of self-efficacy; and therapeutic strategies based on third generation of cognitive behavior therapy—acceptance and commitment therapy. As a non-randomized controlled study, this project involves the development, implementation and validation of the intervention program. To this end, an assessment protocol will be administered to both control and experimental groups. This latter protocol will be administered at three different times: before and after implementation of the program and as a follow-up evaluation 6 months later. This program aims to promote emotional regulation in children with performance anxiety and, concurrently, to improve chances for their possible recovery as well as the reduction of significant school failure rates among Azorean children. The implementation

of this therapeutic group intervention program with elementary school children may also prevent later interventions in other health and educational settings.

Psychological interventions for psychogenic non-epileptic seizures: A meta-analysis

P. Carlson

Central West Neurology & Neurosurgery, Neurology, Orange, Australia

Introduction and objective Psychological interventions for psychogenic non-epileptic seizures (PNES) show promising results. The aim of this meta-analysis is to evaluate and synthesize the available evidence from the previous 20 years regarding the utility of psychological interventions in the management of PNES.

Method Studies were retrieved from MEDLINE via OvidSP and PsychINFO. Selection criteria included controlled and before-after non-controlled studies including case series, using seizure frequency as an outcome measurement. Studies were required to assess one or more types of psychological intervention for the treatment of PNES in adults. Data from 13 eligible studies was pooled to examine the effectiveness of psychological interventions in treating PNES on two primary outcomes: seizure reduction of $\geq 50\%$ and seizure freedom. A meta-analysis was conducted with data extracted from 228 participants with PNES.

Results Interventions reviewed in the analysis included CBT, psychodynamic therapy, paradoxical intention therapy, mindfulness, psychoeducation and eclectic interventions. Meta-analysis synthesized data from 13 studies with a total of 228 participants with PNES, of varied gender and age. Results showed 82% of people with PNES who complete psychotherapy experience a reduction in seizures of $\geq 50\%$. Additional meta-analysis synthesized data from 10 studies with a total of 137 participants with PNES. This analysis found 47% of people with PNES are seizure free upon completion of a psychological intervention.

Conclusion The studies identified were diverse in nature and quality. Findings highlight the potential for psychological interventions as a favorable alternative to the current lack of treatment options offered to people with PNES.

Do not be afraid: Novel approaches to the treatment of anxiety disorders

L. Carvalhão Gil*, M. Lázaro, A. Ponte

Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisboa, Portugal

* Corresponding author.

Introduction Anxiety disorders (AD) are associated with significant morbidity and often are chronic and resistant to the treatment. A fascinating aspect of AD is the interplay of genetic and experiential factors. It is established that abnormal genes predispose to pathological anxiety states; however evidence clearly indicates that traumatic life events and stress are also etiologically relevant. The behavioral theories of anxiety postulates that anxiety is a conditioned response to a specific environmental stimulus. There may be two ways to neutralize fear conditioning either by facilitating a process called extinction or by blocking a process called reconsolidation.

Objectives Review novel approaches to the treatment of AD.

Aims To update on treatment for AD.

Methods A literature search was performed on PubMed database.

Results Cognitive behavioral therapies use exposure techniques, in which the patient has to confront the fear-inducing stimuli in a safe environment in order to facilitate the fear extinction. The therapy is often context-specific, so one way of strengthen extinction learning is by boosting NMDA receptor activation, either with direct acting agonists (D-cycloserine) or with indirect glycine enhancing agents (selective glycine reuptake inhibitors). Memory reconsolidation is based on the notion that memories are dynamic rather than stable. Reactivation of a memory can return it to a labile state from which it must be reconsolidated. Blocking reconsolidation is a therapeutic opportunity of update and alter the memory, weakening traumatic memories. Beta-blockers and opioids may disrupt this process.

Conclusions Psychotherapy and psychopharmacology may have a synergistic role in AD treatment.

⁴ DC Clinics, Verzuimdiagnostiek, Amsterdam, Netherlands

* Corresponding author.

Background and aims Over 50% of adult disability claimants fail some form of SVT. While some over report psychological, affective symptoms, others may report incredible cognitive symptoms. We examined effects of different types of response bias on free recall and self-reported depression.

Participants and methods This is a single site cross-sectional study using a convenience sample ($n = 224$) of disability claimants in the Netherlands. The Green Word Memory Test (GWMT) was administered to all subjects. The Amsterdam Short Term Memory Test (AKTG), the Structured Inventory of Malingered. Symptomatology (SIMS), and the beck depression inventory (BDI-II) were administered in subsamples. Participant classification according to GWMT

and SIMS outcomes resulted in four groups, G+/S+, G+/S-, G-/S+ and G-/S-.

Results Average age of the participants was 46.3 years (SD 9.9), 41.5% were female, and 43% were higher educated. GWMT was positive in 48.2% of all subjects, and 27.6% scored positive on both GWMT and SIMS. Analysis of variance of GWMT Free recall and Beck depression scores showed significant group differences [$F(3, 123) = 33.21, P = .000$] and [$F(3, 106) = 25.17, P = .000$] respectively.

Conclusions Non credible test performance was prevalent in this Dutch study of disability claimants. Insufficient effort and over reporting of psychological symptoms are associated with different score profiles on regular tests and self-rating scales.

* Corresponding author.

Psychoemotional disorders in pregnant women represent a significant medical and social problem as well as the effects caused by this pathology have a profound effect on children born to such mothers, as well as to themselves mothers during and after pregnancy. The goal–psychological correction of psycho-emotional states in pregnant women with hypertensive syndrome by Erickson hypnosis. The study was conducted on the basis of state organization “Research Center for Obstetrics, Gynecology and Perinatology named after Academician VI Kulakov”. The study involved 150 pregnant women with hypertensive syndrome. Seventy-five pregnant women with hypertensive syndrome received psychological correction method of Erickson hypnosis in an amount of 15 sessions. To assess the state of mental and emotional techniques used depression scale Beck Anxiety Scale, Spielberger-Hanin. The study was conducted 4 times—the first, second, and third trimesters of three months after childbirth. When comparing the psycho-emotional state of pregnant women with hypertensive syndrome on the background of psychological adjustment method Erickson hypnosis and in pregnant women with hypertensive syndrome who did not receive psychological correction revealed a statistically significant difference. In pregnant women with hypertensive syndrome who received psychological correction method of Erickson hypnosis, revealed lower levels of depression and situational anxiety than women who did not receive psychological correction. Thus, our study proved the need for psychological correction method of Erickson hypnosis and its effectiveness for stabilizing the psycho-emotional state of pregnant women with hypertensive syndrome and pre-eclampsia prevention.

Comparing the effects of cognitive behavior therapy or regular physical exercise on sleep in the treatment of patients with panic disorder

A. Hovland^{1,*}, I.H. Nordhus¹, E. Martinsen², T. Sjøbø³, B. Gjestad³, H. Johansen³, S. Pallesen⁴

¹ Faculty of Psychology, Department of Clinical Psychology, Bergen, Norway

² Faculty of Medicine, Institute of Clinical Medicine, Oslo, Norway

³ Solli District Psychiatric Centre DPS, Department of Comprehensive Treatment Programs, Nesttun, Norway

⁴ Faculty of Psychology, Department of Psychosocial Science, Bergen, Norway

* Corresponding author.

Introduction Seventy percent of patients with panic disorder (PD) have sleep impairment. Cognitive behavior therapy (CBT) effectively treats PD, but the concomitant effect on sleep is understudied. Physical exercise (PE) improves sleep, but this has not been investigated in patients with PD.

Objective To compare the effects of CBT or PE on sleep in PD-patients, and to determine potential mechanisms of action.

Methods Thirty-six PD-patients were randomized to either group CBT for PD or regular PE. Sleep was assessed pre/post with the Pittsburgh sleep quality index. Effects were investigated with repeated measures ANOVA and t-tests. Expected mediators were added to the general linear model to assess mediation.

Results The effect of time was significant, $F(1.33)=10.11$, $P=0.003$, but not the interaction (Time \times group), $F(1.33)=.48$, $P=0.49$. Symptoms were significantly reduced from pre- to post-treatment: PE, $t(16)=3.03$, $P=.008$, and CBT, $t(17)=2.18$, $P=0.044$. CBT-patients changed significantly ($P<0.05$) on Sleep quality, $t(17)=2.47$ and Sleep disturbance, $t(17)=2.38$. PE-patients changed significantly on sleep duration, $t(16)=2.58$ and sleep disturbance, $t(16)=2.58$. A significant interaction with change in fear of bodily symptoms, $F(1.16)=5.53$, $P=.032$, and with change in depression-level, $F(1.16)=12.13$, $P=0.003$ was only found for CBT. A significant interaction with change in physical fitness, $F(1.15)=5.01$, $P=.041$, was only found for PE.

Conclusion Both interventions improve sleep in PD-patients, but differently. The findings also suggest that these changes are related to different mechanisms for PE and CBT.

Explanatory and confirmatory factor structure of beck anxiety inventory in college sample

S. Kareemi*, B.M. Alansari

Kuwait University, Faculty of Social Sciences, psychology, kifan, Kuwait

* Corresponding author.

Introduction The Beck anxiety inventory (BAI) is a widely used 21-item self-report inventory used to assess anxiety levels in adults and adolescents in both clinical and non-clinical populations. The values for each item are summed yielding an overall or total score for all 21 symptoms that can range between 0 and 63 points. A total score of 0–7 is interpreted as a “Minimal” level of anxiety; 8–15 as “Mild”; 16–25 as “Moderate”, and; 26–63 as “Severe”. There is no study until this date that examines the Explanatory and confirmatory factor structure of BAI in college student in Kuwait.

Objectives The current study investigated the original four-factor structure of the (BAI) in non-clinical sample of college students.

Methods Sample one consisted of 540 males and females while sample two consisted of 600 males and females from Kuwait University undergraduates. The Arabic version of BAI was administered to participants. Explanatory factor analysis based on sample one and conformity factor analysis based on sample 2.

Results The results revealed four factor structures of BAI in the two samples of Kuwaiti students. Which included neuro-physiological, subjective, autonomic, and panic factors.

Conclusions The results of both confirmatory and exploratory factor analysis indicated that the original four-factor structures of the BAI do provide the best fit for the college sample.

Playing video games – Psychological threat to adults?

M. Toś¹, E. Wilk¹, A. Myszczyk¹, A. Bratek², K. Krzysztof^{1,*}

¹ Medical University of Silesia, Department of Rehabilitation Psychiatry, Katowice, Poland

² Medical University of Silesia, Department of Psychiatry and Psychotherapy, Katowice, Poland

* Corresponding author.

Background Video games become increasingly popular form of spending free time, therefore they are often a research subject. Researchers focus mainly on video games influence over children's psyche and their social interactions, although video games can also have an impact on adult's behaviour.

Objectives Incidence of social anxiety disorder and impulsiveness among video game players and non-players.

Material and methods An anonymous online survey included 263 students of medical university of Silesia (112 M and 151 W). In study group, 142 people (54%) declared to be players. Questionnaire contained questions about playing time, Barratt Impulsiveness Scale and Liebowitz Social Anxiety Scale. Statistical analyses were performed using the statistical software package Statistica 12.

Results Using Liebowitz Scale in 168 (64.86%) all studied people lack of phobia was found, moderate social phobia 39 (15.06%), marked social phobia 26 (10.03%), severe social phobia 17(6.56%) and very severe social phobia 9(3.47%). There was no statistical significance between players and non-players (test χ^2 $P=0.6521$). Also in Barratt Scale statistical significance was not found in attentional impulsiveness (test U M-W $P=0.3267$) and in Motor impulsiveness (test U M-W $P=0.3140$). Statistical significance was observed in Non-planning impulsiveness (players: 23.68 V non-players: 22.02; test U M-W $P=0.0036$).

Conclusions The study did not show clear influence adult's video games playing over social phobia and impulsiveness occurrence.

Utilization unspecialized care of patients with anxiety disorder

M. Marachev*, A. Avedisova

V. Serbsky Federal Medical Research Centre for Psychiatry and Narcology- of the, Therapy of Mental & Behaviour Disorders, Moscow, Russia

* Corresponding author.

Introduction The greatest social and economic burden is divided between the three main anxiety disorders: social phobia (SF), generalized anxiety disorder (GAD) and panic disorder (PD).

Objectives To examine the pathways of patients with PD, SF and GAD since the beginning of the first anxiety symptoms and before the first course of a standardized treatment in a specialized mental health facility.

Aims To evaluate the period of delay in seeking specialized care and to identify the main ways of seeking medical/non-medical care.

Methods Retrospective study ($n = 80$). Structured interview were based on WHO instruments: WHO WMH CIDI and WHO Pathways to care encounter form.

Results Average age was 38 years, more females (72.5%). The delay period was 7 years ($GAD = 8.7$; $SF = 8.2$, $PD = 5.9$), during which at least 2 episodes of the disease. The most popular specialists were: neurologists (19%), psychiatrists (17%) (one-time visits to which were not accompanied by the appointment of a standardized course of treatment for an adequate period of time) and therapists (15%). Non-medical care was 10% of all studied (psychologists–5%, healers–3%, priests–2%). SF–psychiatrists (43%), therapists (14%), psychologists (14%); GAD–psychiatrists (22%), neurologists (19%), psychotherapists (11%), ambulance doctor (11%); PD–therapists (22%), neurologists (22%), ambulance doctor (17%), cardiologists (9%).

Conclusions The findings suggest that patients with anxiety disorders have a long period of delay in receiving specialized care that causes the value of the social and economic burden of anxiety disorders in the community.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Generalized anxiety in young adults during college career is a serious public-health problem that untreated has a chronic course. Research has shown that the self-report questionnaire generalized anxiety disorder-7 (GAD-7) is a reliable and valid measure to assess generalized anxiety symptoms severity in heterogeneous psychiatric samples. However, GAD-7 is not available for non-clinical populations and their factor structure has not been re-examined.

Objectives Our objective was to examine factor structure and measurement invariance of the GAD-7 among college students testing two alternatives models.

Aims The original model fit of single-factor was compared to two-factor model that considered in comprehensive approach of generalized anxiety the assessment of cognitive-emotional nature and somatic symptoms.

Methods In this cross-sectional study the GAD-7 was administered to college students ($n = 1031$) recruited in the six schools which compose the Polytechnic Institute of Coimbra, Portugal. Confirmatory factor analysis was used testing two models.

Results Among college students, 32.8% reported significant generalized anxiety symptoms. The original unidimensional structure of GAD-7 was confirmed but the two-factor model comprising cognitive-emotional and somatic factors presented better fit to the data ($\chi^2(1) = 21.01$, $P < 0.001$). This latent factor were positively associated ($r = 0.51$, $P < 0.001$) and presented a good internal consistency ($\alpha = 0.85$ and $\alpha = 0.86$ for cognitive-emotional and somatic items, respectively). The invariance factor of two-factor model across gender was also confirmed.

Conclusions Results indicate that within college communities the GAD-7 integrates two stable generalized anxiety factors related but independent structure. The GAD-7 can be an adequate measure to detected generalized anxiety symptoms in this population.

An investigation of childhood trauma in patients with panic disorder

S.B. Ölmez*, A. Ataoğlu, Z. Başar Kocagöz

Duzce University School of medicine, Psychiatry Department, Konuralp, Turkey

* Corresponding author.

Introduction It is widely known that childhood traumatic life situations are associated with most of the adult life psychiatric disorders such as disassociative disorders, mood disorders, anxiety disorders and so on.

Objectives and aims The purpose of this study to examine the relationship between childhood traumatic experiences and panic disorder development.

Methods The sample of this study consists of 59 outpatients who applied to the department of psychiatry in addition to 61 healthy individuals serving as the control group. These 59 individuals, located within the range of 18 to 65 years, were selected from outpatients who had been diagnosed with panic disorder based on DSM-V diagnosis criteria who did not have any other mental disorder. The 61 healthy individuals in the control group were selected from hospital attendants who had not received any psychiatric diagnosis. The participants were administered the childhood trauma questionnaire (CTQ) and a socio-demographic form.

Results The participants in the panic disorder group were found to have significantly high scores in comparison to the control group with respect to CTQ subscales (i.e., the emotional neglect and the emotional abuse subscale) and the total CTQ score. Hence, there exists a strong relationship between childhood traumatic experiences and panic disorder development.

Conclusion The results revealed that childhood traumatic experiences play an active role in the development of panic disorder. Moreover, it was found that the type and quality of trauma experienced during the childhood period is one of the predictors for the psychiatric disease that can occur in the future years.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Could deficits in the recognition of emotions that indicate social approval be associated with musical performance anxiety?

F.L. Osório*, A.D. Sabino, C.M. Camargo

Medical School of Ribeirão Preto - São Paulo University, Neuroscience and Behaviour, Ribeirão Preto, Brazil

* Corresponding author.

Introduction Proper recognition of facial expressions of emotion is crucial for human social relationships. Impairments in the capacity to process facial information may play an important role in the etiology and maintenance of certain mental disorders, especially music performance anxiety (MPA).

Objective To assess the recognition of facial expressions of emotion in musicians compared to a group of subjects from the general population, considering also the presence/absence of MPA.

Methods Hundred and fifty amateur and/or professional musicians who regularly take part in public performances (GM) and 150 subjects from the general population (GP) completed a task of facial emotion recognition and were assessed in terms of accuracy and reaction time. The group of musicians was subdivided between subjects with and without MPA indicators. Data were analyzed using Student's *t* test ($P < 0.05$) within the statistical package for the social sciences.

Results GM were less accurate and had a longer reaction time in the recognition of facial happiness ($P < 0.001$, effect size: 0.25–0.44) compared to GP. Musicians with MPA had a still lower accuracy in the recognition of happiness, as well as longer reaction times for emotions as a whole ($P < 0.04$; effect size: 0.32–0.40) compared to musicians without MPA.

Conclusion The poorer performance of musicians in the recognition of happiness suggests difficulties to recognize indicators of social approval, which may negatively affect performance through increased anxiety and negative thoughts that can favor the onset of MPA.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A single dose of oxytocin on music performance anxiety: Results involving a situation of simulated performance

F.L. Osório*, A.E. M. Barbar, M.F. Donadon, J.A.S. Crippa

Medical School of Ribeirão Preto - São Paulo University, Neuroscience and Behaviour, Ribeirão Preto, Brazil

* Corresponding author.

Introduction Music performance anxiety (MPA) is a persistent and distressing experience that involves apprehension linked with musical performance in public (individual or collective). Anxious individuals concentrate their anxiety in situations that involve social scrutiny, favoring distorted, dysfunctional, and negative interpretations of that situation followed by experiences of physiological symptoms associated with the exposure. The most commonly used substances in the pharmacological management of MPA are beta-blockers and benzodiazepines. However, these options are not fully efficient and cause relevant side effects that interfere mainly with performance. Therefore, investigations on alternative substances to treat MPA are highly opportune.

Objective To assess the acute effects of oxytocin (OT) on physiological and cognitive variables during an experimental model of simulated performance.

Methods We assessed 12 musicians with MPA pre-treated with intranasal OT (24 UI) or placebo in a crossover trial involving an experimental situation of public performance. Cognitive and physiological measures (heart rate, blood pressure, salivary cortisol) were recorded before/during performance (anticipatory performance anxiety). Statistical analyses were made using Stata Direct.

Results The results showed no effects of OT on physiological symptoms ($P > 0.190$). In respect to anticipatory anxiety, however, we found a tendency for OT to reduce negative cognitions associated with music performance ($P = 0.06$). No side effects were reported by musicians throughout the trial.

Conclusion These tendencies, if confirmed through the expansion of the sample, have important implications for the practice of amateur and professional musicians who could benefit from interventions as the one described, possibly with a lesser impact of side effects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Music performance anxiety: Perceived causes and coping strategies

F.L. Osório^{1,*}, A.B. Burin¹, I.S. Nirenberg², A.E.M. Barbar¹

¹ Medical School of Ribeirão Preto, São Paulo University, Neuroscience and Behaviour, Ribeirão Preto, Brazil

² Rio de Janeiro Federal University, Music School, Rio de Janeiro, Brazil

* Corresponding author.

Introduction The understanding of the causes of music performance anxiety (MPA) and of strategies to cope with it is important for the comprehension/management of this common condition in musicians.

Objective To investigate the causes of MPA reported by Brazilian musicians and the efficacy of the most commonly used strategies to cope with it.

Methods Two hundred and fourteen Brazilian musicians (53% professional/musicians from orchestras, 67% male, mean age: 34.02 years, 65% with over 11 years of education, 42% of which played string instruments) completed different self-rating scales to assess the presence/absence of MPA.

Results Thirty-nine per cent of the musicians had indicators of MPA. The most commonly reported causes were repertoire difficulty (57%), concerns about audience response (52%), and self-pressure (51%). The most common coping techniques included breathing/relaxing techniques (66%) and increased practice (53%), regarded as efficient by at least 49% of the musicians. Strategies like seeing a doctor/psychiatrist/psychologist and taking antidepressant/anxiolytic medication were among the least frequently used in the sample. Also, 18% of musicians with MPA used beta-blockers and 6% used non-prescribed medications. Comparatively, musicians with MPA believed that it was associated with a higher number of conditions and regarded coping techniques as less efficient.

Conclusion Musicians consider internal situations to be the most frequent causes of MPA and use different coping strategies with average effectiveness. Results highlight the poor use of well-established therapeutic resources and the occurrence of self-medication in the sample, which together point to the need for attention on the part of mental health professionals to this specific group.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Somatoform disorders (SD) are an example of the complex interaction between mind and body.

To estimate the efficacy of pregabalin (PG) versus combination of pregabalin and antidepressants in patients with SD who were previously on long-term treatment with at least three antidepressants (SSRI, SNRI, SARIs, SNDIs, MAOI, TCAs) in an adequate therapeutic dose and had a partial response on it. In this open label trial investigators diagnosed 41 patients by standard clinical interview as F 45.0 and F 45.4 according to ICD-10 criteria and divided them in two groups: experimental (Pregabalin, 20 patients) and control

group (Pregabalin + antidepressant, 21 patients). Patients also had comorbid diagnoses as follows: F 41.1, F 32, F 33 or F 34. Assessment was done by 100 mm Visual analogue scale (VAS) and by Clinical Global Impression Scale (CGI). Within both groups there was a statistically significant improvement measured by VAS and CGI scales in all repeated measurements, except for the CGI scale in both groups between the second and ninth month where there was no statistical difference. There were no statistically significant differences between CG and EG on both scales either in the beginning or in repeated measurements. There was no difference in the effects of the drugs between EG and CG on both scales- VAS & CGI. Pregabalin as mono or as an adjuvant therapy had equally good efficiency in patients with SD who had partial response on various antidepressants therapy after long-term treatment.

Disclosure of interest Results from part of this trial were published as abstract in European Psychiatry, Volume 30. Supplement 1, 28–31 March 2015, Pages 534 – “Somatoform Disorders—a New Target for Pregabalin”, [http://dx.doi.org/10.1016/S0924-9338\(15\)30418-1](http://dx.doi.org/10.1016/S0924-9338(15)30418-1).

Dissociation and therapy of depressive and anxiety disorders with or without personality disorders

J. Prasko^{1,*}, A. Grambal¹, Z. Sigmundova¹, P. Kasalova¹, D. Kamaradova¹, K. Vrbova¹, M. Ociskova¹, M. Holubova¹, K. Latalova¹, M. Zatkova², M. Slepecky², A. Kotianova²

¹ University Hospital Olomouc, Department of Psychiatry, Olomouc, Czech Republic

² Faculty of Social Science and Health Care- Constantine the Philosopher University in Nitra, Slovak Republic, Department of Psychology Sciences, Nitra, Slovak Republic

* Corresponding author.

Objective Goal of the study was to analyze the impact of dissociation on the treatment of the patients with anxiety/neurotic spectrum and depressive disorders, and with or without personality disorders.

Methods The sample consisted of inpatients who met the ICD-10 criteria for the Depressive disorder, Panic disorder, GAD, Mixed anxiety-depressive disorder, Agoraphobia, Social phobia, OCD, PTSD, Adjustment disorders, dissociative/conversion disorders, Somatoform disorder or other anxiety/neurotic spectrum disorder. The participants completed Beck Depression Inventory, Beck Anxiety Inventory, subjective version of clinical global impression-severity, Sheehan Patient-Related Anxiety Scale, and Dissociative Experience Scale, at the start and the end of the therapeutic program.

Results The total of 840 patients with anxiety or depressive spectrum disorders, who were resistant to pharmacological treatment in outpatients basis and were referred for hospitalization for the six-week complex therapeutic program, were enrolled in this study. Six hundred and six of them were statistically analyzed. The patients' mean ratings on all measurements were significantly reduced during the treatment. The patients without comorbid personality disorder improved significantly more than patients with comorbid personality disorder in the reduction of depressive symptoms. However, there were no significant differences in change of anxiety levels and severity of the disorder between the patients with and without personality disorders. The higher degree of dissociation at the beginning of the treatment predicted minor improvement. The higher therapeutic change was connected to the greater reduction of the dissociation level.

Conclusions Dissociation presents an important factor influencing treatment effectiveness in the treatment-resistant patients with anxiety/depression with or without personality disorders.

³ National Institute of Mental Health and Neurosciences, Psychiatry, Bangalore, India

⁴ Cairns and Hinterland Hospital and Health Service, Psychiatry, Melbourne, Australia

* Corresponding author.

Introduction Pharmacogenetic studies in obsessive-compulsive disorder (OCD) primarily focussing on serotonergic and dopaminergic polymorphisms, provided inconsistent findings. There is recent evidence for glutamatergic abnormalities in OCD.

Aims Examine the association glutamatergic genes with serotonin reuptake inhibitor (SRI) response in OCD.

Objectives To study pharmacogenetic association between SLC1A1 and GRIN2B polymorphisms with SRI response in OCD.

Methods DSM-IV OCD patients were recruited from a specialty OCD clinic and evaluated using the Yale-Brown obsessive compulsive scale (YBOCS), Mini International Neuropsychiatric Interview (MINI) plus, Clinical Global Impression scale (CGI). They were subsequently reassessed with YBOCS and CGI. To study extreme phenotypes, we included only full responders (>35% YBOCS improvement and CGI-I score of 1 or 2) to any SRI ($n=191$) and non-responders (<25% YBOCS improvement and CGI-I score ≥ 4) to adequate trial of at least two SRIs ($n=84$). Partial responders were excluded. Genotyping was performed using an ABI9700 PCR machine.

Results Genotype frequencies did not deviate significantly from the values predicted by the Hardy-Weinberg equation. Case-control association analyses revealed no significant association between genotype/allele frequencies with SRI response.

Conclusion Our data does not show any association between polymorphisms in glutamatergic genes and SRI response in OCD though such associations have been found in other studies. More SNPs in the same gene could be responsible for the pharmacogenetic associations. More homogenous sample considering symptom dimensions and other phenotypic variables may be needed. It may be critical to go beyond “usual suspect” candidate gene research. In this regard, a novel approach to identify SRI response biomarkers is the use of cellular models.

Long term effect of cognitive behavioral therapy in patients with health anxiety

K.E. Veddegaerde

University of Bergen, Klinisk Institutt 2, Ålesund, Norway

Introduction Cognitive-behavioral therapy (CBT) has been found to be an effective treatment of excessive health anxiety (HA), but the long-term effect over 18 months has not been examined.

Objectives Several studies have shown effect of CBT for HA-patients. However, these effects have been short or immediate after therapy. To our knowledge no studies have examined long-term effect of CBT for HA over 18 months.

Aims To investigate the long-term effect of CBT on HA, focusing on level of HA, quality of life, subjective health complaints and general anxiety. Follow-up time was at least 10 years. Our hypothesis was that the effect was sustained.

Methods Patients with HA received 16 sessions of CBT over a period of 12–18 months, and were followed up over at least 10 years. All patients fulfilled criteria for F45.2, hypochondriacal disorder according to ICD-10.

The patients answered several questionnaires, exploring areas such as HA, Quality of life, somatization, and mental health problems. Questionnaires were answered before CBT, after CBT and at follow up. Mixed model analysis was performed in SPSS 23.0 for all questionnaires.

Results All scores were found to be significant in the Pre-CBT–Post-CBT and Pre-CBT–FU (0.034–<0.001), and none were found to be significant in the Post-CBT–FU.

Conclusions Our findings suggest that for the majority of patients with HA, CBT has a significant and lasting long-term effect. This effect lasts up to ten years post therapy.

Metabolic syndrome in patients with bipolar disorder treated with atypical antipsychotics, their first-degree relatives and control group

S. Arya^{1,*}, H. Ahmadkhaniha¹, B. Arya²

¹ Iran University of Medical Sciences, Mental Health Research Center, Tehran, Iran

² Golestan University of Medical Sciences, Department of General Surgery, Gorgan, Iran

* Corresponding author.

Introduction and objective Patients with serious mental illness have lower life expectancy and higher prevalence of metabolic syndrome compared to normal population. Although, we have little evidence about their first-degree relatives.

Aims To compare metabolic syndrome in patients with bipolar disorder treated with atypical antipsychotics, their first degree relatives and healthy subjects in two age groups: under and over 40.

Methods This cross-sectional study was conducted on 100 patients with bipolar disorder treated with atypical antipsychotics, 50 first degree relatives and 135 healthy subjects. The prevalence of metabolic syndrome was assessed based on National Cholesterol Education Program (NCEP).

Results Under the age of 40, the prevalence of metabolic syndrome was 15.4% in patients with Bipolar disorder, 17.6% in first degree relatives and 7% in healthy subjects. Systolic blood pressure was significantly higher in bipolar disorder patients ($P=0.004$). In those over 40, the prevalence of metabolic syndrome was 31.8% in patients with bipolar disorder, 33.3% in first-degree relatives and 32.8% in healthy subjects. Serum levels of HDL were significantly lower in bipolar disorder patients ($P=0.002$).

Conclusion Patients with bipolar disorder and their first-degree relatives have greater chance for cardiovascular disease due to

higher metabolic syndrome. Further investigations are needed for evaluating serious mental illness patients and their relatives.

The effect of long-term lithium treatment on renal functions in patients with bipolar disorder

B. Ayik^{1,*}, S. Çakır¹, H. Yazıcı², S. Karabulut¹

¹ Istanbul Faculty of Medicine, Psychiatry, Istanbul, Turkey

² Istanbul Faculty of Medicine, Nephrology, Istanbul, Turkey

* Corresponding author.

Introduction The effect of lithium on tubular functions leading to decreased urinary concentrating ability is recognized. Although there are several studies type, severity and frequency of renal impairment and its correlation with duration of lithium therapy are not well established.

Objectives To explore long-term effects of lithium on patients with chronic bipolar disorder.

Aims We aimed to assess patients with bipolar disorder using lithium at least for six years in terms of renal functions, starting from mild impairments to full blown chronic renal failure.

Methods Fifty-one patients with bipolar disorder and 38 age and sex matched healthy controls were enrolled for the study. Serum BUN, creatinine, uric acid, electrolytes, calcium (Ca), phosphorus (P), vitamin D (25-OH D3) and eGFR levels were measured. The correlations between renal function and mean lithium levels, duration of lithium treatment and GAF scores were calculated.

Results Mean eGFR level of patients with bipolar disorder was significantly lower than that of controls. Serum creatinine, uric acid, Ca and PTH levels were higher, 25-OH D3 levels were lower in the patients than in controls. The duration of lithium treatment was positively correlated with serum creatinine and uric acid levels, negatively correlated with eGFR levels. Mean lithium levels were positively correlated with serum creatinine levels and negatively correlated with eGFR.

Conclusions The study revealed that glomerular functioning of the patient group was significantly lower than that of the control group. The findings suggested that both duration of lithium treatment and high serum lithium levels may have a negative impact on glomerular functions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Protocol for developing and validating a multivariable prediction model to individualize the risk of recurrence of bipolar disorder in the perinatal period

M. Casanova Dias^{1,*}, I. Jones¹, A. Di Florio¹, L. Jones², N. Craddock¹

¹ Cardiff University School of Medicine, MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff, United Kingdom

² Institute of Health & Society, Worcester University, Worcester, United Kingdom

* Corresponding author.

Introduction For women with bipolar disorder, childbirth is a high-risk period with 40–50% experiencing a recurrence and 20% developing a severe episode of postpartum psychosis. Bipolar episodes in the perinatal period affect women and their families.

Managing bipolar disorder in pregnancy and postpartum is a challenge. There is lack of literature to inform that and an urgent need for more data.

Objectives To develop and validate a risk prediction model for individual prognosis of the risk of recurrence of bipolar disorder for women in the perinatal period.

Aims To provide evidence-based information to help women and the clinicians that look after them make decisions about their care, taking into account the most recent scientific knowledge and their individual characteristics.

Methods The development of the model will be done in retrospective data from a large clinical cohort from the Bipolar Disorder Research Network (BDRN.org). The validation will be done in a prospectively recruited sample.

Participants will be 2181 parous women with a lifetime diagnosis of bipolar disorder from BDRN and 300 prospectively recruited pregnant women with a history of postpartum psychosis or bipolar disorder.

Predictors will be chosen based on clinical experience and literature, from data collected via semi-structured interview (in pregnancy and 3 months postpartum, medical and psychiatric notes) e.g. medication, smoking, parity, obstetric complications and sleep.

Results N/A.

Conclusions We will present the full prediction model (regression coefficients and model intercept) and report performance measures (with CIs).

We will discuss its potential clinical use and implications for future research.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Review of risk prediction approaches for bipolar episodes in the perinatal period

M. Casanova Dias^{1,*}, I. Jones¹, A. Di Florio¹, L. Jones², N. Craddock¹

¹ Cardiff University School of Medicine, MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff, United Kingdom

² Institute of Health & Society, Worcester University, Worcester, United Kingdom

* Corresponding author.

Introduction The perinatal period is a high-risk period for the development of illness episodes in women with bipolar disorder. Relapse rates vary between 9 and 75% depending on the study. The overall risk of a severe episode is approximately 20%. The impact on women, the relationships with their babies and their families can be devastating. In the UK costs to society are £8.1 billion per year-cohort of births. The advice currently given to women is based of general risk rates. Women's needs of information for decision-making in the perinatal period are not being met.

Objectives To review the risk prediction approaches used for women with bipolar disorder in the perinatal period.

Aims To understand the existing risk prediction models and approaches used for prognosis of risk of recurrence of bipolar disorder for women in the perinatal period.

Methods Systematic literature search of public medical electronic databases and grey literature on risk prediction for bipolar episodes in the perinatal period.

Results We will present the existing models and approaches used for risk prediction of illness episodes in the perinatal period.

Conclusions Awareness of existing risk prediction models for recurrence of bipolar disorder in the perinatal period will allow better informed risk-benefit analysis of treatment and management options.

This person-centred approach will help women and clinicians in their decision-making at this crucial high-risk period.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Fundación San Juan de Dios, Psychiatrist, Barcelona, Spain

⁵ Hospital Mutua de Terrassa, Psychiatrist, Barcelona, Spain

* Corresponding author.

Introduction Bipolar disorder (BD) is related to high prevalence of somatic comorbidities, health care costs, and premature mortality [1]. Some evidence supports the view of BD as chronic, progressive and multisystem disorder in which not only mental system, but also somatic systems are involved [2].

Aim To investigate differences in physical health in patients with bipolar disorder at different stages (early vs. late) of the disease.

Methods Cross-sectional, naturalistic, multicenter study. Sample: 110 outpatients with BD [68 early stage (diagnosed at least 5 years earlier) and 42 late stage (at least 20 years earlier)]. Assessment: demographic and clinical variables; psychopathology: HDRS, YMRS and CGI; biological information: anthropometric, vital signs and lab results.

Results Early stage group: mean age 40.1 (11.9), 66.2% females and CGI = 3.6 (1.4). Late stage group: mean age 55.8 (8.2), 69.0% females and CGI = 4.0 (1.4). Patients in early stage have significantly higher levels of glucose ($t = -4.007$, $P < 0.001$), urea ($t = -2.724$, $P = 0.008$), creatinine ($F = 0.560$, $P = 0.022$), triglycerides ($t = -3.501$, $P = 0.001$), Fe ($t = 2.871$, $P = 0.005$) and insulin ($t = -3.223$, $P = 0.002$). Moreover, they have higher Body Mass Index (BMI) ($t = -3.728$, $P < 0.000$), abdominal circumference ($t = -4.040$, $P < 0.000$) and greater number of somatic comorbidities ($t = -2.101$, $P = 0.041$).

Conclusions – patients with bipolar disorders in late stages have worse physical health than those in early stage.

– these results could be an indication that bipolar disorder might better viewed as a multisystem disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The late-onset bipolar disorder: A comparative study

C. Derbel*, R. Feki, S. Ben Nasr, S. Bouhlel, B. Ben Hadj Ali
CHU Farhat Hached, Psychiatry, Sousse, Tunisia

* Corresponding author.

Introduction Bipolar disorders (BP) with late onset are underestimated by their frequency, their misleading presentations and therapeutic difficulties due to the high prevalence of somatic comorbidities.

Aim To identify sociodemographic, clinical and therapeutic characteristics in subjects with a late-onset BP.

Patients and methods Retrospective and comparative study of 101 patients followed for a BP (12 patients with BP started after 50 years and 89 patients with BP started earlier) from 2009 to 2015, in the department of psychiatry of the University Hospital Farhat Hached, Sousse, Tunisia.

Results The mean age of subjects with late-onset TBP was 46.11 ± 12.85 years. Women were in the majority (65.3%). Ten patients had a novo mania, four patients had a late-onset mania and one patient had a secondary mania. Regarding the socio-demographic data, only the regular professional activity was more reported in the elderly ($P=0.017$). Regarding clinical data, BP type 1 and secondary mania were more reported in elderly with ($P=0.050$ and $P=0.000$ respectively). Elderly had significantly fewer depressive episodes ($P=0.026$), fewer hypomanic episodes ($P=0.000$). The durations of the latest episodes and the last intervals were shorter in elderly ($P=0.045$ and $P=0.000$). Concerning therapeutic data, elderly had fewer hospitalizations ($P=0.045$), required lower mean doses of lithium ($P=0.04$) and greater mean doses of tricyclic antidepressants ($P=0.047$).

Conclusion It is always necessary to look for an organic cause in manic syndrome in late-onset BP. Doses of lithium should be lower. However, doses of TAD should be higher.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁶ Universidade Federal do Rio Grande do Sul, Department of Biochemistry, Porto Alegre, Brazil

* Corresponding author.

Introduction Evidence has suggested that immune imbalance is involved with bipolar disorder (BD); however, its precise mechanism is poorly understood.

Objective This study investigated whether biochemical changes in the serum from BD patients could modulate the phenotype of macrophages.

Methods Eighteen subjects with BD and healthy individuals ($n=5$) were included in this study. The human monocyte cell line U-937 was activated with PMA (phorbol 12-myristate 13-acetate) and polarization was induced with RPMI-1640 media supplemented with 10% serum from each patient for 24h. Gene expression of selected M1 and M2 markers was assessed by qPCR.

Results Macrophages exposed to serum of manic and depressive BD patients displayed an increase of IL-1 β (6.40 ± 3.47 and 9.04 ± 5.84 versus 0.23 ± 0.11 ; $P < 0.05$) and TNF- α (2.23 ± 0.91 and 2.03 ± 0.45 versus 0.62 ± 0.24 ; $P=0.002$ and $P=0.004$, respec-

tively) compared to remitted group. In parallel, U-937 macrophages treated with serum of patients in acute episode displayed a down-regulation of CXCL9 (0.29 ± 0.20 versus 1.86 ± 1.61 ; $P=0.006$) and CXCL10 expression (0.36 ± 0.15 and 0.86 ± 0.24 versus 1.83 ± 0.88 ; $P < 0.000$ and $P=0.04$) compared to remitters.

Conclusions Our results are consistent with previous studies showing that changes in peripheral blood markers could modulate M1/M2 polarization in BD. The evidence of macrophages as source of inflammatory cytokines might be helpful to unravel how the mononuclear phagocyte system can be involved in the etiology of BD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cognitive functions and cognitive styles in young euthymic patients with bipolar I disorder

S. ElGhonemy^{1,*}, P.H. Fakhry², A. Salem²

¹ Ain Shams University, Neuropsychiatry Department, Cairo, Egypt

² Cairo University, Psychiatry, Cairo, Egypt

* Corresponding author.

Background Cognitive deficits impair patients working and functioning status and may have negative impact on other aspects of thinking.

Objectives Assess the prevalence of cognitive dysfunction in patients with bipolar disorder in euthymic state and to explore cognitive style problems.

Method Case-control naturalistic study, 60 patients with bipolar I disorder in euthymic state according to DSM-IV were recruited and subdivided into two groups each contains of 30 patients; (Group BPM) euthymic patients with recent manic episode, Group BPD euthymic patients with recent depressive episode. Both groups were further compared with control group (Group C) consisted of 30 frequency matched healthy volunteers. Groups were subjected to the following: (1) clinical psychiatric examination, (2) (HAM-D-17) and Bech-Rafaelsen Melancholia Scale (MES) for (BPD), (3) (YMRS) and Bech-Rafaelsen Mania Scale (MAS) for (BPM), (4) assessment of euthymic state of mood included both MAS and MES, (5) MMSE, MTS and CDT were performed to assess cognitive functions, (6) cognitive styles evaluation the Social Dysfunction and Aggression Scale SDAS-9 and Arabic Anger Scale.

Results Definite cognitive function impairment and different patterns of cognitive style were detected in case groups. MMSE, MTS and CDT scores were statistically significant. Fear of Failure Scale Scores were higher in BPM; 16 (53.33%) reported severe intensity compared to 16 (53.33%) of BPD Group reporting moderate intensity and 30 (100%) of the control group reporting only mild intensity of fear of failure with statistically significant differences.

Conclusions Patients in euthymic state suffer from cognitive dysfunction and some aspects of cognitive styles that negatively interfere with their performance.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Improving and assessing public beliefs, knowledge and attitudes towards bipolar disorder in Pakistan

S. Zaidi

Fatima Jinnah medical university, Sir Ganga Ram hospital, Lahore, Pakistan

Background Studies have shown that beliefs, attitudes and knowledge towards bipolar disorder are influenced by country-specific social and cultural factors. Our study aims to improve and assess public beliefs, knowledge and attitude towards bipolar disorder in Pakistan.

Methods We targeted 500 population. A questionnaire was organized into four sections in order to investigate knowledge about bipolar disorder, attitudes and beliefs, treatment options and fighting stigma and help seeking attitudes.

Results Of the 500 participants, 28% people were aware of exact definition of bipolar disorder. A widespread belief (85%) was that people suffering from bipolar disorder should avoid talking and telling about their illness. According to 50% respondents people experiencing bipolar disorder “are dangerous to others”, 68% population viewed it as a result of black magic. Sixty-five per cent thought that the best way to recover from bipolar disorder consisted in seeking help from Psychiatrist. Twenty per cent thought to take help from religious people and shrines. Most of people seemed convinced that drugs are addictive (70%) and may cause serious side effects (80%).

Conclusions Mental health illness including bipolar disorder can be improved by the positive influence of education, employment availability, respect, social support, rehabilitative services, justice and equity. Lack of education, stigmatization, and cultural norms are the leading barriers towards.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

EW0028

Association between HbA1c and number of episodes in individuals with bipolar disorder

F. Fellendorf

Medical University of Graz, Psychiatry, Graz, Austria

Introduction Bipolar disorder (BD) is associated with an impaired glucose metabolism (IGM) leading to diabetes mellitus Type II (DM). DM influences the medical state of BD individuals and leads to increased mortality. However, there is evidence that IGM is associated with psychiatric symptoms, as well.

Aim The study aimed to investigate the association between IGM and number of episodes and their ratio in individuals with BD, separated for gender.

Methods HbA1c levels from fasting blood were measured of 162 individuals (46% females) with BD. Furthermore, clinical parameters e.g. number of depressive and (hypo)manic episodes were gathered.

Results After adjustment for illness duration and BMI there was a positive correlation in male individuals between HbA1c and number of depressive ($M = 13.86$, $SD = 14.67$; $r = .308$, $P < 0.05$) as well as (hypo)manic episodes ($M = 17.23$, $SD = 24.24$; $r = 0.263$, $P < 0.05$). There was no association in females as well as between HbA1c levels and ratio of episodes.

Conclusion Associations between HbA1c and number of episodes in male individuals with BD were found. As there are correlations between IGM and somatic co-morbidities as well as the course of illness the treatment of glucose metabolism is important in BD. However, number of episodes might have an impact on the glucose metabolism due to inflammation processes, but further investigations have to focus on the direction of the found correlation. As gender differences are known in different pathways, they should be considered in research, diagnosis and therapy.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Gender difference among admitted patients with bipolar disorder in a psychiatric service during a three-year period

M. Fernandes*, D. Mota, A. Olivera, J. Ribeiro, S. Silva, V. Santos, N. Madeira, P. Celsa, Z. Santos

Centro Hospitalar e Universitário de Coimbra, Centro de Responsabilidade Integrada em Psiquiatria e Saúde Mental, Coimbra, Portugal

* Corresponding author.

Introduction Gender differences in bipolar disorder are becoming apparent, but have been less studied compared with major depression. The presentation, clinical features, course and evolution of bipolar disorder differ between men and women. Research data on these differences will help determine whether gender is important in influencing illness variables.

Objectives Determine whether men and women with bipolar disorder have statistical significant differences in socio-demographic and clinical data.

Methods Charts of all patients with a diagnosis of bipolar disorder admitted in the Coimbra Hospital and University Center over a three-year period (between 2013 and 2015) were reviewed to gather data on socio-demographic, clinical and psychopathological variables to assess differences across genders. Statistical analysis of data with “SPSS21”.

Results During a three-year period, 189 patients were admitted with bipolar disorder, the majority were female patients, with ages between 21 and 84 years old. The authors will analyse if there is any statistical significant difference between gender in the rate of bipolar I or II diagnoses, age at onset, symptom presentation, delay in diagnoses, number of depressive, or manic episodes, hospitalisations, involuntarily admissions, number of suicide attempts, co-morbidity rates, negative life events, family history and treatment options. Sociodemographic characteristics will also be analysed.

Conclusion Gender differences in bipolar disorder is a controversial issue in the literature. The importance of gender on the course and outcome in bipolar disorder has been widely acknowledged. The limited data suggest that the prevalence is similar between sexes but that the course of illness may be different.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Type I and type II classification of bipolar disorder (BD) may not provide useful information to the clinician regarding epidemiological and clinical correlates.

New classifications have recently been proposed, such as the Predominant Polarity (PP) classification, which is based on the tendency of the patient to relapse in the manic (Manic Predominant Polarity [MPP]) or the depressive (Depressive Predominant Polarity [DPP]) poles along the course of the disease.

Objectives To explore the epidemiological and clinical correlates of PP.

Methods We performed a search of the PubMed and Web of Science databases up to June 1st 2016, using the keywords “bipolar disorder”, “polarity” and “predominant polarity”.

Results The initial search identified 1598 articles. Only 17 articles met inclusion criteria. Factors associated with MPP are manic onset, history of drug abuse and a better response to atypical antipsychotics and mood stabilizers. Meanwhile DPP is associated with depressive onset, more relapses, longer acute episodes, and a higher risk of suicide. Moreover, delay until diagnosis, mixed episodes and comorbid anxiety disorders are more prevalent in DPP patients, whose treatment often involves quetiapine and lamotrigine.

Limitations Few prospective studies. Variability of results.

Conclusions PP classification may be useful for the clinical management of BD. Further research in this field is needed. Future research should use standardized definitions and more comparable methods.

Late onset bipolar disorder: Clinical characterization

J. Gomes*, A. Sousa, H. Afonso, G. Lima

Centro Hospitalar Barreiro-Montijo, Psychiatry, Barreiro, Portugal

* Corresponding author.

Introduction Bipolar disease is a chronic mental illness with a deep personal and social impact. Alongside with the considerable progress in understanding and treating bipolar disorder, and despite the growing interest in geriatric psychiatry, late onset bipolar disorder has been relatively little studied so far.

Objectives To review the literature regarding the epidemiology, characteristics and clinical implications of late onset bipolar disorder.

Methodology A literature review was performed by searching articles in Pubmed, using the following search terms: “late onset bipolar disorder” and “elderly bipolar disorder”. All literature in English published in the last 15 years was examined and 11 articles were selected.

Results Although the frequency of bipolar disorder type 1 or 2 decrease with age, approximately 6 to 8% of the new cases of bipolar disorder develop in people over 60 years of age. Clinically, late-onset bipolar disorder appears to be associated with a better level of pre-morbid functioning, a less severe psychopathology as well as a smaller family burden of psychiatric illness. The term “secondary mania” postulated by Krauthmamer Klerman has been used to describe a bipolar disease variant associated with a variety of organic factors that may be responsible for this late-onset disease.

Conclusions Late onset bipolar disorder is probably a different diagnostic than the entity that occurs in younger patients, since it presents with a different clinical presentation. It is a heterogeneous disease with a complex etiology that still needs more research.

High cognitive reserve in bipolar disorders as a moderator of neurocognitive impairment

I. Grande^{1,*}, J. Sanchez-Moreno¹, B. Solé¹, E. Jimenez¹, C. Torrent¹, C.D.M. Bonnín¹, C. Varo¹, R. Tabarés-Seisdedos², V. Balanza-Martínez³, E. Valls¹, I. Morilla¹, A.F. Carvalho⁴, J.L. Ayuso-Mateos⁵, E. Vieta¹, A. Martínez-Arán¹

* Corresponding author.

Background Cognitive reserve (CR) reflects the capacity of the brain to endure neuropathology, minimize clinical manifestations and successfully complete cognitive tasks. The present study aims to determine whether high CR may constitute a moderator of cognitive functioning in bipolar disorder (BD).

Methods One hundred and two patients with BD and 32 healthy controls were enrolled. All patients met DSM-IV criteria for I or II BD and were euthymic (YMRS \leq 6 and HDRS \leq 8) during a 6-month period. All participants were tested with a comprehensive neuropsychological battery, and a Cerebral Reserve Score (CRS) was estimated. Subjects with a CRS below the group median were classified as having low CR, whereas participants with a CRS above the median value were considered to have high CR.

Results Participants with BD with high CR displayed a better performance in measures of attention (digits forward: $F=4.554$, $P=0.039$); phonemic and semantic verbal fluency (FAS: $F=9.328$, $P=0.004$; and Animal Naming: $F=8.532$, $P=0.006$); and verbal memory (short cued recall of California Verbal Learning Test: $F=4.236$, $P=0.046$), after multivariable adjustment for potential confounders, including number of admissions and prior psychotic symptoms.

Conclusions High cognitive reserve may therefore be a valuable construct to explore for predicting neurocognitive performance in patients with BD regarding premorbid status.

Cognitive function in older euthymic bipolar patients

K. Hajbi, I. Baati, S. Ellouze, S. Mkaouer, I. Abida, J. Masmoudi*
CHU Hédi Chaker Sfax, Tunisia, psychiatry “A”, Sfax, Tunisia

* Corresponding author.

Objectives To assess cognitive function in older euthymic bipolar patients. To investigate the relationship between cognitive disorders and clinical features in this population.

Methods We conducted a cross-sectional study during the period from August to November 2015. It included 34 stable bipolar outpatients, aged at least 65 years. We used the Montreal Cognitive Assessment (MoCA) to screen for cognitive disorders. Our patients were clinically euthymic, as checked by the Hamilton depression scale and the Young mania scale.

Results The sex ratio was 1. The mean age of our patients was 68.2 years. Most of them were married (82.4%), unemployed (55.8%),

living in urban area (82.4%), had low educational level (58.8%) and low income (64.7%).

The majority was bipolar type 1 (67.6%). The most recent episode was manic in 55.9% of cases, including psychotic features in 50% of cases. Subsyndromal affective symptoms were noted between episodes in 23.5% of them. The average MoCA score was 23.6. Cognitive disorders were found in 61.5% of patients, who showed impairments across all cognitive domains. The most frequent deficits were found in attention (100%) and executive functions (85.3%).

Cognitive dysfunction correlated to psychotic features during the last episode ($P=0.005$), subsyndromal affective symptoms between episodes ($P=0.13$), high number of mood episodes ($P=0.007$) and hospitalisations ($P=0.014$).

Conclusion Our study confirmed that cognitive dysfunction was frequent in older bipolar patients in Tunisia. Preventing mood episodes, screening for addictive and somatic co-morbidities, as well as cognitive rehabilitation, are suitable strategies for improving cognitive functioning among these patients.

¹ Hédi Chaker University Hospital, Psychiatry, Sfax, Tunisia

² Hédi Chaker University Hospital, Psychiatry 'B' department, Sfax, Tunisia

³ Chaker University Hospital, Psychiatry 'B' department, Sfax, Tunisia

* Corresponding author.

Introduction Many studies on the identification and early treatment of psychotic disorders have focussed less on a solution to the issue of the evolution of an acute psychosis.

Objective To identify some predictive elements of an evolution to bipolar disorder during a first psychotic episode.

Methods We proceed with a retrospective study concerning 55 patients having developed a first psychotic episode and admitted in the psychiatry B department during the period extending between January 2010 and December 2015. Data were collected on a predetermined questionnaire exploring the following items (socio-demographic data, personal and psychiatric family antecedent, prodromes and psychotic episode symptomatology).

Results Our sample was composed by 55 patients divided into 74% ($n=41$) men and 26% ($n=14$) women with a mean age of 26.5 ± 6.27 years. The evolution to a bipolar mood disorder concerned 22% of patients. The prodromal phase was always present. Prodromes correlated with progression to bipolar disorder are: thymic symptoms 44.1% of patients ($P=0.001$), modification of volition 42.9% ($P=0.05$), anger/irritability 66.7% ($P=0.032$) and sadness 83.3% of patients ($P=0.05$). Psychotic episode's symptoms correlated with the evolution towards a bipolar disorder corresponded to thymic symptoms. The latter was present in 44.1% of patients ($P=0.01$).

Conclusion Through our study, we were able to identify some factors positively correlated with a progression towards bipolarity during a first psychotic disorder. So it would be important to monitor closely and to educate our patients and their families about the evolutionary potential of a first psychotic episode.

Emotional face recognition in bipolar disorder

C. Homorogan*, R. Adam, R. Barboianu, Z. Popovici, C. Bredicean, M. Ienciu

Clinical Hospital, Psychiatry, Timisoara, Romania

* Corresponding author.

Introduction Emotional face recognition is significant for social communication. This is impaired in mood disorders, such as bipolar disorder. Individuals with bipolar disorder lack the ability to perceive facial expressions.

Objectives To analyse the capacity of emotional face recognition in subjects diagnosed with bipolar disorder.

Aims To establish a correlation between emotion recognition ability and the evolution of bipolar disease.

Methods A sample of 24 subjects were analysed in this trial, diagnosed with bipolar disorder (according to ICD-10 criteria), who were hospitalised in the Psychiatry Clinic of Timisoara and monitored in outpatients clinic. Subjects were introduced in the trial based on inclusion/exclusion criteria. The analysed parameters were: socio-demographic (age, gender, education level), the number of relapses, the predominance of manic or depressive episodes, and the ability of identifying emotions (Reading the Mind in the Eyes Test).

Results Most of the subjects (79.16%) had a low ability to identify emotions, 20.83% had a normal capacity to recognise emotions, and none of them had a high emotion recognition capacity. The positive emotions (love, joy, surprise) were easier recognised, by 75% of the subjects, than the negative ones (anger, sadness, fear). There was no evident difference in emotional face recognition between the individuals with predominance of manic episodes than the ones who had mostly depressive episodes, and between the number of relapses.

Conclusions The individuals with bipolar disorder have difficulties in identifying facial emotions, but with no obvious correlation between the analysed parameters.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Treatment with risperidone vs. olanzapine in naturalistic study of bipolar manic inpatients

I. Ibanez Plans*, E. Nieto, S. Biel

Hospital San Joan de Déu, C/Dr. Soler S/N, Manresa 08243,

Department of Psychiatry of Althaia Xarxa Assistencial of Manresa, Manresa, Spain

* Corresponding author.

Introduction There are very few comparative controlled trials of risperidone versus olanzapine in manic patients. No previous naturalistic study has compared the efficacy of these two antipsychotics in the natural environment of manic inpatients.

Objective The aim of this retrospective and naturalistic study was to evaluate the efficacy of acute treatment with risperidone vs. olanzapine in Bipolar I manic inpatients.

Methods (1) Patients: the study includes all the inpatients diagnosed with bipolar I manic episode (DSM-IV) who were admitted during the years 2009 to 2014. Patients treated with risperidone and olanzapine concomitantly ($n=6$) and patients not treated with risperidone or olanzapine ($n=129$) were excluded. The patients finally included ($n=183$) were separated in two groups:

- treated with risperidone ($n=89$);
- treated with olanzapine ($n=94$).

(2) The Student-T test was used to compare, between the groups, the mean of scores in YMRS and CGI-S scales and the mean of length of stay.

Results Baseline characteristics were similar between the groups. The majority of patients were also treated with mood stabilizers (46% with lithium and 45% with valproate).

The mean decrease in CGI-S scores from baseline to the day of discharge was significantly ($P < 0.003$) higher in the risperidone group (-2.81 vs. -2.36). The length of stay was significantly ($P < 0.004$) lower in the olanzapine group (mean of 23.03 days vs. mean of 30.3).

Conclusions (1) The CGI-S scores in manic patients treated with risperidone decreased more than in patients treated with olanzapine during admission. (2) The length of stay was significantly lower in patients treated with olanzapine.

Switching bipolar disorder patients treated with clozapine to another antipsychotic medication: A mirror image study

P. Ifteni*, A. Teodorescu

Universitatea Transilvania din Brasov, Facultatea de Medicina, Brasov, Romania

* Corresponding author.

Introduction Bipolar disorder (BD) is associated with periodic symptoms' exacerbations, leading to functional impairment, substance abuse, and increased risk of suicide and accidents. Clozapine has never been approved for the treatment of BD but it is used in severe episodes.

Aims The aim of the study is to evaluate the risks and benefits of switching remitted BD patients treated with clozapine to another antipsychotic medication.

Objectives We assessed the proportion of relapsed patients after switching clozapine, time until relapse, type of relapse and the number of admissions.

Methods This was an observational, mirror image study of 62 remitted BD outpatients treated with clozapine. Following a change in drug reimbursement rules by which clozapine was no longer reimbursable for patients with BD, 25 patients were switched to another antipsychotic and the rest of 37 continued on clozapine agreeing to pay treatment.

Results The mean score of CGI-BP at admission in study was in on both groups almost similar (2.3 vs. 2.4). After switching, a significant proportion of patients relapsed (77%), in 100% cases with a manic episode requiring hospitalisation. The mean YMRS score at relapse was significantly higher compared with the evaluation at the time prior to switching (31.78 (SD = 9.72) vs. 11.99 (SD = 7.29), $P < 0.01$).

Conclusions Despite the limitations of this naturalistic study, the results suggest that switching from clozapine to another antipsychotic may increase the risk of relapses in remitted patients with BD. The risks, costs and consequences of symptoms exacerbation should be weighed against the quest to control pharmacy costs.

Treating cognitive impairments in bipolar disorders: New leads in the cognitive remediation field

C. Isaac^{1,*}, M.C. Castillo², D. Januel¹

¹ EPS Ville Evrard, Unité de Recherche Clinique, Neuilly-Sur-Marne, France

² Université Paris 8, Laboratoire de Psychopathologie et de Neuropsychologie, Saint-Denis, France

* Corresponding author.

Cognitive deficits have been overlooked in bipolar spectrum disorders, despite their significant impact on patients' quality of life. Indeed, nearly sixty percent of stabilized bipolar patients suffer from major cognitive impairments that impede their everyday life functioning. Without proper care, these impairments remain throughout lifespan and increase with hospitalisations, social isolation or pharmacological treatments. Cognitive remediation is a cost-effective tool well accepted by patients and caregivers that has proven its efficacy for treating cognitive impairments in several disorders such as schizophrenia. However, for bipolar disorders, this psychosocial intervention based on brain plasticity is still in its early stages. After depicting the state of the art on cognitive impairments and cognitive remediation in mood disorders, we will introduce the ECo program that was specifically designed for bipolar disorders. We will then present the preliminary results ($n = 18$) of a double-blind randomised controlled study that assessed the effect of this program on cognitive impairments and psychosocial functioning, at short term and long term (three and nine months). First results support the hypothesis of a positive impact of the ECo cognitive remediation program on bipolar patients' neuropsychological functioning, self-efficacy and quality of life. Cognitive remediation may be a promising tool for bipolar disorders that meets the needs of patients, their caregivers and the community.

Bipolar disorder and cannabis

G. Jmii*, M. Zghal, F. Ghali, M. Mezghenni, L. Jouini, L. Robbana, F. Ellouze, F. Mrad

Razi Hospital, Department of Psychiatry G-, Tunis, Tunisia

* Corresponding author.

Introduction People with bipolar disorder frequently struggle with substance abuse and dependence. Typically, cannabis is the most commonly abused drug in individuals with bipolar disorder. Some investigators have implied that cannabis may actually be mood stabilizing in patients with bipolar disorder. However, the relationships between cannabis use and bipolar disorders are complex and remain incompletely described.

Objective The aim of this study was to identify the characteristics of addiction to cannabis in bipolar patients type I and determine the consequences of cannabis on the expression of bipolar illness and prognosis.

Methods This is a comparative cross-sectional study which included patients followed in the psychiatry department of the G Razi hospital for bipolar disorder type I and for substance dependence according to DSM IV diagnostic criteria. Hetero-questionnaire on sociodemographic variables, clinical and treatment.

Results The average age was 41 years. The average hospital stay was 9.18 days. 33.33% of patients were monitored regularly. Most patients were single and worked as a day labourer. Cannabis was the most consumed substance. Cannabis use was prior to the expression of psychiatric illness in 55% of cases. The average number of hospitalisation in patients with a cannabis addiction was significantly greater than that observed in the non-addicted group.

Similarly, the average number of suicide attempts among patients with cannabis addiction was significantly higher than the group without cannabis addiction.

Conclusions Aggressive drug abuse treatment immediately after a first psychiatric hospitalisation might decrease rates of recurrence and new cases of cannabis use disorder in the course of bipolar disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The role of micrnas in regulating redox modulation in bipolar disorder

H. Kim^{1,*}, K. Tyryshkin¹, N. Elmi¹, V. Oliviera², A. Andreazza³, H. Feilotter¹

¹ Queen's University, Pathology and Molecular medicine, Kingston, Canada

² University of Toronto, Department of Psychiatry, Toronto, Canada

* Corresponding author.

Introduction Alterations in redox modulation are consistently reported in bipolar disorder (BD). MicroRNAs are targeted regulators of gene expression.

Objectives and aims We aimed to examine if microRNAs that target redox modulators can discriminate between BD and healthy controls.

Methods Data from brains of individuals with and without BD were obtained from Array Collection datasets. MicroRNAs targeting redox modulators were assessed for their ability to discriminate BD from the control group using machine-learning algorithms. Methylation of microRNAs, expression of their transcription factors and redox targets were assessed with ANCOVA with FDR correction. For validation, we acquired plasma samples belonging to 2 families of individuals with and without BD ($n=9$). Plasma microRNAs were sequenced using the Ion Total RNA Sequencing Kit (Thermo Fisher Scientific), and microRNAs identified from the in silico analysis were examined in the validation dataset.

Results We identified 5 miRNAs (hsa-miR-299, hsa-miR-125a, hsa-miR-145, hsa-miR-30b, hsa-miR424) that were common in two of the four in silico datasets. Target genes glutathione peroxidase 4, ATP5A1, ATP5G1, NDUFS1, NDUFC2, and catalase were expressed at different levels between BD and the control group. Furthermore, our results showed that transcription factors CTCF and USF1 might control the expression of hsa-miR-145, while methylation differences were not found. Finally, hsa-miR-30b was significantly increased in the plasma of patients with BD compared to controls in the validation experiment.

Conclusions Our study demonstrates that microRNAs may have an important role in the initiation of redox changes in BD.

Co-morbid obsessive-compulsive disorder and bipolar disorder in highly endogamous population: Which came first?

A. Bener

Istanbul University, Biostatistics and Public Health, Istanbul, Turkey

The aim of this study was to determine the prevalence of co-morbidity with obsessive-compulsive disorder (OCD) among bipolar disorder (BD) patients in order to assess the impact of

OCD on the socio-demographic and clinical features of patients in a highly endogamous population. A cohort study was carried out on 396 patients enrolled between November 2011 to October 2013. We employed the WHO Composite International Diagnostic Interview (WHO-CIDI) and Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition-IV/Clinical Version for diagnoses, the Yale-Brown Obsessive Compulsive Scale Symptom Checklist for scoring OCD. Patients were grouped in BD patients with OCD (BD-OCD) and BD patients without OCD.

Groups were compared for socio-demographic and clinical variables. There were no significant differences for age, gender, BMI, and marital status, between BD patients with and without OCD. We found significant differences in level of education ($P=0.022$), occupation status ($P=0.025$), household income, ($P=0.049$), cigarette smoking ($P=0.038$), sheesha smoking ($P=0.007$), and prevalence of consanguinity ($P=0.036$) among these groups. Number of hospitalizations and Young Mania Rating Scale score were not different among BD patients with or without OCD whereas there were significant differences in Hamilton-Depression score, Clinical Global Impression-BD Score, duration of illnesses, and Global Assessment of Functioning (GAF). Also specific phobia, somatization, depression, mania, any mood disorder, oppositional defiant disorder, ADHD and personality disorder were more common in BD than OCD-BD group. This study confirms that BD-OCD is a common comorbidity, largely under-recognized in clinical practice, which may significantly change BD presentation and outcome.

A comparison between manic patients with or without antipsychotic continuation treatment: Data from a 12-months follow-up study at mood disorder unit of San Raffaele-Turro hospital

S. Brioschi^{1,*}, D. Delmonte¹, C. Locatelli¹, L. Franchini¹, B. Barbini¹, C. Colombo²

¹ IRCCS San Raffaele-Turro, Division of Neuroscience, Milano, Italy

² Vita-Salute University, San Raffaele Hospital, Division of Neuroscience, Milano, Italy

* Corresponding author.

Introduction Several studies suggest that in severe bipolars there is a long-term benefit in continuing antipsychotic therapy plus a mood stabilizer also after remission from a manic episode. Nevertheless, the long-term use of antipsychotics is associated with significant side effects which can interfere with patient global functioning. In this sense, antipsychotics should not be continued unless the benefits outweigh the risks.

Objectives The present study describes the course of illness between bipolar patients remitted from a manic episode, in continuation treatment with or without antipsychotic therapy during a 12-months follow-up period.

Methods Cinquante-six bipolars (22 male and 44 female) remitted (Young < 12) from a severe manic episode were observed during a 12-months follow-up. According to clinical judge, as continuation treatment, 21/56 (37.5%) took antipsychotic plus mood stabilizer (AP+MS); 35/56 (62.5%) took mood stabilizers monotherapy (MS). During follow-up period YMRS and HAM-D were administered at 6th and 12th month to verify remission.

Results At the end of follow-up up, 33/56 patients (58.9%) maintained remission, 23/56 (41.1%) relapsed (56.5% depressive, 31.4% manic). The greater number of relapses occurred within 6th month: 16/56 (28.8%). In AP+MS group 12/21 patients relapsed (57.14%); in

MS group 11/35 patients relapsed (31.4%). No statistical difference between the two continuation treatment strategies was observed (Chi-square = 3.586; $P = 0.06$).

Conclusions Our data confirm the efficacy of mood stabilizers monotherapy in long-term treatment of our severe (psychotic features, revolving-doors) bipolar patients. In fact, once the remission was obtained, the clinical choice of discontinuing antipsychotic therapy did not worsen the course of illness without a higher risk of relapse.

A psychometric evaluation of the Parents as Social Context Questionnaire (PASCQ), Swedish version

R. Addo*, C. Åslund, K. Nilsson

Landstinget Västmanland, Centre for Clinical Research Västerås, Västerås, Sweden

* Corresponding author.

To understand parent and child relations researchers have used three bipolar dimensions (warmth and rejection, structure and chaos, autonomy support, and coercion). These dimensions are not necessarily bipolar but could work as unipolar dimensions. The Parents as Social Context Questionnaire (PASCQ) has been used in parenting studies but needs to be further investigated in different populations to ensure the validity and reliability of the scale. The present study explored the structures of and provided evidence regarding validity and reliability of the PASCQ. This study aimed to examine whether the Swedish version of the PASCQ is a reliable questionnaire when measuring the six dimension of parenting. The participants consisted of 1634 adolescents (58.6% females) born in 1997 (52%) and 1999. Factor analyses were conducted to investigate whether the Swedish scale generated six dimensions. Regression analyses were conducted to measure the different factors and spearman correlations between dimensions were conducted. The analysis indicates that the PASCQ consists of five dimensions, however rejection (negative) and warmth (positive) loaded on the same dimension and are referred to as two separate factors, making the questionnaire consistent of six dimensions. All items had a factor score >0.4 and loaded in a coherent manner. Therefore, the PASCQ can be used to assess six dimensions of parenting styles. The PASCQ Swedish version can be used as a measure of parenting styles in a Swedish population. Further research is necessary to evaluate the validity and reliability in other samples as well.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Child sexual abuse (CSA) is a major global health problem with serious adverse effects at later ages. Our paper examines the prevalence rates and the demographic and clinical predictors of CSA among adult psychiatric outpatients. A data assessment tool was used to compile information on the demographic and clinical characteristics of all new patients assessed in four psychiatric outpatient clinics between 1st January 2014 and 31st December 2015. The 12-month prevalence rate for CSA among new psychiatric outpatients in Fort McMurray was 20.7% (10.7% for males and 26.9% in females). With an odds ratio for sex of 3.30 (CI = 2.06–5.29), female patients are about three times more likely to report a history of CSA compared to male patients when controlling for other factors. Similarly patients with at most high school education (OR = 1.8, CI = 1.145–2.871) and those with previous contact with psychiatric services (OR = 1.7, CI = 1.124–2.616) were about two times more likely to report a history of CSA compared to the patients with college/university education or those with no previous contact with psychiatric services respectively. Similarly, patients with histories of substance abuse (OR = 1.5, CI = 1.179–2.642) and patients with family histories of mental illness (OR = 1.8, CI = 1.032–2.308) had higher likelihoods of reporting histories of CSA compared to patients without histories of substance abuse or family histories of mental illness respectively. Our findings suggest that victims of CSA are an at-risk population in need of ongoing mental health and educational support.

* Corresponding author.

Introduction Nurturing children with neurodevelopmental disorders such as ADHD is associated with psychological burden to the caregivers. Oman has a pyramidal population structure with the bulk of the population are in the pediatric age group. Previous studies have indicated that ADHD is common in Oman.

Objectives To measure level of burden of care among caregivers of children with ADHD and the relationship between the degree of burden, subtypes of ADHD and socio-demographic factors.

Methods A cross sectional study conducted in a tertiary hospital in Oman. Arabic-version of the Zarit Burden Interview (ZBI) was used to evaluate the level of burden among the caregivers. The severity and subtypes of ADHD were quantified using Vanderbilt ADHD Parent/Teacher Rating Scale. Socio-demographic background and clinical data were gathered from medical records.

Results The study included caregivers of 100 children with ADHD. The mean ZBI score was significantly high for the parents of children with ADHD. As for the relationship with socio-demographic background, mothers of children with ADHD reported a higher mean ZBI score compared to fathers. Factors such as income, number of siblings, and severity/subtypes of ADHD played significant roles.

Conclusion To our knowledge, this is the first study of Arab/Islamic population exploring the burden of care for children

with ADHD. Some of the risk factors appear to have direct effects. If this study will withstand further scrutiny, concerted effort is needed in emerging economies such as Oman to address the issue of burden among the caregivers of children with ADHD.

Caregiver depression screening in a child and adolescent clinic seeking consultation for their children with attention-deficit/hyperactivity in Oman

N. Al Balushi^{1,*}, A.A. Samir²

¹ Sultan Qaboos University, child and adolescent Psychiatry, Barka, Oman

² Sultan Qaboos University, psychology, Muscat, Oman

* Corresponding author.

Introduction Studies have shown that caregivers of children with (ADHD) are at a higher risk of mood disorders such as depression. The presence of mood disorders among the caregivers of children with ADHD has negative repercussion in terms of prognostic indicator, utilization of the health care service and the resultant quality of life.

Objectives To solicit the performance of indices of depression among caregivers of children with ADHD and to explore the relationship between severity of mood score, subtypes of ADHD and socio-demographic factors.

Methods A cross-sectional study conducted in a tertiary hospital in Oman dispensing child and adolescent mental health services. Arabic-version of PHQ-9 was used screen for the presence of depression among the caregivers of children diagnosed with ADHD based on DSM 5. The severity and subtypes of ADHD were quantified using Vanderbilt ADHD Parent/Teacher Rating Scale. Socio-demographic background and clinical data were gathered from medical records or attending caregivers.

Results The study included 100 caregivers of children with ADHD. Most of the primary caregivers were mothers (92%). Using the cut-off score of 12 on the PHQ-9, rates of depression for the mother was 14%. Some socio-demographic factors were strongly associated with severity of depressive symptom.

Conclusion This study suggests that depressive symptoms as elicited by PHQ-9 are common among caregivers of children with ADHD. The rate of depressive symptoms is higher compared to the general population in Oman. This study lays groundwork for contemplating mechanisms to mitigate depressive symptoms among caregivers of children with ADHD.

Prevalence of attention deficit hyperactivity disorder among primary school children in Riyadh, Saudi Arabia; 2015–2016

T. Albatti, Z. ALHedyan*

King Saud University and King Khalid University Hospital, Child and adolescents psychiatry department, Riyadh, Saudi Arabia

* Corresponding author.

Introduction ADHD is one of the most common neurodevelopmental disorder among children. It is described as a chronic impairing disorder that negatively affects the academic attainment and social skills of the child. Furthermore, ADHD symptoms con-

tinue into adulthood in 30–60% of affected children. Consequently, they will most likely be missed from employment many times.

Aims Determine the prevalence of attention deficit hyperactivity disorder among children in Saudi Arabia.

Objectives Determine the prevalence of attention deficit hyperactivity disorder among both governmental and private primary Saudi school children aged 6–9-year-old. And to measure the gender difference of ADHD prevalence. Also, to determine any association between the socio-demographic characteristic of parents of children with ADHD.

Methods An observational cross-sectional study of 1000 primary school children belonging to 1st, 2nd and 3rd grade. The selected students were screened by the ADHD rating scale using multistage sampling technique. The first stage was selection of 20 schools from all Riyadh regions by simple randomization. The second stage was choosing children whom serial numbers were multiplies of five in each class. The ADHD rating scale was filled by both parents and teachers along with a socio-demographic questionnaire for the parents.

Results The estimated prevalence of ADHD was 3.4%. ADHD manifestations affect boys more than girls. In addition, ADHD was more frequent among children of illiterate mothers. Finally, ADHD was significantly more prevalent among first grade children.

Conclusion This epidemiological study filled the data gap of ADHD prevalence in Riyadh. The study's findings go in line with many nearby and global studies.

Benzodiazepines intake at youth–experience from adolescent consultation at centro hospitalar Lisboa Norte

C. Almeida*, S. Paulino, M. Croca, N. Santos
Centro Hospitalar Lisboa Norte, Hospital Santa Maria, Serviço de Psiquiatria e Saúde Mental, Lisboa, Portugal

* Corresponding author.

Introduction The increasing intake of psychotropic medication by children and adolescents is a reality that worries many mental health professionals. Recently, European school survey project on alcohol and other drugs showed that tranquillizers and sedatives were mainly consumed by Portuguese youth, without medical prescription, bringing this topic to medical and health stakeholders' attention.

Objectives Characterize benzodiazepine prescription in the youth population followed in a psychiatric consultation at centro hospitalar Lisboa Norte psychiatric department.

Aims Discuss Portuguese trends in mental health among youths. **Methods** Analysis of 127 adolescents, seen for the first time from January to December of 2015, using Microsoft office excel.

Results Our sample is comprised by adolescents from 12 to 20 years old, 81 female and 46 male. Only 16% of the adolescents were medicated with benzodiazepines, although low neuroleptic doses were often required, and 30% carried out psychotherapy. Sixty-five per cent of the diagnosis corresponds to anxiety, depressive and impulse control disorders.

Conclusion Although trends in Portuguese youth mental health seem to be encouraging, as highlighted by local reports, European Union Joint Action on Mental Health and Well-Being recommends community and school active roles in primary and secondary prevention. Our experience shows that benzodiazepines' use is rarely necessary and symptoms as anxiety, impulsivity and insomnia decreased with other strategies. Coping strategies must be discussed with the adolescents, in formal psychotherapy or in a supportive and containing therapeutic relationship, as well as dis-

cussed in family interventions. Community initiatives promotion and increased mental health care services accessibility should be priorities.

Information to improve awareness, contribution to evidence-based practice – What does the Brazilian population know about autism

C. Amato^{1,*}, C. Varanda², F. Fernandes², D. Molini-Avejonas²

¹ Universidade Presbiteriana Mackenzie, Programa de Pós-graduação em Distúrbios do Desenvolvimento, Sao Paulo, Brazil

² Universidade de São Paulo, Departamento de

Fisioterapia-Fonoaudiologia e Terapia ocupacional, Sao Paulo, Brazil

* Corresponding author.

The present prevalence of autism spectrum disorders (ASD) demands changes in health policies highlights barriers that are inherent to the national diversity and therefore poses great challenges to the planning and delivering specialized services. Systematic data regarding the level of knowledge and information about autism in the general population may help in building a set of evidences to support decision-making processes about intervention proposals directed towards this population. Aiming to contribute to evidence-based practice, this study used a digital-delivered questionnaire to assess the knowledge by the general population about autism in Brazil. A self-explanatory questionnaire was made available on-line. It was comprised by 57 questions divided in five domains: data about the answerer; information about how the person had access to the issue of autism; information about the concept of autism (signs, symptoms and etiology); information about the characteristics of persons with autism and what are the professionals that are essential in the team that assists these individuals. Participants were contacted via e-mail and given full information on the nature of the research. They were 4282 persons living in the five large regions of Brazil. Results indicate that most of the participants were mothers, followed by teachers. The analysis of the answers demands consideration of the hypothesis that although most of the participants have answered that they knew what is Autism, this knowledge is based on lay beliefs and not on scientific-based information. This reality must be taken into account when proposing intervention programs directed to persons with ASD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clinico-social character of delinquent form of dissocial (deviant) behavior

T. Aprasidze^{1,*}, M. Tsirekidze²

¹ M. Iashvili Children's Central Hospital, Neuroscience, Tbilisi, Georgia

² O. Gudushauri National Medical Centre, Psychiatry, Tbilisi, Georgia

* Corresponding author.

Introduction Among great variety of the manifestations of juvenile deviation of behavior, with its social significance, delinquency draws a special attention, in particular, with its aggressive manifestation.

Objectives Our task is specification of psychopathological peculiarities of two forms of aggressive behavior of delinquency.

Methods Fifty delinquent juveniles from 14 to 18 years of age (inclusive) have been examined. Two forms of aggressive mani-

festations have been picked out: non-pathological: 36 (72%) and pathological: 14 (28%).

Results Non-pathological aggression basically is conditioned by the influence of micro-social negative conditions and stress situations. The contents of aggressive acts are closely connected with the peculiarities of characterological features; aggressive behavior is characterized with an episodic appearing, less severity and is often manifested in threatening. Marked cruelty, sadism and vandalism are found comparatively seldom. The violation of social adaptation is found in them in stresses, stipulated with negative micro-social factors; they are more manageable and comparatively quickly regress.

The peculiarities of pathological aggression are represented by super valuable and sadistic manifestations, comparatively seldom—with signs of dysphoria. The aggression, stipulated by pathocharacterological reactions is manifested in the form of pathologically super valued and affective situational acts of behavior.

Conclusions Aggressive behavior of delinquency is chiefly observed in its non-pathological form, which can be explained by the hard social-economical background, visible growth of aggressiveness in an immense part of population, moral and ethic deprivation and frustration. The society itself is a certain indicator of aggressiveness.

Regulation disorders of sensory processing—Understanding the complexities of child-parents relationship

B. Baptista^{1,*}, A. Aguiar², S. Melo², M. Araujo¹

¹ Centro Hospitalar de Vila Nova de Gaia Espinho EPE, Psychiatry and Mental Health, Porto, Portugal

² Centro Hospitalar de Vila Nova de Gaia Espinho EPE, Childhood and Adolescence Psychiatry, Porto, Portugal

* Corresponding author.

Introduction Many authors have agreed on the clinical importance of sensory regulation for a child's cognitive, affective and social development. Sensory regulation abilities are fundamental for an efficient modulation of internal states and the development of appropriately graded responses to the constantly changing sensory experiences. Sensory modulation deficit is an essential feature of regulation disorders of sensory processing (RDSP), that is characterized by difficulties in regulating emotions, behaviors and motor abilities, in response to sensory stimulation and lead to impairment in functioning. We also know that, through daily interactions and early relationship (child's attachment), parents play a crucial role on child's regulation in terms of their emotional and physical availability and how they interpret and respond to child needs.

Objective The authors will present a clinical case of a two-year child who has been diagnosed with RDSP, highlighting the main features, types (hypersensitive; hyposensitive/under-responsive; sensory-stimulation seeking/impulsive) and challenges of this disturb.

Aims Explore the association between sensory regulation difficulties, RDSP and child attachment.

Methods Systematic literature review.

Results Recent studies showed the high prevalence of sensory regulation difficulties (33–76%) and insecure attachment (80%) in children with psychiatric disorders. Results also revealed that children with greater sensory impairment were significantly more likely to show elevated scores of insecurity (avoidance and dependence) to their caregiver.

Conclusions This work underscores the caregiver's role as a facilitator of child integration and response to sensory stimuli and its importance on the development of behavioral and emotional disorders. This can help early diagnosis and better treatment who prevent future psychiatric conditions.

Pediatric autoimmune neuropsychiatric syndrome (PANS), developmental regression and autism

S. Bejerot^{1,*}, E. Hesselmark²

¹ Örebro Universitet, School of Medical Sciences, Örebro, Sweden

² Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, Sweden

* Corresponding author.

Introduction Pediatric autoimmune neuropsychiatric syndrome (PANS) is a term used to describe a clinical picture which includes sudden onset of psychiatric symptoms and a possible autoimmune genesis. The sudden decline in neuropsychiatric functioning as well as the multiple combinations of symptoms may lead to a clinical phenotype similar to that in infantile autism (IA) with regressive features. We are conducting a study with the aim to evaluate a diagnostic test for PANS currently marketed by Moleculera Labs. All patients in Sweden who had taken the test ($n = 154$) were invited to the study.

Objectives The aim of the study is to characterize a subgroup of patients with IA within the PANS diagnosis study.

Methods Participants ($n = 53$) were examined for psychiatric and somatic symptoms and evaluated for PANS caseness by an experienced psychiatrist. Because the criteria for entering the study was having taken the diagnostic test for PANS, the participants in the study comprise a group with mixed symptoms.

Results Twelve participants had IA. Eleven of these reported a developmental regression with loss of abilities. Two of the IA patients also fulfill criteria for PANS. Eight of the IA patients had been treated with antibiotics for psychiatric symptoms and 4 reported a positive effect of this treatment. Nine of the patients had elevated test results suggesting possible PANS according to Moleculera Labs.

Conclusions Very early onset on PANS may be phenotypically similar to IA with regressive features. Further analysis of the immunological attributes of patients with autism with regressive features is warranted.

Psychoaffectives repercussions of autism on parents

R. Ben Soussia*, A. Bouallagui, S. Khouadja, I. Marrag, M. Nasr
CHU Tahar Sfar, Psychiatry, Mahdia, Tunisia

* Corresponding author.

Introduction Caring for a child with autism is a stressful experience for parents. The daily stress of this handicap has a major impact and triggers in the parents a series of adverse psychological reactions.

Aim To reveal sociodemographic characteristics of parents of autistic children and to estimate the prevalence of anxiety and depressive symptoms among these parents.

Methods A cross-sectional study conducted among parents of autistic children supported by four of autistic children rehabili-

tation centers under the Tunisian Association for the Promotion of Mental Health. Data were collected through a questionnaire to explore the sociodemographic data of parents of autistic children. Depressive symptoms were assessed by the Beck scale and anxiety symptoms by the Hamilton scale.

Results Fifty-two parents were collected. The middle age was 35.73 years. They lived in an urban area in 96% of cases. The majority had an average socioeconomic level (88.4%). The respective rates of depressed or anxious parents as Beck scales and Hamilton were 48% and 23%. The association between depressive and anxious symptoms was found in 19%. In addition, depression was more common in mothers ($P < 10^{-4}$) and anxiety was also more evident among mothers ($P = 0.01$).

Conclusion The presence of an autistic child causes profound changes in families and can be a source of tension and stress. The anxious and depressive impact on parents is important and frequent. The intervention that designs the psychiatrist to help children with autism should necessarily include an action for parents.

Introduction Anxiety and mood disorders are common in adolescence and predict poor mental health outcomes and low quality of life in adulthood. Although early intervention seems to be critical, dropouts in the early stages of treatment are frequent and associated with low insight and severe symptoms. Therefore, a diagnostic assessment phase aimed to increase insight and early reduce symptoms appears to be essential in adolescents.

Objectives The objective of this study is to demonstrate that the diagnostic method Cooperative Assessment is able to early reduce symptoms in adolescents with anxiety and mood disorders.

Methods A sample of 88 patients, aged 14–19 years were included. All were recruited at the first visit and evaluated with the Cooperative Assessment. This manualized procedure was created from principles of collaborative and therapeutic assessment and aim to involve the patient in a co-developed diagnosis thor-

ough the collaborative use of test results. Patients were evaluated before (T0), in the middle (T1) and after (T2) the assessment using CGI, GAF, HAM-A, HAM-D and MRS scales.

Results Eighty-eight adolescents, 56.8% females, diagnosed with anxiety (47.7%) and mood disorders (52.3%) completed the protocol. HAM-A, HAM-D, MRS, CGI and GAF significantly improved at T1 and T2 with respect to T0 (T0: HAM-A 17.31 ± 8.22 ; HAM-D 16.97 ± 8.37 ; MRS 5.78 ± 6.17 ; GAF 59.3 ± 11.06 ; CGI 3.63 ± 1.35 ; T2: HAM-A 11.41 ± 6.82 ; HAM-D 11.1 ± 6.91 ; MRS 3.82 ± 3.87 ; GAF 67.5 ± 10.76 ; CGI 3.03 ± 1.26 ; $P < 0.001$; Wilcoxon signed-rank test for repeated measures).

Conclusions Cooperative assessment is able to early improve symptoms in adolescents with mood and anxiety disorders.

Organizational skills training for children with ADHD

A. Bikic^{1,*}, D. Sukhodolsky², S. Dalsgaard³

¹ Child and Adolescents Health Services, Region of Southern Denmark, Aabenraa, Denmark

² Child Study Center, Yale School of Medicine, New Haven, United States

³ National Centre for Register-based Research, Department of Economics and Business- Aarhus University, Aarhus, Denmark

* Corresponding author.

Introduction In addition to problems with inattention and hyperactivity, children with ADHD show poor organizational skills required for managing time and materials in academic projects. Poor organizational skills are associated with academic underachievement as well as psychosocial, occupational and economic difficulties. Behavioral approaches for ADHD are effective in reducing hyperactivity symptoms and behavioral problems, but the effects on academic functioning have been modest. An increasing emphasis on treatment of organizational skills has emerged in recent years, as difficulties with time management and organization of materials tend to persist and increase with age despite medication and behavioral treatments.

Objectives The primary objective is to investigate whether organizational skills training has a positive effect on organizational skills. The secondary and exploratory objectives are to investigate the effect on ADHD symptoms, adaptive functioning, academic performance and cognitive functions with a 24 weeks follow up.

Aims Our goal is to provide cost-effective group-based treatment for children with ADHD and their parents. This will be the first randomized and controlled trial of organizational skills in Denmark. **Methods** Participants are included in two sites in Southern Denmark and will be randomized to Organizational skills training or treatment as usual. Organizational skills training will be provided in a group format for children and parents over 10 weeks.

Perspectives Given the strong association between organizational skills and functional outcome, it is very important to address organizational skills in children and adolescents with ADHD as organizational skills deficits hinder the academic performance of even gifted students with ADHD and increase with age.

EW0056

Children with somatic symptoms disorders and disruptive behavior disorder: Which is the role of anger to caregivers?

F. Bizzi

University of Genoa, Department of Educational Sciences, Genoa, Italy

Introduction The quality of adult-infant interactions represents a critical context in which child adaptation problems could evolve, and child psychopathology could develop. Literature has investigated the role of attachment to caregivers, nevertheless, there is a paucity of studies on middle-childhood and early adolescence in patients with somatic symptoms disorders and disruptive behavior disorders.

Objective This study investigates the attachment to caregivers in children with somatic symptoms disorders and disruptive behavior disorders, focusing on the role of Anger to mothers and fathers.

Aims The aims are to verify the presence of: – high frequency of insecure attachment;

- an overrepresentation of attachment disorganization;
- high levels of Anger to caregivers.

Method Fifty-six patients with somatic symptoms disorders, and 42 patients with disruptive behavior disorders, aged from 8 to 15, are administered the child attachment interview.

Results Findings show: – Insecure attachment in more than half of the patients;

- a significant presence of disorganized attachment with respect to both parents;
- higher levels of anger to father in children with somatic symptoms disorders.

Conclusion Considering the attachment to have a regulatory function, the knowledge of the different attachment strategies in middle-childhood and early adolescence may enhance our understanding and improve the management and the treatment of patients with somatic symptoms disorders and disruptive behavior disorders.

Disruptive behavior disorders in childhood and adolescence: Attachment models and post-traumatic symptomatology

F. Bizzi

University of Genoa, Department of Educational Sciences, Genoa, Italy

Introduction In line with a consistent literature, young patients with disruptive behavior disorders in childhood and adolescence have experienced some traumatic events, such as abuse, rejection and violence assisted. Recent studies are focusing the attention on the role of attachment and post-traumatic symptomatology for a better evaluation of this clinical condition.

Objective This study investigates attachment models and post-traumatic symptomatology in young patients with disruptive behavior disorders.

Aim(s) The following objectives are set by the present study: – to evaluate attachment models in a group of children diagnosed with disruptive behavior disorders;

- to evaluate their post-traumatic symptomatology;
- to test the extent of the association between post-traumatic symptomatology and attachment organization in young patients with disruptive behavior disorders.

Method Forty-two Italian patients aged from 8 to 15 previously diagnosed with disruptive behavior disorders are compared to 42 healthy control subjects. We administer the child attachment interview and trauma symptom checklist for children-adolescent.

Results Insecure attachment are found in more than half of the patients diagnosed with disruptive behavior disorders and disorganization are highly over-represented. Furthermore, low levels of post-traumatic symptoms are found in young patients with disruptive behavior disorders.

Conclusion This study suggests that attachment organization may be a fundamental element to be assessed in the evaluation of disruptive behavior disorders in children and adolescents. Nevertheless, traumatic experiences do not seem expressed through psychic symptoms. The clinical implications are discussed.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Impulsivity in adolescent with depressive disorders

K. Khemakhem, J. Boudabous, L. Cherif, H. Ayadi*, A. Walha, Y. Moalla, I. Hadjkacem, F. Ghribi

Hedi chaker Hospital, child psychiatry, Sfax, Tunisia

* Corresponding author.

Introduction However, impulsivity is more likely to be present in externalizing disorders, little focus seems to have been made on the research of impulsivity in depression.

Objective On this study, we sought to investigate impulsivity among adolescent with Depressive disorder compared to a control sample.

Subjects and methods Employing a matched case-control study, participants included 100 adolescents divided into two groups: 30 adolescents (12 to 17 years) with depressive disorder and a control sample of 70 adolescents. Participants were recruited during a period of 2 years (2015, 2016). Depressive disorder patient were drawn from the consultation unit or inpatient unit of the department of child psychiatry in Sfax, Tunisia. Controls were recruited from two secondary schools and they haven't depressive symptoms according to the child depression inventory (CDI). Impulsivity was evaluated in the two groups by the Barratt Impulsiveness Scale (BIS-11), an instrument designed to measure trait impulsivity.

Results Adolescents with depressive disorder displayed significantly higher total BIS-11 impulsivity scores than controls (71.6 ± 16 vs 61.6 ± 9 ; $P=0.003$). They scored significantly higher than the controls on motor ($P=0.0001$) and attentional impulsivity ($P=0.006$). There was no difference in non-planning Impulsivity between the two groups. Motor impulsivity was high in adolescents with history of suicide attempt.

Conclusion Our findings suggest that trait impulsivity is increased among adolescents with depressive disorder. Impulsivity seems to be a risk factor for suicide attempts, so it that should be systematically evaluated in depressive disorder.

Aerobic exercise training in children and adolescents with inflammatory bowel disease: Influence on psychological functioning, sleep and physical performance

L. Maehlmann¹, M. Gerber², R.I. Furlano³, C. Légeret³, N. Kalak¹, D. Sadeghi Bahmani¹, E. Holsboer-Trachsler¹, S. Brand^{1,*}

¹ Psychiatric University Hospital, Center for Affective- Stress and Sleep Disorders, Basel, Switzerland

² University of Basel, Department of Sport, Exercise and Health, Division of Sport and Psychosocial Health, Basel, Switzerland

³ University Children's Hospital Basel, Paediatric Gastroenterology & Nutrition, Basel, Switzerland

* Corresponding author.

Background and aims Patients with inflammatory bowel disease (IBD) report increased mental health issues, poorer sleep quality

and less engagement in physical activity (PA). Standard treatment consists of immune modulating pharmaceuticals, though evidence is growing that aerobic exercise training (AET) might serve as adjuvant option to reduce disease symptoms and improve mental health. The aim of the present study was to investigate possible AET effects on psychological functioning, depressive symptoms, sleep and PA behavior in paediatric patients with IBD.

Methods Twenty-one paediatric patients with IBD and 23 gender and age-matched healthy controls (HC) were assessed. The IBD group was split into a "remission-group" (IBD-RE; $n=14$) and an "active disease group" (IBD-AD; $n=7$). All participants completed an 8-week AET exergame intervention reaching 60–80% of maximal heart rate for 5 days per week. At baseline and after 8 weeks, psychological functioning, depressive symptoms, objective sleep EEG, subjective sleep and objective and subjective PA were assessed.

Results AET significantly improved the exercise capacity of all participants. Self-reported fitness and daily PA behavior significantly increased in IBD-AD, but not in IBD-RE and HC. No improvements were observed for psychological functioning, depressive symptoms and subjective or objective sleep dimensions. Descriptively, the IBD-AD group reported lower psychological functioning and poorer subjective sleep quality.

Conclusions Results suggest that children and adolescents in an active disease state were at increased risk to descriptively report lower scores of psychological functioning and sleep. Further, an exergaming intervention has the potential to improve exercise capacity, self-reported fitness and daily PA.

Disturbed sleep and activity in toddlers with early signs of ADHD

A.K. Bundgaard*, N. Bilenberg, J. Asmussen, N. Vigholm Stokbæk

Child and Adolescent Psychiatry Odense, University of Southern Denmark, Odense C, Denmark

* Corresponding author.

Introduction Attention-deficit-hyperactivity-disorder (ADHD) is a frequent psychiatric disorder present in childhood, where sleep-problems are a prominent, pervasive and clinically important feature. However, our understanding of whether sleep-problems mimic or exacerbate daytime ADHD-symptom expression remains insufficient.

Objective Research examining sleep and daily activity in toddlers with early signs of ADHD might help identify early risk factors.

Aims To investigate whether disturbed sleep patterns and daily activity level is associated with early signs of ADHD in toddlers.

Methods Twenty-four toddlers from the Danish Odense Child Cohort scoring above the 93rd percentile on the ADHD scale of the Child Behaviour Checklist for ages 1½–5 were categorized as cases and compared to 25 age and gender-matched controls scoring below the 50th percentile. Daytime and nocturnal activity for 49 toddlers were assessed through seven days of actigraphy. Parents completed Children's Sleep Habits Questionnaire (CSHQ) and the ADHD Rating Scale IV Preschool Version (ADHD-RS).

Results Actigraphic data revealed an increased night-to-night variability, prolonged total sleep time, fewer sleep interruptions and fewer minutes in moderate-to-vigorous-physical activity (MVPA) in cases compared to controls. Increased night-to-night variability was found significantly associated with higher total scores on both the CSHQ and ADHD-RS. Further, fewer minutes in MVPA were associated with a higher parent-reported motor activity on the ADHD-RS.

Conclusion Findings show that early signs of ADHD are associated with irregular sleep patterns and lower daytime activity, as illus-

trated by actigraphy. Studies investigating early ADHD risk factors could lead to a preschool ADHD risk index to help guide future early intervention.

Executive functioning, response inhibition and attentional process impairments in impulsive children

F. Mozaffarinejad^{1,*}, N. Nazarboland²

¹ BA, Clinical Psychology, Tehran, Iran

² Shahid Beheshti University, Consulting, Tehran, Iran

* Corresponding author.

Impulsivity is a multidimensional concept that incorporates failure of response inhibition, rapid processing of information, novelty seeking, and inability to delay gratification. Aggressive, suicidal and violent behaviors have been shown to be associated with impulsivity and difficulty in inhibiting responses. As explorers of executive function (EF) and impulsivity research areas believe this two are generally considered conceptually distinct, and suggest that they may be antipodes (i.e., widely separated on a common continuum, upon which they are related), We selected subjects with high ($n = 25$) and low ($n = 25$) levels of impulsivity among 537 students of ages 8 to 10 years-old, who were measured by Conners Teacher Rating impulsivity Scale. Using computerized versions, response inhibition was examined by their performance in a Go/No Go task, general performance in executive functions (EF) was measured by tower of London Test and continuous performance test (CPT) was used to assess their attentional processes. Using independent t-test and ANOVA, the results revealed that overall performance of executive functions in impulsive children in all three areas were remarkably damaged: they had impaired performance regarding Go/No Go task results; also have consumed more time and committed more errors and a worse general performance; and had more errors and weaker performance in attentional processes. The results of this study along with similar results would be effective in achieving a brighter image of impulsive children's cognitive problems in order to provide efficient treatments focused on improving their executive functions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction In adolescence experiencing weight and physical appearance concerns is common. These body and weight-related preoccupations are associated with anxiety and may lead adolescents to avoid social situations where their body image is exposed.

Aim The present study aimed to conduct an exploratory factor analysis and explore the psychometric properties of a new measure of social situations discomfort and avoidance due to weight or physical appearance (DASSWPA) in a sample of adolescents.

Methods The sample comprised 357 adolescents aged between 12 and 18-years-old, 195 males and 162 females, with a mean age of 14.69 (SD = 1.68). Participants completed a set of self-reported questionnaires concerning anxiety, stress and depression symptoms (DASS-21), bullying experiences (BIVES-A) and body image related shame feelings (BISS).

Results The DASSWPA is comprised of two separate scales: one regarding discomfort/anxiety and another one related to avoidance of social situations. Results suggested that both scales presented a similar two-factor structure. Both scales revealed good psychometric properties, including high internal consistency ($\alpha = 0.91$) and an excellent temporal stability. Moreover, DASSWPA showed significant and positive associations with body image related shame feelings, victimization experiences, and anxiety, stress and depression symptoms. Gender differences were also found, with girls presenting significantly higher levels in the anxiety/discomfort scale than boys.

Conclusion The DASSWPA proved to be a reliable and stable measure to assess anxiety and avoidance of social situations due to one's physical appearance and weight in adolescents.

Medication effects on EEG biomarkers in attention-deficit/hyperactivity disorder

M. Cebi^{*}, N. İsitin, B. Metin, B. Sütçübaşı, N. Tarhan

Uskudar University, Faculty of Humanities and Social Sciences, Istanbul, Turkey

* Corresponding author.

EEG biomarkers have become increasingly used to aid in diagnosis of ADHD. Despite several studies suggesting that EEG theta/beta ratio may help discriminating ADHD from other disorders, the effect of medications on theta/beta ratio is not known. Forty-three children with ADHD that were evaluated with quantitative EEG before and after methylphenidate were included in the study. Theta/beta ratio, theta and beta powers for whole brain, central and frontal areas were calculated. Theta/beta power decreased significantly after treatment; however this change was largely due to an increase in beta power, rather than a fall in theta power. The results suggest that beta power is sensitive to medication effects, while theta power remains as a trait biomarker unaffected by medication status. The value of EEG biomarkers for monitoring neuropsychological performance and clinical status should be explored by future studies.

The association between problem behaviors and Yin-Yang temperament in Korean middle school students

S.J. Lee¹, H. Chae^{2,*}

¹ Kyungil University, Department of Psychotherapy, Kyungsan, Republic of Korea

² Pusan National University, School of Korean Medicine, Yangsan, Republic of Korea

* Corresponding author.

Objectives The Yin-Yang represents two opposing and complementary traits of nature such as introvert-extrovert and passive-active, and has been primary framework of medicine for thousands of years in the East. The purpose of this study was to examine the problem behaviors of the middle school students, which is a major social and psychopathological issue in Korea, from the Yin-Yang temperaments.

Methods Subjects of 670 middle school students (365 boys and 305 girls) finished Korean version of youth self-report (YSR) for describing the problem behaviors and Sasang personality questionnaire (SPQ) for measuring Yin-Yang temperament. The high (30%) and low (30%) SPQ score groups were shown to represent Yin and Yang temperament groups with acceptable reliability and validity. We examined the correlation between YSR and SPQ, and YSR subscale differences between high and low SPQ score groups.

Results The SPQ significantly ($P < 0.01$) correlated positively with YSR externalizing problem ($r = 0.148$, $r = 0.182$) and negatively with YSR Internalizing Problem ($r = -0.212$, $r = -0.177$) in boys and girls, respectively. The Yang temperament group (8.42 ± 6.24 , 8.36 ± 6.59) is significantly ($P < 0.01$) higher than Yin group (6.17 ± 4.82 , 5.83 ± 5.32) in Externalizing Problem, and the Yin temperament group (9.55 ± 7.72 , 11.38 ± 8.18) is significantly ($P < 0.01$) higher than Yang group (6.01 ± 5.95 , 8.28 ± 7.49) in Internalizing Problem with boys and girls, respectively.

Conclusion These results showed that the Yin-Yang temperament of traditional eastern medicine might be clinically useful for screening psychopathological problems in adolescents. Implications and suggestions for cross-cultural psychological study of the East and West are also suggested.

Cognitive vulnerability to depression in adolescents with depression, their healthy siblings and a control group: A cross-sectional study

G. Chartier^{1,*}, P. Garel², C. Herba³, L. Boojij⁴

¹ The University of British Columbia, Psychiatry, Vancouver, Canada

² CHU Ste-Justine, Psychiatry, Montréal, Canada

³ Université du Québec à Montréal, Psychologie, Montréal, Canada

⁴ Université de Concordia, Psychologie, Montréal, Canada

* Corresponding author.

Introduction At least half of first depressive episode appear before adulthood. A negative cognitive bias is present among individuals who suffer from major depression. This bias is also reported among individuals at high risk of major depression (e.g. child of depressed mother). When present, cognitive vulnerability may predispose to major depression. No study to date aimed to evaluate the cognitive vulnerability of siblings of depressed individuals.

Objectives and aims To review the principles behind cognitive vulnerability. To assess cognitive vulnerability in depressed adolescents, in healthy siblings and in a control group.

Methods Eighty adolescents (27 adolescents treated for depression, 24 healthy siblings and 29 controls), aged between 12 and 20 years old, were recruited and assessed using validated measures of bio-psycho-social vulnerabilities. All diagnoses were confirmed using a K-SADS interview. Cortisol level samples were obtained through morning saliva. Cognitive vulnerability was assessed using self-report questionnaires (CES-D, LEIDS-R, EPQ) as well as computer-based tasks (Ekman's tasks of facial recognition and the movie for assessment of social cognition [MASC]). We translated the MASC from German to French. The parents of the adolescents also filled the LEIDSR and the CESD.

Results The LEIDS-R presented a significant increase in certain subscales (hopelessness, aggression and rumination) compared to

the healthy siblings and the controls. Interestingly, there was also a correlation between the LEIDS R results of the parents and of the depressed adolescent ($r = 0.43$, $P = 0.04$).

Conclusions The LEIDSR appears to be the most sensitive task to detect cognitive vulnerability. A relation between the parent response and the depressed adolescent response could be found.

The relationship between physical and mental disorders in a pediatric population

G. Chartier¹, D. Cawthorpe^{2,*}

¹ The University of British Columbia, Psychiatry, Vancouver, Canada

² University of Calgary, Psychiatry, Calgary, Canada

* Corresponding author.

Introduction Few studies examine comorbidity in a pediatric population. This poster presents results that extend our understanding of the relationship between mental disorder and physical disorders using a population-based study approach.

Objectives and aims To review the evidence behind comorbidity of psychiatric disorders and other medical disorders. To propose an informatic approach that evaluates those comorbidity on a population-scale.

Methods Using an informatics approach, a dataset containing physician billing data for 235,968 (51% male) individuals up to 18 years old spanning sixteen fiscal years (1994–2009) in Calgary, Alberta, was compiled permitting examination of the relationship between physical disorders and mental disorders, based on the International classification of diseases (ICD).

Results All major classes of ICD physical disorders had odds ratios with confidence intervals above the value of 1.0, ranging from 1.08 (Perinatal Conditions in 4–6 year olds) to 4.95 (Respiratory Conditions in 0–3 year olds). Distinct major class ICD disorder patterns arise in comparing all children with adults and specific age strata for those under 19 years of age.

Conclusions This study represents the first evidence reported in a population-based data set of the effect of mental disorders on each major class of ICD diagnoses related to a physical disorder. The focus on the early intertwinements between physical and mental disorders in a pediatric population may help to target strategic areas for future research and investment.

Psychosis in adolescence: A prognosis or a diagnosis? Integrated treatment with psychodynamic peer support

L. Ciampa*, F. Gucci

Villa Camaldoli Alma Mater s.p.a., Psychodynamic Integrated Psychiatry Department, Napoli, Italy

* Corresponding author.

Introduction Our work comprises an integrated intervention strategy for the treatment of psychotic manifestations and functioning in adolescents which, following the theories of Laufer and Chan, questions the usefulness of the diagnosis 'psychotic' during adolescence. We apply an "open light treatment" (IPOLT), which includes psychodynamically oriented peer-support.

Objectives To build a new form of therapeutic alliance with peer-support based on shared real life experiences enabling adolescents to reintegrate within their environment and re-establish cogni-

tive functioning which has become disorganised, aiding a gradual return of the cohesion of ego and self and in some cases, cessation of psychotic symptoms.

Methodology An observational study of one year on a group of ten adolescents aged 17 to 20 in institutional and private settings with psychotic manifestations and functioning. The group were tested at the start and end of the study using WAIS-IV and MMPI-A.

Results The adolescents recruited showed a faster recovery of the cohesive processes of their fragmented ego as well as a quicker resumption of social relations. Our model provided an organising function and a flexible yet secure 'container' (Bion, 1988) for the young people's psychic structure. The tests showed a demonstrable improvement in their verbal comprehension, visual-spatial reasoning, fluid reasoning, working memory and processing speed.

Conclusions Psychotic manifestations occurring in adolescence may decrease with an immediate integrated and rehabilitative intervention, without need of an institutional psychiatric setting. In conclusion, we find that "psychosis" in adolescence is a prognosis and not a diagnosis.

⁴ Psychiatric Department, Odense University Hospital, Odense, Denmark

⁵ Institute of Clinical Research, Child and Adolescent Psychiatric Department, Odense, Denmark

* Corresponding author.

Introduction Vitamin D deficiency is widespread globally in pregnant women and is suggested to contribute to offspring risk of symptoms of autism spectrum disorders (ASD), but findings are inconsistent.

Objectives To investigate whether low prenatal 25OHD exposure and 25OHD status in early life increase risk of early symptoms of ASD.

Aims To investigate early signs of ASD.

Methods From the prospective birth cohort, Odense child cohort ($n=2.549$), Denmark, we included singletons with their mothers with available serum concentrations of 25OHD at early pregnancy ($n=1.231$), late pregnancy ($n=1.361$), and birth ($n=2.082$). ASD symptoms were rated by parents on the pervasive developmental problem (PDP) scale of the Child behavior checklist for ages 1½-5 (CBCL 1½-5). Associations between 25OHD and PDP score were analyzed by multiple linear and logistic regression models. A priori included covariates were gestational age, child gender, birth weight, season of birth, parity, parental psychiatric diagnoses, maternal age, smoking habits, alcohol consumption, education level, vitamin D supplementation, and pre-gestational BMI.

Results Means (SD) of 25OHD for early pregnancy, late pregnancy, and cord were 65.5 (21.5), 78.7 (27.0), and 47.0 (21.7) nmol/L, respectively. PDP data were obtained at a mean (SD) of 2.7 (0.6) years of age. Data from the regression analyses are pending.

Conclusions In this well-off cohort with relatively high levels of cord 25OHD, power calculations allows us to detect a true change

of 0.02 PDP scores per 10 nmol/L change in 25OHD. Further studies will clarify whether early PDP scores track later ASD diagnosis.

Psychiatric assessment of cases with self-inflicted poisoning in a sample of Egyptian children and adolescents

H. El Rafei*, M. Ghanem, H. Gamaluddin, M.M. Mohamed, A.M. Abdel Samiee', N. Shaker

Psychiatry Institute, Ain Shams University, Cairo, Egypt, Psychiatry Department, Cairo, Egypt

* Corresponding author.

Introduction Suicide in children and adolescents is commonly underreported and studied. It is an interplay area of multiple static (sociodemographic), and modifiable (impulsivity, psychiatric morbidities, adverse life events (ALE), abuse, bullying) variables.

Objectives and aim To assess and identify relative significance of dependent and independent risk factors in youngsters attempting self-inflicted poisoning.

Methods Consecutive recruitment of patients aged 7–18, with normal IQ, admitted to poison control centre over 13 continuous months, with self-induced poisoning. All were assessed after guardians' written informed consent for different risk factors identified for suicidal behavior using appropriate scales (PPS, SRRS-Y, FSSCS, BIS-11, J-TCI, Mini-Kid). Controls with no history of suicidal attempt were matched for age, sex and sociodemographics among their families.

Results One hundred and twenty cases (16.7 years \pm 1.6 SD, 91% females) and 100 controls (age 16.4 years \pm 1.7 SD, 90.8% females) were assessed. In cases, 90.8% were of low/middle socioeconomic status, 73.5% had previous attempt, average within 10 months, 17.5% planned their attempt, 10.8% had a witnessed attempt. Stressor within 2 days was reported in 75.9%, severe in 40%. Impulsivity was more in its cognitive, planning and motor components ($P=0.001$ in each) among attempters. Cases scored more on Novelty seeking, harm avoidance and reward dependence than controls who had more persistence, self-directedness and cooperativeness. Attempters had significantly more past medical and psychiatric history ($P=0.001$, 0.05 respectively), 77.5% had a working psychiatric illness, 2% in controls.

Conclusion Repeated suicidal attempts were the majority, with impulsivity as a predictive risk, especially if psychiatric morbidity or ALE in youths were encountered.

Families of children with autism spectrum disorders: Communication and mental health

F.D. Fernandes*, S. Leticia

University of São Paulo, FMUSP, Cotia-SP, Brazil

* Corresponding author.

Persons with autism need special care during all life and therefore the caretakers need attention too. Parental stress in families with children with autism is significantly higher than the observed in families with children with other disorders or with typical development. Communication is specially affected in autism, is one of parent's first concerns and may increase stress. This study asked if parents of non-verbal children with autism have higher levels of stress than parents of verbal children with autism. The purpose

of this study was to assess the stress levels of parents of children with autism and to verify its association with the inability of verbal communication and the relationship to quality of life. Participants were parents of 75 children with autism and 100 parents with no complaints about their children development. They were divided in 3 groups. All participants responded to questionnaires regarding: socio-demographic date, stress level and quality of life. Most parents presented medium level of stress. Presence of speech did not yield to significant differences. More parents of children with autism reported high levels of stress. Associations between the stress level and the quality of life were also observed. It can be concluded that the stress level of parents of children with autism not influenced by their lack of verbal communication.

⁴ University of Lund, Department of Clinical Sciences Lund, Obstetrics and Gynecology, Center of Reproduction Epidemiology, Lund, Sweden
* Corresponding author.

Introduction The last two decades increase in early detection and diagnosing children with autism spectrum disorders (ASD) has challenged child and youth habilitation centers to offer the best and most appropriate treatment and support.

Objectives and aims To evaluate an ongoing Comprehensive Intensive Early Intervention (CIEI) program for children with ASD based on principles of behaviour learning and developmental science, implemented in the child's natural setting.

Method The change in autism symptoms among children participating in CIEI (intervention group, $n=67$) was compared with children who received traditional habilitation services only (comparison group, $n=27$). Symptom changes were measured as evaluation-ADOS-R-scores, total-, severity-, and module-adjusted-scores (ADOS-MAS), minus the corresponding baseline-scores, divided by the time between baseline and evaluation, and estimated using ANOVA adjusting for confounders. The ADOS-MAS were developed to allow improved communicative functions to be counted in the overall symptom improvement.

Results Children in both study groups improved their autism symptoms as measured with the ADOS-MAS, and the improvement was statistically significantly larger among children without any developmental delay ($P<.001$). When adjustments were made for developmental delay, there was a statistically significant larger improvement of ADOS-MAS among children in the intervention group than in the comparison group ($P=0.047$). Similar results were found for ADOS-R-total and ADOS-severity scores ($P=0.023$ and $P=0.060$, respectively).

Conclusion The results of the current study indicate that the CIEI program significantly improve social and communicative skills among children with autism, and that children with developmental delay could benefit to a similar degree as other children.

Emotional and behavioral problems in early adolescents and association with socio-demographic risk factors

L. Dostovic Hamidovic

University Clinical Center Tuzla, Department of Pediatrics, Tuzla, Bosnia and Herzegovina

Aim The aim is to analyse the frequency emotional and behavioural problems early adolescents and association with socio-demographic risk factors.

Subject and methods We analysed a group of 240 early adolescents (11–15 years) from the area of Tuzla Canton, Bosnia and Herzegovina, in the general population. For the assessment of children's emotional and behavioural problems, the Strength and Difficulties Questionnaire – SDQ is used. Data were processed by descriptive statistics. For the assessment association between socio-demographic risk factors and emotional and behavioural problems in early adolescents we used Pearson correlation test.

Results The result show that the frequency of emotional and behavioural problems are present in 3% of cases, The results of correlation sociodemographic risk factors and emotional and behavioral problems, showed that unemployed mothers have a significant increased risk of developing behavioral disorders in early adolescents ($P<0.05$). Low family economic status leads to a significantly higher frequency of emotional symptoms in early adolescents, poor attitude towards society and significantly higher overall difficulties ($P<0.05$). Higher levels of parental education was significantly associated with a higher frequency of behavioral problems and illness in the family leads to a much more emotional problems ($P<0.05$).

Conclusion The obtained results of this study indicate that early adolescents showed low levels of emotional and behavioral problems. There is a significant correlation between socio-demographic risk factors and emotional and behavioral problems early adolescents.

What are the mental health impacts on adults coming from childhood bullying?

A. Hashorva, T. Pengili*, M. Lici, I. Prifti

University Hospital Center "Mother Teresa", Psychiatric department, Tirana, Albania

* Corresponding author.

Though there is no universal definition of childhood bullying, the term is often used to describe when a child repeatedly and deliberately says or does things that causes distress to another child. Research shows that persistent bullying can cause depression and anxiety and contribute to suicidal behaviour.

This paper will bring into focus some studies done by the Department of Mental Health that show that the impact of bullying in childhood can cause depression, anxiety and especially OCD in adult. Also strongly contributes to bullying in suicidal behaviour. The study involved 177 children aged 9–15 years old and were followed until they were 19–25 years old. The study ended in 2013. The subjects in this group were found to be 6 times more likely to have a serious physical illness, or develop a psychiatric disorder in adulthood than those who were not involved in bullying.

Another study in 2014 found that the negative effects at social, physical and mental health of childhood bullying are still evident up to 40 years later. Victims of bullying are 6 times more likely to

have a physical nature of infectious diseases, to burn regularly or develop a mental disorder in adulthood more than those not exposed to bullying, 11 times more likely to develop anxiety disorder but especially obsessive-compulsive disorder.

Some experts think that bullying results in a kind of “toxic stress” that affects children’s physiological responses, possibly explaining why some victims of bullying go on to develop health problems.

* Corresponding author.

Introduction Individuals with attention-deficit/hyperactivity disorder (ADHD) may require long-term medication.

Objectives To measure growth and sexual maturation of children and adolescents with ADHD receiving lisdexamfetamine dimesylate (LDX) in a 2-year trial (SPD489-404).

Aims To investigate the impact of long-term LDX treatment on growth and maturation.

Methods Participants (6–17 years) received dose-optimized, open-label LDX (30–70 mg/day) for 104 weeks. Weight, height and BMI z-scores were derived using the Centers for Disease Control and Prevention norms [1]. Sexual maturation was assessed using the Tanner scale (participant-rated as closest to their stage of development based on standardized drawings).

Results Of 314 enrolled participants, 191 (60.8%) completed the study. Mean z-scores at baseline and last on-treatment assessment (LOTA) were 0.53 (standard deviation, 0.963) and 0.02 (1.032) for weight, 0.61 (1.124) and 0.37 (1.131) for height, and 0.32 (0.935) and –0.27 (1.052) for BMI. In general, z-scores shifted lower over the first 36 weeks and then stabilized. At LOTA, most participants remained at their baseline Tanner stage or shifted higher, based on development of hair (males, 95.5%; females, 92.1%) or genitalia/breasts (males, 94.7%; females, 98.4%).

Conclusions Consistent with previous studies of stimulants used to treat ADHD [2], z-scores for weight, height and BMI decreased, mostly in the first year, then stabilized. No clinically concerning trends of LDX treatment on sexual maturation or the onset of puberty were observed.

The effect of cognition enhancement program using toy-robot for children

M.S. Shin^{1,*}, H.J. Jeon², J.R. Park², J. Lee², H.W. Shin²

¹ Seoul National University College of Medicine, Department of Psychiatry, Seoul, Republic of Korea

² Seoul National University Children’s Hospital, Department of Child and Adolescent Psychiatry, Seoul, Republic of Korea

* Corresponding author.

Objectives The purpose of this study was to verify the effect of Cognition Enhancement Program (CEP) using toy-robot for children aged 5–10 years. We thought that CEP using toy-robot might be a more kids-friendly method for improving cognitive ability than traditional programs. The enhancement of cognitive functions such as attention, response inhibition, memory, and working memory after the cognition training were the focus of the study.

Methods One hundred and twenty children aged 5 to 10 were randomly assigned to 3 groups: (1) experimental group receiving CEP training using toy-robot, (2) control group receiving previously developed internet-based cognitive training, (3) waiting list. The children of experiment and control groups received individual 8 training sessions. The effect of the program was measured with Smart Toyweb’s cognitive assessment tools we had developed (smart device based assessment) as well as traditional neuropsychological tests throughout 3 times (pre-training, post-training, and 1-month follow-up).

Results The training is in progress since it started in October 2016. We observed some of children on the CEP training tend to show improvement of cognitive function. The final assessment is planned for February 2017.

Conclusions The CEP using toy-robot could be very promising and useful in that it is a non-invasive and non-pharmacological treatment for children with attention or memory problem in home and clinical settings.

Treated versus untreated mental health problems in adolescents: A six-year comparison of emotional and behavioral problem trajectories

F. Jörg^{1,*}, D. Raven¹, E. Visser¹, R. Schoevers², T. Oldehinkel¹

¹ University Medical Center Groningen UMCG, ICPE, Groningen, The Netherlands

² University Medical Center Groningen UMCG, UCP, Groningen, The Netherlands

* Corresponding author.

Introduction Multidisciplinary guidelines in adolescent mental health care are based on RCTs, while treatment efficacy can be different from effectiveness seen in ‘the real world’. Studies in the real world conducted so far suggest that treatment has a negligible effect on follow-up symptomatology. However, these studies did not incorporate the pre-treatment trajectory of symptoms nor investigated a dose-response relationship.

Objectives To test whether future treatment users and non-users differed in emotional and behavioural problem scores, whether specialist mental health treatment (SMHT) was effective in reduc-

ing problem levels while controlling for pre-treatment trajectory, and to seek evidence of a dose-response relationship.

Methods Six-year follow up data were used from the Tracking Adolescents' Individual Lives Survey (TRAILS). We identified adolescents with a clinical level of problem behaviour on the Child Behaviour Checklist or Youth Self Report and first SMHT between the ages 13 and 16. Adolescents with a clinical level of problem behaviour but without SMHT use served as control group. A psychiatric case register provided data on number of treatment contacts. Using regression analysis, we predicted the effect of treatment on post-treatment problem scores.

Results Treated adolescents more often had a (severe) diagnosis than untreated adolescents. Pre-treatment trajectories barely differed between treated and untreated adolescents. Treatment predicted an increase in follow-up problem scores, regardless of the number of sessions.

Conclusion The quasi-experimental design calls for modest conclusions. We might however need to take a closer look at real-world service delivery, and invest in developing treatments that can achieve sustainable benefits.

Perceived competence in adolescents having prosocial behaviour: A Tunisian study

N. Charfi¹, W. Kammoun^{2,*}, J. Ben Thabet¹, M. Mâalej Bouali¹, N. Zouari¹, L. Zouari¹, M. Mâalej¹

¹ Hedi Chaker University Hospital, psychiatry, Sfax, Tunisia

² Hedi Chaker University Hospital, Child and adolescent psychiatry, Sfax, Tunisia

* Corresponding author.

Introduction Perceived competence (PC) is a self-perception of an individual in its capabilities and ability to control his environment. It is posited to orient individuals to the possibility of success and to facilitate the adoption of approach goals.

Objectives We aimed to assess the PC of adolescents engaged in prosocial activities and to determine factors that influence it.

Methods We led a transversal study, over four months, from June until September 2016. It included 90 adolescents aged 14–20 years and members of voluntary association in Sfax (Tunisia). PC was assessed using the “perceived competence in life domains” (PCLD) for the life spheres of leisure, interpersonal relationships, school, and general domains.

Results The average age of participants was 16 (14 to 20 years). The sample was female-dominated (53%). All participants were secondary school pupils. Almost 70% were from a high socio-economic level and over 60% had parents' high level of education.

The mean scores of PC ranged from 19 (SD = 5.4) in leisure domain to 16 (SD = 4) in interpersonal relationships domain. PC was significantly correlated with socio-economic level ($P = 0.00$), participating in sports and extra-curricular activities ($P = 0.00$), academic proficiency ($P = 0.01$) and smoking ($P = 0.00$).

Conclusion Overall, our results evidenced the positive self-perception of competence among adolescents having prosocial activities. It indicated that high socio-economic level, participating in sports and extra-curricular activities and smoking were enhancing factors of adolescents PC.

Evaluation of anxiety in children with acute leukemia: A prospective study of 20 cases

K. Baccouche^{1,*}, A. Walha¹, M. Medhaffar², W. Kammoun¹, H. Ayadi¹, Y. Moalla¹, M. Elloumi², F. Ghribi¹

¹ Hedi Chaker University Hospital, Child and adolescent psychiatry, Sfax, Tunisia

² Hedi Chaker University Hospital, hematology, Sfax, Tunisia

* Corresponding author.

Introduction The occurrence of acute leukemia (AL) in childhood causes a profound upheaval in the child itself and also within his family. Exposure to this test could contribute to the emergence of anxiety.

Objective Our work aims to describe the characteristics of anxiety in this population during the management of the AL.

Patients and methods Our study, still in progress, is prospective and conducted among 20 children hospitalised in hematology department of UMC Hedi Chaker Sfax (Tunisia) during the year 2015–2016. It is performed in two times. The anxiety was assessed using the STAI scale.

Preliminary results The average age of our population is 7 years (minimum age = 4 years, maximum age = 11 years). The majority of our patients come from urban areas (76.9% of cases). About their sibling rank, they are mostly the youngest in 53.8% of cases, the oldest in 30.8% of cases and juniors in 7.7% of cases. The most common diagnosis is the lymphoblastic B AL (46.2% of cases).

Referring to the STAI scale, 30% of our patients were anxious and had high scores during the first evaluation. Then, the anxiety level attenuates gradually during management period and only 15% were anxious at the 2nd evaluation time.

Conclusion Several factors such as hospitalisation, diagnosis announcement and cancer treatment contribute to the triggering and maintaining of anxiety. Early detection of anxiety and the good listening between the care team and the parents could appease the high level of anxiety and ensure better management.

Early screening for autism spectrum disorder

C. Kamuk^{1,*}, C. Cantio², N. Bilenberg²

¹ University of Southern Denmark, Faculty of Health Sciences, Odense C, Denmark

² Institut of Clinical Research- University of Southern Denmark, Department of Child and Adolescent Mental Health Odense-Research Unit, Odense, Denmark

* Corresponding author.

Introduction Most parents to children with Autism Spectrum Disorder (ASD) can report concerns about their child's development within the first year of life. In spite of this, children with ASD are rarely diagnosed before the age of 3–4 years. Early identification allows early intervention, which seems to be substantial for improvement of core behavioural symptoms in children with ASD. The Child Behaviour Checklist for ages 1½ to 5 (CBCL/1½–5) have shown promising utility for early detection of children with ASD.

Objectives This study will estimate the positive predictive value of CBCL/1½–5 Pervasive Developmental Problems (PDP) scale in a 2 phase screening study. Furthermore, it will analyse the stability of the CBCL/1½–5 PDP-score in pre-school children from 2½ to 5 years.

Aims The present study aims to validate CBCL/1½–5 for early screening of ASD in a general population sample.

Methods Parents, enrolled in the Odense Child Cohort (OCC), answered the CBCL/1½–5 when the child reached 27 months of age. Parents with children above the age of four and a raw score ≥ 5 (90th percentile) on the PDP scale, received the Social Responsiveness Scale (SRS) questionnaire. Children with a high score on the SRS were invited to a clinical examination consisting of ADOS and ADI-R. Children in OCC were re-assessed with CBCL/1½–5 again at age five years.

Results Results will be presented at the EPA conference 2017 in Florence.

Conclusions The results may contribute to enhance the outcome of treatment by detecting children with ASD at an earlier age.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Prevalence and predictors of ADHD symptoms in adults admitted for substance use disorder treatment: A prospective cohort study

K. Abel*, E. Ravndal, T. Clausen, J. Bramness
Norwegian Center for Addiction Research SERAF, University of Oslo, Faculty of Medicine, Oslo, Norway

* Corresponding author.

Introduction Substance use disorders (SUD) are common in adults with ADHD. A co-occurring ADHD diagnosis is associated with poorer treatment outcomes for both the ADHD and the SUD and higher rates of relapse to substance use.

Objectives To explore the relationship between ADHD and SUD longitudinally to identify factors to help improve treatment outcomes.

Aims Prevalence of ADHD symptoms was investigated in a national cohort of SUD patients one year after SUD treatment initiation. Factors at baseline related to ADHD symptoms were explored at follow up.

Methods Five hundred and forty-eight individuals were interviewed in a multi-center study involving 21 treatment facilities at treatment initiation and one year later ($n = 261$). ADHD symptoms were measured by the Adult ADHD Self Report Scale (ASRS-v.1-1) at follow-up. Individuals who screened positively for ADHD (ADHD+) were compared to those who screened negatively on baseline variables. Emotional distress was measured by Hopkin's Symptom Check List-25.

Results At follow-up 35% screened positively for ADHD. In bivariate analysis the ADHD+ group was older, was less likely to have children, reported lower educational level, had more frequent use of stimulants, cannabis and benzodiazepines, and experienced higher degree of emotional stress. When controlling for other significant variables in a logistic regression analysis, the ADHD+ group was associated with more frequent use of cannabis (OR 2.14; CI 1.08–4.23) and of higher psychiatric symptom burden (OR 1.79; CI 1.22–2.61).

Conclusions A high prevalence of ADHD symptoms and associated challenges underline the importance of systematic screening of individuals entering SUD treatment.

The duration of undiagnosed bipolar disorder: Impact of substance use disorders co-morbidity

S. Ben Mustapha*, W. Homri, L. Jouini, R. Labbane
Razi Hospital, service de psychiatrie C, Mannouba, Tunisia
* Corresponding author.

Aims Study the impact of substance use disorders (SUD) co-morbidity on the duration of undiagnosed bipolar disorder (DUBP).
Methods Case-control study during a period of six months from July 2015 to December 2015. One hundred euthymic patients with BD (type I, II or unspecified) were recruited in the department of psychiatry C Razi Hospital, during their follow-up. Two groups were individualized by the presence or not of a SUD co-morbidity. In our study DUBP was defined as the period between the first symptoms and the beginning of treatment by a mood stabilizer.

Results The beginning of addictive behaviour preceded the installation of bipolar disease in 32% of cases. Installation of bipolar disorder preceded the installation of addictive behaviour in 12% of cases. The beginning of addictive behaviour was concomitant with the installation of bipolar disease in 6% of cases. The average DUBP in the full sample was 4.80 years with a standard deviation of 8.04 and extremes ranging from 0.08 to 37.5.

The average DUBP in patients with SUD co-morbidity was 5.91 years with a standard deviation of 8.16 and extremes ranging from 0.08 to 35, and 3.68 years with a standard deviation of 7.84 and extremes ranging from 0.08 to 37.5 in patients without SUD co-morbidity.

Conclusions According to studies over two thirds of patients with bipolar disorder received misdiagnoses before diagnosis of BD, and among the factors involved can report the presence of SUD co-morbidity. Hence, we should detect BD among patients with SUD.

Introduction Smoking is a serious health problem for people with mental illness like the bipolar disorder patients. The developmental of motivational tools such as brief intervention it is necessary in the context of community care.

Objectives Evaluating the change in motivational stage after brief intervention and evaluating the clinical and smoking factors in relation with this.

Methods Two hundred and twenty patients diagnosed with bipolar disorder (according DSM-5 criteria) that were in the euthymic phase (defined as less than 7 points in YMRS and 10 points in HDRS) and attended the community care centers of three provinces of Andalusia (Spain). Patients who consumed in the last month qualified for the level of motivation for change (measured by URICA scale).

Results After brief intervention the 29.3% of the smoking patients change in their motivational stage. The results of the multivariate analysis showed three factors in relation with difficult the progression of the evolution of motivation to change. The high punctuation in Hamilton anxiety scale (OR = 0.53; IC95%, $P = 0.002$), the high punctuation in the Fageström scale (OR = 0.56, IC95%, $P = 0.01$), and have high autoperception of the capacity of change (OR = 0.52; IC95%, $P = 0.002$).

Conclusions The anxiety (measure with Hamilton anxiety scale) plus factors in relation with smoking, like the punctuation in Fageström scale and the autoperception of the capacity of change decrease the possibilities to change.

Psychiatric vulnerability in adults with intellectual disability and autism: A literature review

S. Coli*, D. Scuticchio, M. Bertelli
Fondazione San Sebastiano, CREA, Firenze, Italy

* Corresponding author.

Introduction Adults with Intellectual disability (ID) and Autism Spectrum Disorder (ASD) are more vulnerable to mental health problems than the general population.

Objectives/aims This study investigates presence and rate of psychiatric disorders in comparison with ID or ASD alone, and appropriateness of assessment and diagnostic procedures or tools.

Methods A systematic mapping of the literature was carried out on the basis of the above mentioned issues. The search was conducted using PubMed and ScienceDirect, according to the following keywords: psychiatric comorbidity, psychiatric disorders, autism, ASD, intellectual disability, mental health problems, adults, assessment tools, diagnosis. Twenty-eight papers were selected for pertinence to mapping issues among more than 500.

Results Many studies show that ASD is an important vulnerability factor for psychiatric co-morbidity and for challenging behaviors (CBs) in adults with ID. Highest rates were reported for psychotic, mood, anxiety, and obsessive-compulsive disorders. Few studies show that the difference between adults with ID plus ASD and adults with only ID are not statistically significant, but for the presence of CBs in those with ID plus ASD. The disagreement of results is based on a variety of factors such as diagnostic over-shadowing, scarcity of specific assessment tools, consideration of the introspective and communication difficulties, incompleteness of medical records, and low reliability of information sources.

Conclusions Although low studies concordance, the literature mapping suggests the presence of ASD in ID to be associated with higher rates of psychopathology. Since the relevant implications for prevention and clinical management, further research with high-level evidence is hoped.

The influences of antipsychotics therapy at cognitive impairments in schizophrenia spectrum disorders

J. Dedovic^{1,*}, A. Tomcuk², T. Mijatovic-Papic³, N. Matkovic⁴
¹ Special Psychiatric Hospital, Forensic Psychiatric Unit, Kotor, Montenegro

² Special Psychiatric Hospital, Mental Health Promotion Centre, Kotor, Montenegro

³ Special Psychiatric Hospital, Chronic Female Ward, Kotor, Montenegro

⁴ Special Psychiatric Hospital, Addiction Ward, Kotor, Montenegro

* Corresponding author.

Significant degree of cognitive impairment represents one of the basic cornerstones among clinical manifestations of the schizophrenia spectrum disorders and accordingly to some authors it is present in up to 75% patients with these syndromes. The aim of this study was to examine degree of cognitive impairment, firstly among patients on first generation antipsychotics therapy (FGA) compared to the patients on second generation antipsychotics therapy (SGA), and secondly to compare both groups of patients with healthy controls.

Material and methods Prospective, parallel research was conducted, in which the sample of patients and employees of Specialized Psychiatric Hospital Kotor was tested with Montreal Cognition Scale (MoCA). There were 66 participants in the samples and they were divided on four subgroups: (1) patients with FGA; (2) patients with SGA; (3) patients with combined FGA and SGA; (4) Healthy controls.

Results All groups of patients had statistically significantly lower mean MoCA scores in the comparison with healthy controls. The fact that among 83.7% of patients was diagnosed significant degree of cognitive decline (MoCA score below 26) strongly speaks in favour of high sensitivity of MoCA test in detection of cognitive impairment among patients with schizophrenia spectrum psychotic disorders. In addition, the group of patients with FGA also had statistically significantly lower mean MoCA score compared to patients with SGA.

Discussion The mechanisms of explanation of these results can be additionally enlightened with further studies on larger samples of patients, which would investigate the correlation between extrapyramidal symptomatology, anticholinergic therapy and cognitive deficit.

Subtypes of psychosis among difficult-to-treat patients – A cluster analytical replication study among chronically psychotic, institutionalized dual diagnosis patients

R. Dost-Otter^{1,*}, L. Timmerman², M. Van Veen³, W. Diekman³

¹ GGZ Drenthe, FACT Assen, Meppel, The Netherlands

² GGZ Drenthe, Location Assen, Assen, The Netherlands

³ GGZ Drenthe, Duurzaam Verblijf, Meppel, The Netherlands

* Corresponding author.

Background Research is lacking on possible subtypes of psychosis in difficult-to-treat patients that require long-term institutionalisation due to a combination of psychosis, substance abuse and problem behaviours after multiple failed treatments.

Aim The aim of this study is to increase our knowledge of this group of patients in order to apply more targeted interventions.

Objective To identify subtypes of psychosis among this group by cluster analysis and compare these subtypes on different clinical variables.

Methods PANSS data was acquired for 117 patients. Separate clusters were identified by using Ward's method of hierarchical cluster analysis, replicating Dolfus et al., 1996 [1], who used this method in a cohort of schizophrenia patients. Subtypes of psychosis were identified using PANSS items. Clusters were compared on several clinical variables, f.e. course of admission.

Results Four distinct clusters were identified (Fig. 1): (1) a 'positive cluster', (2) a 'mild cluster', (3) a 'negative cluster', and (4) a 'mixed group'. These clusters are similar to those found by Dolffus et al.

There was a significant association between cluster and co-morbid personality disorder, $P < 0.05$. No significant association was found between clusters and other clinical variables.

Conclusions Among difficult-to-treat institutionalised patients four distinct subtypes of psychosis could be identified, comparable to those found in a cohort of schizophrenia patients.

Fig. 1 Dendrogram showing a 4 cluster solution.

* Corresponding author.

Objective The aim of the present study was to evaluate relationship of severity of ADHD symptoms with the presence of psychological trauma while controlling the effect of impulsivity in a sample of university students.

Method Participants included 321 volunteered university students. Participants were evaluated with the Short Form Barratt Impulsiveness Scale (BIS-11-SF), the Adult ADHD Self-Report Scale (ASRS) and the Traumatic Experiences Checklist (TEC).

Results Age and gender did not differed between those with the history of psychological trauma ($n = 271$, 84.4%) and those without ($n = 50$, 15.6%). BIS-11-SF and subscale scores did not differ between groups, other than motor impulsivity, which was higher among those with the history of psychological trauma. ASRS score, inattentiveness and hyperactivity/impulsivity subscale scores were higher among those with the history of psychological trauma than those without. Severity of ADHD symptoms, particularly inattentiveness score, predicted the presence of psychological trauma, together

with the severity of motor and attentional impulsivities in a logistic regression model.

Conclusion These findings suggest that the severity of ADHD symptoms may be related with the presence of psychological trauma, while severity of motor and attentional impulsivities may have an effect on this relationship among young adults.

Dual diagnosis: On the way to an integrated treatment model?

I. Ezquiaga^{1,*}, Z. González Vega², P. Rossi¹, F. Fonseca¹,

C. Tamarit¹, C. Castillo¹, I. Castro¹, M. Torrens¹

¹ Institut de Neuropsiquiatria i Addiccions, Parc de Salut Mar-, Psychiatry, Barcelona, Spain

² Hospital Obispo Polanco, Psychiatry, Teruel, Spain

* Corresponding author.

Introduction Substance use disorders (SUD) with psychiatric comorbidity (dual diagnosis) represent a challenge for both mental health and addiction networks. Dual patients present greater disorder severity and worse prognosis than those with SUD or psychiatric disorders alone. There is a lack of consensus regarding which treatment model (sequential, parallel or integrated) is the most appropriate for them. Despite integrated treatment is seen as the model of excellence, it is a standard difficult to achieve.

Objectives/Aims To describe the presence of dual diagnosis and treatment model received in a sample recruited from a drug abuse community center in Barcelona (CAS Barceloneta).

Methods Cross-sectional descriptive analysis of an outpatient center for SUD clinical sample regarding psychiatric co-morbidity (DSM-IV-TR criteria), social-demographic characteristics and treatment model received.

Results In the moment of this study, a total of 574 SUD patients are attended at CAS Barceloneta. Of them, 300 (52%) present a dual diagnosis, 64% men, mean age = 48 (SD = 11.29). Thirteen percent ($n=40$) of dual patients have psychotic disorder (PsyD) diagnosis and their SUD co-morbidities are: alcohol-UD (12.5%, $n=5$), cocaine-UD (7.5%, $n=3$), cannabis-UD (15%, $n=6$), opioids-UD (17.5%, $n=7$) and multiple SUD (47.5%, $n=19$). Half of dual patients with PsyD ($n=20$) are attended in parallel in community mental health centers.

Conclusions Our results suggest there is an important percentage of SUD patients that present psychiatric co-morbidity treated in drug abuse community centers. Parallel treatment is mainly for PsyD patients and sometimes they get lost in the gaps. We would need to develop specific dual programs to give these patients an integrated assistance.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction A rich body of literature dealt with somatic co-morbidities of psychiatric illnesses. However, relatively few explored the association of somatic and psychiatric co-morbidities with psychiatric treatment success.

Objective Objective of this analysis was to explore chronic somatic and psychiatric co-morbidities association with the average number of psychiatric re-hospitalisations annually.

Methods This cross-sectional analysis was done on the baseline data of prospective cohort study "Somatic co-morbidities in psychiatric patients" started during 2016 at Psychiatric hospital Sveti Ivan, Zagreb, Croatia. We included 798 patients. Outcome was the average number of psychiatric re-hospitalisations annually since the diagnosis. Predictors were number of chronic somatic and psychiatric co-morbidities. Covariates that we controlled were sex, age, BMI, marital status, number of household members, education, work status, duration of primary psychiatric illness, CGI-severity at diagnosis, treatment with antidepressants and antipsychotics.

Results Interaction of somatic and psychiatric co-morbidities was the strongest predictor of the average number of psychiatric re-hospitalisations annually ($P < 0.001$). Mean number of re-hospitalisations annually adjusted for all covariates, was increasing from 0.60 in patients with no chronic co-morbidities,

up to 1.10 in patients with ≥ 2 somatic and ≥ 2 psychiatric co-morbidities.

Conclusion Somatic and psychiatric co-morbidities are independently associated with the psychiatric treatment success. Further studies should look at possible causal pathways between them, and interdisciplinary treatment of psychiatric patients is urgently needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Obsessive Compulsive Personality Disorder (OCPD) is a common, highly co-morbid disorder. Subjected to comparatively little research, OCPD shares aspects of phenomenology and neuropsychology with obsessive-compulsive spectrum disorders and neurodevelopmental disorders such as autism spectrum disorder (ASD). A greater understanding of this interrelationship would provide new insights into its diagnostic classification and generate new research and treatment heuristics.

Aims To investigate the distribution of OCPD traits within a cohort of OCD patients. To evaluate the clinical overlap between traits of OCPD, OCD and ASD, as well as level of insight and treatment resistance.

Method We interviewed 73 consenting patients from a treatment seeking OCD Specialist Service. We evaluated the severity of OCPD traits (Compulsive Personality Assessment Scale; CPAS), OCD symptoms (Yale-Brown Obsessive Compulsive Scale; Y-BOCS), ASD traits (Adult Autism Spectrum Quotient; AQ) and insight (Brown Assessment of Beliefs Scale; BABS).

Results Out of 67 patients, 24 (36%) met DSM-IV criteria for OCPD, defined using the CPAS. Using Pearson's test, CPAS scores significantly ($P < 0.01$) correlated with total AQ and selected AQ domains but not with BABS. Borderline significant correlation was observed with Y-BOCS ($P = 0.07$). OCPD was not over-represented in a highly resistant OCD subgroup.

Conclusion Disabling OCPD traits are common in the OCD clinic. They strongly associate with ASD traits, less strongly with OCD severity and do not appear related to poor insight or highly treatment-resistant OCD. The impact of OCPD on OCD treatment outcomes requires further research.

* Corresponding author.

Background and rationale Psychiatric co-morbidities are shown to be very prevalent in patients diagnosed with Autism Spectrum Disorder (ASD), up high to 53% for mood, 50% anxiety and 43% for ADHD disorders in an European cohort of adults with HFA. Using a new approach, our study proposes to explore aspects of co-morbidities in the largest French cohort of HFA adults (C0733/InfoR) by implying qualitative and quantitative clinical tools.

Aims To explore: (1) the prevalence rates of psychiatric co-morbidities; (2) the interplay between co-morbidities and the ASD symptoms.

Methods Diagnosis was made according to DSM 5 criteria. Dimensional evaluation used Social Responsiveness Scale (SRS), Systemizing Quotient (SQ) and Empathy Quotient (EQ). We used T-test, Mann–Whitney test and linear regression models.

Results We included 103 patients (mean age 29.3, sex ratio M/F: 3.4:1). Lifetime prevalence rates of 53.5% for depressive disorder 73.5% for anxiety disorders and 37.5% for ADHD were found. Subjects with psychotic co-morbid symptoms had a more severe social deficit (SRS score 66.2 vs 77.9 $P < 0.05$); patients with ADHD, lower cognition (mean IQ total 107.7 vs 99.0 $P < 0.05$). SQs ($P < 0.05$) were significantly higher in patients with co-morbid psychosis, dysthymia, suicide attempts, and depressive disorders and directly correlated with age ($\beta = 0.35$, $P < 0.05$). SQ and EQ were inversely correlated.

Discussion The results reproduce the high prevalence of co-morbidities in other studies and explore its association with social functioning and cognition. Identification of associated psychiatric conditions in subjects with HFA is therefore a crucial clinical issue potentially guiding the treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Group experience and dual pathology and addictions in a regional hospital in Spain

M.G. García Jiménez

Psychiatrist, Madrid, Spain

Introduction Dual pathology is a term applied to those subjects suffering simultaneously from addiction and other mental disorder. Group psychotherapy can be used in people who have both diagnoses with good results in improvement of addiction and disease stabilization.

Objectives The purpose of this study is to analyse to efficacy of a group of psychotherapy for patients with alcohol addiction and other mental disorder, and analyse the presence of personality disorder in this group and how it affects its evolution.

Methods The study was conducted on a sample of 16 patients diagnosed with alcohol abuse or dependence with psychiatric co-morbidity who attended a therapy group for 6 months from January 16 to June 16. The study was conducted in ambulatory care (outpatient), being an open and heterogeneous group.

Results Main diagnosis was unspecified personality disorder and mood disorder (25%) followed by borderline personality disorder and mood disorder (18.75%), attention deficit disorder and hyperactivity (18.75%), mood disorder (12.5%), substance use disorder without other psychiatric co-morbidity (12.5%), narcissistic personality disorder (6.25%) and impulse control disorder (6.25%). Regarding progress in the stages of change, results were as follows: 31.5% of patients progressed to the stage of preparation for action, 25% alternating periods of abstinence from alcohol with brief relapse, 25% advanced to the stage of action, 18.5% managed to stay alcohol withdrawn.

Conclusions In our sample, we can conclude that a therapeutic group including patients at different stages of change and diagnoses is positive. At the end, improvement in mood and anxiety was observed.

The impact of cannabis in Schizophrenia: Pafip three-year longitudinal study on outcome and functionality after a first episode of psychosis

M. Gomez Revuelta^{1,*}, M. Juncal Ruiz², O. Porta Olivares², M. Fernández Rodríguez², D. Abejas Díez², L. Sánchez Blanco², R. Landera Rodríguez², R. Medina Blanco², B. Crespo Facorro², I. Madrazo Del Río Horteiga², R. Gutierrez Martin²

¹ Hospital Universitario de Álava–Sede Santiago, Vitoria-Gasteiz, Psychiatry, Vitoria-Gasteiz, Spain

² Hospital Universitario Marqués de Valdecilla, Psychiatry, Santander, Spain

* Corresponding author.

Introduction The association between cannabis and psychosis makes crucial the intervention on cannabis use disorder at first episodes of psychosis (FEP), especially among young population. In this group of patients, the harmful potential of cannabis is more evident by its influence on neurodevelopment. However, the nature of the association cannabis–psychosis is not clearly described. It seems to represent a mediating factor for an increased risk of psychosis in healthy and high-risk populations, determining an earlier age of onset and worsening long term outcome.

Objectives To assess the impact of cannabis in terms of functional and clinical prognosis in patients recruited after a FEP.

Material and methods PAFIP is an early intervention program for early stages of psychosis. One hundred and sixty-three were included, followed-up at regular intervals of six months for three years with administration of clinical and functional scales (BPRS, SAPS, SANS, CDRS, GAF and Drake). Patients were divided into three groups: (1) those non-users neither before the onset nor during follow-up (nn) PEP, (2) consumers before the FEP and during follow-up (ss) and (3) consumers before the FEP that gave up consumption during follow-up (sn).

Results No statistically significant differences were observed in terms of functionality at three-year follow-up endpoint but a trend to a better-preserved functionality in the sn group. The sn group presented lower scores in scales for positive symptoms with respect to the comparison groups.

Conclusions The interruption in cannabis use may have a beneficial effect on short-term clinical prognosis and functionality on long term.

Dual diagnosis and medical co-morbidity: Data from a specialized brief psychiatric in-patient unit

M. Gomez Revuelta^{1,*}, M. Juncal Ruiz², O. Porta Olivares², L. Sanchez Blanco², D. Abejas Diez², G. Pardo de Santayana Jenaro², R. Landera Rodriguez², N.I. Nuñez Morales³, L. Garcia Ayala³

¹ Hospital Universitario de Álava-Sede Santiago, Vitoria-Gasteiz, Psychiatry, La Penilla, Spain

² Hospital Universitario Marques de Valdecilla, Psychiatry, Santander, Spain

³ Hospital Universitario de Álava-Sede Santiago, Psychiatry, Vitoria-Gasteiz, Spain

* Corresponding author.

Introduction Previous research on the prevalence of medical disorders among adults with dual diagnosis (DD) has been inconclusive.

Objectives The purpose of this study was to assess dual diagnosis and medical co-morbidity at the Brief Psychiatric Inpatient Unit of Marqués de Valdecilla Hospital, Santander in the period from January 2014 until March 2015.

Methods Ninety-three patients were admitted at our hospital from December 2014 until March 2015. The sample was analyzed retrospectively. Sixty-two of the patients (66.7%) met criteria for Dual Diagnosis. We collected socio-demographic variables, drug abuse, mental pathology, and treatment received.

Results The mean age of the sample was 42.95 years (± 14 DS) with a male:female ratio of 1.8:1 (no significant differences by gender). Hypertension was more prevalent among patients without dual pathology (22.5%). Patients with dual diagnosis presented hypertension less likely (6.5%) ($P < 0.005$). This can be explained by the fact that patients without dual diagnosis had a higher mean age (47 years) than patients with dual diagnosis (42 years). We did not found statistically significant differences between both groups respect to diabetes mellitus, vascular brain disease, HIV and dyslipidemia.

Conclusions Hypertension was less likely to appear among patients with dual pathology admitted to an ultra brief psychiatry unit. This could be explained for an earlier mean age at admission among these patients.

The association between autistic traits and post-traumatic stress disorder: Preliminary findings among typically-developing adults in Israel

D. Horesh^{*}, N. Haruvi-Lamdan, S. Lebediger, O. Golan
Bar Ilan University, Psychology, Ramat Gan, Israel

* Corresponding author.

Background and aims Although studies show that those suffering from autism spectrum disorders (ASD) face an increased risk of exposure to trauma (bullying, physical abuse), the co-morbidity between autistic symptoms/traits and post-traumatic stress disorder (PTSD) was almost entirely neglected by researchers. The aim of this preliminary study is to explore the possible associations between these two conditions among typically-developing college students.

Methods Participants were 39 students, recruited from 2 Israeli universities. Twenty-four participants were psychology students, and 15 were business administration students. Participants completed self-report questionnaires tapping sociodemographic background, trauma exposure, PTSD (the PTSD Checklist-5, PCL-5), and autistic traits (the Autism Spectrum Quotient, AQ).

Results Our preliminary findings revealed a positive association between symptoms of PTSD and autistic traits. More specifically, among those in the 3rd and 4th highest quartiles of AQ scores, 87.5% met the cut-off score for a probable PTSD diagnosis ($\chi^2(3) = 8.25, P < 0.05$). In addition, t-tests comparing the PTSD and non-PTSD groups showed significant differences in 3 out of 5 AQ sub-scales: social skill ($t(37) = -2.12; P < 0.05$), attention switching ($t(37) = -2.09; P < 0.05$) and communication ($t(37) = -2.80; P < 0.01$). Thus, higher AQ scores were reported by those in the PTSD group.

Conclusions ASD may serve as a significant risk factor for post-traumatic symptomatology. The associations between these two conditions may be mediated by a variety of potential shared vulnerabilities, including increased rumination, dysregulated emotion and impaired social cognition. Further research is needed in order to explore these mechanisms, as well as to assess co-morbidity in clinical samples of both ASD and PTSD.

* Corresponding author.

Introduction Diet and physical activity interventions are effective in psychiatric outpatients that suffer from obesity, namely those treated with antipsychotic drugs. However, there is less evidence related to these interventions in hospitalised acute patients.

Aim To evaluate the effect of a diet and physical activity program on weight and BMI variation in acute psychiatric patients during hospitalisation.

Methods Matched case-control study from January to September 2016. Inclusion criteria: patients with at least 15 days of hospitali-

sation in an acute psychiatry ward, evaluated by a nutritionist in the admission and medical discharge. The intervention consisted in a diet and physical activity program, with total restriction to visitors to bring food to the patients. Statistical analysis was done with T-student and multiple linear regression taking into account the effect of age, sex, daily dose of antipsychotics, and days of hospitalisation. **Results** Sixty-six patients were studied (34 cases and 32 controls). Groups were statistically similar concerning the average of age, daily dose of antipsychotics, days of hospitalisation and sex. The differences of weight gain during hospitalisation were 0.088 kg (cases) versus 1484 kg (controls), $P < 0.05$. And the differences of the increased BMI during the hospitalisation were 0.041 kg/m² (cases) versus 0.509 kg/m² (controls), $P < 0.05$.

Conclusions Obesity presents challenging health problems for individuals with severe mental illness that require inpatient treatment. This study provides evidence that individuals with acute mental illness can benefit from weight control interventions during their hospitalisation, in special a total restriction to visitors to bring food to the patients.

Update and revision of the RANZCP clinical practice guidelines for mood disorders

M. Hopwood

The Royal Australian and New Zealand College of Psychiatrists, OPCEO, Melbourne, Australia

In 2015, the Royal Australian and New Zealand College of Psychiatrists (RANZCP) published its new Clinical Practice Guidelines (CPGs) for Mood Disorders. The Mood Disorder CPG focuses on 'real world' clinical management of depressive and bipolar disorders, addressing mood disorders as a whole to recognise the overlap between distinct diagnoses and changes in diagnoses along the mood disorder spectrum. This presentation will provide an overview of the process and methodology used in the development of the guidelines, as well as the key principles established in the new CPG for the assessment and management of depressive and bipolar disorders.

Psychiatry's and psychiatrists' contract with society

B. Janse van Rensburg

University of the Witwatersrand, Psychiatry, Johannesburg, South Africa

Introduction The World Psychiatric Association (WPA) is a worldwide association of national psychiatric associations, aiming to increase knowledge and skills necessary for work in the field of mental health and care of the mentally ill. It was suggested that Psychiatry's relationship with society should be seen as a contract [1]. This implicit understanding usually specifies the scope, principles, quality and outcome of this agreement. It also implies a series of reciprocal rights and duties, privileges and obligations, as well as expectations from both sides.

Aim To investigate the extent of existing social contracting of WPA Member Associations (MAs) and WPA structures regarding:

- communities they serve;
- general public;
- medical institutions;

- other practitioner groups in the multidisciplinary team;
- administrations, managers and funders.

Objectives Include to describe the current scope of psychiatric practice across WPA regions and the content of existing social contracts.

Methods A mixed-methods, explorative, descriptive, theory generating inquiry, with different phases, including a systematic review of literature and WPA documentation, electronic questionnaires to MAs and focus group discussions with WPA ZS chairs/representatives.

Results MA profiles and progress indicators were identified and summarised. A transcription of group discussions was made, while pertaining documents, questionnaires and in depth/focus group interview content was analysed.

Conclusions This presentation will report on progress with this study to date.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Effect of electroconvulsive therapy on serum serotonin level in patients with treatment-resistant major depressive disorder

P. Agha Mohammad Hasani^{1,*}, M. Mokhtaree¹, M.M. Fatemeh², N. Mohammad¹

¹ Rafsanjan university of medical sciences, Psychiatry, Rafsanjan, Iran

² Rafsanjan university of medical sciences, laboratory sciences, Rafsanjan, Iran

* Corresponding author.

Background This study aimed to determine the effect of Electroconvulsive Therapy (ECT) on serum serotonin level of patients with major depressive disorder (MDD).

Methods In this experimental study, 36 patients (age: 20–65 years old) with MDD were allocated to ECT group ($n = 21$) and non-ECT group ($n = 15$). Serum serotonin level of the ECT group was measured before ECT, 15 minutes and two, six, and 24 hours after the first session, and 24 hours and 30 days after the last ECT session. Measurements were performed at the time of admission and one month after hospitalisation in the non-ECT group. Data analysed with t-tests, repeated measures analysis of variance by SPSS16.

Results The mean serotonin levels of the two groups were significantly different 24 hours and 30 days after the last session of ECT ($P = 0.048$ and $P = 0.04$, respectively). The difference of mean serotonin levels in the ECT group before & 15 min after ECT ($P = 0.044$) before & 6 hour after ECT ($P = 0.015$), before & 24 hour after ECT ($P = 0.007$), before & 24 hour after last ECT (0.002) was meaningful.

Conclusion Altogether, our results showed that serum serotonin levels significantly increase following ECT in MDD patients.

³ Alberta Health Services, Department of Public Health, Fort McMurray, Canada

⁴ Alberta Health Services, Research Priorities and Implementation and Research Innovation and Analytics, Calgary, Canada

⁵ Alberta Health Services, Addiction and Mental Health Strategic Clinical Network, Edmonton, Canada

* Corresponding author.

Background Depression is projected to be the primary cause of disability worldwide by 2030. Our aim was to test the feasibility of a supportive text messaging mobile health intervention in improving treatment outcomes in depressed patients.

Methods We performed a single-rater-blinded randomised trial involving 73 patients with Major Depressive Disorder. Patients in the intervention group ($n = 35$) received twice-daily supportive text messages for 3 months while those in the control group ($n = 38$) received a single text message every fortnight thanking them for participating in the study.

Results After adjusting for baseline BDI scores, a significant difference remained in the three month mean BDI scores between the intervention and control groups: (20.8 (SD = 11.7) vs. 24.9 (SD = 11.5), $F(1, 60) = 4.83$, $P = 0.03$, $\eta^2 = 0.07$). The mean difference in the BDI scores change was significant with an effect size (Cohen's d) of 0.67. Furthermore, after adjusting for baseline scores, a significant difference remained in the three month mean self-rated VAS scores (EQ-5D-5L scale) between the intervention and control groups, 65.7 (SD = 15.3) vs. 57.4 (SD = 22.9), $F(1, 60) = 4.16$, $P = 0.05$, $\eta^2 = 0.065$. The mean difference in change mean self-rated VAS scores was also statistically significant with an effect size (Cohen's d) of 0.51.

Conclusions Our findings suggest that supportive text messages are a potentially useful psychological intervention for depression, especially in underserved populations. Further studies are needed to explore the implications of our findings in larger clinical samples.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Mobile health program to reduce psychological treatment gap in mental healthcare in Alberta through daily supportive text messages – Cross-sectional survey evaluating Text4Mood

V. Agyapong^{1,*}, K. Mrklas², M. Juhás¹, J. Omeje³, A. Ohinmaa⁴, S. Dursun¹, A. Greenshaw¹

¹ University of Alberta, Department of Psychiatry, Edmonton, Canada

² Alberta Health Services, Research Priorities and Implementation and Research Innovation and Analytics, Calgary, Canada

³ Alberta Health Services, Department of Public Health, Fort McMurray, Canada

⁴ University of Alberta, School of Public Health, Edmonton, Canada

* Corresponding author.

Background To complement the oversubscribed counselling services in Alberta, the Text4Mood program which delivers daily supportive text messages to subscribers was launched on the 18th of January, 2016. This report presents an evaluation of self-reports

of the impact of the program on the mental wellbeing of subscribers.

Methods An online link to a survey questionnaire was created by an expert group and delivered via text messages to mobile phones of all 4111 active subscribers of the Text4Mood program as of April 11, 2016.

Results Overall, 894 subscribers answered the survey (overall response rate 21.7%). The response rate for individual questions varied and is reported alongside the results. Most respondents were female (83%, $n = 668$), Caucasian (83%, $n = 679$), and diagnosed with a psychiatric disorder (38%, $n = 307$), including Depression (25.4%, $n = 227$) and Anxiety (20%, $n = 177$). Overall, 52% ($n = 461$) signed up for Text4Mood to help elevate their mood and 24.5% ($n = 219$) signed up to help them worry less. Most respondents felt the text messages made them more hopeful about managing issues in their lives (81.7%, $n = 588$), feel in charge of managing depression and anxiety (76.7%, $n = 552$), and feel connected to a support system (75.2%, $n = 542$). The majority of respondents felt Text4Mood improved their overall mental well-being (83.1%, $n = 598$).

Conclusion Supportive text messages are a feasible and acceptable way of delivering adjunctive psychological interventions. Given that text messages are affordable, readily available, and can be delivered to thousands of people simultaneously, they present an opportunity to help close the psychological treatment gap for mental health patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Explanatory and confirmatory factor structure of beck scale for suicide ideation in non-clinical sample

R. Alsaman*, B. Alansari

Department of Psychology, Kuwait University, Kuwait, Kuwait

* Corresponding author.

Introduction The Beck Scale for Suicidal Ideation (BSS) is a self-report 19-item scale preceded by five screening items. The BSS and its screening items are intended to assess a patient's thoughts, plans and intent to commit suicide. All 24 items are rated on a three-point scale (0 to 2). In this study, scores from the five screening items were included in the overall score. Therefore, total scores could range from 0 to 48. There is no study until this date that examines the factor structure of BSS among Kuwaitis.

Objectives The current study investigated the original three-factor model of the (BSS) in non-clinical sample.

Methods Sample one consisted of 285 males and 300 female students from Kuwait University while sample two consisted of 201 males and 302 females from Kuwait University. The Arabic version of BSS was administered to participants. Explanatory factor based on sample 1 and conformity factor analysis based on sample 2 of BSS were used in this study.

Results The explanatory and confirmatory factor analysis of (BSS) extracts three factors and three structures of BSS. Factor I = active suicidal desire; Factor II = preparation; Factor III = passive suicidal desire. In addition, the results revealed no significant gender differences in the factor structure of BSS.

Conclusions The results of both confirmatory and exploratory factor analysis indicated that the original three-factor model provided the best fit for the two genders.

Targeting kynurenine pathway in olfactory bulbectomised mice: Inflammatory and neurodegenerative pathway of depression

Y. Bansal*, A. Kuhad, R. Singh, P. Saroj
Pharmacology Lab, Panjab University, University Institute of Pharmaceutical Sciences, Chandigarh, India

* Corresponding author.

Aims and objectives The aim of study was to evaluate the pharmacotherapeutic efficacy of NDGA in experimental paradigm of depression i.e. olfactory bulbectomy (OB) specifically targeting kynurenine pathway.

Materials and method Depression like behaviours was induced in OB mice and evaluated by assessment of various behavioural (olfactory deficit test, forced swim test, splash test, open field test, sucrose preference test), biochemical (catalase, reduced glutathione, SOD, nitrite, MAO-A, MDA, corticosterone), inflammatory cytokines (TNF- α , IL-1 β , IL-6, IFN- γ) levels and alterations in delta sleep was recorded using EEG. Kynurenine pathway metabolites were determined in plasma and brain using HPLC method. After 14 days post-surgery, olfactory bulbectomized (OBX) mice were administered nordihydroguaiaretic acid (5 mg/kg, 10 mg/kg and 25 mg/kg) daily i.p.

Results We have developed a new HPLC method for simultaneous estimation of monoamines and kynurenine pathway metabolites in plasma and brain samples of mice. Chronic treatment with nordihydroguaiaretic acid significantly restored all behavioural, biochemical and neurochemical alterations in OBX mice and increase in quinolinic acid and decrease in kynurenic acid point out the neurodegeneration hypothesis of depression.

Conclusion Nordihydroguaiaretic acid showed potent neuropharmacotherapeutic effect in OBX mice by virtue of its strong anti-oxidant, anti-inflammatory, anti-stress and by restoring quinolinic acid levels.

Prefrontal theta cordance in the prediction of antidepressant response to various classes of antidepressants in patients with depressive disorder

M. Bares^{1,*}, T. Novak¹, M. Brunovsky², M. Hejzlar¹

¹ 2nd Department, National Institute of Mental Health Czech Republic, Klecany, Czech Republic

² EEG Department, National Institute of Mental Health Czech Republic, Klecany, Czech Republic

* Corresponding author.

Introduction and objectives Previous studies demonstrated efficacy of reduction of QEEG prefrontal theta cordance (RC) after the first week of treatment in the prediction of antidepressant response.

Aims The study aimed to compare the ability of RC in the prediction of response to various antidepressant classes.

Methods All patients ($n = 142$) were treated with antidepressants (SSRI-58, SNRI-47, NDRI-22, NaSSA-15) for ≥ 4 weeks. Response was defined as MADRS reduction $\geq 50\%$. EEG were performed at baseline and week 1 of treatment and cordance was calculated for 3 prefrontal electrodes (Fp1, Fp2, Fz).

Results Logistic regression identified RC as a predictor of response to SSRI, SNRI and NDRI but not for NaSSA. Predictive parameters of RC for response to mentioned antidepressant classes are displayed in the [Table 1](#).

Areas under curves of ROC analysis (AUC) of RC for response prediction were not significantly different among antidepressant classes. **Conclusion** The predictive efficacy of RC for response to SSRI, SNRI and NDRI was comparable.

This study was supported by the grants of MH CZ nr.15-29900A, MH CZ – DRO (NIMH-CZ, 00023752) and by the project Nr. LO1611 from the MEYS under the NPU I program.

Table 1

	SSRI	SNRI	NDRI
n	58	47	22
AUC RC week 1 (95%CI)	0.77 (0.65–0.87)	0.77 (0.62–0.88)	0.87 (0.66–0.97)
Positive predictive value of RC week 1 (95%CI)	0.81 (0.64–0.93)	0.72 (0.51–0.87)	0.91 (0.59–1.00)
Negative predictive values of RC week 1 (95%CI)	0.73 (0.52–0.89)	0.84 (0.60–0.97)	0.82 (0.48–0.98)
Accuracy of prediction	0.78	0.77	0.86

Major depressive disorder: Recurrence risk factors

R. Ben Soussia*, S. Khoudja, I. Marrag, S. Younes, M. Nasr
Psychiatry, CHU Tahar Sfar, Mahdia, Tunisia

* Corresponding author.

Introduction In spite of the frequency and the gravity of the depressive episodes, the major depressive disorder (MDD) is diagnosed and treated today insufficiently and the risk factors of its recurrence are little approached.

Aims of the study Describe the socio-demographic, clinical and therapeutic characteristics of patients with MDD and identify the factors involved in the recurrence risk.

Methodology This is a retrospective study carried out in the university hospital of Mahdia, Tunisia during two years. We have included patients with a follow up for at least two years and diagnosed with MDD, isolated episode or MDD, recurrent episode according to the DSM-IV-TR criteria. Data collection was performed using two pre-established questionnaires respectively with 51 and 92 items. We have estimated the time to recurrence with the Kaplan-Meier estimator.

Results We have collected 150 patients. The time to recurrence was 109 months. Five factors were associated with recurrence: early age at onset of the disorder, family history of mood disorders, severity of the index major depressive episode, persistent residual symptoms and ceasing treatment.

Conclusion Depression is a very common mental illness that is highly recurrent in individuals. There is great interest in the development of strategies that might reduce the recurrence of depression.

A person-centered approach to burnout-depression overlap

A. Lichtenthaler, R. Bianchi*

University of Neuchâtel, Institute of Work and Organizational Psychology, Neuchâtel, Switzerland

* Corresponding author.

Introduction Burnout has widely infiltrated the popular culture and has been extensively studied in both psychiatry and psychology. However, there are currently no consensual or binding diagnostic criteria for burnout. A major obstacle to the elevation of burnout to the status of nosological category is the overlap of burnout with depression.

Objectives We examined whether burnout and depressive symptoms can be distinguished from each other using a person-centered approach.

Methods A total of 1759 French schoolteachers took part in the present study (77% female; mean age: 41; mean length of employment: 15). Burnout symptoms were assessed with the Shirom-Melamed Burnout Measure (14 items) and depressive symptoms with a dedicated module of the Patient Health Questionnaire (9 items). Data were primarily processed using two-step cluster analysis. Correlation analysis and analysis of variance (ANOVA) were additionally carried out.

Results Considered as continuous variables, burnout and depression were found to be closely intertwined ($r=0.81$; disattenuated correlation: 0.91). Our cluster analysis revealed four different participant profiles, identifiable as “minimal burnout-depression” ($n=542$; 31%), “low burnout-depression” ($n=566$; 32%), “medium burnout-depression” ($n=412$; 23%), and “high burnout-depression” ($n=239$; 14%). Burnout and depression played equivalently important roles in cluster construction. Our ANOVA confirmed that the four clusters differed from each other in terms of burnout and depressive symptoms.

Conclusions Our findings are consistent with the view that the burnout syndrome is depressive in nature. A diagnostic category dedicated to burnout may therefore not be needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Is it time to characterize burnout as a depressive syndrome? A review of recent researchR. Bianchi^{1,*}, I.S. Schonfeld², E. Laurent³¹ *University of Neuchâtel, Institute of Work and Organizational Psychology, Neuchâtel, Switzerland*² *The City College of the City University of New York, Department of Psychology, New York City, NY, USA*³ *University of Franche-Comté, Department of Psychology, Besançon, France*

* Corresponding author.

Introduction More than 40 years after the introduction of the construct in the literature, the status of “burnout” remains unclear. Whether burnout is anything other than a depressive syndrome has been increasingly discussed in recent years.

Objectives We examined the extent to which burnout can be considered distinct from depression.

Methods We reviewed the literature dedicated to burnout-depression overlap over the last decade.

Results Recent research suggests that burnout and depression overlap in terms of (a) etiology, with (chronic) unresolvable stress a common, key causal factor, (b) clinical picture and course, with burnout and depressive manifestations inextricably linked such that they increase or decrease together over time, (c) cognitive

biases, with burnout and depressive symptoms similarly predicting increased attention to negative stimuli and decreased attention to positive stimuli, (d) dispositional correlates (e.g. neuroticism, rumination, pessimism), and (e) allostatic load—an index of the biological cost of adaptation to life adversity. Hypocortisolism has been linked to both burnout and depression with atypical features—a highly prevalent form of depression. The often-invoked argument that burnout is singularized by its job-related character is actually invalid given that (a) depression can also be job-related and (b) the “job-relatedness” of a syndrome is not nosologically discriminant in itself.

Conclusions Robust evidence that burnout overlaps with depression has accumulated in recent years. The burnout construct is unlikely to capture a distinct pathological phenomenon. We propose that burnout be characterized as a depressive syndrome for the sake of conceptual parsimony, theoretical clarity, and effective public health policies.

Antidepressants augmented with aripiprazole in the treatment of major depressive disorderS. Bise^{1,*}, G. Sulejmanpasic², D. Begic³, M. Ahmic⁴¹ *Psychiatric hospital, women, Sarajevo, Bosnia and Herzegovina*² *Clinical Center University of Sarajevo, Psychiatric clinic, intensive care, Sarajevo, Bosnia and Herzegovina*³ *Psychiatric hospital, intensive care, Sarajevo, Bosnia and Herzegovina*⁴ *Psychiatric hospital, men, Sarajevo, Bosnia and Herzegovina*

* Corresponding author.

Introduction Major depressive disorder (MDD) does not consistently respond to any single antidepressant (AD) therapy. Adjunctive therapy with atypical antipsychotics (AA) showed higher response rates compared with AD monotherapy. Aripiprazole, an oral quinolinone, is the first AA agent to be approved in the US as adjunctive treatment in adult patients with MDD.

Aim The aim was to evaluate the efficacy and safety of adjunctive low-dose aripiprazole combined with AD versus AD monotherapy in patients with MDD with minimal improvement after 4 weeks of prior AD monotherapy.

Methods Ten patients with MDD and a history of minimal improvement to 4 weeks of AD monotherapy (escitalopram 10–15 mg/day, sertraline 50–100 mg/day) were included in this study. The patients were randomly assigned to 2 groups: one ($n=5$) with AD plus aripiprazole 5–7.5 mg/day and the other ($n=5$) with AD alone. After baseline assessment, the subjects were followed up at weeks 2, and 4. The primary efficacy was the mean change in (HAM-D17) and CGI-I.

Results The aripiprazole group exhibited significantly better efficacy than the AD group in mean total score changes of HAM-D17 and CGI from the baseline to weeks 2, and 4. The item “work and social activities” of HAM-D 17 showed significant improvement at week 4, and the item “somatic symptoms (GI)” showed significant improvement at week 2.

Conclusions Adjunctive aripiprazole therapy significantly improved depressive symptoms in MDD who didn’t respond to AD monotherapy. Aripiprazole augmentation is an efficacious, well-tolerated and safe treatment for patients with MDD.

Mood disorders in elderly patients hospitalized for acute exacerbation of COPD

I. Bonfitto^{1,*}, G. Moniello², M. Pascucci¹, A. Bellomo¹

¹ University of Foggia, Department of Mental Health ASL-FG-SPCD, Foggia, Italy

² Azienda Ospedaliera-Universitaria "Ospedali Riuniti", Operative Unity of Geriatrics, Foggia, Italy

* Corresponding author.

Introduction Chronic obstructive pulmonary disease (COPD) represents the most common cause of chronic respiratory failure and it's associated with several comorbidities such as depression. Depression is about four times more frequent in elderly patients with COPD compared to peers who are not affected and its prevalence increases with the degree of disease severity.

Objective To assess mood and perception of the quality of life in elderly patients hospitalized for acute exacerbation of COPD.

Methods Thirty-five elderly patients hospitalized for reactivation of COPD were examined; they were subjected to spirometry test for the calculation of FEV1 and to COPD Assessment Test (CAT) and Hamilton Rating Scale for Depression (HAM-D) to evaluate impact of COPD on patients' quality of life and depressive symptomatology, respectively. The number of COPD exacerbations in the last year prior to hospitalization and the number of recovery days required for the stabilization of patients were also recorded.

Results There were strongly significant correlations ($P < 0.001$), positive between HAM-D scores, CAT scores, number of exacerbation in the last year and hospital length of stay and negative between HAM-D scores and FEV1 values. Furthermore, females were more depressed, with lower FEV 1 ($P = 0.043$) and with a longer length of stay ($P = 0.039$) as compared to males.

Conclusions A greater severity of depressive symptoms is related to a greater severity of COPD exacerbations, disability associated with it and perceived by the patient, as well as a higher number of recovery days and annual acute exacerbations, particularly in female gender.

Cortisol awakening response and depression in acute coronary syndrome patients

V.M. Buonomenna^{1,*}, F. Marciello¹, V. Caivano¹, G. Cascino¹, G. D'Agostino¹, D. Nunziata¹, P. Monteleone²

¹ Seconda Università di Napoli, Department of Psychiatry, Naples, Italy

* Corresponding author.

Introduction Although the available evidence strongly supports an association between depression and coronary heart disease (CHD), the possible biological link between these two conditions still remains to be clarified. The hypothalamus-pituitary-adrenal (HPA) axis is the main endogenous system mediating the stress response and changes in cortisol secretion have been associated with depressed mood in patients with CHD. Therefore, the study of the correlation between cortisol levels and depressed mood in acute coronary syndrome (ACS) patients could help to clarify the nature of the relationship between ACS and the risk to develop a depressive syndrome.

Objective We aimed to explore the relationships between HPA axis activity and depressed mood in ACS patients.

Aims The purpose of this study was to determine whether the cortisol awakening response (CAR) is associated and/or predict depressive symptoms in patients with an ACS.

Method Patients admitted to an ACS ward were asked to fill in the Beck Depression Inventory (BDI) and to collect saliva samples in the morning to measure their CAR. All the procedures were carried out within 1 week after an ACS. Patients were asked again to fill in the BDI six months after their ACS.

Results A lower CAR was associated with higher BDI scores after 6 months from an ACS.

Conclusions Our preliminary results suggest that hypoactivity of the HPA axis in the first week of an ACS may predict more severe depressive symptoms after 6 months from the ACS.

Rewarding network mechanism of left orbito-frontal cortex transcranial magnetic stimulation in depression

Q. Dai^{1,*}, Y. Xuntao², F. Zhengzhi³

¹ Third Military Medical University, Department of Nursing psychology, Chongqing, China

² Third Military Medical University, Radiological department, the Southwest Hospital of the Third Military Medical University, Chongqing, China

³ Third Military Medical University, Department of psychology, Chongqing, China

* Corresponding author.

Objective The difficulties in the clinical antidepressant treatment lead to the pursuing of more effective methods such as transcranial magnetic stimulation (TMS). Mixed findings from DLPFC targeted TMS result in the exploration of optimal stimulation location. Disturbed function of orbitofrontal cortex (OFC) has been indicated in depression, which is involving in the remission of depression. However, whether it could be a more specific treating target is not tested. Simultaneously, disturbed reward network (RN) has been confirmed in depression, however, whether this could be improved by TMS treatment remains unclear.

Methods Fourteen patients with major depressive disorder (MDD) were allocated in a four-week course of OFC targeted TMS. Motivated by the literature, before and after the treatment, the function connectivity of RN with the seed of ventral striatum was conducted. The results were also compared with the data from 33 healthy controls.

Results The OFC targeted TMS improved the clinical depression significantly and enhanced the function connectivity within the RN effectively. Specifically, lower baseline dorsolateral striatum connectivity predicted strong therapeutic effect of TMS on depression, while lower baseline insula connectivity predicted weak therapeutic effect on depression.

Conclusions The findings offer the first experimental evidence of the therapeutic effect of OFC targeted TMS on clinical depression, enhanced function connectivity within RN might be the potential neural mechanism (Fig. 1). Lower dorsolateral striatum connection might be a reliable neural biomarker of strong responding for TMS treatment, which helps to identify the patients who will be cured by TMS most effectively.

* Corresponding author.

Introduction Antepartum depression has garnered wide recognition from the scientific community in recent years. This has led to the replacement of the term postpartum with perinatal in the 5th edition of the DSM with regards to pregnancy associated depression. Personality may play a significant role in the susceptibility for developing perinatal depression.

Objectives The current research aimed to analyze the role of different facets of personality in mediating the occurrence of both, perinatal depression and perinatal anxiety, in women who gave birth in our region.

Methods A prospective survey was conducted at “Bega” Clinic Timisoara in 118 women being monitored during their antepartum period. Of these, 80 women attended to the second assessment between 6 to 8 weeks of their postpartum period. Postnatal depression was assessed by the Edinburgh Postnatal Depression Scale using a cut-off > 13. Personality was assessed by using the NEO-FFI Inventory that is five-factor model based.

Results The presence of antepartum depression was identified in 28 (23.7%) of pregnant women while postpartum depression was detected in 7 new mothers (8.8%). Among the NEO-FFI Inventory factors only Neuroticism had significant higher mean scores in both antepartum and postpartum depressive women ($P=0.003$ and $P=0.016$ respectively). There were also significant correlations between Neuroticism and antepartum and postpartum levels of both trait and state anxiety.

Conclusions In the psychological management and approach of delivering women Neuroticism should be taken into account as a possible mediating factor for both depression and anxiety during their perinatal period.

The subjective perception of time as a factor of the course of depressive disorders

V. Fedchenko*, T. Panko, G. Kalenska

“Institute of Neurology Psychiatry and Narcology of National Academy of Medical Science of Ukraine” SI, Borderline Pathology, Kharkiv, Ukraine

* Corresponding author.

Introduction Personal peculiarities of the individual are the separate significant factor of formation and course of depression that has a predictive value.

Objectives Investigation of an emotionally significant attitude of patients to their past, present, future and also depending on the severity of depressive symptoms.

Methodology Forty patients with depressive episodes (F 32.0, F 32.1, F 32.2) and 35 persons without mental disorders were examined. An integrated approach was applied using the method of “Semantic time differential”.

Results Correlation analysis showed that in mild depression patients experienced their present condition changed, it is associated with emotional assessment of the past ($r=-0.441$) and extrapolated their experiences for the future—feeling doubt about their implementation in the future, including its activity ($r=-0.484$) and size ($r=-0.523$). In a moderate degree of depression patients in the present acutely realized that they had depression and from the point of view of this condition perceived their past and future—feeling a structureness and size of the past ($r=0.500$) and worrying about the emotional background, structureness and activity of the future ($r=-0.500$, $r=-0.756$ and $r=-0.500$, respectively). In severe depression patients did not associate their condition with the past, realized the presence of depression in the present, and did not expect to improve their emotional conditions in the future ($r=-0.432$).

Conclusions The data can be used to assess the dynamics of patient’s conditions with depressive episodes as well as to develop an adequate psychotherapy.

* Corresponding author.

Introduction Cognitive impairment in patients with depressive disorder is a subject of intensive research.

Objectives This study deals with the cognitive impairment in patients with severe depressive episode with psychotic symptoms and patients with major depressive disorder during the acute state of illness.

Aims The aim was to define domains and the level of cognitive impairment in both groups of patients.

The next aim was to compare profiles of cognitive impairment in both groups of patients.

The last aim was to find out a relationship between cognitive performance and severity of depressive episode during the acute state of illness.

Methods We have used neuropsychological test battery (Auditory–Verbal Learning Test, Rey–Osterrieth Complex Figure Test, Logical Memory, Digit span test, Trail making test, Verbal Fluency Test, Block Design and Benton Visual Retention Test) for the evaluation of the cognitive functions in patients with severe depressive episode with psychotic symptoms ($n=5$) and patients with major depressive disorder ($n=8$).

Results We found cognitive impairment in all examined domains in both groups of patients.

More profound cognitive impairment was found in patients with severe depressive episode with psychotic symptoms, particularly in visual memory, visuo-constructive abilities, speed of cognitive processing and executive functions. We found no correlation between cognitive performance and severity of depressive episodes.

Conclusions Our findings suggest a strong correlation between psychotic symptoms in depression and cognitive performance.

Maternal depressive symptom trajectories and psychosocial functioning in young adults: A 27-year longitudinal study

I. Luoma^{1,*}, M. Korhonen², R. Salmelin³

¹ Tampere University Hospital, Child Psychiatry, Tampere, Finland

² Helsinki University Hospital, Child Psychiatry, Helsinki, Finland

³ University of Tampere, School of Health Sciences, Tampere, Finland

* Corresponding author.

Introduction Maternal depression is a well-known risk factor for child development. Longitudinal studies extending from pregnancy to adulthood, however, are rare.

Objectives The aim of the study was to investigate whether maternal high depressive symptom trajectories (chronic or intermittent depressive symptom patterns) from pregnancy to the adolescence of the children predict lower adaptive functioning or higher levels of emotional or behavioural symptoms in young adults.

Methods The sample comprised 329 first-time mothers from maternity centres in Tampere, Finland. Maternal depressive symptoms were assessed with the Edinburgh Postnatal Depression Scale (EPDS) antenatally and at two months, six months, 4–5 years, 8–9 years and 16–17 years after delivery. A model including four symptom trajectories (very low, low-stable, high-stable and intermittent) was selected to describe the symptom patterns over time. Adaptive functioning and problems of the children ($n=144$) were assessed by the Adult Self Report forms (Achenbach & Rescorla) at the age of 27 years.

Results High maternal depressive symptom trajectories did not predict self-reported lower adaptive functioning of the children in adulthood. However, children of mothers with chronic or intermittent depressive symptom patterns reported higher levels of internalising problems as well as symptoms of depression and anxiety in young adulthood than the children of mothers with very low or low stable symptom patterns.

Conclusions High maternal depressive symptom trajectories predict higher levels of emotional symptoms of children in young adulthood. The mechanisms of intergenerational transmission are important topics for further research.

Objective To assess the efficacy and tolerability of quetiapine as add-on to antidepressant agents in treatment-resistant late-life major depression.

Methods A group of 15 patients, 8 male and 7 female, mean age 68.2, evaluated in our department for clinical symptoms that made possible a DSM 5 diagnosis of major depressive disorder, were initiated on quetiapine XR, flexible daily dose 50–300 mg QD. All patients were on treatment with an antidepressant—either a selective serotonin reuptake inhibitor (SSRI) ($n=10$), or venlafaxine ($n=5$)—for at least 6 weeks and presented no improvement during current treatment administered at therapeutic doses. Patients were assessed using Montgomery Asberg Depression Rating Scale (MADRS), Clinical Global Impression–Severity (CGI-S), Global Assessment of Functioning (GAF), and Columbia Suicide Severity Rating Scale (C-SSRS) every 4 weeks for 3 months.

Results After 12 weeks, patients had a mean improvement in MADRS score of $45.7 \pm 2.3\%$, with a final mean MADRS score of 13.5 ($P < 0.01$). No variations were registered depending on the specific SSRI or venlafaxine concomitant treatment. Quetiapine XR mean daily dose administered during the study was 125 mg. C-SSRS didn't register significant variations in suicidal ideation or behavior throughout the trial. Overall GAF score increased with 22.1 points, and CGI-S decreased with a mean of 1.5 points at week 12 ($P < 0.01$). Tolerability of add-on quetiapine was very good, no serious adverse event being reported.

Conclusions Quetiapine was efficient and well tolerated in late-life resistant major depression, as add-on to SSRIs or venlafaxine, during the 12 weeks of the trial.

The clinical course of depression: Chronicity is the rule rather than the exception

J. Verhoeven*, J. Verduijn, Y. Milaneschi, A. Beekman, B. Penninx

VU University Medical Center, Psychiatry, Amsterdam, The Netherlands

* Corresponding author.

Introduction Major depressive disorder (MDD) is often considered an episodic disorder. However, literature might underestimate the chronicity of MDD since results depend on follow-up dura-

tion and the extent to which psychiatric co-morbidity is taken into account.

Aim To determine, whether MDD should be considered an episodic or chronic disorder.

Objective To examine the 6 year course of MDD, incorporating data of multiple time points and taking common psychiatric co-morbidities into account.

Methods Data were from 903 patients with current MDD at baseline in the Netherlands study of depression and anxiety, with subsequent data from 2 year, 4 year and 6 year follow-up. Four course trajectories were created taking all information during follow-up into account classifying patients as (1) recovered, (2) recurrent without chronic episodes, (3) recurrent with chronic episodes or (4) consistently chronic. A chronic episode was defined as having symptoms consistently over 2 years.

Results The recovery rate of MDD was 58% at 2 year follow-up but looking at 6 year follow-up and taking into account co-morbid dysthymia, (hypo) mania and anxiety disorders reduced this recovery rate to 17%. Moreover, more than half of the patients experienced chronic episodes.

Conclusions Longitudinal data of this psychiatric cohort study showed that full recovery is the exception rather than the rule. MDD follows a chronic course and, moreover, persons are prone to switch to other psychiatric disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁵ University Psychiatric Hospital Vrapče, Department of Forensic Psychiatry, Zagreb, Croatia

* Corresponding author.

Introduction NaSSA antidepressant mirtazapine and SARI trazodone has proven efficacy on MDD.

Aim To compare differences in mirtazapine and trazodone efficacy on MDD in different age and sex groups.

Methods A consecutive sample of 60 MDD outpatients were randomized to mirtazapine 30 mg/day or trazodone 150 mg/day for a 3 months stable dosing period at the department of biological psychiatry and psychogeriatrics of the university psychiatric hospital Vrapče, Croatia. Outcome was relative lowering of HAM-D-17 scale result. The study was single blind: rater was blinded, while patients informed regarding prescribed medication.

Results Overall efficacy of mirtazapine and trazodone was comparable (84% lowering of HAM-D-17 in both cases; difference $P=0.754$). After adjustment for MDD baseline severity (CGI-S), education, marital and working status, interaction of age and sex significantly moderated two drugs' efficacies. In patients older than 47 years, in male patients trazodone was significantly more effective, and in female patients significantly less effective than mirtazapine. This effect was increasing by aging.

Conclusion Mirtazapine and trazodone efficacy on MDD is moderated by patients' age and sex.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Shalvata Mental Health Center, Child and Adolescent Outpatient clinic, Hod Hasharon, Israel

* Corresponding author.

Introduction The evaluation of response to pharmacological treatment in MDD requires 6–8 weeks. Therefore, the ability to predict response, and especially lack of response to treatment, as early as possible after treatment onset or change, is of major significance. Many studies demonstrated significant results regarding the ability to use EEG and ERP markers. However, these markers are derived from long EEG/ERP samples, often from multiple channels, which render them impractical for frequent sampling.

Methods We developed a new electrophysiological attention-related marker from a single channel (2 electrodes) and 1 minute samples. This work presents an initial evaluation of the ability to harness this marker, for early differentiation between responders and non-responders to anti-depressive treatment, in 26 patients with various levels of depression and heterogeneous treatment interventions and 10 healthy controls. Subjects who initiated treatment for depression were followed clinically through their Hamilton depression scores as well as their EEG activity twice a week for a period of 8 weeks. Any acceptable anti-depressive treatment been included. The improvement in Hamilton scores at the end of 8 weeks used to discriminate responders and non-responders.

Results Within two weeks, we could differentiate between non-responders and responders to anti-depressive treatment, with absolute discrimination between subjects with moderate to severe depression, and with 0.71 sensitivity and 0.96 specificity within the whole depressed subjects.

Conclusions This is a proof of concept for an easy to use, cheap and quick marker for the lack of respond to anti-depressive treatment within two weeks of anti-depressive treatment.

The dopaminergic polymorphisms in psychomotor retardation of depression: A pathway-based imaging genetics association study

Y. Yin*, Y. Yuan

Affiliated ZhongDa Hospital and Institute of Neuropsychiatry of Southeast Univer, Department of Psychosomatics and Psychiatry, ZhongDa Hospital School of Medicine Southeast University, Nanjing, China

* Corresponding author.

Introduction Several lines of evidence implicate dopamine is involved in the psychomotor retardation (PMR) in major depressive disorder (MDD). Besides, abnormal cerebral blood flow (CBF) of PMR was also found in the cortico-basal ganglia-thalamo-cortical

(CBTC) circuitry. We hypothesize that the polymorphisms of the dopaminergic pathway should be associated the abnormal CBF in the CBTC circuitry.

Objective To investigate the association of the polymorphisms throughout the dopaminergic pathway with the cerebral blood flow (CBF) of PMR in MDD.

Methods The blood sample of 63 patients (23 PMR, 40 NPMR) were collected for genotyping the dopaminergic polymorphisms (92 SNPs from 10 genes). After quality controlling, 15 SNPs in 8 candidate genes were entered into the mass univariate modeling analysis. For the statistical analysis, patients with unqualified fMRI image and unmatched demographic data were ruled out. Consequently 56 patients (23 PMR, 33 NPMR) were taken into the statistical analysis.

Results Genotype-by PMR associations with the CBF differences predominately distributed in bilateral prefrontal cortex (PFC), temporal cortex, and striatum, the left thalamus, the right primary motor cortex, insular cortex, fusiform gyri, and lingual gyri. There were significant negative correlation between the CBF of the PFC and the PMR severity. However, the CBF of the striatum and the thalamus were positively correlated with the PMR severity.

Conclusions The polymorphisms of dopaminergic pathway are associated with not only CSTC circuitry, but also some other brain regions involving in cognition and emotion controlling. While the increased CBF of PFC might suppress PMR, the increased CBF of striatum and thalamus adversely aggravate PMR.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction ADHD is one of the most common neuropsychiatric disorders in children. The worldwide prevalence is estimated to be between 2–18%. The exact cause of ADHD is still unknown, but some factors have been found to increase the risk of having ADHD like increase TV exposure time and video games.

Objectives To study the association between time spent on computer tablets (iPads or Android tablets) by children and ADHD.

Methods This cross sectional study targeted children from 3 to 12 years old who use computer tablets. Two non-random sampling techniques were used to distribute self-administered questionnaires to one of the caregivers of 275 children, 36 of them installed an application in their children's computer tablets that measures the actual time spent by the children. The questionnaire contains demographics, validated Arabic ADHD rating scale and questions to assess the parental attitude. The SPSS package was used for statistical analysis.

Results The results showed that the overall prevalence of ADHD is 22.2% and it is higher in males. There is no statistically significant association between ADHD and all variables except for the time spent on computer tablets, which showed that children using computer tablets more than the average time have an increased chance of having ADHD with an odds ratio of 1.9 with 95% confidence interval from 1.08 to 3.40.

Conclusion This study shows an association between time spent on computer tablets by children and ADHD. There is need for longitudinal studies to demonstrate the temporality and to confirm the association.

Disclosure of interest The authors have not supplied their declaration of competing interest.

“Tell me more and help me to decide, doctor” – Information seeking attitudes and use of information resources in patients with depression

H. Almeida^{1,*}, M. Figueiredo-Braga²

¹ Hospital Magalhães Lemos, B, Porto, Portugal

² University of Porto, Department of Clinical Neurosciences and Mental Health Faculty of Medicine, Porto, Portugal

* Corresponding author.

Introduction Shared decision-making (SDM) has shown to improve adherence, decrease hospitalization, and enhance knowledge of the illness and satisfaction with mental health services. Eliciting each patient's preferences for information allows tailoring the physician behavior according perspectives and expectations. Patients with depression (PWD) have frequently limited information regarding the availability and efficacy of psychiatric treatments.

Aims/objectives Unveil information seeking attitudes of patients with depression and their a priori use of digital sources of information.

Methods A convenience sample of PWD was submitted to a battery of self-report questionnaires. Standardized instruments were used to measure information seeking attitudes and the accessibility and usage of digital information resources.

Results Thirty-six patients were inquired, with a mean age of 39.8 (13.4) years. Information-seeking preferences were high, with an API-I score of 90.1 (13.8). Preferences for information-seeking behaviors were higher in severely depressed ($P=0.010$) and less educated ($P=0.026$) patients. Preferences were negatively correlated with length of psychiatric treatment ($r=-0.514$; $P=0.002$). Sixty-one percent had a priori information regarding their psychiatric problem, and 68.8% considered it was influential in the decision-making behavior. Access and use of digital resources were correlated with education level (0.644; $P=0.000$ and 0.554; $P=0.003$), age (-0.357 ; $P=0.001$ and -0.559 ; $P=0.007$) and illness severity (-0.431 ; $P=0.04$).

Conclusion Patients with depression want to be informed about their mental condition and treatment options. Few resources are used and decision mostly relies on health professional's opinion and guidance. Accessible resources seem scarce and future research shall address the acceptance and impact of decisional-aid instruments on this population.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Remote cognitive behavior therapy for obsessive-compulsive disorder in Egypt: A randomized trial

R. Aly

Egyptian Association of Cognitive Behavior Therapy, Research, Cairo, Egypt

Introduction Recently, cognitive behavior therapy has gone from being a promising new treatment to the most well established psychological treatment. In several hundreds of randomized controlled trials, it has shown effectiveness in treating obsessive-compulsive disorder. In addition, CBT is thus a highly promising treatment from a societal cost-effectiveness perspective.

Objectives Several forms of CBT have been developed using remote communication methods, the general idea is that CBT delivered through the Internet or using telephone communication reflects the content of conventional CBT, but is administered as a form of therapist-guided treatment protocol.

Aims Estimation of applicability and efficacy of remote cognitive behavior therapy for treating patients suffering from obsessive-compulsive disorder in Egypt.

Methods A group of patients suffering from obsessive-compulsive disorder was randomized into two groups; one received CBT as usual and the intervention group received CBT using telephone and/or the Internet. Both groups were assessed pre- and post treatment using the Yale Brown Scale for OCD symptom severity and Beck depression inventory for symptoms of associated depression. The quality of life scale was also applied to all patients participating in the study.

Results Pre- and post-study measures indicated a statistical and clinically relevant change in patients of two groups.

Conclusions Delivering CBT for patients suffering from OCD in Egypt using remote communication methods appears to be effective in alleviating symptoms and improving the quality of life. Yet some adaptations to the standardized treatment protocol are mandated to render the protocol applicable through remote communication and enhancing cultural reception.

Developing a platform for online psychotherapy sessions

M. Bran^{1,*}, M. Ladea¹, M. Sarpe²

¹ University of Medicine and Pharmacy "Carol Davila", Psychiatry, Bucharest, Romania

² CMI "Marcel Sarpe", Psychiatry, Focsani, Romania

* Corresponding author.

Introduction Providing mental health services by real-time videoconferencing has been increasingly adopted as a method of reaching hard-to-serve populations since the early 1990s. There is a growing body of evidence investigating the efficacy of delivering online mental health care. Though studies vary in quality, they generally demonstrate that online mental health care is effective across multiple age groups. Online is generally well accepted by patients and specialists and its implementation is feasible. It is also convenient and cost effective.

Objectives Due to the fact that almost 75% of Romanian population have internet access and that mental health services are still stigmatized we perceived the opportunity to develop an online platform where patients can easily find and interact with mental health specialists using secured videoconference.

Methods During a timeframe of two years a multidisciplinary team managed to develop and test an online platform where patients can access psychotherapy sessions. Main design and devel-

opment targets were usability and confidentiality/security. The platform has an appointment tool, a secure videoconference solution and an integrated online payment service.

Results The platform can be accessed at <https://atlashelp.ro>. It was launched in mid July 2016 and it already gathers more than 50 mental health specialists. The feedback was excellent from both specialists and patients.

Conclusions The solution developed is compliant with most of international standards and offers easy to access and high quality psychotherapeutic services for Romanian patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Automatic analysis of psychotherapy videos by using synchrony signal

T. Gargot^{1,*}, G. Varni², M. Chetouani², D. Cohen¹

¹ Hopital de la pitie salpetriere, Departement de psychiatrie de l'enfant et de l'adolescent, Paris, France

² Universite Pierre et Marie Curie, Institut des Systemes Intelligents et de la Robotique, Paris, France

* Corresponding author.

Introduction Some techniques of psychotherapy are now widely evidence-based and very cost effective, especially cognitive and behavioral therapies. Most of the studies are indirectly based on patient reported outcomes or problematic behaviors evaluated before and after the psychotherapy. Unfortunately, studies struggle to control for what is actually happening during psychotherapy, especially the non-specific aspects, like the interaction between the patient and the therapist, that is a known predictor of psychotherapeutic efficacy. Consequently, it is difficult to make precise links between theory and practice, control its application and understand which of its ingredients are the most important.

Objectives Here, we suggest a research framework to extract automatically social signals from psychotherapy videos. We focused on the extraction of synchrony of the motor signal since it was considered to be a predictor of psychotherapeutic outcome in an earlier study and a relevant signal for the study of mother-child interactions.

Methods We developed open source python and R scripts to compute this synchrony of motion history on a database of interaction between a parent and a child <http://bit.ly/syncpsy>

Results We confirmed that synchrony, was a relevant signal for studying social interactions since the scores are completely different from synchrony scores computed on shuffle motion history data. However, these scores alone are unable to distinguish the two periods of the videos (with and without disagreement).

Conclusion Synchrony of motion history is a promising marker of social interactions.

Telemedicine – How does it work in practice?

J. Kachnic, M. Wojtuszek, J. Wutke, K. Krysta*, M. Krzystanek

Medical University of Silesia, Department of Rehabilitation

Psychiatry, Katowice, Poland

* Corresponding author.

Introduction Today telemedicine is a very popular and rapidly growing area, which allows the treatment, regardless of the distance between the patient and doctor. We present the latest research, conducted amongst polish doctors about the usefulness of telemedicine as a therapeutic tool in different medical specialties.

Objectives and aims The aim of the study was to examine doctors' attitude to telemedicine and usefulness of Platform 'Moneo' in the therapy of the areas other than psychiatry.

Methods The first part was the polish telemedical project (grant no. POIG.01.04.00–04–219/12) conducted to assess medical Platform 'Moneo'. It was based on a questionnaire filled by participants in scale 1 to 5. The second study based on authors' anonymous questionnaires was distributed amongst 105 psychiatrists from Poland. **Results** Everybody noticed advantages of medical platform. The Platform's functionalities, rated as the best by healthcare directors were: educational materials, appointment and therapy planning. Managers indicated parts, which could be improved in e-prescribing system, the process of collecting information about hospitalizations and operations. Functionalities indicated by doctors as desirable to increase the utility of the platform is e-prescribing system, reporting side effects, planning visits, educational materials. In study addressed to psychiatrists, only 15% of them claimed to have an extensive knowledge on telepsychiatry, but they had confirmed the potential of telemedicine in psychiatry. **Conclusion** Telemedicine is a useful method, which can improve quality of healthcare services and make an access to it possible for some people. However, lots of improvements in telemedical services are needed to make it an efficient medical tool.

Smartphone for mental health patients: A double-edged weapon?

M. Mâalej*, M. Turki, C. Nada, S. Hentati, O. Sana, Z. Nassreddine, Z. Lobna, B.T. Jihène, M. Mohamed Hedi Chaker University Hospital Faculty of Medicine Of Sfax, Psychiatry "C", Sfax, Tunisia

* Corresponding author.

Introduction The current development of new technologies dedicated to healthcare, such as smartphones, provides an interesting opportunity to improve both assessment and follow-up of different illnesses, particularly mental diseases.

Aim To investigate, the contributions and risks of smartphone use among mental health patients.

Methods We conducted a literature research of PubMed and Scencedirect using the key words "smartphone"; "bipolar disorder"; "schizophrenia"; "anxiety disorders"; "addiction"; "dementia".

Results Literature data provide several examples of the use of the smartphone's features for patient monitoring. One such example involved patients with Alzheimer disease. An attempt to deal with the risk of wandering was proposed with the use of the Android app iWander, which works by using the smartphone's GPS to track the patient at all times. As for bipolar disorder, several applications have been proposed both for diagnostic instruments... and interventional purposes (applications that offer subjects psychoeducation in the form of emotional self-awareness...). Several other applications can be used in the management of schizophrenia, social anxiety disorder and addictions. Along with its obvious benefits, however, the smartphone use has a dark side. Problematic smartphone use is one form of behavioral addiction recently identified. In addition, the access to Internet through the smartphone opens the door to Internet addiction and its sub-types (cybersexual addiction, cyber-relationship addiction...).

Conclusion The use of smartphone for medical purposes must be cautious among mental health patients, because of a field of vulnerability that promotes the appearance of other mental diseases, especially addictions, which may darken their prognosis.

Online clinic, a new method of delivering psychotherapy

M. Omrani^{1,*}, N. Alavi², M. Rivera³, S. Khalid-Khan³

¹ Rutgers University, Brain Health Institute, Piscataway, USA

² University of Toronto, Psychiatry, Toronto, Canada

³ Queen's University, Psychiatry, Kingston, Canada

* Corresponding author.

Introduction Psychotherapy is one of the most widely investigated and practiced forms of treatment used in the treatment of different mental health problems. However, there are some barriers in delivering this treatment, including long waiting lists, therapist shortage and lack of access to therapists in remote areas. Therefore, using alternative methods to overcome these barriers seems necessary.

Method The division of psychiatry at Queen's university provides different psychotherapy groups for individuals suffering from different kinds of mental health problem. We gave the participants the opportunity to choose online psychotherapy through an online clinic or the live group sessions. All the patients were assessed by different questionnaires for evaluation of the efficacy of the treatment. The online clinic was designed to facilitate the communication between patients and clinicians and the material was delivered in PowerPoint format through the online platform. All user activities were logged for security purposes.

Results Statistical analysis showed that this method of delivering psychotherapy significantly reduced patients' symptoms and also decreased the number of people on the waiting list and increased the amount of compliance in patient's taking part in psychotherapy and number of people who were able to receive psychotherapy.

Conclusion Despite the proven short and long-term efficacy of psychotherapy, there are some barriers in delivering this treatment. It is an unequivocal public health needs to overcome these barriers through alternative methods of therapy. With Internet use ever rising, developing an online clinic could be a new way in delivering different kinds of psychotherapy.

Disclosure of interest I am a co-founder at the Canarmony Corp, which has developed an online psychotherapy platform named OPTT.

New technologies in suicide prevention

M. Pompili

Sapienza University of Rome, Department of Neurosciences, Mental Health and Sensory Organs, Rome, Italy

Introduction The use of new technologies is beginning to be embraced by volunteers and professionals, from crisis lines, suicide prevention centers, mental health centers, researchers and politicians.

Objectives New technologies have entered the field of suicide prevention with high expectations for the future, despite a relatively slow start. Internet, smartphones, apps, social networks and self-help computer programs have a strong potential to achieve, sustain and help people at risk of suicide, their families, teachers, health professionals and for the survivors.

Aims To provide comprehensive overview on the role of new technologies in suicide prevention.

Methods Given the relatively early and underdeveloped state of this area of inquiry, the author viewed his task as gathering and critically appraising the available research relevant to the topic, with the aim of formulating a hypothesis to be tested with further research.

Results New cheaper services will soon be available to effectively reach and assist the most vulnerable people and prevent suicides.

The potential to help vulnerable people who do not use conventional mental health services and people in regions with inadequate psychiatric facilities represents an attractive target with favourable perspectives for suicide prevention. Smartphone, apps, websites, avatar coach, and virtual suicidal subjects are important for both delivering help as well as to educate mental health professionals as in the case of role playing.

Conclusions Shadows and lights are emerging through the use of new technologies. If more people can be reached there are however concern for improper use of social network and pro-suicide websites.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Ecological momentary assessment of bipolar disorder episodes with a smartphone application: Study protocol

M. Blom¹, U. Karilampi¹, H.K. Carlsen¹, M. Ioannou¹, M. Sörhag¹, S. Steingrimsdóttir^{2,*}

¹ Sahlgrenska University Hospital, Psychiatry, Gothenburg, Sweden

² Sahlgrenska Academy, Centre of Ethics, Law and Mental Health CELAM, Gothenburg, Sweden

* Corresponding author.

Introduction Subclinical symptoms of depression or mania, present prior to clinical manic or depressive episodes in individuals with bipolar disease. Mobile applications that measure habitual behavioral patterns such as mobility, physical activity level and social engagement present an opportunity to identify state transitions preceding relapse. This could lead to earlier intervention and improved treatment outcome.

Aims To identify associations between changes in habitual behavioral patterns measured with smartphone usage and psychiatric emergency room visits or admissions for bipolar patients.

Methods In a case-crossover study, around 70 patients at a specialized outpatient clinic for bipolar disorder will be offered to install MoodMapper[®], an application that registers text message and calls (but not communication content or recipients), mobility (but not location), number of steps taken, screen-time, and battery level. A baseline level for each individual will be established. Deviations from baseline habitual behavioral patterns in the time preceding a psychiatric emergency room visits or admissions will be analyzed in order to establish predictor variables. The patients will be followed up to 18 months.

Results Preliminary results will be presented.

Discussion Smartphone-collected behavioral data can be used to predict worsening or improvement of a patient's condition. As smartphone ownership becomes more commonplace, mobile apps present a unique opportunity to detect digital real-time signatures of mental illness in a way that is minimally invasive to individual's daily life and privacy.

Searching the Internet is one of the main sources for obtaining health and medical information. When searching the Internet, users can find information published by various organizations, companies, agencies or institutions and also information posted by users on the user-oriented Internet platforms, such as forums, blogs, and various social networks. There are no single, standardized mechanisms to ensure the truthfulness, objectivity, credibility and comprehensibility of health information available on the Internet. Moreover, a very small proportion of medical content on the Internet is revised or moderated by health experts. The aim of this study was to examine the motives for using schizophrenia Internet forums in Croatia. The study sample consists of user-generated posts on the largest Croatian schizophrenia Internet sub-forum over a period of one year, analyzed using qualitative methodology-grounded theory. The results showed that the majority of users use schizophrenia Internet forums to receive emotional support from others with the same diagnosis. Other important reasons were to exchange information about medications, symptoms and prognosis of the illness. It was noted that a large number of entries, with information about drugs and symptoms of the illness, contain inaccurate information. Posts about treatment and symptoms of schizophrenia provided by Internet forums often contain unverified information and can potentially harm users of such forums and also undermine doctor-patient relationship. Expert moderation of these forums and better education of patients by their physician, could help patients receive better medical care and to strengthen the confidence of patients in their physicians.

Structured risk assessment: Aggression and safety in ambulatory emergency service

M. Arts^{1,*}, P. Sanderse-Besselink², H. Terburg², R. Van De Sande³

¹ University of Groningen, University Medical Center Groningen, Department of Old Age Psychiatry, Groningen, The Netherlands

² GGZWNB, Old Age Psychiatry, Bergen op Zoom, The Netherlands

³ University of Applied Sciences Utrecht HvU, Nursing Science, Utrecht, The Netherlands

* Corresponding author.

Introduction Discussing the threat of aggression is not always at the forefront in ambulatory care providers. A structured risk analysis model for ambulatory emergency psychiatry is currently not available, while aggression does occur regularly.

Objectives and aims The aim of this study is to evaluate the added value of a risk analysis model and implement the best available model in emergency outpatient practice.

Methods The study design is a mixed method model. Semi-structured questionnaires were administered by nurses and psychiatrists. A benchmark study took place at an outpatient

emergency service in South Netherlands. A literature search was performed using PubMed and CINAHL for the period 2000–2014.

Results From this research, we found a discrepancy between the perception and the actual occurred aggression. Care workers often do not discuss aggression related issues, however, case studies show that aggression does occur frequently. In literature studies we have found several risk assessment models, most of which are used within the inpatient psychiatry.

Conclusion To avert aggression incidents and prevent recurrence, it is important to maintain a solid risk analysis model. Introducing a checklist risk crisis service (CRC) can promote a critical reflection on the threat of aggression and bring awareness on the theme of aggression. Implementation of a CRC in daily practice can be of great value.

Incidence of Gamma-Hydroxybutyrate (GHB) abuse and dependence in a rural crisis resolution team in the Netherlands

P. Michiels^{1,*}, L. Propadalo¹, M. Arts²

¹ Mental Health Western Northern Brabant, Out Patient Clinic General Adult Psychiatry, Halsteren, The Netherlands

² Mental Health Western Northern Brabant, Old Age Psychiatry, Halsteren, The Netherlands

* Corresponding author.

Introduction GHB abuse and dependence are common in the Western region of Northern Brabant, a rural region in the south of the Netherlands.

Aim The main goal is to look at the incidence and management of GHB abuse and dependence seen by the CRT in a rural area.

Method This is a retrospective data analysis based on patient files of all assessments of the Western Northern Brabant crisis resolution team (CRT) from 2013 till 2015. Inclusion criterion was current or recent (<24 hours) use of GHB with or without alcohol and other drugs. Several parameters were studied: frequency, duration and dose of GHB use, reason for referral and treatment/policy, which is used (admission, prescribed medication).

Results On a total of 4093 cases 50 persons were included. It shows that the percentage over the years has remained about the same (resp. 1.13%, 1.54% and 1.02%). Of all cases 41.5% used GHB only, 39.6% also used other drugs, and 9.4% GHB with alcohol and other drugs. During the assessment in the emergency department 37.7% was treated with a benzodiazepine, while 43.4% received no psychotropic medication.

Conclusion GHB abuse and dependence are not commonly seen in the CRT, but the withdrawal symptoms can be challenging and GHB withdrawal is often accompanied by aggressive outbursts. Therefore, it is very important to make a decision whether outpatient or inpatient treatment is necessary and if psychotropic medication is needed.

EW0134

Clinical effects of the suicide attempt with topiramate

G. Montero*, I. Alberdi, L. Niell, R.Á. Baena

Instituto de Psiquiatría y Salud Mental, Department of Psychiatry, Hospital Clínico San Carlos, Madrid, Spain

* Corresponding author.

Objectives We report the case of a 45-year-old male diagnosed with mixed personality disorder brought the hospital for strange behavior. He is being treated with fluoxetine, lorazepam and topiramate; and visited his psychiatrist 72 hours ago.

Results He has an adequate level of consciousness and describes retrograde amnesia of the last 72 hours. We found blocks of thought and abnormal behaviors such as dressing and undressing or sorting his belongings repetitively. Urine was only positive for benzodiazepines. In arterial blood gas analysis it performed highlights compensated metabolic acidosis. After ruling out neurological diseases and administering fluids i.v. the symptoms remitted, persisting only the amnesia, establishing the diagnosis of suicide attempt with topiramate.

Conclusions The use out-of-guidelines of topiramate in personality and eating disorders is an increasingly common habit in daily clinical practice, as well as suicide attempts with this drug. In therapeutic doses, over 40% of patients taking topiramate, have asymptomatic metabolic acidosis, which in stressful situations may have clinical relevance. In case of acute poisoning, metabolic acidosis is more frequent and severe, manifesting itself by hyperventilation, hypertension and varying degrees of impaired consciousness and cognitive functions. There is also a paradoxical increase in the frequency of seizures. Treatment is supportive and there is no antidote, being lethal cases exceptional. Gastric lavage and administration of activated charcoal have limited use. The determination of plasma concentrations of topiramate is not available for most centers and is not useful in acute poisoning.

Disclosure of interest The authors have not supplied their declaration of competing interest.

How involuntary admission might have been avoided: An interview study of referring general practitioners

K. Røtvold¹, R. Wynn^{2,*}

¹ University Hospital of North Norway, Division of Mental Health and Addictions, Tromsø, Norway

² UiT The Arctic University of Norway, Department of Clinical Medicine, Tromsø, Norway

* Corresponding author.

Introduction The legal criteria for involuntary admission in Norway are that the patient has a serious psychiatric disorder (i.e. psychosis) and is in need of admission to secure needed treatment or that there is a risk of danger. While there have been some studies focusing on coercion in hospitals, less is known about the processes leading up to involuntary admission and the reasoning of referring doctors. In Norway, it is primarily general practitioners (GPs) that refer patients.

Aims To study which factors that GPs who had recently referred patients to involuntary admission thought might have made their latest referral unnecessary.

Methods Seventy-four GPs were interviewed by phone. They had all recently referred patients involuntarily to a major Norwegian university psychiatric hospital. One central question concerned how their latest involuntary referral might have been avoided.

Results These are the main factors that the GPs thought could have been of importance in avoiding involuntary referral of their patients:

- that the patient took the prescribed medication (28%);
- that they personally had the opportunity to closely follow up the patient in the following days (22%);
- that other health care staff could follow up the patient closely in the patient's own home (i.e. home care nursing, etc.) (19%);
- that a family member of the patient could help the patient (8%).

Conclusions The GPs suggested that an increased availability of resources and more assistance from other parts of the health service

were some of the factors that could be of importance in reducing involuntary admissions.

EW0136

Comparison of self-reported to observational agitation scales

L. Zun^{1,*}, L. Downey²

¹ Mount Sinai Hospital, Emergency Medicine, Chicago, USA

² Roosevelt University, Health Policy, Chicago, USA

* Corresponding author.

Background Increasingly, psychiatric patients are presenting to the emergency department (ED) with agitation. ED staff rarely, if ever, use scale to assess agitation or use any self-assessment tools to determine a patient's level of agitation.

Objectives To evaluate the relationship between a patient's self-reported level of agitation and other validated agitation assessment tools.

Methods This is a prospective study using a convenience sample of patients presenting to the ED with a psychiatric complaint. This study was conducted in an urban, inner-city trauma level 1 center with 55,000 ED visits a year. After obtaining consent, a research fellow administered observational tools, PANSS-EC and ACES and BAM and Likert scale self assessment tools on arrival to the ED. SPSS version 24 was used. The study was IRB approved.

Results A total of 139 patients were enrolled. The most common ED diagnoses were depression, schizophrenia, or bipolar. Majority of patients were African-American (59%), falling in the 25–44 year old age range (56%) 52% male. Self-reported agitation was rated as moderate to high in 72.4% of these patients on the Likert scale and 76.3% on the BAM. There was a significant correlation between the self-reported score versus the BAM ($F = 11.2$, $P = 0.00$). However, the self-reported scores were significantly different from the scores assessed by observational tools ($P < 0.05$).

Conclusions ED providers should assess a patient's self-reported level of agitation because a patient could be feeling markedly agitated without expressing outward signs detected by observational tools.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Intrafamilial homicide: A descriptive study of fratricide in Quebec

D. Bourget^{1,*}, P. Gagné², A. Labelle¹

¹ The Royal Ottawa Mental Health Centre, Psychiatry, Ottawa, Canada

² University of Sherbrooke, Psychiatry, Sherbrooke, Canada

* Corresponding author.

Introduction Fratricide comprises approximately 2% of all intra-familial homicides. Analyses of national data on fratricide show that adult males are considerably more likely to be offenders and victims or fratricide. A previous study suggested there were two main categories of fratricide: related to alcohol intoxication or associated with mental disorder.

Objectives Present and discuss the results of an original study comprising 28 cases of fratricide.

Aims To provide up-to-date scientific knowledge on fratricide.

Method This is a retrospective study of 28 cases of fratricides, extracted from a sample of over 1000 consecutive cases of

coroners' files of victims of domestic homicide occurring between 1990–2015.

Results Two victims out of three were males, most of adult age. There were only 2 female offenders in the whole sample. A majority of victims were Caucasians while 21% were aboriginals. Most victims were stabbed to death. The murders usually occurred at the residence of the victim. In total, 39% of offenders suffered from a major mental illness; 21% were acutely intoxicated at the time. In victims, 29% were under the influence of alcohol and 18% of offenders were free from mental problems.

Conclusion Our data indicates that fratricides are most often impulsive and lack preparation. The most common method was the opportunistic use of a knife, suggestive of impulsive killing, and this is consistent with the rest of the information including the high rate of alcohol use and intoxication at the time. The study confirmed two main categories of fratricide: impulsive killing in the context of alcohol and dispute and killing associated with psychosis.

A residential psychiatric approach for forensic patients: The experience of "Tiziano" facility

C. Cargioli^{*}, L. Polese, G. Macchia

USL Toscana Nord Ovest, Psychiatry, Aulla MS, Italy

* Corresponding author.

Introduction Italian forensic mental hospitals closed on March 31st, 2014 and offenders sentenced to need a psychiatric care are restrained in facilities. Since 2002, the residential psychiatric facility "Tiziano" (Aulla, Massa-Carrara) hosts forensic patients, on appointment with national health system and compulsorily admitted by the justice system.

Methods This descriptive and prospective study provides a thorough report on the main epidemiological, clinical, and criminological features of 60 mentally ill offenders hosted in the "Tiziano" facility between 2002 and June 2016.

Results Most forensic patients were male (90%, $n = 54$; average age: 33 years). Sixty percent of subjects ($n = 36$) had a clinical diagnosis of psychosis (19.4% affective psychosis, 72.2% non-affective psychosis, 8.4% organic psychosis), and about one third of them (31.6%, $n = 19$) had a personality disorder (63.1%, $n = 12$, antisocial personality disorder, 42.1%, $n = 8$, borderline personality disorder, 21.0%, $n = 4$ other personality disorders). Mental insufficiency was diagnosed in 11.6% ($n = 7$) of subjects, while substance use disorder affected 35.0% ($n = 21$) and alcohol use disorder 26.6% ($n = 16$). Forty-nine patients (81.7%) had committed serious crimes against people; 15% ($n = 9$) were murderers or attempted murderers, and 46.7% ($n = 28$) had committed more crimes. The average length of stay is 22 months.

Conclusions To date, there are no data about long-term follow-up and clinical outcome of mentally ill offenders restrained in Italian psychiatric facilities. Additional studies are needed to assess psychopathology and differentiate treatment according to diagnosis, and to identify risk factors of relapse for criminal behavior relapse.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A systematic review and synthesis of outcome domains for use within forensic services for people with intellectual disabilities

R. Alexander¹, V. Chester^{2,*}, P. Langdon³

¹ Partnerships in Care Learning Disability Services, Psychiatry, Norwich, United Kingdom

² Partnerships in Care Learning Disability Services, Psychiatry, Palgrave, Diss, Norfolk, United Kingdom

³ University of Kent, Tizard Centre, Kent, United Kingdom

* Corresponding author.

Aims In response to the Winterbourne scandal, and the large number of people with intellectual disabilities (IDs) and offending behavior being treated in psychiatric hospitals, this study identified the domains that should be used to measure treatment outcomes of this group.

Methods A systematic search of relevant databases was undertaken to identify domains. Sixty studies met the eligibility criteria, and findings were synthesized using content analysis. The findings were refined within a consultation and consensus exercises with carers, service users, and experts.

Results The final framework encompassed three a priori superordinate domains (a) effectiveness, (b) patient safety, and (c) patient and carer experience. Within each of these, further subdomains emerged from our systematic review and consultation exercises. These included severity of clinical symptoms, offending behaviors, reactive and restrictive interventions, quality of life and patient satisfaction.

Conclusions To index recovery, services need to measure outcome using this framework.

Abuse during childhood and burnout

E. Di Giacomo^{1,*}, F. Pescatore², F. Colmegna³, F. Di Carlo³, M. Clerici⁴

¹ PhD program in Neuroscience, Doctorate School of the University of Milano-Bicocca, Psychiatric Department S. Gerardo Health Care Trust-Italy, Milan, Italy

² University of Milano Bicocca, School of Medicine and Surgery, Monza, Italy

³ S. Gerardo Health Care Trust, Psychiatric Department, Monza, Italy

⁴ University of Milano Bicocca, School of Medicine and Surgery, Milano, Italy

* Corresponding author.

Background Childhood maltreatment is the most important risk factor for the onset of psychiatric disorders. Revictimization is really frequent as well as substance or alcohol abuse, often linked to self-treatment. Accordingly, our pilot study aims to analyze possible implication of childhood maltreatment on resilience and burnout.

Methods Patients admitted to outpatients psychiatric department in a six month period (1st January 2015–30th June 2015) complaining low to moderate anxiety or depression have been administered childhood trauma questionnaire (CTQ) and Maslach burnout inventory.

Results CTQ results in 71 (87%) Emotional Neglect (EN), 2 (2.4%) Sexual Abuse (SA) and 2 (2.4%) Physical Abuse (PA). Twenty-one showed high emotional exhaustion, 21 high depersonalization, 9 moderate personal accomplishment while 1 showed low personal accomplishment. None of the patients who suffered child sexual abuse shows depersonalization or personal accomplishment difficulties linked to burnout. Patients negative to CTQ show respec-

tively moderate emotional exhaustion ($M = 20 \pm 20.15$), moderate depersonalization (11 ± 9.42) and high personal accomplishment (17 ± 12.38). Patients who suffered emotional neglect show the poorest profile at Maslach, particularly regarding emotional exhaustion. ANOVA reaches statistical significance among the 3 groups of detected abuse (EN, SA, PA) in personal accomplishment ($P = 0.013$) confirmed at POST HOC between EN and SA ($P = 0.0004$).

Conclusion The results obtained in this pilot study highlight two important considerations. First, it seems urgent to stress the huge prevalence of emotional neglect among those referred to psychiatric outpatient department due to moderate anxiety or depression complain. Moreover, emotional neglect appears to be the most compromised factor of burnout, especially if compared to sexual abuse.

Mental health problems among male offenders and youths with conduct problems

G. Halilaj¹, N. Fanaj^{2,*}, F. Drevinja¹

¹ Kosovo Forensic Psychiatry Institute, Forensic Psychiatry, Prishtina, Kosovo

² Community Based Mental Health Center, Mental Health Center, Prizren, Kosovo

* Corresponding author.

Background Mental health problems among youth, are frequent especially in offenders and as such is very important to identify as early as possible.

Objectives To estimate and compare level of some mental health problems between three groups of male youths: juvenile offenders in correctional center, adolescents with conduct problems and university students.

Method It is cross-sectional quantitative study. The sample consisted of three male groups: 41 offenders placed in one correctional center (Mean age = 18.02; SD = 2.20); 41 male students of secondary school with conduct problems (Mean age = 16.97; SD = 61) and 42 male university students randomly selected (Mean age = 19.7; SD = 1.77). They filled questionnaire MAYSI-2. Data processing was done with SPSS 21.0 and Microsoft Excel 2013.

Results Juvenile offenders in correctional center scored significantly higher than other two groups of youth in alcohol/substance abuse subscale ($P = 001$), Suicidal ideation subscale ($P = 048$) and traumatic stress subscale ($P = 003$) based on Kruskal-Wallis Test. Juvenile offenders in correctional center scored higher but non-significantly in angry/irritable and depression/anxious subscales. Students of secondary school with conduct problems scored higher but non-significantly in thought disturbance and somatic subscales.

Conclusion Male juvenile offenders have significantly more mental health difficulties. Mental health needs of youths in Kosovo (especially juvenile offenders) seem to be numerous and is important to be addressed properly.

Causes of institutionalization of children and adolescents in a shelter in Brazil

E. Guilherme^{1,*}, S.D. Dos Santos²

¹ Instituto de Psiquiatria, Universidade de São Paulo, Brazil, Núcleo Forense, Mafra-SC, Brazil

² Universidade do Contestado, Psychology, Mafra, Brazil

* Corresponding author.

Introduction A growing number of studies investigating the relationship between violence and problems in child psychiatry. Consistent findings have been verified in studies related to aggressive behavior, antisocial and post-traumatic stress disorder with the violence against children. The financial costs associated with child abuse and neglect, including future lost earnings and expenses with mental health treatments were estimated at \$ 94 billion US in 2010. The abuse and child neglect can cause permanent changes in the body's response to stress, with profound changes in the brain development.

Methods Consisted of an exploratory study of character quantitative and qualitative, with document design. Records of children and adolescents who stayed in the shelter from 2011 to 2015 were surveyed. In order to collect data was used input and shutdown records used for shelter.

Conclusions Unlike Brazil and the rest of the world's data, the leading cause of institutionalization in this work in the town of Mafra, was neglect rather than abuse. Perhaps for the under-reporting of abuse cases. This, coupled with the fact that there are no typically physical findings associated with sexual abuse, made the detection more difficult. This paper alerts the importance to increase our ability to identify all child abuse experiences, for protecting our children. Not only sexual abuse, but also physical abuse could benefit from strategies to enhance detection.

Addiction and violence among people with severe mental illnesses: An updated literature review

I. Khemiri*, F. Fekih Romdhane, A. Belkhiria, J. Lamia, R. Trabelsi, I. Ghazeli, R. Ridha

Hospital Razi, Forensic Psychiatry Department, Tunis, Tunisia

* Corresponding author.

Introduction Violence has important relevance for the criminal justice and health care systems especially forensic psychiatry. Previous studies reported the relation between violence, mental illness and substance abuse. We purpose to investigate the association between addiction and violence among people with severe mental illness through a review of literature.

Method we conducted a Medline and Pubmed literature search of studies published between "2000 and 2015", combining the terms "psychotic disorders", "addiction" "substance use disorder".

Results The studies published showed that much of the excessive violence observed in patients with severe psychiatric disorders is due to co-morbid substance use. Increasing violence associated with substance use disorders in these patients had same level than that observed among subjects without severe psychiatric disorders. Increasing violence in subjects with substance use disorder but without severe mental disorders was higher than in patients with only severe mental disorders. In fact, mental disorders could increase the risk of installing on substance use disorders, and therefore increase the risk of partner violence. Among the substances used, if alcohol is frequently identified as a consumer risk for the emergence of violence among subjects with severe psychiatric disorders, stimulants could be causing more violence than alcohol.

Conclusions Severe mental illnesses are associated with violence. However, most of the excess risk appears to be mediated by substance abuse co-morbidity. This finding improves the need of prevention of substance use disorders and emphasizes the fact that patients with severe mental disorders are more often victims than perpetrators of violence.

Experiences of young offenders and health-care professionals involved in transitions from forensic adolescent mental health services: A qualitative study

M. Livanou*, V. Furtado, S. Singh

University of Warwick, Warwick Medical School Division of Mental Health and Wellbeing, Coventry, United Kingdom

* Corresponding author.

Introduction Transitions from child and adolescent mental health services to adult mental health services have been quite troublesome for young people in the UK. There is strong evidence throughout the literature that long waiting lists and rigid adult services criteria hamper dramatically transitions across services. Little knowledge exists about transitions from forensic adolescent services to adult services.

Objectives To interview health-care professionals and young offenders in transition of care from forensic child and adolescent mental health services in England.

Aims This study aimed to bridge the current literature gap in regards to transitions across forensic services and the complexities resulting from disruptive care.

Methods This study adopted a prospective design to identify young offenders referred to adult services over a six-month period. We utilized semi-structured interviews. Health-care professionals were interviewed about their transition views and perspectives. Young offenders were followed-up within a month of their transition and were interviewed.

Results The numbers of transitions within forensic settings are much lower compared to those of general transitions across mental health services in England. Transition delays were a repetitive theme across interviews due to lack of bed availability, especially in medium secure hospitals, and poor multi-agency communication. Commissioning determines age boundaries along with transfer destination for each service.

Conclusions Ineffective liaison among different sectors might impact adversely young people and hallmark their long-stay in the system. Therefore, continuity of care within forensic services should be looked warily along with the role of policy shaped by commissioning. Multiple transitions can repeatedly traumatize young people moving across services.

Social determinants, which encourage the criminal desistance in young people in conflict with the law

M. Orlando

Member Of The Argentinian Law Court, Criminal Justice, Buenos Aires, Argentina

Introduction Previous studies about young people in conflict with the law (YPCL) have a tendency to focus on the risk factors that contribute to trigger antisocial criminal behavior. Instead, this study aims to research the social determinants that encourage the criminal desistance: understood as a gradual process taking place in the periods of absence of crime and desire to abandon the criminal activity.

Objectives From a sample that is made up of 100 YPCL, the main objective is to deduce the social determinants, which encourage the criminal desistance in YPCL, it means young people who commit crimes.

Aims To infer the social determinants (circumstances in which people are born, grow, live, including the health system) which foster the desistance in YPCL.

Methods The results of a sample of 100 YPCL were assessed with three profiles as follows: I: DSM-IV personality disorders (PD T-Scores). II: swap personality syndromes (Q-Factor T-Scores). III. factor T-scores.

Results This research shows the prevalence of the following social determinants associated with the desistance: (1) integrated families. (2) Educational and cultural opportunities (3) academic progress. (4) Healthy relationships that support and help. (5) Stable living arrangements (6) social conditions preserved the use of psychoactive substances and alcohol abuse.

Conclusions It is possible to identify the prevalence of social determinants which encourage the desistance in YPCL. Those allows them to transform their risk path in another that shows a positive development, associated with individual transformations that take them away from the criminal life and reintegrate into the community.

Assessing violence in psychosis – A clinical prediction rule

F. Seena^{1,*}, A. Wolf¹, T. Fanshawe²

¹ University of Oxford, Psychiatry, Oxford, United Kingdom

² University of Oxford, Department of Primary Health Care Sciences, Oxford, United Kingdom

* Corresponding author.

Background Current approaches to stratify patients with psychosis into risk groups are limited by inconsistency, variable accuracy, and unscalability.

Methods This paper will present an overview of current approaches based on a systematic review. It will also present a novel scalable approach based on a total national cohort of 75 158 Swedish individuals aged 15–65 with a diagnosis of severe mental illness (schizophrenia, schizophrenic-spectrum, bipolar disorder, and other psychotic illnesses). We developed predictive models for violent offending through linkage of population-based registers and tested them in external validation. We measured discrimination and calibration for prediction of violent offending at 1 year using specified risk cut-offs.

Findings : A 16-item model was developed from pre-specified routinely collected criminal history, socio-demographic and clinical risk factors. In external validation, the model showed good measures of discrimination (c-index 0.89) and calibration. For risk of violent offending at 1 year, using a 5% cut off, sensitivity was 64% and specificity was 94%. Positive and negative predictive values were 11% and 99%, respectively. The model was used to generate a simple web-based risk calculator (OxMIV).

Interpretation We have developed a prediction score in a national cohort of all patients with psychosis that can be used as an adjunct to decision-making in clinical practice by identifying those who are at low risk of future violent offending and higher risk individuals who may benefit from additional risk management. Further evaluation in other populations and countries is needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW0147

Forensic psychiatric assessment of individuals with mental and behavioral disorders due to use of alcohol, who committed homicide

A. Survilaite

National forensic psychiatry service, adult department, Vilnius, Lithuania

Introduction The rate of pure alcohol consumption per capita in Lithuania is reported to be one of the highest in Europe Union. Many studies illustrate the relationship between alcohol and violent crimes. Though dual diagnosis of severe mental disorder and alcohol dependency is common.

Aim To evaluate peculiarities of mental status of individuals with mental disorders due to use of alcohol, who had committed homicide.

Methods Forensic psychiatry examination reports in alcohol consumption cases and homicide acts (n 110) were taken from archive of national service of forensic psychiatry in Lithuania, 2010–2014.

Results In total, 93% (n 91) men and 100% (n 12) women at the time of homicide act were under the influence of alcohol. A total of, 83% (n 91) of cases reported impulsiveness, emotional lability and personality degradation due to long term of alcohol consumption; 52% (n 57) of cases motives for violence remained unclear: offenders indicated they remember nothing because of alcohol intoxication, also possible malingering was evaluated. In total, 100% women (n 12) and 97% men (n 95) were criminally responsible. Only 2 individuals committed homicide as a result of psychosis due to paranoid schizophrenia and 1 individual had significant intellectual deficiency due to moderate mental retardation, which lead them to inability to appreciate the dangerous nature of their acts and to control their behavior. Compulsory medical treatment was recommended to all three of them.

Conclusion Impulse control deficiency and emotional lability are prevalent amongst homicide offenders with mental disorders due to use of alcohol. Only 3 individuals were irresponsible for their criminal acts as a result of severe mental disorders.

Assessments of need for treatment and danger in decisions about community treatment orders

H.K. Stuen¹, A. Landheim¹, J. Rugkåsa², R. Wynn^{3,*}

¹ Innlandet Hospital Trust, Norwegian National Advisory Unit on Concurrent Substance Abuse and Mental Health Disorders, Brummundal, Norway

² Akershus University Hospital, Health Services Research Unit, Lørenskog, Norway

³ UiT The Arctic University of Norway, Department of Clinical Medicine, Tromsø, Norway

* Corresponding author.

Background A total of, 14 Norwegian assertive community treatment (ACT) teams have been established. During the teams' first year of operation, approximately 35% of the enrolled patients were subjected to community treatment orders (CTOs) at intake. CTOs are a legal mechanism to secure treatment adherence, and may be used in Norway when severely mentally ill patients refuse necessary treatment ('treatment criterion') or when they are considered a danger to themselves or others ('danger criterion'). Even if the use of CTOs seems to increase in Norway, few have examined in detail how and why these decisions are made. The purpose of the present study was to explore assessments of need for treatment and danger in decisions about CTOs.

Method Semi-structured interviews with eight responsible clinicians and four focus-group interviews with 20 ACT providers were recorded and transcribed. We also read case files and observed selected treatment planning meetings. The data were analyzed with a modified grounded theory approach.

Results The ACT teams provided high-intensive services over longer periods of time, which gave the teams important knowledge about the patients, reduced clinical uncertainty, and allowed for well-informed decisions about the need for coercive interventions. The treatment criterion was typically used to justify the need for CTOs. However, the danger criterion was in some cases used when patients had to be readmitted to hospital.

Conclusions According to the clinicians that were interviewed, patients' need for treatment was most often used to justify the CTOs in the Norwegian ACT teams.

Postpartum depression in a public hospital in Cyprus. Prevalence, risk factors

K. Argyropoulos¹, G. Andreou², D. Avramidis^{1,*}, P. Gourzis³, G. Charalambous², E. Jelastopulu¹

¹ Medical School, University of Patras, Public Health, Patras, Greece

² Frederick University, Postgraduate Program Health Management, Nicosia, Cyprus

³ Medical School, University of Patras, Psychiatry, Patras, Greece

* Corresponding author.

Introduction Postpartum depression (PPD) is a serious mental health condition. Untreated PPD places the mother and infant at risk and is associated with significant long-term effects on child development and behavior.

Objectives Appropriate screening for and prompt recognition and treatment of depression after the birth of a child are essential for maternal and child well-being.

Aims The purpose of the present study was to estimate the prevalence of PPD in the first 5 days after the birth of a neonate and to investigate associations with several risk factors.

Methods A cross-sectional study was conducted among 150 mothers, in a public obstetric hospital in Nicosia, Cyprus. A questionnaire was administered including socio-demographic characteristics. The Greek version of the Edinburgh postnatal depression scale (EPDS), a 10-item questionnaire to identifying women who are at risk of PPD, was used to estimate depression among the participants.

Results According to EPDS, 42% of the mothers screened positive for risk of developing PPD. Higher risk was observed in very young mothers (<20 years) (66.6% vs 15%), in women with history of psychological disorders (86.95% vs 33.85%), in single mothers (71.69% vs 22.8%), in women with serious problems during the pregnancy (74% vs 23.95%) and in mothers with not healthy neonate (75.7% vs 32.4%).

Conclusion The study reveals a high prevalence of PPD and identifies various risk factors associated with developing PPD. The use of maternal depression screening programs such as the EPDS may help to recognize an elevated risk of postpartum depression and to ensure a healthier mother-child relationship.

Antidepressant use during pregnancy and the risk of major congenital malformations in a cohort of depressed pregnant women: A re-analysis of the Quebec pregnancy cohort

A. Bérard^{1,2,*}, J.P. Zhao¹, O. Sheehy¹

¹ CHU Sainte-Justine, Research Center, Montréal, Canada

² University of Montreal, Faculty of Pharmacy, Montréal, Canada

* Corresponding author.

Objective To quantify the association between first-trimester antidepressant exposure and the risk of major congenital malformations (MCM) in a cohort of depressed women.

Method Data were obtained from the Quebec pregnancy cohort. All pregnancies with a diagnosis of depression or anxiety, or exposed to antidepressants in the 12 months before pregnancy, and ending with a live-born singleton were included. Antidepressant classes (selective serotonin reuptake inhibitors (SSRI), serotonin norepinephrine reuptake inhibitors (SNRI), tricyclic antidepressants (TCA), and other antidepressants), and types were individually compared to non-exposure during the first-trimester (depressed untreated). MCM overall and organ-specific malformations in the first year of life were identified.

Result Eighteen thousand four hundred and eighty-seven depressed pregnant women were included. Citalopram use during the first-trimester was increasing the risk of MCM (aOR 1.36, 95%CI 1.08, 1.73; 88 exposed cases). Antidepressants with serotonin reuptake inhibition effect (SSRI, SNRI, amitriptyline (the most used TCA)) were increasing the risk of certain organ specific defects: paroxetine was increasing the risk of cardiac defects (aOR 1.45, 95%CI 1.12, 1.88), and ventricular/atrial septal defects (aOR 1.39, 95%CI 1.00, 1.93); citalopram was increasing the risk of musculoskeletal defects (aOR 1.92, 95%CI 1.40, 2.62), and craniyosynostosis (aOR 3.95, 95%CI 2.08, 7.52); TCA was associated with eye, ear, face and neck defects (aOR 2.45, 95%CI 1.05, 5.72), and digestive defects (aOR 2.55, 95%CI 1.40, 4.66); and venlafaxine was associated with respiratory defects (aOR 2.17, 95%CI 1.07, 4.38).

Conclusion Antidepressants with effects on serotonin reuptake during embryogenesis are increasing the risk of some organ specific malformations in a cohort of pregnant women with depression.

Dealing with specific cognitive dysfunctions associated with psychiatric vulnerability in intellectual developmental disorders

D. Scuticchio, A. Bianco*, M. Rossi, M. Piva Merli, M.O. Bertelli

CREA Research and Clinical Center, San Sebastiano Foundation,

Misericordia Di Firenze, Florence, Italy

* Corresponding author.

Introduction Despite the increasing evidence of common neurodevelopmental alterations and high simultaneous or sequential co-occurrence, the relationship between specific cognitive dys-

functions and psychiatric vulnerability has not been adequately studied, not even in people with intellectual developmental disorders (IDD), whose rate of mental health problems is up to 4 times higher than the general population.

Aim The aim of the present paper is to investigate the correlation between specific cognitive dysfunctions or dysfunctional cognitive patterns and the presence of specific psychiatric symptoms and syndromes in people with IDD.

Methods A sample of 52 individuals with IDD consecutively attending a clinical facility for multidisciplinary evaluation, in Florence, Italy was assessed through the SPAID (psychiatric instrument for intellectual disabled adult) system, the WAIS III - R (Wechsler adult intelligence scale III - Revised), the TMT (trial making test), and other neuropsychological tools. Psychiatric diagnoses were formulated by expert clinicians in accordance to DC-LD or DM-ID criteria. The main procedure of the data statistical elaboration was the calculation of frequency and correlation indexes.

Results Some relevant correlations have been found, that between executive frontal functions, autistic traits and impulse control disorder, and that between working memory and bipolar disorder were among the strongest.

Conclusions In people with IDD some cognitive alterations or 'characteristics' significantly correlate with the presence of psychiatric disorders. The possibility to understand the nature of this relationship seems to increase with the degree of specificity of variables in both the cognitive and the psychopathological assessment.

QulQ (quick instrument for quality of life): A new instrument for a rapid assessment of generic quality of life

A. Bianco*, D. Scuticchio, M. Piva Merli, M.O. Bertelli
CREA Research and Clinical Center, San Sebastiano Foundation,
Misericordia di Firenze, Florence, Italy

* Corresponding author.

Introduction Recently, new patient-oriented outcome measures have emerged in mental health research and practice. Among these, generic quality of life (GQoL) has gained a central place and has come to represent a valid endpoint in most settings, from basic care programs to clinical trials, especially for the field of intellectual disability (ID). However, most studies still refer to health-related QoL, and the tools for the assessment of GQoL present many issues related to the structure complexity and administration time.

Aim The purposes is to evaluate psychometric properties of a new rapid tool for the GQoL assessment named QulQ (quick instrument for quality of life), originally constructed for use for people with ID.

Methods Two hundred and ten persons with ID were consecutively administered with the QulQ. A part of them were also assessed with the BASIQ, the Italian adaptation of the quality of life instrument package. QulQ has the same conceptual framework and refers to the same areas of the BASIQ, but include a low number of dimensions (only attribution of importance and perception of satisfaction) and a factor way of score attribution such as visual analogue scale and graphic geometrical mean calculation.

Results QulQ showed good internal coherence (Cronbach's $\alpha = 0.92$), inter-rater reliability (Cohen's $K > 0.93$), and concurrent validity (> 0.8) with BASIQ.

Conclusion These findings seem to display for the QulQ good psychometric characteristics. They also suggest that it could be possible to apply rapid QoL assessment to all the range of people with ID. This could have very important implications for future massive use in different settings.

Predictors of the use of psychosocial interventions in Portugal: Results from the SMAILE project

G. Cardoso¹, A. Antunes^{2,*}, A. Loureiro², P. Santana²,
J. Caldas-de-Almeida², M. Silva²

¹ NOVA Medical School, Faculdade de Ciências Médicas, NOVA University of Lisbon, Chronic Diseases Research Centre CEDOC, Lisboa, Portugal

² University of Coimbra, CEGOT, Centre of Studies on Geography and Spatial Planning, Coimbra, Portugal

* Corresponding author.

Introduction The treatment of psychiatric disorders depends on a combination of different types of care, such as psychiatric treatment and psychosocial interventions. However, there is little research on the factors that determine access to care, particularly to psychosocial interventions.

Objectives To characterize the use of psychosocial interventions (psychotherapy, day hospital, and psychosocial rehabilitation) in users of outpatient psychiatric services in Portugal.

Aims This retrospective study analyses all outpatient psychiatric visits in four Portuguese departments of psychiatry in the metropolitan areas of Lisbon and Porto, and aims to evaluate the socio-demographic and clinical determinants of psychosocial interventions.

Methods Socio-demographic and clinical variables were obtained from clinical charts of outpatients' visits in 2002, 2007 and 2012 ($n = 2621$). All patients were characterized regarding the use of any psychosocial intervention beyond psychiatric consultations. Logistic regression analysis was performed to evaluate the predictors of psychosocial interventions use.

Results Being followed in 2012, being single, having no professional activity, and having a diagnosis of psychosis or common mental disorder were significantly associated ($P < 0.05$) with higher odds of accessing psychosocial interventions. On the other hand, a lower level of education was associated with less use of this type of care.

Conclusions Socio-demographic and clinical characteristics of psychiatric services, outpatients are determinants of the use of psychosocial interventions. Evidence suggests that social inequalities may influence the access to psychosocial interventions in Portugal.

The burden of mental disorders in the eastern Mediterranean region, 1990–2013

R. Charara^{1,*}, A. Mokdad²

¹ American University of Beirut Medical Center, Psychiatry, Beirut, Lebanon

² Institute for Health Metrics and Evaluation, University of Washington, Global Health, Seattle, USA

* Corresponding author.

The eastern Mediterranean region (EMR) is witnessing an increase in mental illness. With ongoing unrest, this is expected to rise. This is the first study to quantify the burden of mental disorders in the EMR. We used data from the global burden of disease study (GBD) 2013. DALYs (disability-adjusted life years) allow

assessment of both premature mortality (years of life lost–YLLs) and nonfatal outcomes (years lived with disability–YLDs). DALYs are computed by adding YLLs and YLDs for each age-sex-country group. In 2013, mental disorders contributed to 5.6% of total disease burden in EMR (1894 DALYs/100,000 population): 2519 DALYs/100,000 (2590/100,000 males, 2426/100,000 females) in high-income countries, 1884 DALYs/100,000 (1618/100,000 males, 2157/100,000 females) in middle-income countries, 1607 DALYs/100,000 (1500/100,000 males, 1717/100,000 females) in low-income countries. Females had a greater proportion of burden due to mental disorders than did males of equivalent ages, except for those under 15 years. The highest proportion of DALYs occurred in the 25–49 age group. The burden of mental disorders in EMR increased from 1726 DALYs/100,000 in 1990 to 1912 DALYs/100,000 in 2013 (10.8% increase). Depressive disorders accounted for most DALYs, followed by anxiety disorders. Palestine had the largest burden of mental disorders. Nearly all EMR countries had a higher mental disorder burden compared to global level. Our findings call for EMR health ministries to increase provision of mental health services and to address stigma of mental illness. Our results showing the accelerating burden of mental health are alarming as the region is seeing an increased level of instability.

Facial emotion recognition ability in psychiatrists, psychologist and psychological counselors

M. Dalkiran^{1,*}, E. Yuksek², O. Karamustafalioglu¹

¹ Sisli Hamidiye Etfal Hospital, Psychiatry, Istanbul, Turkey

² Viransehir public hospital, Psychiatry, Sanliurfa, Turkey

* Corresponding author.

Objectives Although, emotional cues like facial emotion expressions seem to be important in social interaction, there is limited specific training about emotional cues for psychology professions. **Aims** Here, we aimed to evaluate psychologist', psychological counselors' and psychiatrists' ability of facial emotion recognition and compare these groups.

Methods One hundred and forty-one master degree students of clinical psychology and 105 psychiatrists who identified themselves as psychopharmacologists were asked to perform facial emotion recognition test after filling out socio-demographic questionnaire. The facial emotion recognition test was constructed by using a set of photographs (happy, sad, fearful, angry, surprised, disgusted, and neutral faces) from Ekman and Friesen's.

Results Psychologists were significantly better in recognizing sad facial emotion than psychopharmacologists (6.23 ± 1.08 vs 5.80 ± 1.34 and $P=0.041$). Psychological counselors were significantly better in recognizing sad facial emotion than psychopharmacologists (6.24 ± 1.01 vs 5.80 ± 1.34 and $P=0.054$). Psychologists were significantly better in recognizing angry facial emotion than psychopharmacologists (6.54 ± 0.73 vs 6.08 ± 1.06 and $P=0.002$). Psychological counselors were significantly better in recognizing angry facial emotion than psychopharmacologists (6.48 ± 0.73 vs 6.08 ± 1.06 and $P=0.14$).

Conclusion We have revealed that the psychologist and psychological counselors were more accurate in recognizing sad and angry facial emotions than psychopharmacologists. We considered that more accurate recognition of emotional cues may have important influences on patient doctor relationship. It would be valuable to investigate how these differences or training the ability of facial emotion recognition would affect the quality of patient-clinician interaction.

Family functioning, trauma exposure and PTSD in a middle-income community sample

S. Dorrington*, H. Zavos, H. Ball, P. McGuffin, A. Sumathipala, S. Siribaddana, F. Rijdsdijk, S.L. Hatch, M. Hotopf
King's College London, Institute of Psychiatry, London, United Kingdom

* Corresponding author.

Introduction Only a minority of trauma-exposed individuals go on to develop post traumatic stress disorder (PTSD). Previous studies in high-income countries suggest that maladaptive family functioning adversities (MFFA) in childhood may partially explain individual variation in vulnerability to PTSD following trauma. We test in a lower middle income setting (Sri Lanka) whether: (1) MFFA moderates the association between exposure to trauma and later (a) PTSD (b) other psychiatric diagnoses; (2) any moderation by MFFA is explained by experiences of interpersonal violence, cumulative trauma exposure or other psychopathology.

Methods We conducted a population study of 3995 twins and 2019 singletons residing in Colombo, Sri Lanka. Participants completed the composite international diagnostic interview, including nine traumatic exposures and a questionnaire on MFFA.

Results In total, 23.4% of participants reported exposure to MFFA. We found that (1) MFFA moderates the association between trauma exposure and both (a) PTSD and (b) non-PTSD diagnosis. (2) This was not explained by interpersonal violence, cumulative trauma exposure or other psychopathology.

Conclusions In our sample MFFA moderates the association between trauma and PTSD, and the association between trauma and non-PTSD psychopathology.

Kbg syndrome and the establishment of its neuropsychological phenotype

J. Egger^{1,*}, L. Van Dongen¹, C. Stumpel², E. Wingbermuehle¹, T. Kleefstra³

¹ Vincent van Gogh Institute, Centre of Excellence for Neuropsychiatry, Venray, The Netherlands

² Maastricht University Medical Centre, Department of Genetics, Maastricht, The Netherlands

³ Radboud University Medical Centre, Department of Genetics, Nijmegen, The Netherlands

* Corresponding author.

Objective KBG syndrome is caused by a mutation in the ANKRD11 gene, characterized by short stature and specific dental, craniofacial and skeletal anomalies. Scarce literature on the phenotypical presentation mention delayed speech and motor development as well as mild to moderate intellectual disabilities. As to psychopathology, often, autism and ADHD are mentioned but not yet substantiated in terms of neurocognitive variables.

Aim Aim of the current study was to investigate neurocognitive aspects of KBG syndrome.

Participants and Methods Seventeen patients (aged 6–66 years; ten females) with a proven ANKRD11 mutation were compared with two different groups of patients with a genetic disorder and similar developmental ages ($n=14$ and $n=10$). Neuropsychological assessment was performed focusing on the level of intellectual

functioning and on attention, memory, executive functioning, and social cognition.

Results In KBG patients, mild to moderate intellectual disabilities (WAIS IV Total IQ = 63.5 ± 10.7 , range: 45–84) were established with a mental age that was lower than mean chronological age (6.4 ± 2.6 years versus 11 ± 5.7 years, respectively). When compared to both control groups, results indicated a relatively strong processing speed and social cognitive functioning of patients with KBG while direct recall of auditory memory was relatively poor most probably due to attentional dysfunction.

Conclusions The cognitive profile of this group of 17 patients with KBG is characterized by mild intellectual disability and diminished sustained attention in verbal tasks. Implications for diagnostic procedures and clinical management of the syndrome are discussed, also with regard to the question how this relates to classificatory diagnosis of ADHD.

Deaf blindness and mental health – Prevalence of Mental disorders of an upper Austrian outpatient service

M. Fellinger^{1,*}, E. Sacherer², J. Fellinger²

¹ Medical University of Vienna, Psychiatry and Psychotherapy, Vienna, Austria

² Hospital of St. John- Linz, Institute for Neurology of Senses and Language, Linz, Austria

* Corresponding author.

Introduction People with deaf blindness are a vulnerable group concerning mental health problems. Due to their constraints in orientation, mobility, access to information and communication they often suffer from a lack of interpersonal relationships and accessibility to health care.

Aims To assess the prevalence of mental disorders in patients with deaf blindness and exam associations with forms of communication.

Methods A retrospective data evaluation of all outpatient charts of patients treated between 2000–2013 in a specialized outpatient unit that provides primary care for all deaf people for the whole catchment area of Upper Austria was conducted. Data were analysed regarding the degree of visual and hearing impairment and the presence of a mental disorder.

Results Forty-seven of 1500 patients were identified as deaf blind including 12 suffering from Usher Syndrome. Of those 29 (61.7%) were at least once diagnosed with a mental disorder, most frequently with a mood disorder (MD) (F30–F39) in 40.4%; an anxiety, stress-related, somatoform disorders (AD) (F40–F49) in 12.8% and a schizophrenia, schizotypal and delusional disorders (F20–F29) in 10.6%. Deaf blind patients suffered compared to deaf patients more often from a MD (40.4% vs. 11.3%) however less often from an AD (12.8% vs. 32.6%). No significant association between the form of communication and being diagnosed with a mental disorder could be found.

Conclusion Patients with deaf blindness suffer to a high extend from mental disorders, especially MDs. It is of utmost importance to reduce the burden of this population and improve access to specialized services to diminish isolation as major risk factor.

Anxious distress is associated with increased immune dysregulation in patients with major depressive disorder

R. Gaspersz^{1,*}, F. Lamers¹, G. Wittenberg², A. Beekman¹, A. van Hemert³, R. Schoevers⁴, B. Penninx¹

¹ VUMC, Psychiatry, Amsterdam, The Netherlands

² Janssen Research & Development- LLC, Neuroscience, Raritan New Jersey, USA

³ Leiden University Medical Center, Psychiatry, Leiden, The Netherlands

⁴ University Medical Center Groningen, Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction Although depression with anxious distress appears to be a clinically relevant subtype of Major Depressive Disorder (MDD), whether it involves specific pathophysiology remains unclear. Inflammation has been implicated, but not comprehensively studied. We examined within a large MDD sample whether anxious distress and related anxiety features are associated with differential basal inflammation and innate cytokine production capacity.

Methods Data are from 1078 MDD patients from the Netherlands study of depression and anxiety. Besides the DSM-5 anxious distress specifier, we studied various dimensional anxiety scales (e.g. Inventory of Depressive Symptomatology anxiety arousal subscale [IDS-AA], Beck Anxiety Inventory [BAI], Mood and Anxiety Symptoms Questionnaire Anxious Arousal scale [MASQ-AA]). Basal inflammatory markers included C-reactive protein, interleukin (IL)-6 and tumor-necrosis factor (TNF)- α . Innate production capacity was assessed by 13 lipopolysaccharide (LPS)-stimulated inflammatory markers. Basal and LPS-stimulated inflammation index scores were created.

Results Basal inflammation was not associated with anxious distress in MDD patients (anxious distress prevalence 54.3%), except for modest positive associations for IDS-AA and BAI scores. However, anxious distress was associated with higher LPS-stimulated levels (interferon- γ , IL-2, IL-6, monocyte chemotactic protein (MCP)-1, macrophage inflammatory protein (MIP)-1 α , MIP-1 β , matrix metalloproteinase-2, TNF- α , TNF- β , LPS-stimulated index). Other anxiety indicators (number of specifier items and anxiety diagnoses, IDS-AA, BAI, MASQ-AA) were also associated with increased innate production capacity.

Conclusions Within a large MDD sample, the anxious distress specifier was associated with increased innate cytokine production capacity but not with basal inflammation. Results from dimensional anxiety indicators largely confirm these results. These findings provide new insight into the pathophysiology of anxious depression.

Psychiatric disorders in adults with intellectual disabilities: A preliminary study of prevalence and associated factors

A. Görmez^{1,*}, K. İsmet²

¹ Istanbul Medeniyet University, Psychiatry, Istanbul, Turkey

² Bezmialem Vakıf University, Psychiatry, Istanbul, Turkey

* Corresponding author.

Introduction Studies have shown that people with Intellectual Disabilities (ID) develop mental illness at rates similar to or higher than general population¹.

Objectives There is no previous study on mental health of adults with ID in Turkey.

Aim The purpose of this study was to investigate the prevalence and associated factors of mental disorders in adults with ID in Turkey.

Methods 151 participants with ID aged 18 and over were recruited from care homes, rehabilitation centers and from people attending to psychiatry outpatients for the first time. Every participant underwent face to face assessment by a psychiatrist supported by an informant and previous notes. A structured purpose designed socio-demographic form was used. Diagnoses were drawn according to DSM-5. Point prevalence of disorders was calculated and associated factors were investigated.

Results 63.5% of the participants met criteria for one psychiatric disorder, 21% had more than one disorder. The most common disorders were: challenging behavior (34%), autism spectrum disorders (%13.9), and anxiety disorders (13.9%) and attention deficit hyperactivity disorder (10.6%). Living in a care home and being young were associated with mental ill health ($P < 0.05$) [1].

Conclusion This study demonstrates high psychiatric comorbidity in adults with ID. Young age and care homes were the associated factors in this sample. These results are important to raise awareness of professionals and service providers about mental health of adults with ID.

Disclosure of interest This project was funded by the Scientific and Technological Research Council of Turkey (TUBITAK) with a project number of BİDEB 115C015. The funding body did not have any involvement with data collection, analysis or writing up.

Using quality improvement methodology to achieve NICE compliant care for people with intellectual disabilities whose behavior challenges

N. O’Kane*, I. Hall

East London NHS Foundation Trust, Community Learning Disability Service, London, United Kingdom

* Corresponding author.

Background In May 2015, NICE published guidelines for people with intellectual disabilities whose behavior challenges (NG11). Eight quality standards were subsequently developed by NICE to help service providers, health and social care practitioners and commissioners implement the necessary recommendations within the new NG11 guidelines.

Methods We used a Quality Improvement (QI) methodology including process mapping, driver diagrams, and fortnightly QI team meetings. We conducted a baseline audit of the quality standards and used Plan-Do-Study-Act (PDSA) cycles to pilot interventions generated by the team to improve compliance with the standards.

Results Baseline compliance with the quality standards was low. We identified four priority areas for intervention: annual physical health checks, recording the indication of medication, multidisciplinary case discussion and concurrent psychosocial interventions for those prescribed medications for challenging behavior. Using a PDSA cycle for each intervention, we have demonstrated improved compliance with the NG11 guidelines. Compliance for the recording of indication of medication for all case reviews was previously

0% and now 100%. At least one target case is discussed at each MDT team meeting. Full results for annual health checks are awaited, but intervention has already shown an improvement in the uptake from 40% to 70%. Staff and carers knowledge of psychosocial interventions for people with challenging behavior showed an improvement after training.

Conclusions Quality Improvement methodology was successful in improving adherence to NG11 guidelines. We are currently assessing whether this is leading to reductions in challenging behavior and improvements to people’s well-being.

An online survey of the stigma attached to psychiatry and psychiatrists in India

P. Jadhav^{1,*}, A. Dhandapani¹, S. Hatti², S. Armugam¹, S. Chaturvedi¹

¹ National Institute of mental Health and Neuro Sciences, Psychiatry, Bangalore- Karnataka, India

² Gadag Institute of Medical Sciences, Psychiatry, Gadag, India

* Corresponding author.

Introduction Stigma in psychiatry is pervasive, it does not stop at illness and marks all those who are ill, their families across generations, institutions that provide treatment, psychotropics, and mental health professionals. Stigma directed towards psychiatry as a branch & psychiatrists in particular has not been systematically studied in the Indian context.

Objectives To study the Indian psychiatrists perspective of stigma directed towards psychiatry & psychiatrists.

Methods An online survey containing “The World Psychiatric Association Stigma Questionnaire” was sent to the members of the Indian Psychiatric Society. Two hundred and three Indian psychiatrists filled out the questionnaire which assesses the stigmatization of psychiatry and psychiatrist as perceived by the psychiatrists themselves.

Results One hundred and thirty-two psychiatrists completed the survey with a completion rate of 65%, 75% of the respondents were male and most of their clientele was from urban catchment area. Sixty percent of the psychiatrists were either working in a psychiatry hospital or a psychiatry unit in a general hospital setting. More than a third had high-perceived stigma but had a very low stereotype agreement. Discrimination experiences were noted by more than 75% of psychiatrists, however less than 8% had a negative stigma outcome.

Conclusions Though most of the Indian psychiatrists perceive themselves as being stigmatized, the stereotype agreement was found to be low and the discrimination experiences did not have significant impact on job performance. Though this might reflect resilience, we must attempt to improve the image of psychiatry and strive towards achieving a larger public acceptance of mental health services in India.

Changes in utilization of psychiatric hospital facilities in Denmark by patients diagnosed with Schizophrenia from 1970 through 2012: The advent of ‘revolving door’ patients

R.M. Jeppesen*, T. Christensen

External researcher, Department of psychiatry- Aarhus University Hospital Risskov Skovagervej 2 DK-8240 Risskov, Aarhus N, Denmark
* Corresponding author.

Introduction The Danish psychiatric system has gone through several structural changes in the last four decades. The deinstitutionalization of the mental healthcare system was implemented in Denmark in the late 1970s with the intention of increasing outpatient treatment. One of the aims in the reorganization was to treat the patient in the local environment rather than during long-term hospitalization.

Objectives This study focuses on the changes in the utilization of hospital facilities for patients diagnosed with schizophrenia.

Aims The aims of this study were to analyze the development of admission/readmission, bed days and occupancy rates over four decades (1970–2012) in Denmark in schizophrenia treatment using admission statistics for in-patients only.

Methods Using register data from secondary healthcare treatment of patients diagnosed with schizophrenia in Denmark 1970–2012, we analyzed the development in the use of hospital facilities.

Results Our major finding was a 220% increase between 1970 and 2012 in the total number of hospital admissions due to schizophrenia each year, while at the same time the number of annual schizophrenia bed days was reduced by 76%. Furthermore, the readmission rate within a year after discharge with a diagnosis of schizophrenia reached 70% in 2012 compared to 51% in 1970. Finally, the total bed occupancy continued to rise over the four decades and has exceeded 100% in several years since 1999.

Conclusion The findings indicate that the reorganization of the Danish mental healthcare system has created a problem of “revolving door” schizophrenia patients’ who since the 1970s have been increasingly hospitalized but for shorter periods.

² Psychiatric Clinic, Department of Neuroscience, University of Padua, Italy, Padua, Italy

³ NHS Local Health Authority Portogruaro, Department of Mental Health, Portogruaro, Italy

* Corresponding author.

Introduction International treatment guidelines recommend that key elements to reduce the burden of psychosis are the early identification of people and the adoption of specific evidence based interventions.

Objectives To investigate the pathway to care and patterns of interventions provided by community based-mental health services (CMHS) to a cohort of first-episode psychosis (FEP) patients over 5-years period, exploring in which degree guidelines are met in routine clinical practice.

Methods Study conducted in the context of the Psychosis Incident Cohort Outcome Study (PICOS), a multisite naturalistic research conducted in the Veneto Region (Italy) on FEP patients in a 4.6 million inhabitants catchment area. A comprehensive set of stan-

dardized measures was used, including *ad hoc* schedules to collect information on referrals to psychiatric services and on pharmacological and psycho-social treatments according to a multiwave follow-up design (1-, 2- and 5 years).

Results Three hundred and ninety-seven FEP patients were assessed at BL, 286 at 1 year, 233 at 2 years and 205 at 5 years. 47.4% of patients were helped to seek care by a relative and more than one half entered the treatment route through an emergency access. Regarding the interventions received, 96% of patients had been prescribed neuroleptics and atypical were the most prescribed class (66.9%). Only half received a psychosocial intervention during the first year and this percentage progressively decreased at each FU.

Discussion Findings highlight discrepancies between interventions provided by CMHS and the best treatment options recommended by guidelines, suggesting the need to implement specific initiatives aiming to close the gap between research and clinical practice.

The relation between socio-environmental factors and intellectual disability: Unraveling the knot

E. Rondini*, M. Bertelli, D. Scuticchio

Fondazione San Sebastiano, CREA Centro di Ricerca e Ambulatori, Florence, Italy

* Corresponding author.

Background and aim The current literature indicates that people with intellectual disabilities (ID) present quantitative and qualitative peculiarities of various socio-environmental factors than the general population. Although the identification of such peculiarities would have very important implications for the development of preventive, rehabilitative and inclusive procedures, valuable data are still lacking. The aim of the present paper was to assess the significance of the relationship between socio-environmental variables in person with ID, with particular reference to individual history and life contexts.

Methods A consecutively recruited sample of 112 participants with ID attending residential or clinic/rehabilitative services across Italy was evaluated by the administration of ISTORIA (Historiographical organized interview for adult intellectual retard), a semi-structured questionnaire designed to investigate clinical and personal history of the person. A considerable percentage of the samples have co-occurrent psychiatric disorder. Scores obtained were statistically processed through frequency analysis and calculation of correlation indexes.

Results Significant correlations were found between the family, the educational/professional environments, and the inclusion in society. Further associations concerned social relationships within and outside the family, the changes of living accommodation, and the level of environmental stimulation received.

Conclusions Both findings from previous research and the ones of this work confirm the importance of investigating the mechanisms involved in the acquisition of social skills by persons with ID, through family dynamics and participation in community life, as protective factor against the worsening of disabilities and potentially of psychopathological vulnerability that affects this population.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Behavioural equivalents as predictors of psychiatric disorder in people with intellectual disability

M. Rossi*, D. scuticchio, M.O. bertelli

Fondazione San Sebastiano, Misericordia di Firenze, Firenze, Italy

* Corresponding author.

Introduction The last decades' considerable advances of the psychiatric assessment in People with Intellectual Disability (PwID) do not include the ability to identify Behavioural Equivalents (BE) of psychiatric symptoms and their relationship with different psychiatric syndromes. Recent reports have found BE to be differentially associated with one or more specific Psychiatric Disorders (PD).

Aims The present study was aimed at evaluating the correlations between BE and DSM-5 syndromic groups of symptoms, in a wide multicentric sample of PwID.

Methods An observational cross-sectional analysis was performed for a sample of 843 adults with ID, randomly or consecutively recruited among those living in residential facilities of the National Healthcare System, or in private institutes of care, or those attending psychiatric outpatient clinics. The total sample was administered with the SPAID-G (Psychiatric Instrument for Intellectual Disabled Adult - General version), which is a checklist for the detection of significant behavioural changes from the baseline. The items of the checklist represents BE of the symptoms of the main psychiatric disorders included in the DSM-5.

Results Many significant correlations were found, some of the most relevant were for mood disorders. Psychomotor agitation, aggressivity, disorganised behaviour and distractibility were most pronounced in bipolar patients; for depressed patients, irritability and weight loss had higher correlations than in other diagnostic groups.

Conclusions Although not diagnostically specific, some BE seem to be more strongly related with specific PD. This line of research could improve the definition of the specific expression and clustering of psychiatric symptoms in PwID.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Perceptions of residents and non-residents in psychiatry on training needs and care of patients with intellectual disability and mental health problems: A study from Singapore

S. Sajith^{1,*}, W. Wong², J. Chiu¹, P.C. Chiam³¹ Institute of Mental Health, General Psychiatry, Singapore, Singapore² Institute of Mental Health, Community Psychiatry, Singapore, Singapore³ Institute of Mental Health, Geriatric Psychiatry, Singapore, Singapore

* Corresponding author.

Background and Objective Psychiatric assessment and care of people with Intellectual Disability (ID) is complex due to their cognitive and communication impairments. Demand for further training in this area by trainees in psychiatry has been well documented. The main aims of this study were to explore the attitudes and perceptions of psychiatry residents and non-residents (non-trainees) with regards to care of patients with ID as well as their knowledge and training in this area.

Method The study was conducted as an anonymous survey at the Institute of Mental Health, Singapore. A survey questionnaire devel-

oped by the study team was sent to residents and non-residents in psychiatry.

Results Forty-eight out of the 76 questionnaires were returned with a response rate of 63.16%. Twenty-eight participants described themselves as non-residents and the rest were residents. All participants responded that postgraduate training was required in the area of ID and mental health and majority reported that available training was inadequate. Ninety percent of respondents believed that people with ID were vulnerable to exploitation by other patients in the inpatient unit and 94% of respondents believed that people with ID should be managed by a specialist team.

Conclusion Currently residents and non-residents in psychiatry see that training in ID and mental health as well as services for people with ID as inadequate. Efforts should be made to include specialist training in psychiatry of ID in the Singapore psychiatry curriculum to enhance the confidence and expertise of psychiatrists in this field.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Does a bespoke intellectual disability (ID) epilepsy service reduce mortality? A 11 year study of sudden unexpected death in epilepsy (SUDEP) in Cornwall UK

R. Shankar

Cornwall Foundation NHS Trust, ID neuropsychiatry, Truro, United Kingdom

Aim Epilepsy is the second most common cause of premorbid mortality in the ID population. Rates of SUDEP are considered up to 9 times higher in the ID population. Cornwall UK (population 600,000 i.e. 1% of UK) runs a specialist ID epilepsy community service for adults with ID. It delivers reasonable adjustments and person centered care to this population. We measured how service outcomes on SUDEP compared to regional and national averages.

Methods Data of all Cornwall epilepsy deaths 2004–2015 using the Cornwall Coroner's database and the Public Health Cornwall was reviewed systemically. We identified patients with and without ID.

Results There were 113 epilepsy deaths of which 57 were SUDEPs of which 3 were identified to have a clinical diagnosis of ID. In another 2 cases it was not evident if they had an ID or not. None of the 5 was known to the ID Epilepsy service. Mean and 95% confidence intervals were calculated using a binomial calculation, making no prior assumptions about the population distribution.

Conclusion Cornwall's specialist ID epilepsy service is a rarity in the UK. A recent study using the Leicestershire ID Register revealed 26 people with ID of the total deaths of 83 SUDEP. This contrasts greatly with Cornwall only 5.26% of SUDEP deaths had ID compared to 23.4% in Leicestershire and similarly when compared to neighboring Plymouth (population 300,000) which had 26% ID deaths in its SUDEPs between 2004–2012. It is possible that having an ID dedicated epilepsy service saves lives.

Meta-analysis update of association between dopamine transporter SLC6A3 gene polymorphism, smoking cessation

H. Choi

Yeungnam University, College of Pharmacy, Gyeongsan-Gyeongbuk, Republic of Korea

The SLC6A3 gene is involved in the dopamine pathway, which influences smoking behavior. This study was conducted to present updated results of a meta-analysis to evaluate the association between SLC6A3 polymorphism and smoking cessation. In total, eight studies were assessed, and 9-repeat alleles and no 9-repeat alleles were compared by smoking cessation outcomes. No significant association between SLC6A3 genotype and smoking cessation was observed for the main analysis (odds ratio = 1.128; 95% confidence interval = 0.981–1.298). In conclusion, the genetic variations in SLC6A3 are not associated with smoking cessation, which is not consistent with the results of the previous meta-analysis.

Qualitative meta-analysis to identify genomic variants that are correlated with the development of Schizophrenia

G. Chondrou*, G.P. Patrinos, E.E. Tsermpini

University of Patras, Department of Pharmacy, Patras, Greece

* Corresponding author.

Introduction Schizophrenia is a devastating and complex disease, which occurs in approximately 1% of the general population. Symptoms include hallucinations, delusions and patients' social withdrawal. Schizophrenia's etiology remains unclear, however, both patients' genetic profile and environmental factors play a significant role.

Objectives Our study's primary objective was to identify genetic variants related with schizophrenia's development in non-Caucasians populations and to explore whether these polymorphisms can be also found in schizophrenia patients of Caucasian origin.

Methods To achieve that, we screened Science Direct and PubMed medical literature databases to identify research articles correlating genes and variants with the development of schizophrenia. Next step was the categorization of studies according to samples' origin and the identification of genomic variants that are correlated with schizophrenia ($P < 0.001$) but have never been studied in Caucasian populations.

Results In total, 108 and 47 studies, in non-Caucasian and Caucasian populations respectively, were identified, in which 157 ($P < 0.05$) and 18 ($P < 0.001$) variants were associated with the development of the disease in non-Caucasian populations.

Conclusions From our qualitative meta-analysis 18 variants that were correlated with schizophrenia's etiology were identified ($P < 0.001$), which will be further investigated in a multi-cultural Caucasian cohort.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Hospital Clinico Universitario De Valladolid, Family Medicine And Community Health, Valladolid, Spain

* Corresponding author

Introduction Neurocognitive disorders are the only psychiatric disorders which underlying pathogeny can potentially be determined. This has important implications, for it makes possible the use of biomarkers in order to gain better diagnosis, and opens a door to more accurate treatments. Nonetheless, as biomarkers are not exclusive of a single disorder, the lengths of its utility are still unknown.

Objectives and aims To understand the values and limitations of biomarkers in differential diagnosis of dementias.

Methods We present three cases followed in the Neurology ward of our hospital, in which they were admitted for diagnosis and treatment of a subacute form of dementia. Medical history, core symptoms, screening tests for cognitive impairment, MRI, EEG and biomarkers in cerebrospinal fluid were used for diagnosis.

Results Two cases had consistent clinical features and complementary explorations, and they were respectively diagnosed as Creutzfeldt-Jakob Disease and Lewy Body Dementia; however, the last case showed contradictory results between clinic and complementary explorations, particularly 14-3-3 protein, which was positive and led to the initial diagnosis as Creutzfeldt-Jakob Disease, which was proven wrong once necropsy was practiced.

Conclusions Although complementary explorations, and biomarkers in particular, are of invaluable utility in the accurate diagnosis of multiple psychiatric diseases, they must always be considered within a context given by biography and clinical features, because, when failing to do so, they can lead to misdiagnosis and delay of correct treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Spatio-temporal perception and boundaries of self: Evaluation of peripersonal space in schizotypy traits

G. Di Cosmo^{1,*}, F. Fiori¹, F. Ferri², A. Saloni¹, M. Corbo¹, M. Costantini², G. Martinotti¹, M. di Giannantonio¹, L. Marzetti¹

¹ University "G. D'Annunzio" Chieti, Neuroscience, Imaging and Clinical sciences, Chieti, Italy

² University of Essex, Centre for Brain Science, Department of Psychology, Colchester, United Kingdom

* Corresponding author.

Introduction The peripersonal space is described as that area within the boundary between self and non-self. An accurate judgment of peripersonal space boundaries may depend on the capacity to create an organized and structured mental representation that integrates signals from different sensory modalities and

brain regions. Empirical evidence suggests that these functions are altered in schizotypy, which is thought to reflect the subclinical expression of the symptoms of schizophrenia in the general population. A number of clinical studies reported that interpersonal interaction and social stimulation have an impact on the onset and progress of schizophrenia.

Objectives We conducted a study on personal space in a sample of student screened for schizotypal traits using a paradigm that was not affected by emotional and social interference.

Aims The aim was to evaluate the relationship between personal space and schizotypy traits.

Methods Thirty-four subject recruited for the study completed the Schizotypal Personality Questionnaire (SPQ). According to the SPQ results participants were splitted into two groups (High, Low). Each participant performed a PeriPersonal Space (PPS) task.

Results Our results show a more extended boundary of the peripersonal space in people with high schizotypy compared to people with low schizotypy even without emotional and social interference.

Conclusions People with high traits of schizotypy suffer from a difficulty in social integration because of being unable to adapt the social behavior. A better understanding of the mechanisms for abnormal interactive behavior could provide significant valid guidelines for innovating insertion programs that aims to improve social functioning.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Finding the right medication in psychiatry can be very demanding both for the doctor and for the patient. It becomes extremely grueling when the patient has a rare type of metabolizing enzymes, and many drugs may be ineffective or cause side effects.

Objectives To highlight the therapeutic difficulties in psychiatric treatment of the patient with complex genetic cytochrome P450 system alterations.

Aims To provide an example on a complicated treatment course of the patient that is poor CYP2D6 and ultrarapid CYP2C19 metabolizer.

Methods Literature review in scientific database–Pubmed–and case report presentation.

Results We report a case of a woman in her early twenties who was repeatedly referred for psychiatric treatment. A diagnosis of paranoid schizophrenia was established, but all treatment rounds were unsuccessful, the illness kept progressing, and major depressive disorder aggravated the clinical picture. The patient became suicidal and injured herself. During the sixth hospitalization in one year the CYP2D6, CYP2C19 and CYP2C9 genotyping was done. CYP2C19 ultrarapid (*1/*17) and CYP2D6 poor metabolizer (*4/*5) profile was discovered. Drugs, that should have been avoided due to the patient's genetic profile, had been prescribed throughout five hospitalizations in a row.

Conclusions As ultrarapid CYP2C19 metabolizers compose around 3–4% and poor CYP2D6–6–10% of Caucasians, this case presents a rare genetic variant that only 0.18–0.4% of Caucasian population may have. These cases can be extremely clinically challenging and affect healthcare outcomes and costs. Further studies that would include clinical effectiveness, drug concentration and genetic testing results are needed.

Insight gained from genome-wide interaction and enrichment analysis on weight gain during citalopram treatment

H. Corfitsen, A. Drago*

Psykiatrisk Forskningsenhed Vest, Department of Clinical Medicine, Aarhus University, Herning, Denmark

* Corresponding author.

Introduction Weight gain is a side effect of pharmacological antidepressant treatments, causing a poorer compliance, increasing the risk of metabolic syndrome and periods of untreated disease.

Objectives The ability to precisely prescribe pharmacological treatments based on personal genetic makeups would increase the quality of the current antidepressant treatments.

Aims The molecular pathways enriched during citalopram induced weight gain are identified.

Methods 643 depressed citalopram treated individuals with available clinical and genome-wide genetic information were investigated in the present contribution in order to identify the molecular pathways that holds the key to weight gain. Statistics were conducted in R environment (Bioconductor and Reactome packages), ANOVA and MANCOVA served when appropriate. Plink was used for genetic analysis in a linux environment.

Results One hundred and eleven individuals had their weight increased after treatment with citalopram. The axon guidance (P . adjust=0.005) and the developmental biology pathway (P . adjust=0.01) were found to be enriched in genetic variations associated with weight gain.

Conclusions The development biology pathway includes molecular cascades involved in the regulation of beta-cell development, and the transcriptional regulation of white adipocyte differentiation. A number of variations were harboured by genes whose products are involved in the synthesis of collagen (*COL4A3*, *COL5A1* and *ITGA1*), activity of the thyroid-hormones (*NCOR1* and *NCOR2*), energy metabolism (*ADIPOQ*, *PPARGC1A*) and myogenic differentiation (*CDON*). A molecular pathway analysis conducted in a sample of depressed patients identifies new candidate genes whose future investigation may grant relevant insights in the molecular events that drive weight gain during antidepressant treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Predicting antidepressant response from genes

H. Corfitsen, A. Drago*

Psykiatrisk Forskningsenhed Vest, Department of Clinical Medicine, Aarhus University, Herning, Denmark

* Corresponding author.

Introduction Pharmacogenetics may inform an accurate prescribing of antidepressants by identifying the genetic background

specifically responding to a certain drug. Despite decades of efforts though, pharmacogenetics appears to be still in its infancy.

Aim A clearer understanding of the pharmacodynamics and pharmacokinetics events in combination with the genetic and epigenetic controls of cells and molecular cascade must inform the future of personalised medicine.

Objectives To systematically review the current cutting edge knowledge about pharmacogenetics in the search for the next groundbreaking biological key events that may provide the keys to future treatments.

Methods The major online databases are systematically searched with common keywords by two independent researchers and conflicting findings are solved during regular meetings dedicated to the topic in object. Manual searching of single bibliographies is also put in place.

Results Genes belonging to the serotonergic, dopaminergic, glutamatergic and GABAergic systems are classic candidates for pharmacogenetics whose role was not confirmed by GWAS analyses, which, on the other hand, identified genes related to molecular pathways not associated with direct target of drugs used for the treatment of depression.

Conclusion Both hypothesis driven candidate genetic investigations and GWAS analyses have been conducted so far, leading to the identification of a handful of potential good candidates, but the replication rate of the positive association findings lags behind expectations. The current knowledge about the pharmacodynamic and pharmacokinetic genetic determinants of antidepressant response is critically analysed and new candidates are presented discussed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A molecular pathway analysis informs the genetic risk for arrhythmia during antipsychotic treatment

E.K. Fischer^{1,*}, H. Dyrby Andersen¹, M. Braun Jepsen², A. Drago¹

¹ Psykiatrisk Forskningsenhed Vest, Forskningsenheden, Herning, Denmark

² Region Psykiatri Vest, Herning, Denmark

* Corresponding author.

Background Arrhythmia is a potentially fatal side effect of antipsychotics. A biologic predictive tool to prevent it is missing.

Aim Identification of a genetic profile at risk for antipsychotic induced arrhythmia.

Objective Identifying a molecular pathway enriched for antipsychotic induced QT-modifications.

Methods Seven hundred and sixty-five SKZ individuals, $M=556$, age = 40.93 ± 11.03 were included. QT-variation was a phase-specific created variable. A nested mixed regression served in R for clinical and molecular pathway analyses. Plink served for genetic analyses. Quality checking was standard, inflation factor was controlled by lambda values.

Results Quetiapine and Perphenazine were associated with QT variation ($P=0.002$; Estimate = 5.79 and $P=5.67e-06$; Estimate = 8.96 respectively). No other significant association was detected. No inflation was detected. Axon guidance and Collagen biosynthesis (Table 1) were associated with QT variation at a conservative (adjusted) P value <0.01 .

Conclusions Two molecular pathways were identified as possibly involved in QT modifications during antipsychotic treatment in SKZ patients. Previous evidence supports a role of the same pathways in cardiac disorders [1,2]. Interaction of specific SNPs with the drugs will be focus of further research.

Table 1 Molecular pathways enriched in association with QT modifications.

ID	Description	Gene Ratio	BgRatio	P-value	P.adjust	Qvalue
422475	Axon guidance	19/135	292/6750	4.6e-06	0.0022	0.0021
1650814	Collagen biosynthesis and modifying enzymes	8/135	59/6750	1.9e-05	0.0047	0.0044

Disclosure of interest The authors have not supplied their declaration of competing interest.

A molecular pathway analysis stresses the role of inflammation towards cognition in Schizophrenia

E.K. Fischer^{1,*}, C. Holm², M. Christensen², A. Drago¹

¹ Psykiatrisk Forskningsenhed Vest, Forskningsenheden, Herning, Denmark

² Via University College, Herning, Denmark

* Corresponding author.

Background Cognitive processes are impaired in Schizophrenia (SKZ). The nature of such impairment escapes definition.

Aim Identification of a genetic profile at risk of cognitive impairment.

Object Identifying a molecular pathways enriched for mutations associated with cognitive impairment.

Methods Seven hundred and sixty-five individuals from the CATIE, $M=556$, mean age = 40.93 ± 11.03 were included. Verbal memory was outcome. R and Plink served for the analyses. Inflation factor was controlled by lambda values. Input for the pathway analysis were SNPs associated with outcome ($P < 0.05$) genomewide.

Results Gender (male, $P=2.34e-05$; $t=-4.26$) and years of education ($P=1.57e-03$; $t=6.502$) were associated with verbal memory. Inflammation and oxidation were associated with outcome (Table 1, adj- $P < 0.01$).

Conclusions Being male and poorly educated were associated with poorer verbal memory. Inflammation and the arachidonic acid pathway were enriched in mutations associated with poorer verbal memory. This finding is in line with previous reports [1,2,3].

Table 1 Pathways enriched in association with verbal memory.

Description	GeneRatio	BgRatio	Pvalue	P.adjust
Synthesis of Leukotrienes	5/105	17/6750	4.42E-06	0.0009
Arachidonic acid metabolism	7/105	45/6750	5.03E-06	0.0009
Glutathione synthesis and recycling	4/105	11/6750	1.68E-05	0.0021

Psychiatric symptomatology as the initial presentation of brain cancer

A. Fornelos*, P. Macedo, A. Figueiredo, M. Roque
Psiquiatria e Saúde Mental, Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real, Portugal
* Corresponding author.

Glioblastoma multiforme is the most common primary adult brain tumor. Clinically, non-specific psychiatric symptoms may arise as their first and only manifestation, prior to any neurological deficits. The most form of psychiatric presentation of neurological diseases are depressive complaints, although these may also be accompanied by behavioral and/or cognitive, anxious and psychotic symptoms. By explaining this case report we aim to emphasize the importance of considering the diagnosis of an organic brain disease, even when only primary psychiatric symptoms are evident. The bibliographic research was made using PubMed and Scielo, and analysis of the electronic patient process. Man of 68 years with a history of hypertension, nephrectomy, splenectomy and left brachial plegia after a car accident. He had been previously seen by a psychiatrist for a 6-month history of depressive symptoms, which had been successfully treated. He later developed new behavioral changes such as heteroaggressiveness, social maladjustment and disfasia, for which he was sent to the emergency room. Brain-CT scan displayed a left front temporal expansive injury. Admitted to the Neurology Department for further diagnostic investigation. Subsequent MRI, detected massive infiltrative lesion with significant mass effect and cystic/necrotic area. The anatomopathology disclosed a glioblastoma grade IV. This case reinforces the importance of carrying a imagiologic workup in cases like this, especially on patients with atypical presentation of psychiatric symptoms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Differential effects of mGluR5 receptor blockade on behavior, schizophrenia-relevant gene expression and neuronal activation patterns from development to aging mice

P. Gass^{1,*}, D. Inta¹, A. Luoni², M.A. Riva²

¹ *Psychiatry and Psychotherapy, Central Institute of Mental Health, Mannheim, Germany*

² *University of Milan, Center of Neuropharmacology, Milano, Italy*

* Corresponding author.

Introduction The glutamate system is implicated both in mood disorders and schizophrenia. Mice lacking metabotropic mGlu5 receptors (mGluR5 KO) display schizophrenia-like abnormalities. Additionally, mGluR5 antagonists represent promising alternative anxiolytics/antidepressants. However, the underlying age-specific molecular/cellular mechanisms are only partially understood.

Objectives We aimed at identifying molecular alterations associated with a genetically induced mGluR5 deletion, which results in a schizophrenia-like phenotype. Additionally, we investigated age-specific effects of mGluR5 antagonists on emotional behaviour and c-fos activation.

Methods For analysis of mRNA and protein levels we performed Real-time RT-PCR and Western blot investigations of brains from mGluR5 KO and wild-type mice. Additionally we used classical behavioral tests for determining anxiety- and depression-like changes triggered by the mGluR5 antagonist 2-Methyl-6-(phenylethynyl)pyridine (MPEP). Finally, we used profiling of c-Fos expression, as marker of neuronal activity, induced by MPEP from postnatal day 16 (P16) to adulthood (P90).

Results We found reduced expression levels of reelin, GAD65, GAD67, parvalbumin, as well as NMDA and AMPA receptor subunits in mGluR5 KO mice, especially in the prefrontal cortex (PFC). We measured age-specific alterations in emotional behaviour of mGluR5 KO mice, with marked increase of anxiety during aging. There was a remarkably conserved activation of the paraventricular nucleus of the hypothalamus, implicated in stress regulation, by MPEP at all investigated ages, whereas the extended amygdala was specifically activated in adulthood only.

Conclusions Our animal data provide new insights into the potential role of mGluR5 in neurochemical and behavioural changes associated with schizophrenia and mood disorders during the life-span.

³ *Center of Epidemiology, Biostatistics and Medical Information Technology, Polytechnic University of Marche, Ancona, Italy*

⁴ *Psychiatric Unit, Department of Experimental and Clinical Medicine, Polytechnic University of Marche, Ancona, Italy*

* Corresponding author.

Introduction Reactivity to acute psychosocial stress in the framework of a physiological multidimensional pattern affects several individual-level systems that include genetic factors and features related to personality development. The 5-HTTLPR genotype has been implicated in the modulation of susceptibility to environmental stimuli.

Objectives In the present study, 91 healthy young women were investigated (i) for their reactivity to a standardized psychosocial laboratory stressor (TSST), as measured by changes in salivary cortisol; (ii) in terms of 5-httlpr genotype and (iii) in terms of their personality profile according to the post-rationalist personal meaning organizations (PMOs), which are considered as adaptive modes of response to environmental stressors.

Methods Participants were divided into three 5-HTTLPR genotype groups (s/s; s/l, and l/s). The quantitative and qualitative variables that may affect circulating cortisol were compared among the three groups. A multiple linear quantile regression analysis was then performed to evaluate the effect of the personality profile, as Outward/Inward PMO, and 5-HTTLPR genotype on the median level of cortisol, considered as dependent variable.

Results Comparison of the variables that may affect circulating cortisol no significant differences. Salivary cortisol changed significantly in the course of the TSST. Reactivity to stress was affected by personality profile and the 5-HTTLPR genotype and also by body mass index and age.

Conclusions The present data suggest that the psychosocial stress response is a multidimensional physiological event that is affected by a variety of factors as diverse as 5-HTTLPR genotype, personality profile, BMI, and age.

Skin conductance response to emotional stimuli and injury location in patients with single right hemisphere damage

S. Álvarez¹, G. Lahera^{2,3,*}

¹ Foundation Alicia Koplowitz Research Fellow, New York University Child Study Center, Child Psychiatry, NY, USA

² Psychiatry, University of Alcalá, Alcalá de Henares, Madrid, Spain

³ Cibersam, Mental Health, Madrid, Spain

* Corresponding author.

Introduction Right hemisphere damage (RHD) has been related to alterations in emotion processing. However, results regarding physiological responses are limited and inconsistent. More research regarding specific brain areas involved in emotional physiological responses is needed.

Objectives To examine the skin conductance response (SCR) to emotion eliciting images in patients with single RHD. To explore the relationship between SCR and brain injury location in patients with single RHD.

Aims To examine the relationship between SCR and cortical and subcortical damage in RH regarding emotional processing.

Method Forty-one individuals with RHD due to stroke were assessed (mean age 68.5, SD 12.2, 51.1 males). The amplitude of event-related SCR was registered through a biofeedback system while observing 54 photographs from the international affective picture system (IAPS). Emotional images were classified using two different approaches: emotional valence (pleasant, unpleasant, neutral) and social vs. non-social content. Brain damage location, determined through medical records, included cortical (frontal, parietal, temporal and occipital lobes) as well as sub-cortical (caudate nucleus, thalamus, lenticular nucleus, insular cortex, basal ganglia and limbic system) structures.

Results Amplitude of SCR to emotional images was significantly lower in individuals with occipital cortex injury compared to those with damage in other brain locations ($P < 0.05$). These results were consistent through all stimuli categories but non-social pictures, which presented the same pattern though, did not reach statistical significance.

Conclusions Results show a relationship between occipital areas in HD and SCR to emotional eliciting stimuli, suggesting occipital right lobe involvement in physiological emotional processing.

The use of polygenic risk scores to inform aetiology of mood and psychotic disorders

J. Harrison*, S. Mistry

Cardiff University School of Medicine, MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff, Wales, United Kingdom

* Corresponding author.

Introduction Polygenic risk scores (PRS) incorporate many small genetic markers that are associated with conditions. This technique

was first used to investigate mental illnesses in 2009. Since then, it has been widely used.

Objectives We wanted to explore how PRS have been used to the study the aetiology of psychosis, schizophrenia, bipolar disorder and depression.

Aims We aimed to conduct a systematic review, identifying studies that have examined associations between PRS for bipolar disorder, schizophrenia/psychosis and depression and psychopathology-related outcome measures.

Methods We searched EMBASE, Medline and PsychInfo from 06/08/2009 to 14/03/2016. We hand-searched the reference lists of related papers.

Results After removing duplicates, the search yielded 1043 publications. When irrelevant articles were excluded, 33 articles remained. We found 24 studies using schizophrenia PRS, three using bipolar PRS and nine using depression PRS. Many studies successfully used PRS to predict case/control status. Some studies showed associations between PRS and diagnostic sub-categories. A range of clinical phenotypes and symptoms has been explored. For example, specific PRS are associated with cognitive performance in schizophrenia, psychotic symptoms in bipolar disorder, and frequency of episodes of depression. PRS have also demonstrated genetic overlap between mental illnesses. It was difficult to assess the quality of some studies as not all reported sufficient methodological detail.

Conclusions PRS have enabled us to explore the polygenic architecture of mental illness and demonstrate a genetic basis for some observed features. However, they have yet to give insights into the biology, which underpin mental illnesses.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Identification of biological pathways to Alzheimer's disease using polygenic scores

J. Harrison*, E. Baker, L. Hubbard, D. Linden, J. Williams, V. Escott-Price, P. Holmans

Cardiff University School of Medicine, MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff, Wales, United Kingdom

* Corresponding author.

Introduction Single nucleotide polymorphisms (SNPs) contribute small increases in risk for late-onset Alzheimer's disease (LOAD). LOAD SNPs cluster around genes with similar biological functions (pathways). Polygenic risk scores (PRS) aggregate the effect of SNPs genome-wide. However, this approach has not been widely used for SNPs within specific pathways.

Objectives We investigated whether pathway-specific PRS were significant predictors of LOAD case/control status.

Methods We mapped SNPs to genes within 8 pathways implicated in LOAD. For our polygenic analysis, the discovery sample comprised 13,831 LOAD cases and 29,877 controls. LOAD risk alleles for SNPs in our 8 pathways were identified at a P-value threshold of 0.5. Pathway-specific PRS were calculated in a target sample of 3332 cases and 9832 controls. The genetic data were pruned with $R^2 > 0.2$ while retaining the SNPs most significantly associated with AD. We tested whether pathway-specific PRS were associated with LOAD using logistic regression, adjusting for age, sex, country, and principal components. We report the proportion of variance in liability explained by each pathway.

Results The most strongly associated pathways were the immune response (NSNPs = 9304, $= 5.63 \times 10^{-19}$, $R^2 = 0.04$) and hemostasis (NSNPs = 7832, $P = 5.47 \times 10^{-7}$, $R^2 = 0.015$). Regulation of endocytosis, hematopoietic cell lineage, cholesterol transport, clathrin and

protein folding were also significantly associated but accounted for less than 1% of the variance. With APOE excluded, all pathways remained significant except proteasome-ubiquitin activity and protein folding.

Conclusions Genetic risk for LOAD can be split into contributions from different biological pathways. These offer a means to explore disease mechanisms and to stratify patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Psychiatry department, McGill University, Montreal, Canada

⁵ Biomedical Science department, Università degli studi Di Cagliari, Cagliari, Italy

⁶ Psychiatry department, Nîmes Academic Hospital, Nîmes, France

* Corresponding author.

Introduction Micro-RNAs are short non-coding sequences playing a major role in regulating gene expression. Peripheral levels of the micro-RNA miR-1202 have been shown to predict antidepressant response and to change during treatment. However, it is not clear to what extent these peripheral measures reflect central neural changes in vivo.

Objectives We aimed at investigating a potential link between peripheral micro-RNA and neuroimaging measures.

Methods At baseline and after 8 weeks of desvenlafaxine (50–100 mg die), twenty depressed patients were scanned with 3 T magnetic resonance imaging, first at rest then during the Go/NoGo task, a classical test of response inhibition. Blood samples were taken for RNA extraction.

Results During resting state, baseline miR-1202 levels were predictive of decreased connectivity between the posterior cingulate and the prefrontal, occipital and parietal cortices. Changes in miR-1202 levels were correlated with changes in activity in right precuneus within the default-mode network, and with decreased connectivity between the posterior cingulate and the temporal and prefrontal cortices, and the precuneus. During the Go/NoGo task, baseline levels and changes in these levels were correlated with activity changes in different regions, including bilateral prefrontal, insular, cingulate, and temporal cortices. Finally, secondary analyses suggest an association between miR-1202 levels and glutamate levels measured by spectroscopy in dorsomedial prefrontal cortex.

Conclusions This is the first study showing that baseline and changes in peripheral levels of one micro-RNA were associated with changes in brain activity and connectivity during an antidepressant treatment. MiR-1202 may act through the modulation of the glutamatergic system.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Research Institute of Medical Genetics, Tomsk National Research Medical Center, Russian Academy of Sciences, Laboratory of Hereditary Pathology, Tomsk, Russia

⁴ Diagnostic Center of Altai Region, Medical and Genetic Clinic, Barnaul, Russia

* Corresponding author.

Introduction Over 20% of patients with developmental delay (DD) has copy number variations (CNV) of unknown significance. Some CNV may be associated with disease in a patient and also present in their apparently healthy parents. According to the two-hit model another CNV may contribute to phenotypic variation of such genomic disorders.

Objectives DD diagnostics improvement.

Aims Understanding the pathogenic significance of concomitant 3q13.31 and 22q13.32–q13.33 microdeletions.

Methods Ring chromosome 22 was first detected by conventional cytogenetics. Microdeletions at 3q13.31 and 22q13.32–q13.33 were revealed by agilent technologies 60 K microarray and confirmed by qPCR. Ring chromosome was confirmed by FISH.

Results We present a four-year-old girl with del22q13.32–q13.33 resulted in a ring chromosome 22 and a single TUSC7 gene microdeletion at 3q13.31. The del22q13.32–q13.33 originated de novo, whereas del3q13.31 was inherited from healthy mother. The 22q13.32–q13.33 locus is associated with Phelan-McDermid syndrome (PHMDS, OMIM 606232). The patient demonstrated features both typical for the syndrome (psychomotor and speech development delay, autistic signs, aggression, sleep alteration, seizures) and atypical – attention deficit-hyperactivity disorder (ADHD), ventriculomegaly, and reduced size of cerebella hemispheres (Dandy-Walker variant). ADHD and ventriculomegaly were previously described in patients with del3q13.31 (OMIM 615433) but Dandy-Walker variant was observed in our patient for the first time. Possibly, atypical for PHMDS features, may result from trans-epistasis of microdeletions.

Conclusions Multiple CNVs in one patient complicate genotype-phenotype correlations due to possible overlapping phenotypes and/or modifying effect of variants. This study was supported by Russian Science Foundation, grant no. 16-15-10231.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Department of Human and Medical Genetics, Vilnius University, Center for Medical Genetics, Vilnius, Lithuania

* Corresponding author.

Introduction Individualized treatment decisions in psychiatry may be important, since substantial part of first choice drugs are

ineffective or cause side effects. Polymorphic variants of genes that code CYP450 enzymes cause differences in their activity and therefore in efficacy and safety of drugs that are metabolized by them.

Aim of the study Determine whether pharmacogenetic testing of CYP2D6, CYP2C19 and CYP2C9 polymorphism would have had influence on selected patients' treatment courses.

Methods Five patients that were diagnosed for treatment-resistant mood disorders in Vilnius university hospital Santariskiu clinics centre of neurology, department of psychiatry were invited to give blood samples for genetic testing retrospectively. Patients' CYP2C19, CYP2D6 and CYP2C9 enzymes genetic polymorphism results were compared with previous empirical pharmacological treatment courses of these patients.

Results In four out of five cases significant polymorphism of CYP2C19 enzyme allele was detected. In all of these cases 1*/2* variant, that conditions intermediate metabolizer phenotype, was identified. Alterations in CYP2D6 and CYP2C19 regions were not found. In three cases the presence of varied genetic variant could have been clinically relevant. In two of these cases Sertraline and valproates, that are both metabolized by CYP2C19 enzyme, were taken by patients and side effects were observed. Unsuccessful treatment was repeated without effect, both in clinical and outpatient environment. Continuous rehospitalization took place until appropriate empirical treatments were established.

Conclusions Pharmacogenetic testing could have had influence on treatment choices for three out of five selected patients leading to less side effects and rehospitalizations.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Mthfr Allele distribution in Romanian schizophrenia patients

B. Nemes*, D. Cozman

Iuliu Hatieganu University of Medicine and Pharmacy Cluj-Napoca, Department of Medical Psychology, Cluj-Napoca, Romania

* Corresponding author.

Introduction Currently available data on the aetiology of schizophrenia suggests a major involvement of epigenetic mechanisms. One such mechanism could be the alteration of activation and silencing of genes, which involves DNA methylation and de-methylation. The main limiting enzyme involved in the methyl-donor cycle is methylene-tetra-hydro-folate-reductase (MTHFR), and the most frequently observed mutation in the MTHFR gene, altering its activity, is the C677T mutation.

Aim In the present study, we investigated the frequency of MTHFR C677T mutation and total plasma homocysteine (tHcy) concentrations in a sample of Romanian schizophrenia patients as compared to healthy controls.

Methods Seventy schizophrenia patients (35% females) with a mean age of 38.8 ± 20.5 years and 50 healthy controls (50% females) with a mean age of 36.3 ± 11.6 years were included. MTHFR genotype was determined through polymerase chain reaction and tHcy levels were determined through reversed phase high-pressure liquid chromatography.

Results Schizophrenia patients, registered higher frequency of the T allele, with the CC genotype observed in 39.4% of them, as compared to a frequency of 60.6% in the control group ($P=0.002$ –Fisher's exact test). tHcy concentrations did not differ between the two groups (10.7 ± 4.2 vs. 11.2 ± 4.1 , $P>0.005$ –Mann–Whitney U test).

Conclusions Romanian schizophrenia patients have a significantly higher frequency of the MTHFR C677T mutation, but without significant effect on tHcy concentrations.

Influence of 5-HTR2C polymorphisms on metabolic syndromes in Thai schizophrenia patients

A. Puangpetch^{1,*}, C. Na Nakorn¹, W. Unaharassamee², C. Sukasem¹

¹ Pathology service, Faculty of Medicine, Ramathibodi hospital, Mahidol University, Bangkok, Thailand

² Psychiatry, Somdet Chaopraya Institute of Psychiatry, Bangkok, Thailand

* Corresponding author.

Introduction Metabolic syndrome is a significant problem in the schizophrenia patients. Previous research demonstrated that single nucleotide polymorphisms in the serotonin 2C receptor (5HTR2C) genes are associated with metabolic syndrome related to schizophrenia patients taking atypical anti-psychotic drugs. This study aimed to investigate whether the effect of 3 SNPs in 5HTR2C gene on the presence of the metabolic syndrome in Thai schizophrenia patients.

Method We conducted a cross-sectional study and 154 patients were recruited. The schizophrenia patients were identified from a diagnostic and statistical manual of mental disorders, 4th edition, (DSM-IV) and criterion and determined the metabolic syndrome according to the 2005 international diabetes federation (IDF) Asia criteria. Patients were genotyped for the 5HTR2C rs51,8147, rs126,881,02, rs128,367,71 polymorphisms.

Results The preliminary analysis from 154 patients showed the metabolic syndrome prevalence was 38.73%, with 46.50% in male and 53.48% in female patients. The results showed that the patients who have heterozygous and homozygous variant on 5HTR2C gene (rs518,147 and rs126,881,02) showed a significant difference in the presence of metabolic syndrome when compare with patients who carry homozygous wild type ($P=0.007$), especially in male patients ($P=0.002$). The association between 5HTR2C polymorphisms and metabolic syndrome was found in male patients but not found in female patients.

Conclusion These findings suggest that 5HTR2C genotypes are associated with the metabolic syndrome in patients taking atypical anti-psychotics. However, the metabolic syndrome results from the multigenetic effects. The further studies should focus on the other genes, which were involved in metabolic syndrome.

Introduction The gene CYP2D6 is of great interest also due to its highly polymorphic nature, and involvement in a high number of medication metabolisms. The presence of polymorphisms in the CYP2D6 gene may modulate enzyme level and activity, thereby affecting individual responses to pharmacological treatment.

Materials and methods Allele and genotype frequency distributions of CYP2D6*10 variants and predicted phenotypes were analyzed in blood samples of 123 patients (53 patients from north-western region and 69 patients from Siberian region) using polymerase chain reaction (PCR)-restriction fragment length polymorphism, PCR-single-strand conformation polymorphism.

Results The T/T, C/T, and C/C genotype frequencies of the CYP2D6*10 allele were significantly different ($P < 0.01$) in regional groups. The frequency of the wild homozygous variant C/C of the CYP2D6*10 allele (extensive metabolizers) in the Siberian region was the highest, while the north-western region of Russia had the lowest frequency ($P < 0.001$), which are 82.6% and 64.2%, respectively. The frequency of the heterozygous variant C/T of the CYP2D6*10 allele (intermediate metabolizers) was significantly a bit high in the north-western region, while the Siberian region of Russia had the lowest frequency ($P < 0.001$), which are 35.8% and 17.4%, respectively. The homozygous variant T/T of the CYP2D6*10 allele (poor metabolizers) was not identified.

Conclusion The C100T polymorphism of the CYP2D6 gene may be associated with several drug-induced reactions in patients with depression, schizophrenia, epilepsy etc. The differences in the prevalence of intermediate metabolizers in north-western and Siberian regions of Russia may be due to genetic drift and accumulation of alleles typical of European and Asian populations.

Introduction Anxiety symptoms are frequent during pregnancy, and they adversely affect pregnancy outcomes and offspring development. The underlying biological mechanisms are not known, but may in part be explained by alterations in certain maternal metabolic pathways. No metabolomic studies have investigated possible metabolic alterations in anxious pregnant women.

Objective This pilot study compared the metabolic profiles of anxious and non-anxious pregnant women using a mass spectrometry-based quantitative metabolomics system.

Methods Cases were 20 participants of the Kuopio birth cohort study (www.kubico.fi) with first and third trimester symptoms of anxiety (Edinburgh postnatal depression scale, anxiety subscale – EPDS-3A ≥ 4), but no depression (EPDS ≤ 12). Controls were 20 participants with low anxiety (EPDS-3A ≤ 3) and depression (total EPDS ≤ 9) in both the first and third trimester. Maternal metabolic profiles were analyzed from serum samples drawn when the mothers arrived at the delivery hospital.

Results Metabolic pathway analyses revealed significant enrichment in the glycine, serine and threonine metabolism ($P = 0.046$), as well as in the betaine ($P = 0.048$) metabolism pathways. Homocysteine was the only metabolite to significantly differentiate between cases and controls (VIP score 3.3), with lower concentrations in cases ($P = 0.003$) even when excluding non-users of folic acid supplementation ($n = 5$; $P = 0.002$), C-sections ($n = 5$; $P = 0.013$), or samples taken immediately postpartum ($n = 2$; $P = 0.004$). No other metabolites significantly differed between the groups.

Conclusions Physiological adaptation induced by pregnancy, which may have homogenized the study populations, could explain the only minor metabolic differences between the two groups. Further research in larger samples, comparing metabolic alterations in umbilical cord blood and maternal blood is warranted.

Hippocampal volume recovery after depression: Evidence from an elderly sample

I. Bensassi*, J. Lopez-Castroman, R. Calati, P. Courtet
 Inserm U1061, Colombière Hospital, Adult Psychiatry, Montpellier, France

* Corresponding author.

Objectives Structural neuroimaging studies have revealed a consistent pattern of volumetric reductions in both the hippocampus and the anterior cingulate cortex (ACC) of individuals with a major depressive episode (MDE). This study investigated hippocampal and ACC volume differences in the elderly comparing currently depressed individuals and individuals with a past lifetime history of MDE versus healthy controls.

Methods We studied non-demented individuals from a cohort of community-dwelling people aged 65 and over (ESPRIT study). T1-weighted magnetic resonance images were used to acquire anatomical scans from 150 currently depressed individuals, 79 individuals with at least one past MDE, and 310 healthy controls. We derived quantitative regional estimates of subcortical volume of hippocampus and ACC using FreeSurfer Software (automated method). Concerning hippocampus, we also used a manual method of measurement. General Linear Model was used to study brain volumes in current and past depression adjusting for gender, age, education level, total brain volume, and anxiety disorder comorbidity.

Results After adjustment, current depression was associated with a lower left posterior hippocampal volume ($F=10.38$, $P=0.001$) using manual estimation of volume. No other significant differences were observed. A positive correlation was found between time since the last MDE and left posterior hippocampal volume.

Conclusions The finding of left posterior hippocampal volume reduction in currently depressed individuals but not in those with a past MDE compared to healthy controls could be related to brain neuroplasticity. Additionally, our results suggest manual measures to be more sensitive than automated methods.

Introduction to mindfulness: A pilot exploratory study among memory clinic attendees

C. Dolan^{1,*}, I. Bruce², B.A. Lawlor³

¹ St. James's Hospital, General Adult Psychiatry, Dublin, Ireland

² St. James's Hospital, Medicine for the Elderly, Dublin, Ireland

³ Trinity College Dublin, Old Age Psychiatry, Dublin, Ireland

* Corresponding author.

Background Evidence from the literature suggests that group mindfulness interventions result in improved quality of life, less depressive symptoms and improved subjective sleep quality among patients with memory problems [1].

Objectives To design and pilot a brief mindfulness intervention for Memory Clinic attendees.

Aims To develop a non-pharmacological low-resource intervention for Memory Clinic attendees.

Methods An introduction to mindfulness pack, designed by author CD, includes a booklet introducing the concept of mindfulness, instructions for meditation exercises with an accompanying CD. Memory clinic attendees diagnosed with subjective memory complaints or mild cognitive impairment were invited to take part. Participants completed standardised questionnaires pre- and post-intervention, which examined subjective memory, depression and anxiety symptoms, subjective sleep quality, worry and mindfulness levels. Qualitative information was also gathered.

Results Of twenty-four participants (66.6% female, mean age 60.8 years), 14 (58.3%) completed the 6-week study. There was no statistical difference in anxiety and depressive symptoms, quality of life, sleep quality and worry levels pre- and post-intervention among participants. However, 100% of participants found the mindfulness intervention beneficial, with 64.3% ($n=9$) reporting a subjective improvement in both memory and concentration.

Conclusions In this small pilot study, a brief self-guided mindfulness intervention was found to be acceptable to a heterogeneous group of Memory Clinic attendees.

Economic recession and mental health distress: Does age matter?

D. Frasilho*, G. Cardoso, A. Ana, M. Silva, J.M. Caldas-de-Almeida

Cedoc, Chronic Diseases Research Center, Nova Medical School, Universidade Nova de Lisboa, Lisboa, Portugal

* Corresponding author.

Introduction The association between economic crises and mental health problems can be attributed to a number of factors. Among these, age seems to be an important determinant.

Objectives The aim of this study was to assess whether mental health of the Portuguese population following the onset of the 2008 recession, differs by age groups.

Methods A follow-up study (2015) on the population aged 18 to >65 years old, using the National Mental Health Survey ($n=911$). The age-group prevalence of mental health distress assessed by the ten-item Kessler's Psychological Distress Scale (K10) was calculated using χ^2 statistics and mental distress as a categorical variable ($P<0.05$).

Results Mean mental distress score differed significantly according to age group, $\chi^2(3)=10.684$, $P<0.05$. The results showed that the older groups (50–64 and 65+ years old) were more frequently under mental distress (17–19%) compared to younger people (18–49 years old), which were less likely to report being distressed (8–12%).

Conclusions Age seems to be an important determinant of distress levels during the economic crisis in Portugal. Older adults reported to be more distressed compared to younger individuals. There are several hypotheses for a differential expression of psychological distress between age groups such as working status and retirement, which can express differential access to coping resources under such contextual negative pressure of economic recession. Further research on age groups is thus needed to better understand how recession generates adverse effects on mental well-being.

The effect of apolipoprotein E $\epsilon 4$ (APOE E4) on visuospatial working memory in healthy elders and amnesic mild cognitive impairment patients: An event-related potentials study

L. Gu

Nanjing Zhongda Hospital, Southeast University, School of Medicine, Department of Neuropsychiatry, Nanjing, China

Introduction Previous studies provided inconsistent evidences for the effect of apolipoprotein E $\epsilon 4$ (APOE $\epsilon 4$) status on the visuospatial working memory (VSWM). Our study was the first investigation with event-related potential (ERP) to explore the effect of APOE $\epsilon 4$ on VSWM in healthy elders and aMCI patients.

Objective The aim was to investigate the effect of APOE $\epsilon 4$ on VSWM with event-related potential (ERP) study in healthy elders and aMCI patients.

Methods Thirty-nine aMCI patients (27 APOE $\epsilon 4$ non-carriers and 12 APOE $\epsilon 4$ carriers) and 43 their matched control (25 APOE $\epsilon 4$ non-carriers and 18 APOE $\epsilon 4$ carriers) performed an N-back task, a VSWM paradigm that manipulated the number of items to be stored in memory.

Results Our study detected reduced accuracy and delayed mean correct response time in aMCI patients than healthy elders. P300 was elicited by VSWM and its amplitude was lower in aMCI patients at the central-parietal and parietal electrodes than healthy controls. In healthy elders, P300 amplitude declined prior to task performance change in APOE $\epsilon 4$ carriers than non-carriers. Regarding aMCI patients, P300 amplitude result revealed exacerbated VSWM deficits in APOE $\epsilon 4$ carriers than APOE $\epsilon 4$ non-carriers. Additionally, standardized low-resolution brain electromagnetic tomography analysis (s-LORETA) result showed enhanced brain activation in right parahippocampal gyrus during P300 time range in APOE $\epsilon 4$ carriers than non-carriers in aMCI patients (Fig. 1, Tables 1 and 2).

Conclusions It demonstrated that P300 amplitude might serve as a biomarker for recognizing aMCI patients and contribute to early detection of worse VSWM in APOE $\epsilon 4$ carriers than non-carriers.

Fig. 1 The sLORETA images showing statistical differences between aMCI- APOE $\epsilon 4$ - and aMCI- APOE $\epsilon 4$ + group (3D-view and slice-view) in the P300 time-range. The three slice-view images below located the maximal difference between aMCI- APOE $\epsilon 4$ - and aMCI- APOE $\epsilon 4$ + group (MNI coordinates $x, y, z=10, -35, 0$). Negative difference was in blue color with reference of aMCI- APOE $\epsilon 4$ + group. Abbreviations: aMCI: amnesic mild cognitive impairment; APOE: apolipoprotein E; MNI: Montreal Neurological Institute; sLoreta: standardized low-resolution brain electromagnetic tomography analysis.

Charles Bonnet Syndrome (CBS): Successful treatment of visual hallucinations due to vision loss with agomelatine in three cases

H.C. Hsu^{1,*}, Y.S. Huang², W.X. Fan³, T.C. Chen⁴

¹ Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Department of Psychiatry, Chia-yi county, Taiwan ROC

⁴ Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Department of Metabolism and Endocrinology, Chia-yi county, Taiwan ROC

* Corresponding author.

Background CBS becomes more prevalent as the population ages. CBS is characterized by the triad of impairment of vision, complex visual hallucinations with insight, mentally normal people. Although visual hallucinations in the elderly are often associated with dementia with Lewy body, Alzheimer's disease and delirium, they are excluded from the diagnosis of typical CBS. Here, we describe three typical CBS patients whose visual hallucinations developed after bilateral severe visual impairment due to diabetic retinopathy. The effectiveness of agomelatine adds to evidence implicating serotonergic and melatonergic pathways in the pathogenesis of visual hallucinations.

Case report The average age of these three patients (2 males and 1 female) is 71. Except for the visual hallucinations, all patients showed no psychiatric symptoms or cognitive decline or neurological focal signs. They were frequently upset by the fact of hallucinating, fearing that they are losing their minds. They lived in fear of impending insanity, guilty feeling, unhappy mood, insomnia. The frequency of visual hallucinations stopped with agomelatine 25 mg/day for 3 weeks in these cases.

Discussion To our knowledge, this is the first report describing the effectiveness of agomelatine in treating typical CBS patients and indicates that agomelatine is a safer option for the treatment of CBS, especially in the elderly, diabetic population. Therapeutic options for CBS still remain poor and of uncertain benefit for the individual patient. CBS has a high prevalence rate (0.4%–30%) among the visually impaired. Clinicians must ask elderly people with visual impairment whether they have hallucinations. Firm reassurance that the syndrome is not related to mental illness is a major relief to an elderly person burdened already with failing vision.

White matter hyperintensities as a new predictor of driving cessation in the elderly

K.Y. Lim^{1,*}, S.J. Son², M. Jang², C.H. Hong²

¹ Ajou University School of Medicine, Department of Psychiatry, Suwon, Republic of Korea

² Ajou University School of Medicine, Psychiatry, Suwon, Republic of Korea

* Corresponding author.

Background/aims Motor, perceptual, and cognitive functions affect driving competence. White matter hyperintensities (WMH) changes on brain MRI are associated structural brain changes along with cognitive and motor performance. The aim of this study was to investigate the association between WMH and driving ability in the elderly.

Methods Participants ($n = 540$) were drawn from a nationwide, multicenter, hospital-based, longitudinal cohort study. Each participant underwent clinical evaluations, neuropsychological tests, and interview for caregiver including driving capacity, which was categorized as 'now driving', and 'driving cessation (driving before, not now)'. A total 540 participants were divided into three groups (389 mild, 116 moderate, and 35 severe) depending on the degree of WMH. The same evaluations of them were followed after each year. The statistical analyses were performed using χ^2 test, an analysis of variance (ANOVA), structured equation model (SEM), and generalized estimating equation (GEE).

Results In a SEM, greater baseline degree of WMH was directly associated with driving cessation regardless of cognitive and motor dysfunction ($\beta = -0.110$, $P < 0.001$). In GEE models controlling for age, sex, education, cognitive, and motor dysfunction, the more severe changes of the degree of WMH was associated with the

faster change from 'now driving' state to 'driving cessation' state over time in the elderly ($\beta = -0.508, P < 0.001$).

Conclusion In both cross-sectional and longitudinal aspects, the degree of WMH might be one of the predictive factors for driving cessation in the elderly, reflecting both motor and cognitive functions or independently.

* Corresponding author.

Introduction Several studies have reported controversial links between swallowing disturbances (SD) and psychiatric disorders in older age. The available data on the epidemiology of SD in the general population are scarce and often conflicting, because of numerous methodological factors source of possible confounders. **Objectives** We aimed to screen the presence of psychiatric and cognitive disorders associated with SD in a random sampling of the general population ≥ 65 .

Methods A sample of 1127 elderly individuals collected in a population-based study (GreatAGE) in Castellana Grotte (53,50% males, mean age 74.1 ± 6.3 years), South-East Italy, were mailed a validated self-report questionnaire to assess SD (Eating Assessment Tool-EAT10). Psychiatric disorders and symptoms [assessed with Semi-structured Clinical Diagnostic Interview for DSM-IV-TR Axis I Disorders, Geriatric Depression Scale-30 (GDS-30) and Symptom Checklist Revised-90 (SCL-90R)], cognitive functions were assessed with a comprehensive neuropsychological battery, neurological exam, and demographics were compared in participants with and without SD using *t*-tests and Mann-Whitney *U*-test.

Results The prevalence rates of SD amounted at 5.97%. Psychiatric diagnosis (24.22% of the sample) was statistically significant associated with SD ($EAT \geq 3, P = 0.038$), and a trend was found for major depressive disorder and generalized anxiety disorder. Among SCL-90R domains, only anxiety showed a significant association with $EAT \geq 3$ ($P = 0.006$). GDS-30 score was found to be higher in subjects with SD ($P = 0.008$). Cognitive functions did not differ between the two groups except for an increasing trend for Clinical Dementia Rating Scale in $EAT \geq 3$ ($P = 0.058$).

Conclusions These preliminary results showed an association between SD in older age and late-life major depression and anxiety disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction The validity of the 30-item Geriatric Depression Scale (GDS-30) in detecting late-life depression (LLD) requires a certain level of cognitive functioning. Further research is needed in population-based setting on other socio-demographic and cognitive variables that could potentially influence the accuracy of clinician rated depression.

Objective To compare the diagnostic accuracy of two instruments used to assess depressive disorders [(GDS-30) and the Semi-structured Clinical Diagnostic Interview for DSM-IV-TR Axis I Disorders (SCID)] among three groups with different levels of cognitive functioning (normal, Mild Cognitive Impairment – MCI, Subjective Memory Complain – SMC) in a random sampling of the general population 65+ years.

Methods The sample, collected in a population-based study (GreatAGE Study) among the older residents of Castellana Grotte, South-East Italy, included 844 subjects (54.50% males). A standardized neuropsychological battery was used to assess MCI, SMC and depressive symptoms (GDS-30). Depressive syndromes were diagnosed through the SCID IV-TR. Socio-demographic and cognitive variables were taken into account in influencing SCID performance.

Results According to the SCID, the rate of depressive disorders was 12.56%. At the optimal cut-off score (≥ 4), GDS-30 had 65.1% sensitivity and 68.4% specificity in diagnosing depressive symptoms. Using a more conservative cut-off (≥ 10), the GDS-30 specificity reached 91.1% while sensitivity dropped to 37.7%. The three cognitive subgroups did not differ in the rate of depression diagnosis. Educational level is the only variable associated to the SCID diagnostic performance ($P = 0.015$).

Conclusions At the optimal cut-off, GDS-30 identified lower levels of screening accuracy for subjects with normal cognition rather than for SMC (AUC 0.792 vs. 0.692); educational attainment possibly may modulate diagnostic clinician performance.

Introduction Elderly patients in nursing homes (NH) are often prescribed medications for many physical and mental health problems, with polypharmacy. There is a considerable number of studies documenting this extensive prescription of psychotropic medication, despite the raised concerns about their overuse/misuse, due to serious adverse effects, including increased rate of cognitive decline associated with antipsychotics.

Aims To characterize the prescription of psychotropics in elderly sample with cognitive impairment living in NH.

Methods Elderly living in three Portuguese NH were included in this cross-sectional study. All residents were eligible, unless they were unwilling or unresponsive. Participants' medication was obtained from medical records. Guidelines of ATC were used to categorize the drugs. Participants were assessed with MMSE and GDS. **Results** The sample included 172 elderly, mostly women (90%), with average of 81(sd=10) years and median lengths of stay of 3 years. Overall, 79.1% used ≥ 1 nervous system-acting drugs. Anxiolytics (54.7%), antidepressants (29.1%) and antipsychotics (23.3%) were the most frequent. The majority (58%) presented cognitive impairment (MMSE). Among those, 46.2% presented depression (GDS) and 79.6% took at least one drug for the CNS and 41.9% ≥ 3 . Antipsychotics were received by 26.5%, while 57.1% used anxiolytics, 31.6% antidepressants and 16.3% anti-dementia drugs. No significant relation between GDS and antidepressants was found.

Conclusion This study confirms the high usage of CNS drugs in patients with cognitive impairment in NH. These rates were comparable with previous studies. Antidepressants appear to be under-used, which can be related to the under-recognition of depression. Also, potential harmful psychotropic drugs such as anxiolytics and antipsychotics are overused.

⁴ Clinic of Psychiatry and Mental Health, CHSJ, Porto, Portugal

* Corresponding author.

Introduction Suicide rates worldwide are highest in elderly people compared to younger ages. The recognition of risk factors for late life suicide may be crucial, since one in four attempts is consummated. In this context, pain has been identified as a major event raising the probability for suicide in elders although very little research has examined this association.

Objective To conduct a systematic review to examine whether pain is a risk factor for suicidal behaviour (suicide ideation/attempt/suicide) in elderly people.

Methods The Cochrane Collaboration's guidelines and PRISMA statement were used. The electronic databases considered were MEDLINE, ISI Web of Knowledge, Scopus and PsycARTICLES. Search terms were "pain", "suicide" and "elderly". Studies that assessed the relation between pain and suicidal behavior among people aged ≥ 60 years were included.

Results Of the 2655 references founded, only 41 articles met the inclusion criteria. Most of the quantitative studies concluded that there is a relationship between pain and late life suicidal ideation, in particular severe and chronic pain. Physical or psychological pain was also reported as the cause of attempting suicide in two studies and was considered an important risk factor for committed suicide in eight of them.

Conclusion The results suggest that pain is a risk factor for suicidal behaviour in elderly people, especially suffering from severe and chronic pain, which are in accordance with previous reviews in this field. Future studies are needed to clarify this association and highlight about the importance of pain in suicide prevention initiatives for elders.

* Corresponding author.

Background Long-term care for the elderly by their family members represents a serious burden in Italy. The physical and psychological health of informal caregivers is a growing public health issue. Old patients often seek urgent medical attention in the Emergency Department (ED) and hospitalisation is frequent event among the elderly.

Aim Aim of the study was (1) to investigate the burden of care among the caregivers of old patients; (2) to examine the influence of the burden experienced by the caregivers on ED and hospital admissions of the elderly.

Methods We conducted a descriptive study of patients aged 75 years or older and their caregiver admitted to the ED from 10/1/15 to 6/10/15 (77 patient-caregiver pairs). The caregivers were evaluated using the Caregiver Burden Inventory (CBI). A case manager collected the patient's data.

Results CBI score is the highest among patients seeking ED evaluation due to caregiver's concern. The majority of the elderly admitted to the ED whose caregiver shows elevated emotional burden at the CBI do not present with serious or urgent medical condition and are not hospitalised. Emotional burden is the high-

est among the caregivers of demented subjects who share the same house.

Conclusion Our findings indicate that the burden experienced by caregiving family members plays a role in elderly people avoidable ED visits.

³ Jeju National University School of Medicine, Jeju National University Hospital, Department of Psychiatry, Jeju, Jeju-do, Republic of Korea

* Corresponding author.

Background The study aims to examine whether cognitive deficits are different between patients with early stage Alzheimer's disease (AD) and patients with early stage vascular dementia (VaD) using the Korean version of the CERAD neuropsychological battery (CERAD-K-N).

Methods Patients with early stage dementia, global Clinical Dementia Rating (CDR) 0.5 or 1 were consecutively recruited among first visitors to a dementia clinic, 257 AD patients and 90 VaD patients completed the protocol of the Korean version of the CERAD clinical assessment battery. CERAD-K-N was administered for the comprehensive evaluation of the neuropsychological function.

Results Of the total 347 participants, 257 (69.1%) were AD group (CDR 0.5 = 66.9%) and 90 (21.9%) were VaD group (CDR 0.5 = 40.0%). Patients with very mild AD showed poorer performances in Boston naming test (BNT) ($P=0.028$), word list memory test ($P<0.001$), word list recall test ($P<0.001$) and word list recognition test (WLRcT) ($P=0.006$) than very mild VaD after adjustment of T score of MMSE-KC. However, the performance of trail making A (TMA) was more impaired in VaD group than in AD group. The performance of WLRcT ($P<0.001$) was the worst among neuropsychological tests within AD group, whereas TMA was performed worst within VaD group.

Conclusions Patients with early-stage AD have more cognitive deficits on memory and language while patients with early-stage VaD show worse cognitive function on attention/processing speed. In addition, as the first cognitive deficit, memory dysfunction comes in AD and deficit in attention/processing speed in VaD.

The effectiveness and long-term prognosis of the intravenous course of cerebrolysin in patients with the amnesic MCI

E. Ponomareva

Mental Health Research Center of RAMS, Alzheimer disease and Related Disorders Research Center, Moscow, Russia

Early diagnosis and treatment in the predementia stage of Alzheimer's disease, i.e. in amnesic MCI (aMCI) may improve patient quality of life and promote slowing of conversion to dementia. The purpose of the study was to analyze the effectiveness

and long-term prognosis of the course of cerebrolysin therapy in aMCI patients. Twenty elderly aMCI patients were included in the study and treated with a 20-day course of therapy with daily intravenous infusions of 30 mL cerebrolysin. Cognitive functions were assessed by the battery of neuropsychological scales and tests: MMSE, MoCA-test, MDRS, the Boston naming test, the Clock Drawing Test, Frontal Assessment Battery, the test "10 words", the Digit Repetition Test. The level of the auto-antibodies to a short peptide fragment of the neurotrophins P75 receptor has been investigated by ELISA in the patient blood serum 3 times per 6 months (0, 10 and 26 weeks). Analysis of the data showed a statistically significant improvement in psychometric tests at the therapy end and also at 10 and 26 weeks of the study. Long-term therapeutic effect (5 months) proved to be significantly correlating with the following parameters: patient's age older than 70 years, basic indices of the MoCA-test and the test "memory" of the dementia Matisse scale. The decline serum level of autoantibodies to the fragment 155–164 receptor of neurotrophins P75 also provided to be an indicator of the long-term effectiveness of the therapy. These results could determine those aMCI patients who could have positive long-term therapeutic effect following cerebrolysin treatment.

Risk factors of increased mortality during hospitalization in acutely-ill elderly patients with altered state of consciousness

P. Sá Esteves^{1,*}, D. Loureiro¹, E. Albuquerque¹, F. Vieira¹, L. Lagarto², S. Neves¹, J. Cerejeira¹

¹ Centro Hospitalar e Universitário de Coimbra, Psychiatry, Coimbra, Portugal

² Centro Hospitalar de Entre o Douro e Vouga, Psychiatry, Santa Maria da Feira, Portugal

* Corresponding author.

Introduction A significant proportion of acutely ill hospitalised elderly patients have impaired consciousness and this has been associated with increased mortality. It remains unclear which factors underlie this relation. Identification of mortality predictors in this population is important to improve care.

Objectives Determine if advanced age, cognitive impairment, high burden of co-morbidities and poor functional status are predictors of increased mortality during hospitalisation in acutely-ill medical hospitalised elderly patients with altered state of consciousness.

Methods All male patients (>65 years) admitted to a medical ward (>48 h) between 01/03/2015 to 31/08/2015 with delirium or RASS lower than -2 were included in the study. Patients were excluded if unable to be assessed due to sensorial deficits, communication problems or medical condition precluding the evaluation. Baseline evaluation included socio-demographic variables, RASS, CAM, IQCODE-SF, DSM-IV-TR criteria for dementia, Charlson Comorbidity Index and Barthel Index. The variables were entered in a logistic regression model (significance level <0.05).

Results The final sample consisted of 75 male subjects with altered state of consciousness, 14 of them died during hospitalisation. Dementia and Barthel Index were significantly associated with mortality during hospitalisation ($P=0.01$ and $P<0.01$, respectively). On the other hand, age and Charlson Co-morbidity Index were not associated significantly with mortality during hospitalisation ($P=0.22$ and $P=0.1$, respectively).

Conclusions Acutely ill elderly patients with altered state of consciousness at admission have higher risk of death during hospitalisation if they have prior dementia or poor functional status.

Health care should be improved to provide better response to this type of patients.

* Corresponding author.

Introduction Brain health has garnered increasing attention as a requisite condition for healthy aging. The rapid growth in mobile health and increasing smartphone ownership among older adults has paved the way for smartphones to be utilized as effective tools for improving mental fitness.

Objectives There are few studies that have explored the efficacy of smartphone-based cognitive training. The present study examined the memory-enhancing effects of smartphone-based memory training for older adults.

Aims We explored whether newly developed application “Smartphone-based brain Anti-aging and memory Reinforcement Training (SMART)” improved memory performance in older adults with subjective memory complaints.

Methods A total of 53 adults (mean age: 59.3 years) were randomized into either one of two smartphone-based intervention groups (SMART vs. Fit Brains[®]) or a wait-list group. Participants in the intervention groups underwent 15–20 minutes of training per day, five days per week for 8 weeks. We used objective cognitive measures to evaluate changes with respect to four domains: attention, memory, working memory (WM), and executive function (inhibition, fluency, etc.). In addition, we included self-report questionnaires to assess levels of subjective memory complaints.

Results The performance on WM test increased significantly in the SMART group ($t[17]=6.27, P<0.0001$) but not in the control groups. Self-reports of memory contentment, however, increased in the Fit Brains[®] group only ($t[18]=2.12, P=0.048$).

Conclusions Use of an 8-week smartphone-based memory training program may improve working memory function in older adults. However, objective improvement in performance does not necessarily lead to decreased subjective memory complaints.

Drug–drug interactions between antibiotics and psychopharmaceuticals in Slovenian nursing homes: A retrospective observational cohort study from a national perspective

M. Stuhec^{1,*}, P. Ines², D. Stepan³, U. Lea³, M. Petek Ster³, B. Beović⁴

¹ Faculty of Pharmacy, Biopharmacy and Pharmacokinetics, Ljubljana, Slovenia

² Faculty of Pharmacy Ljubljana, Biopharmacy and Pharmacokinetics, Ljubljana, Slovenia

³ Faculty of Medicine Ljubljana, Department of Family Medicine, Ljubljana, Slovenia

⁴ Faculty of Medicine Ljubljana, Department of Infectious Diseases, Ljubljana, Slovenia

* Corresponding author.

Background Drug–drug interactions (DDIs) between antibiotics and psychopharmaceuticals in large national data have not been described yet.

Objectives In most European countries, there is no national data on DDIs in patients within nursing homes.

Aim To present the most important DDIs in the Slovenian nursing homes to avoid serious DDIs in the future.

Methods A retrospective study was carried in 2015 and with 233 patient on antibiotic treatment. All study data from the patients' records were obtained from the patients' charts. DDIs were determined by different interaction classes with Lexicomp Online[™] 19.0 version and only X (major interactions) and D (minor interactions) were included.

Results A total of 233 patients (age = 83.5, SD = 9.8) were treated with antibiotics (only 2 without psychopharmaceuticals). The number of patients with at least 1 interaction was: 72 (30.9%) for X and 172 (73.8%) for D and the average number of medication/patient was 10.9 (SD = 3.9). Twenty-seven patients (11.5%) were treated with at least 1 X DDIs (17 patients ciprofloxacin, 6 moxifloxacin, 3 azithromycin and 1 levofloxacin). Quetiapine and ciprofloxacin was most frequent DDIs occurred in 12 patients. Twenty-seven DDIs were pharmacodynamic (QTc prolongation) and 3 pharmacokinetic (ciprofloxacin-tizanidine, ciprofloxacin and duloxetine in 2 patients; $n=3$). Quetiapine was most frequent prescribed psychopharmaceutical in X DDIs.

Conclusions DDIs between these two groups are seen very often. If an antidepressant should be used in these patients, we recommend sertraline instead of escitalopram and venlafaxine instead of duloxetine and mirtazapine instead of quetiapine. We also recommend a use of penicilins instead of ciprofloxacin and azithromycin.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Efficacy of rivastigmine on loss of appetite in patients with Alzheimer's disease

N. Tsuno^{*}, T. Mori, Y. Nakamura

Kagawa University, Department of Neuropsychiatry, Miki-cho, Kita-gun, Japan

* Corresponding author.

Introduction It has been said that nearly 30% of the patients with Alzheimer' disease (AD) manifest loss of appetite, which might increase cognitive impairments and the incidence of neuropsychiatric symptoms, and malnutrition. As a result, a vicious cycle decreases functionality and quality of life in patients with AD. Cholinesterase inhibitors (ChEIs) is the first-line drugs in the treatment of AD. On the one hand, appetite or weight loss can be seen due to gastrointestinal side effects in the treatment of ChEIs. On the other hand, there are some reports in clinical-settings that patients with AD treated with rivastigmine transdermal patch showed the improvement of appetite loss.

Objectives To evaluate the efficacy of rivastigmine transdermal patch in AD patients with poor appetite.

Methods In this 16-weeks, multicenter prospective study, patients with mild to moderate AD, who manifest loss of appetite and began to receive rivastigmine transdermal patch therapy, were enrolled. The amount of food, total time-eating, body weight, Mini Mental State Examination (MMSE) and Neuropsychiatric Inventory (NPI) were evaluated.

Results The amount of food eaten by treated patients significantly increased 10.5% at 8 weeks after the initiation of rivastigmine transdermal patch therapy.

Comments This preliminary results might show favourable effects of rivastigmine transdermal patch therapy on AD patients with loss of appetite.

⁵ University of Nottingham, Institute of Mental Health, Nottingham, United Kingdom

⁶ VU University, Medical Center, Amsterdam, The Netherlands

* Corresponding author.

Introduction The Meeting Centre Support Programme (MCSP) is a community-based approach to support people living with dementia and their families. It was developed in the Netherlands and has been implemented in other European Countries (Italy, Poland and the UK) within the JPND-MEETINGDEM project.

Aims To assess the relationship between background characteristics of people with dementia participating in MCSP, mood, quality of life (QoL) and experienced stigma, and to explore if and how the experienced stigma changed after 6 months of participation in MCSP.

Methods A pretest (M1) post-test (M7) control group design with matched groups regarding severity of dementia was applied. In each country, a minimum of 25 participants using MCSP were compared with people with dementia receiving 'usual care'. Data were collected with the Stigma Impact Scale, Cornell Scale for Depression in Dementia, Global Deterioration Scale and two QoL scales (QoL-AD & DQoL). Differences in background characteristics were taken into account in the analyses.

Results The preliminary analysis on 116 participants at baseline shows that the level of stigma was low to moderate. People felt more socially rejected in the UK than in Poland and Italy. The level of perceived stigmatization appeared negatively correlated with QoL areas and positively correlated with negative mood. Changes after 6 months will be presented.

Conclusions It is expected that after 6 months people living with dementia participating in MCSP will experience less stigma, as in contrast with usual care MCSP promotes social integration of people with dementia and person-centered support.

What predicts adjustment to aging among lesbian, gay and bisexual older adults?

S. Von Humboldt*, I. Leal, F. Carneiro

ISPA-Instituto Universitário, William James Center for Research, Lisbon, Portugal

* Corresponding author.

Introduction Intervention programs that highlight predictors of adjustment to aging (AtA) for minority older lesbian, gay and bisexual (LGB) populations are scarce.

Objective The aim of this preliminary study is to build a structural model to explore whether socio-demographic, health and lifestyle-related variables, are correlates of AtA in a group of LGB older adults.

Methods The sample comprised 287 LGB older adults aged 75 years old and older. Convenience sampling was used to gather questionnaire data. Measures encompassed the adjustment to aging scale, the satisfaction with life scale, demographics and lifestyle and health-related characteristics. Structural equation modeling was used to explore a structural model of the self-reported AtA, comprising all the above variables.

Results The structural model indicated the following significant correlates: perceived health ($\beta=0.456$; $P<0.001$), leisure ($\beta=0.378$; $P<0.001$), income ($\beta=0.302$; $P<0.001$), education ($\beta=0.299$; $P=0.009$), spirituality ($\beta=0.189$; $p<0.001$), sex ($\beta=0.156$; $P<0.001$), physical activity ($\beta=0.142$; $P<0.001$), satisfaction with life ($\beta=0.126$; $P<0.001$), and marital status ($\beta=0.114$; $P=0.008$). The variables explain respectively 76.4% of the variability of AtA.

Conclusions These outcomes suggest that policy making and community interventions with LGB older adults may benefit of including variables, such as, perceived health, leisure and income, as these were pointed out as significant for this group of older adults for promoting adjustment to aging in late adulthood.

Predictors of satisfaction with life among older adults

S. Von Humboldt*, I. Leal

ISPA Instituto Universitário, William James Center for Research, Lisbon, Portugal

* Corresponding author.

Introduction Increasing longevity brings challenges for older adults' satisfaction with life (SWL).

Aims This study aims at exploring a structural model of predictors of SWL in a cross-national sample of older adults.

Methods A community-dwelling sample of 1234 older adults was assessed regarding SWL, sense of coherence (SOC) and socio-demographic, lifestyle and health-related characteristics. Structural equation modeling was used to investigate a structural model of the self-reported SWL, comprising SOC, socio-demographic characteristics (age, sex, education, marital and professional status, household, adult children, income, living setting and religion), lifestyle and health-related characteristics (physical activity, recent disease and medication).

Results Significant predictors are SOC ($\beta=.733$; $P<.001$), religion ($\beta=.725$; $P<.001$), income ($\beta=.551$; $P<.001$), adult children ($\beta=.546$; $P<.001$), education ($\beta=-.403$; $P<.001$), living setting ($\beta=-.292$; $P<.001$) and medication ($\beta=-.197$; $P<.001$). The variables accounted for 24.8% of the variability of SWL. Moreover, differences between the four nationality groups ($F_{(3, 671)} = 3.671$, $P=.066$) were not found concerning SWL.

Conclusions Sense of coherence is the strongest predictor of self-reported SWL. Other predictors are religion, income, adult children, education, living setting and medication. The four nationalities did not present significant differences, concerning SWL. This study highlights the factors that influence older adults' SWL, namely, SOC,

religion and income, as promoters of aging well, within a salutogenic model of health for older populations.

Burden of care of the caregivers of Alzheimer's disease patients and relationship with burnout syndromes

E. Yildizhan^{1,*}, N. Ören², A. Erdoğan²

¹ Neurology and Neurosurgery, Department of Psychiatry, Bakirkoy Research and Training Hospital for Psychiatry, Istanbul, Turkey

² Department of Clinical Psychology, Beykent University, Istanbul, Turkey

* Corresponding author.

Introduction Increased caregiver burden and burn out in Alzheimer disease is associated with a spectrum of problems, like depression or anxiety.

Objectives To examine the relationship between the burden of care and burnout level of professional staff dealing with Alzheimer's disease patients in geriatric inpatient centers in Turkey.

Methods Zarit Caregiver Burden Scale to measure the level of burden of care, and Maslach Burnout Inventory were used to measure the level of burnout. Relationships between the socio-demographic data of the sample group, burden of care and burnout level were investigated. Sample group was consisting of 203 caregivers working in 8 geriatric care centers in Istanbul.

Results The surveyed caregivers' "burden of care giving" level was low (35.3 ± 9.9); "emotional exhaustion" level was weak (2.3 ± 0.8); "depersonalization" level was weak (1.9 ± 0.6); "a feeling of low personal accomplishment" level was weak (2.5 ± 0.8); "general burnout" level was weak (2.3 ± 0.5). There was positive correlation between caregiver burden and burnout level. According to the sociodemographic data, married women with children were especially in increased risk for burnout. Low level of education was associated with increased caregiver burden and burnout. Caregiver burden and depersonalization points were also higher with increasing age.

Conclusions Supportive interventions are needed to decrease the burnout and caregiver burden especially for the caregivers with increased risk.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Assessment of renal function in elderly with dementia is a difficult clinical problem due to the high prevalence of malnutrition and creatinine limits as a marker of glomerular filtration in this context.

Objectives To assess the correlation between renal function and dementia diagnosis.

Aims To highlight differences between methods of assessment of renal function based on creatinine and cystatin C.

Methods Cross-sectional study. Patients institutionalized at Bucharest City-Center of Socio-Medical Services (a nursing home) from 04/2014 to 11/2014 were included in the study. Dementia diagnosis was established by a psychiatrist. We determined serum creatinine by Jaffe method and serum cystatin C by nephelometry. Renal function was determined using several formulas based on serum creatinine/cystatin C: Cockcroft-Gault, MDRD, creatinine CKDEPI/cystatin/creatinine + cystatin, Berlin Initiative Study (BIS1, BIS2), Lund-Malmö LM-LBM. To highlight a link between dementia and renal function, we determined Spearman correlation coefficients.

Results Thirty-one patients were included in the study, mean age 78.6 (63–97) years, 64% women. The diagnosis of dementia (1 = positive, 0 = negative) had the following statistically significant correlations: CKDEPI/cystatin: $\rho = -0.390$, $P = 0.015$; CKDEPI creatinine-cystatin: $\rho = -0.332$, $P = 0.032$; BIS2: $\rho = -0.346$, $P = 0.02$. We did not find statistically significant correlations between the diagnosis of dementia and formulas for assessing renal function based on creatinine only.

Conclusions Elderly patients with dementia present decreased kidney function as determined by formulas based on cystatin/cystatin + creatinine, but not on creatinine alone. Assessment of renal function using cystatin C might represent a useful method for detection of renal dysfunction in these patients and for proper dosage of medication.

EW0213

Are we using mass media to raise awareness about psychiatric disorders?

M.Á. Álvarez de mon*, M. Arrieta, P. Molero, M. Santos
Psychiatry, Clinica Universidad de Navarra, Pamplona, Spain

* Corresponding author.

Introduction The global burden of mental disorders is large and continues to grow. Depression is the leading cause of disability worldwide. Every 40 seconds somebody dies from suicide. People with mental disorders are amongst the most marginalized in society. The stigma they experience puts them at an increased risk of poverty, discrimination and human right violations.

Objectives To study the presence of psychiatric disorders in the media.

Methods We selected and analyzed the top media Twitter accounts of general news outlets, based on their number of followers. Our research strategy focused on the search of several psychiatric terms of interest (ex: "insomnia") on each Twitter account. The search includes tweets from the beginnings of Twitter in 2007 up to May 2016, and yielded a database of more than 10,000 news.

Results The terms with the highest impact in mass media referred to suicide, depression, addictions and gender dysphoria. Disorders related to anxiety (Generalized anxiety, phobias, panic disorder, obsessive-compulsive disorder), dysthymia and bipolar disorder were the psychiatric disorders with the lowest impact. We noticed that the presence of psychiatric disorders in the media is increasing. However, it does not accurately reflect the actual impact it has on society.

Conclusions The media can be a useful tool for the implementation of strategies for the promotion and prevention of mental disorders. However, we are not fully taking advantage of the benefits that mass media has to offer in order to educate and raise awareness about said disorders.

Icehearts: Sport-based early support program for children at risk

K. Appelqvist-Schmidlechner^{1,*}, J. Wessman², M. Kekkonen³
¹ Mental health Unit, National Institute for Health and Welfare, Helsinki, Finland

² Equality and inclusion Unit, National Institute for Health and Welfare, Helsinki, Finland

³ Children, adolescents and families Unit, National Institute for Health and Welfare, Helsinki, Finland

* Corresponding author.

Icehearts program aims to prevent social exclusion, to promote socio-emotional skills and mental well-being and to provide a secure, long-term adult commitment throughout the child's life using team sport as a tool. The program is facilitated by an Icehearts-mentor providing sports activities as well as support at school and home for a period of 12 years starting at age of 7. Currently, the program is reaching about 500 children in 29 Icehearts teams in Finland. The longitudinal study aims at investigating: (1) the psychosocial well-being and (2) the life course of participating children as well as perceived impact, benefits and challenges of the program. The baseline data was gathered in 2015–2016 by questionnaires and interviews among 7 years old program participants ($n = 46$) and controls at same age not participating in the program ($n = 180$), their parents, and teachers. The measures included i.e the Strengths and Difficulties Questionnaire (SDQ). According to the SDQ-scores assessed by the teachers, two of third among program participants had behavioural difficulties. One-fourth had used mental health services. The parents of program participants reported need for more support for their parenting. The results showed that the Icehearts program is reaching out a target group in need for help and support. Further, the study provides valuable information about the role of a NGO organisation offering long-term and intensive support with the help of sport-based intervention program targeted at vulnerable children. In the presentation, the program, study design and the baseline results are presented in more detail.

Relationships between leisure time physical activity, physical fitness and mental health among young adult males

K. Appelqvist-Schmidlechner^{1,*}, J. Vaara², J. Mäkinen²,
 T. Vasankari³, H. Kyröläinen⁴

¹ National Institute for Health and Welfare, Mental health Unit, Helsinki, Finland

² Department of leadership and military pedagogy, National Defence University, Helsinki, Finland

³ UKK institute, Tampere, Finland

⁴ Department of biology and physical activity, University of Jyväskylä, Jyväskylä, Finland

* Corresponding author.

Physical activity has been seen as an important tool to prevent both physical and mental disorders like depression and anxiety. However, previous research has mainly focused on mental health problems rather than positive mental health. The aim of the present study was to investigate the association of leisure time physical activity (LTPA) and physical fitness with mental distress and positive mental health. The study sample consisted of 792 men (mean age 26 years) who participated in the study prior their military refresher-training course. Cardio-respiratory and muscle fitness tests were measured, and LTPA, positive mental health (Warwick–Edinburgh Mental Wellbeing Scale, SWEMWBS) and mental distress were assessed with a questionnaire. Analysis of variance and linear regressions were used as statistical methods. Younger age and lower military education were associated with mental distress, whereas older age and higher military education were inversely associated with high positive mental health (flourishing). Moreover, individuals reporting vigorous LTPA at least 1–2 times per week had lower level of mental distress and were more commonly experiencing flourishing compared to their less physically active counterparts. Physical fitness (both aerobic and muscular) was associated with lower mental distress, but not with flourishing. In conclusion, leisure time physical activity and physical fitness may contribute to mental health. The present results highlight that even low amount of leisure-time physical activity may promote mental health and prevent mental disorders. Leisure time physical activity, rather than physical fitness, seems to be more essential for positive mental health.

The impact of the transition from primary school to secondary school on young adolescents

C. Fontaine^{*}, C. Connor, S. Channa, C. Palmer, M. Birchwood
 Warwick Medical School, University of Warwick, Coventry, United Kingdom

* Corresponding author.

Introduction Previous research suggests that adult anxiety disorders begin in adolescence and the transition from primary school to secondary school is the first challenge many young adolescents face, which could test their resilience for the first time.

Objectives To examine students' anxiety scores before and after their transition, and what protective and risk factors are present during this challenge.

Aims To determine how the transition can impact anxiety in children, and if protective factors can help decrease the disruption that the transition can cause.

Methods One hundred and eighty-four pupils completed questionnaires in their last term of primary school and during the first term of secondary school. At time 1: the attachment, school membership, and bullying and victimization measures were compared with pupils' anxiety scores, along with whether their friends or siblings will be attending the same secondary school as them. These analyses will also be conducted once the pupils start secondary school, at time 2.

Results Secure attachment was associated with lower anxiety and transition anxiety ($F(2.56) = 7.255, P = .002; F(2.52) = 19.245, P = .000; F(2.181) = 10.181, P = .000; F(2.53) = 20.545, P = .000$). School membership was associated with lower transition anxiety ($F(2.181) = 4.151, P = .017; F(2.181) = 3.632, P = .028$). Low victimisation was also associated with low anxiety and transition anxiety ($F(2.181) = 14.024, P = .000; F(2.181) = 14.529, P = .000; F(2.181) = 9.381, P = .000$).

Conclusions These preliminary results suggest that attachment, school membership and victimisation all impact on pupils anxiety

before they transition to secondary school. Therefore, schools could work together to increase school membership and decrease victimisation, particularly for pupils who they suspect will struggle with the transition.

Relationship between pain coping strategies with mental disorders symptoms in patients referring to dental clinics

A. Homayouni^{1,*}, R. Ahmadi¹, G. Nikpour²

¹ Department of psychology, Bandargaz Branch, Islamic Azad University, Bandargaz, Iran

² Department of psychology, Allameh Tabatabaiee University, Tehran, Iran

* Corresponding author.

Introduction The study aimed to assess the relationship between mental disorders symptoms with pain coping strategies in dentistry clinics.

Method One hundred and twenty people with dental pain that attended in dentistry clinics were randomly selected and responded to Rosenstein and Keefe's Pain Coping Strategies Questionnaire (PCSQ) and Derogatis's Symptom Checklist (SCL-90-R). PCSQ assesses six pain coping strategies: diverting attention, reinterpretation pain sensation, self-negotiation, ignoring pain, disastrous thought, hope-praying, and SCL-90 measures nine dimensions: somatization, obsessive compulsive, interpersonal sensitivity, depression, anxiety, hostility, phobic anxiety, paranoid ideation, and psychoticism. The data were analysed with Pearson correlation coefficient and independent *t*-test.

Results Findings showed positive and significant relationship between disastrous thought with all mental disorders symptoms; and reinterpretation pain sensation with depression and anxiety. Also there is negative significant relationship between ignoring pain with obsessive compulsive, interpersonal sensitivity and somatization; and hope – praying with interpersonal sensitivity, depression, anxiety, paranoid ideation and psychoticism. Meanwhile there were significant differences in males and females. Females got more scores in ignoring pain than males, and males got more scores in anxiety, hostility and paranoid ideation than females.

Discussion With regard to findings, it is recommended that in addition to drug treatment, for changing the attitudes and thinking in patients with dental pain, psychiatrists and psychologists apply psychological treatments specially cognitive-behavior therapy to reduce abnormal thinking level about pain so that the length during of treatment declines, and as a results reduce the personality and health problems that is related with dental pain before and in during of drug treatment.

The utilization of a creative strategy in the prevention of the use of psychoactive substances with children and adolescents

J. Jaber*, S. Humel, S. Leite, A. Tomé, A. Hollanda, B. Reys

Clínica Jorge Jaber, Saúde Mental, Rio de Janeiro, Brazil

* Corresponding author.

Introduction The work describes a successful experience in the utilization of art as a tool to work the prevention of the use of

drugs. The experience was developed with children and adolescents between the ages of 3 and 17 who reside in a risky area near Latin America's biggest dump, located in the city of Taguatinga, FD, Brazil.

Objectives Create a therapeutic space to make possible the dialog with the children and adolescents, promoting the prevention and the consciousness about the harm of the use of psychoactive substances, providing clarification on the theme, through art, being the use of formal language and terms, like "illicit drugs", unnecessary.

Methods The children, who participated in the project, used, as expression tool, several painting items. The public was divided by age in two groups: the children received ludic approach, allowing the team nearness and interaction with them, in such a way that the former transmitted information and guidance about the harm on the use of psychoactive substances.

Results The results were satisfactory. All the children and adolescents involved in the project demonstrated adherence to the use of the offered tools and established a communication link, which allowed the receptivity of information about prevention in the use of psychoactive substances.

Conclusions Through the developed activities, it was observed that the strategy utilization of art as a language had better efficiency than a formal approach since the children and adolescents could have a learning space in a spontaneous way, demonstrating interest.

The relationship between neurocognitive functioning and metabolic syndrome (MetS) parameters and the interaction effect of cognitive insight in non-psychiatric individuals

S. Kilian*, L. Asmal, S. Suliman, S. Seedat, R. Emsley
Psychiatry, Stellenbosch University, Cape Town, South Africa

* Corresponding author.

Introduction Metabolic syndrome (MetS) parameters are: elevated waist circumference (WC), triglycerides (TG), fasting glucose (FBG) and blood pressure (BP) and reduced high-density lipoprotein cholesterol (HDL). MetS parameters are associated with poor cognition and this association should be studied in the context of other factors. In particular, factors that are involved in maintaining poor lifestyle choices – MetS is largely a lifestyle illness. One factor important to consider is cognitive insight – an individual's ability to be flexible in how you think about yourself and others and to question your own thoughts.

Objectives To conduct an exploratory cross-sectional study investigating the influence of cognitive insight on the relationship between MetS parameters and cognition in non-psychiatric individuals.

Aims To explore the nature of the relationship between cognition and MetS parameters and test whether cognitive insight moderates the association.

Methods Our sample consisted of *n* = 156 participants with mixed-ancestry. Correlations between MetS parameters and cognition were tested. ANOVA was used to test interaction effects and logistic regression was done to test the predictive power of selected factors.

Results BP correlated with attention, delayed memory, and RBANS total scale score. The BCIS self-certainty subscale moderated the relationship between BP and immediate memory and attention. Age and BCIS self-certainty were the only predictors of elevated BP.

Conclusions Good cognitive insight act as protective factor and reduce the impact of elevated BP on cognition. Cognitive insight may be a predictor of elevated BP.

* Corresponding author.

Introduction Fatigue is a common and debilitating problem in cancer survivors. Research show that this symptom endures even in disease-free patients affecting quality of life. Returning to work is physically and emotionally demanding for this population and fatigue levels seems to predict the time taken to return to work and the ability of the worker.

Objective Our main objective was to explore the direct effect of the fatigue on work ability and quality of life of professionally active cancer survivors. Aims Fatigue levels, work ability and overall quality of life of survivors group were compared with a sample of individuals without cancer history. Relationship between fatigue symptoms and work ability and quality of life were examined within of the survivors group.

Methods This cross-sectional study included 57 cancer survivors and 57 controls ($n = 114$) and data was collected from two Central Hospitals of Portugal. Participants completed the Functional Assessment of Chronic Illness Therapy-Fatigue, the Work Ability Index and the Functional Assessment of Cancer Therapy-General.

Results Cancer survivors reported higher levels of fatigue than controls and worse work ability and quality of life ($P < .001$). Controlling the effect of the age and gender, fatigue of the cancer survivors group influenced negatively their overall quality of life ($\beta = -.315$, $P = .013$, $R^2 = .143$) but not their work ability.

Conclusions Although the fatigue has not affected directly the work ability of the cancer survivors, two years or more after the conclusion of the treatments, this symptom has a significant effect on the quality of life.

Paediatric mental health training to school teachers in London, UK

K. Nijabat

Child and Adolescent Psychiatry, UCLH Partners, London, United Kingdom

Introduction The British National Foundation for Educational Research poll found that two thirds of school teachers feel they lack the appropriate training to help identify mental health issues in pupils.¹ I contacted 10 schools in London and teachers gave similar responses to the above poll, stating teachers did not feel confident identifying or managing common mental health issues in children and adolescents aged 5–18.

Aim To deliver mental health training in a user friendly way to teachers and enable them to identify common mental health issues in young people.

Objectives Address underlying concerns teachers have regarding pupils mental health. Discuss strategies to manage common mental health issues.

Method I delivered a 2-hour training workshop to 25 teachers in two different schools in London, June 2016. The training included a lecture on emotional/behavioural and communication disorders in children. There was interactive discussion with teachers, discussing various scenarios, such as children becoming tearful, showing limited eye contact and displaying aggressive behaviour. We discussed how teachers were dealing with this and how better they could manage the situation.

Results I got excellent feedback from teachers, 100% of teachers found the training very useful and would like to have more training of this kind in the future. A multidisciplinary approach is needed to improve the management of mental health in young people.

Conclusions There is a gap in the knowledge teachers have on mental health within the young people and the stigma of mental health makes it more difficult for teachers to address these issues.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Psychological characteristics of emotion control in physicians and teachers

E. Nikolaev

Department of Social and Clinical Psychology, Chuvash State University, Cheboksary, Russia

Introduction Emotional control can play positive role in professional growth. Are there any negative effects of emotional control on the professional activity of physicians and teachers?

Objectives and aims To reveal the specifics of emotional control in groups of physicians and teachers with different self-reported health levels.

Methods The study involved 160 physicians and 179 school teachers. Gender ratio and mean age in both groups were similar. The instruments used: SF-36 health survey and Ban on the emotional expression questionnaire.

Results In general, physicians, and teachers more often than control group controlled the expression of their emotions. Physicians in comparison with teachers were more likely to restrict both positive (joy) and negative emotions (sadness, anger). Teachers with a high level of health by SF-36 had a minimal ban on the expression of sadness ($P < 0.01$). The maximum level of the ban on the expression of anger ($P < 0.001$) and fear ($P < 0.05$) and an aggregated ban of emotional expression was revealed in teachers with average level of health by SF-36 ($P < 0.001$). Expression of joy in teachers was not directly related to the self-reported health level ($P > 0.05$). Physicians who showed the maximum ban on the emotion expressions reported only the low health level by SF-36 ($P < 0.05$). It was more related to the ban on joy, and less to the ban on anger.

Conclusions The revealed models of emotional expression control can strengthen both professional and everyday stresses in physicians and teachers. Different prevention programs are needed for these groups of professionals.

Improving recruitment in psychiatry: The impact of a psychiatry summer school on attitudes towards psychiatry in medical students and foundation doctors

C. O'Prey^{1,*}, D. Hyland², C. O'Flaherty³, G. Bramham³

¹ Crosby and Maghull Community Mental Health Team, Mersey Care NHS Trust, Liverpool, United Kingdom

² Mersey Care NHS Trust, Clock View Inpatient Unit, Liverpool, United Kingdom

³ Health and Sciences, University of Liverpool, Liverpool, United Kingdom

* Corresponding author.

Introduction In 2011, the Royal College of Psychiatrists in UK published a five-year plan to boost recruitment to a 95% fill rate for core training posts. Psychiatric summer schools were one of the methods outlined to improve recruitment. These are 3-day courses allowing attendees to explore different subspecialties and showcase inspiring psychiatrists who are leaders in their field.

Aims To evaluate whether attending a Psychiatry Summer School improves scores on the attitudes towards Psychiatry Scale (ATP-30) in Medical Students (MS) and Junior Doctors (JD).

Methods Two free courses were held; one for MS in August 2016 and one for JD in November 2015. These involved interactive talks from consultant psychiatrists in various sub-specialties and a day in a forensic setting. All attendees were asked to complete ATP-30 before and immediately after attendance. A higher ATP-30 score indicates a more positive the attitude the minimum score is 30 and the maximum is 50. Paired scores were analysed using a paired *t*-test.

Results Thirty-three out of 45 attendees completed ATP-30 MS ($n=20/24$) and JD ($n=13/21$) before and after the course. The mean ATP30 score was 116 before attendance and 128 after the course, the mean difference was +12. When the two samples were compared using a paired *t*-test, there was a significant positive difference $P<0.0005$.

Conclusions Psychiatry summer schools can improve attitudes towards psychiatry in medical students and junior doctors.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Difference in cognitive emotional regulation strategies used by mothers with conflict and barrier personal meaning of child's illness

E. Pervichko^{1,*}, D. Dovbysh²

¹ Faculty of Psychology, Lomonosov Moscow State University, Moscow, Russia

² Faculty of Higher Nursing Training, Psychology and Social Work, Department of Education and Medical Psychology, I. M. Sechenov First Moscow State Medical University, Moscow, Russia

* Corresponding author.

Introduction A number of studies have noted a high level of symptoms of depression and anxiety in mothers bringing up children with burn injury. The emergence of such symptoms show high importance of child's disease situation to mother and suggests the formation of a special personal meaning of child's illness for mother (conflict or barrier). The aim of this study is to describe specific patterns of mothers responding on the situation of the child burn injuries : special cognitive emotion regulation strategies and personal meaning of illness.

Methods Clinical interview to assess personal meaning of illness, State Trait Anxiety Inventor, Cognitive Emotion Regulation Questionnaire.

Participants Twenty-eight mothers (aged between 22 to 43 years), children received burn 5-7 days ago ; 2 mothers (aged between 24 to 37 years), children had burns over a year ago.

Results We found a strong correlation between using certain strategies of cognitive emotion regulation and different personal meaning of child's illness : mothers with a conflict meaning characterized by using of « Ruminantion » and « Self-Blame » strategies ; mothers with barrier meaning – « Refocus on planning ». This connection is maintained throughout the child's illness and does not depend on medical specialties. A number of strategies of cognitive emotion regulation are used by all mothers at different stages of the child's illness, regardless of the mother's personal meaning of illness : immediately after injury the most popular strategies are "Catastrophizing" and « Self-Blame » ; in the long-term rehabilitation – « Putting into perspective » is the most common one.

The role of cognitive insight in reduction of positive symptoms in youth with ultra-high risk for psychosis

E. Rasskazova^{1,*}, M. Omel'chenko², V. Kaleda²

¹ Clinical Psychology, Moscow State University, Mental Health Research Center, Moscow, Russia

² Department of endogeneous mental disorders and affective states, Mental Health Research Center, Moscow, Russia

* Corresponding author.

Introduction Cognitive insight was shown to be impaired in schizophrenia while its high level predicts improvement of psychotic symptoms. However, later studies demonstrated that in other mental disorders and healthy subjects cognitive insight might play ambiguous role being related to anxiety and lack of self-confidence.

Objectives Development of clinical criteria for high and ultra-high risk for psychosis allows to study the role of cognitive insight in these patients.

Aims The aim was to examine the role of cognitive insight in different clinical groups of youth with ultra-high risk for psychosis.

Methods Seventy-six male patients 16–25 years old with non-psychotic mental disorders (with preliminary diagnoses of mood disorders – 30, personality disorders – 25, schizotypal disorder – 21 patients) meeting criteria of ultra-high risk for psychosis and 55 healthy male controls filled Beck Cognitive Insight Scale, Symptom Checklist 90-R. The Scale of Prodromal Symptoms was used twice upon hospitalization and after 1-month period.

Results Moderation analysis reveals that in patients with preliminary diagnoses of mood disorders and schizotypal disorder cognitive insight is related to higher anxiety and obsessiveness and to poorer improvement on SOPS and positive symptoms. In patients with symptoms of personality disorders, it predicts better symptoms improvement.

Conclusions Results demonstrate importance of differentiation of the functions of cognitive insight in different patients with ultra-high risk for psychosis both in clinical psychological assessments and CBT.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW0226

True and variable response inconsistency as indicators of psychological distress in the normative sample and mental disorders

E. Rasskazova^{1,*}, A. Spivakovskaya², A. Tkhostov²¹ Clinical Psychology, Moscow State University, Mental Health Research Center, Moscow, Russia² Clinical Psychology, Moscow State University, Moscow, Russia

* Corresponding author.

Introduction Despite a long psychological discussion on the inconsistency and fragmentation in self-appraisals as factors of neuroses and personality disorders (Horney, 1991, Lynch, 2014) classical psychodiagnostic considers response inconsistency as an indicator of protocol invalidity only.

Objectives Using MMPI-2 True and Variable Response Inconsistency scales (TRIN, VRIN), we suggest that the inconsistency (within normative range) is related to poorer psychological well-being in the normative sample and is higher in affective disorders.

Aim To study the relationship between response inconsistency and psychological well-being.

Methods In total, 1443 healthy controls and 190 patients with mental illnesses (50 with affective disorders, 21 with addictions, 73 with schizophrenia and schizotypal disorder, 46 with adjustment disorder) who scored within normative range on all the validity scales of the Russian version of MMPI-2 participated in the study.

Results In the normative sample, TRIN and VRIN correlated with social and emotional alienation as well as conative lack of ego mastery ($r = .27-.33$) and were higher in affective disorders ($P < .05$) and in patients having symptoms of personality disorders (as appraised by their doctors). In patients with affective disorders and adjustment disorders, they were related to higher likelihood of invalidity due to mental illness.

Conclusions Response incoherence within normative range is a sign of poorer well-being in the normative sample (in the form of fatigue, apathy, feelings of excessive strain, lack of understanding from others and injustice). In line with psychological theories of self-fragmentation, incoherence is related to affective disorders (and poorer adjustment to them) and symptoms of personality disorders.

Illness representation as a factor of quality of life in youth with mental illnesses

E. Rasskazova^{1,*}, A. Spivakovskaya², A. Tkhostov²¹ Clinical Psychology, Moscow State University, Mental Health Research Center, Moscow, Russia² Clinical psychology, Moscow State University, Moscow, Russia

* Corresponding author.

Introduction Cognitive perspective considers beliefs as key factors of compliance and adjustment in mental disorders (Beck, 2011) that are especially important in youth. In psychosis illness, representation is related to CBT efficacy.

Objectives We suggest that in different mental disorders different illness-related beliefs are important for quality of life domains.

Aim To reveal relationships between illness representation and quality of life in mental disorders controlling for psychopathological symptoms.

Methods One hundred and eighteen male patients 17 – 27 years old : 33 with mood disorders, 26 with personality disorders, 27 with

schizotypal disorder and 32 with schizophrenia recovering after first episode of psychosis filled Illness Perception Questionnaire, Symptom Checklist 90-R, Quality of Life and Enjoyment Questionnaire (version for mental illnesses).

Results After statistical control for psychopathological symptoms, in personality disorders feeling of personal and treatment control ($\beta = .43-.52$, $P < .01$) as well as belief in longer ($\beta = .42$, $P < .05$) but not cyclic ($\beta = -.65$, $P < .05$) illness duration predicted satisfaction with health while belief in longer duration and less consequences correlated with better satisfaction with leisure time ($\beta = .87$, $P < .01$). In mood disorders, feeling of treatment control ($\beta = .32$, $P < .05$) and belief in shorter illness duration ($\beta = -.37$, $P < .05$) were related to better satisfaction in emotional sphere.

Conclusions Beliefs about illness duration, consequences and control could be important in assessment and CBT for youth with personality disorders while treatment control and illness duration are important in work with youth with mood disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Attitudes towards help seeking behaviour and professional psychiatric help in Slovenia

S. Roškar^{1,*}, M. Bračič¹, U. Kolar¹, N. Konec Juričič¹, K. Lekić¹, T.G. Alenka¹, B. Dobnik², V. Poštuvan³, M. Vatovec⁴¹ NIJZ, National Institute of Public Health, Department of Health promotion and disease prevention, Ljubljana, Slovenia² National Association for Quality of Life, OZARA, Department for Intervention Programs, Ljubljana, Slovenia³ Institute Andrej Marušič, Slovene Centre for Suicide Research, Koper, Slovenia⁴ Slovene Association for Suicide Prevention, Posvet counselling Centre, Ljubljana, Slovenia

* Corresponding author.

Introduction Knowledge about signs and treatment of mental illnesses is often not enough to seek professional help. Hence, it is important to gain understanding of other determinants, i.e. attitudes, stigma, which influence help-seeking behaviour.

Objectives Based on Ajzen's theory of planned behaviour, we aimed at collecting data of determinants known to be related to behavioural action, in our case help seeking.

Aims To examine how attitudes, stigma and normative beliefs influence help seeking behaviour and whether these determinants differ in relation to demographic data and mental health indicators of the respondents' region.

Methods A representative sample of adult Slovene population ($n = 594$) was recruited via an on-line invitation. They were asked to (i) provide basic demographic data (region, age, gender, mental health history. . .) and (ii) to complete the inventory of attitudes toward seeking mental health services. The inventory variables (attitudes, knowledge and stigma) were linked to demographic data and mental health indicators in Slovenia.

Results The respondents dispose of good knowledge of where and when to seek help either for themselves or others. However, the readiness to seek help was significantly lower, in particular so in men, younger, single persons and respondents from regions with lower mental health indicators. Accordingly, stigma was significantly higher pronounced in the same groups. More than 50% of respondents have already experienced mental distress, however only 25% have sought help.

Conclusions Reasons for this "help seeking gap" should be further scrutinized. Future interventions shall be focused on changing attitudes and destigmatization mental health issues.

“To live”: An experimental brief therapy for patients who attempt suicide

D. Silva^{1,*}, A. Coutinho², A. Marques³, R. Silva¹

¹ Centro Hospitalar Vila Nova de Gaia, Serviço de Psiquiatria e Saúde Mental, Vila Nova de Gaia, Portugal

² Centro Hospitalar Vila Nova de Gaia, Serviço de Psiquiatria e Saúde Mental, Vila Nova de Gaia, Portugal

³ Centro Hospitalar Vila Nova de Gaia, Psiquiatria e Saude Menatl, Vila Nova de Gaia, Portugal

* Corresponding author.

Background/introduction It is widely known that attempted suicide is the main risk factor for suicide and repeated suicide attempts. However, there is a lack of evidence for follow-up interventions/treatments reducing suicidal behavior in this population. The aim of the present study was to describe a novel-therapy as a potential treatment with effectiveness in reducing suicidal behavior. One of the main objectives of this project is to potentiate the benefits of the usual treatment in patients with history of suicidal attempt.

Description and method “To live” is a proposal of short psychotherapeutic intervention program for patients with recent suicide attempts. The participants were randomly allocated in two groups, one worked as our control group ($n=8$), which had the usual treatment (individual outpatient care), and the other group ($n=8$) underwent the usual treatment plus the experimental treatment. This treatment consists of a well structured program, in which participants receive eight group sessions followed by regular contact through telephonic calls over 12 months. In order to evaluate its impact and measure results, a set of structured interviews and clinical questionnaires have been applied in different times: time zero (before admission), time one (in the end of the intervention), time 2 (1 month after intervention), then at each every 3 months over a 12 month follow up period.

Results/conclusion By the time this study was conducted, the experimental program was being administered, therefore no results could be taken. However, preliminary findings suggest the effectiveness of the program in reducing suicidal behavior in a real-world clinical setting.

⁴ Frederick University of Nicosia, Doctoral Program Health Management, University of Patras, Department of Public Health, Medical School, Patra, Greece

* Corresponding author.

Introduction The term emotional intelligence (EI) has gained more and more popularity in the last two decades and has been studied in various workplace settings.

Objectives/aims The purpose of the present study was to estimate the EI in nursing personnel, to examine which factors are associated with EI and how EI correlates with their emotional state.

Methods A cross-sectional study was conducted from April to May 2016 in a representative sample of nursing personnel from seven public hospitals of Cyprus. A total of 585 nurses completed the Greek Emotional Intelligence Scale (GEIS), consisting of 52 items measuring four basic emotional skills and scored on a 5-point Likert scale (from low (52) to high (260) EI). Furthermore, the Depression, Anxiety, and Stress Scale (DASS 21) was applied. Statistical analyses were performed using the SPSS v.20.0.

Results Overall mean EI scores were 184.11 for males and 184.82 for females. Being married and having children as well as having leading position was associated with higher EI ($P=0.024$, $P=0.002$, $P=0.012$, respectively). The highest EI scores were identified between the middle aged nurses (36–50 years, $EI=191.5$, $P=0.000$) and nurses with more years of work (>12 years, $EI=189.59$, $P=0.000$). The overall EI scores have moderate negative correlation with the emotional state of the nurses ($P=0.000$).

Conclusions The present study reveals under-optimal EI scores and confirms the negative relationship with the emotional state of nurses. Based on the literature, the EI can be developed, thus suitable programs could substantially improve the emotional skills in nursing personnel.

Help-seeking and psychological distress in university students: Findings from a cross-sectional online survey in the UK

R. Wadman¹, L.A.D. Webster^{2,*}, H. Stain²

¹ Durham University, School of Medicine, Pharmacy & Health, Durham, United Kingdom

² Leeds Trinity University, Psychology, Leeds, United Kingdom

* Corresponding author.

Introduction With most mental health disorders emerging in the later teenage years, university students are arguably an at-risk population with increased mental health support needs. This population is characterised by important, life-changing transitions (moving away from home, friends and family) and new potential stressors (including increased academic pressures and relational challenges). Research to examine determinants of mental health help-seeking behaviours in university students is needed to ensure emotional health needs are being met at this critical time.

Objectives To examine levels of psychological distress and mental health help-seeking behaviours in a sample of UK university students. By identifying factors associated with help seeking, we can better understand the mental health needs of this population and inform support provision.

Methods This study draws on data from the social and emotional well-being in university students (SoWise) study, an online survey which aimed to examine risk and resilience for social and emotional well-being in young people attending a UK university.

Results Whole sample analysis ($n=461$) showed help seeking was significantly associated with psychological distress, current life stressors and anxious attachment and not associated with perceived mental health stigma. Sub-group analysis ($n=171$) suggests being female and older significantly predicted help seeking in students with mild/moderate psychological distress.

Conclusions Younger males with mild/moderate psychological distress are less likely to seek mental health support and repre-

sent an “invisible” at risk group. Results also suggest that global anti-stigma campaigns in universities may not prove effective in encouraging help seeking.

Formal thought disorder in schizophrenia and bipolar disorder: A systematic review and meta-analysis

K. Alptekin^{1,*}, B. Yalincetin², E. Bora¹, A. Berna¹

¹ Dokuz Eylul University, Psychiatry, Izmir, Turkey

² Medical Sciences, Neuropsychiatry, Izmir, Turkey

* Corresponding author.

Historically, formal thought disorder has been considered as one of the distinctive symptoms of schizophrenia. However, research in last few decades suggested that there is a considerable clinical and neurobiological overlap between schizophrenia and bipolar disorder (BP). We conducted a meta-analysis of studies comparing positive (PTD) and negative formal thought disorder (NTD) in schizophrenia and BP. We included 19 studies comparing 715 schizophrenia and 474 BP patients. In the acute inpatient samples, there was no significant difference in the severity of PTD ($d = -0.07$, $CI = -0.22-0.09$) between schizophrenia and BP. In stable patients, schizophrenia was associated with increased PTD compared to BP ($d = 1.02$, $CI = 0.35-1.70$). NTD was significantly more severe ($d = 0.80$, $CI = 0.52-0.1.08$) in schizophrenia compared to BP. Our findings suggest that PTD is a shared feature of both schizophrenia and BP but persistent PTD or NTD can distinguish subgroups of schizophrenia from BP and schizophrenia patients with better clinical outcomes.

The split version of Global Assessment of Functioning scale – application and utility in remitted psychotic patients

S. Andric^{1,*}, M. Mihaljevic², T. Mirjanic³, N. Maric⁴

¹ University of Belgrade, Faculty of Medicine, Dpt. for Research and Early Interventions in Psychiatry, Belgrade, Serbia

² Clinic for Psychiatry, Clinical Centre of Serbia, Research and Early Interventions in Psychiatry, Belgrade, Serbia

³ Special hospital for Psychiatric disorders Kovin, Psychosis, Kovin, Serbia

⁴ Clinic for Psychiatry Clinical Center of Serbia, Research and Early Interventions in Psychiatry, Belgrade, Serbia

* Corresponding author.

Introduction Current knowledge about the advantages of using split version of GAF scale – having separate Symptom (GAF-S) and Functioning (GAF-F) subscales is insufficient and has number of gaps. Present study analyzed the manner in which young adult remitted psychotic patients with different functional levels vary in their symptom severity and how GAF-F reflects presence/absence of well-known psychosis risk factors.

Methods Sample comprised 37 remitted psychotic patients (56.8% male, 29.4 ± 6.1 years), categorized based on GAF-F scores into groups: ‘Moderate remission’ (GAF-F 41–60, $n = 19$) and ‘Good remission’ (GAF-F > 61, $n = 18$). Participants were assessed using the GAF-S, WAIS-R, Nottingham Onset Schedule, Premorbid Adjustment and Brief Core Schema scales, childhood trauma and bullying questionnaires. Mann–Whitney and Student’s *t*-tests were used to assess between-group differences.

Results Groups did not differ in age, sex and education. When compared to ‘Good remission’ group, ‘Moderate remission’ group exhibited earlier illness’ onset ($P = 0.01$), greater symptom severity ($P = 0.00$), negative self-evaluation ($P = 0.02$), more childhood physical abuse ($P = 0.01$) and bullying ($P = 0.01$). Moreover, trend-like significances ($P = 0.08$) were observed for poorer adolescence adjustment and negative evaluation of others. There were no between-group differences regarding IQ and duration of untreated/treated illness.

Conclusions GAF scale is in the continual use since early 1990, however, evidence of further development of the instrument itself is sparse. Present research is demonstrating that GAF-F scores reflect diverse factors related to psychosis risk, the illness’ course and quality of remission. Moreover, the results contribute to surmount some of the gaps in knowledge about the split version of GAF scale.

Disclosure of interest The authors have not supplied their declaration of competing interest.

C-reactive protein and parathyroid hormone in acute severe psychotic disorders (schizophrenia, bipolar disorder and methamphetamine-induced psychotic disorder)

S. Arya^{1,*}, H. Ahmadkhaniha¹, K. Alavi¹, B. Arya², Z. Zarei¹

¹ Iran University of Medical Sciences, Mental Health Research Center, Tehran, Iran

² Golestan University of Medical Sciences, Department of General Surgery, Gorgan, Iran

* Corresponding author.

Introduction and objectives Schizophrenia accompanies with elevated C-reactive protein (CRP) and vitamin D deficiency. However, there are scarce documentations regarding bipolar disorder and methamphetamine-induced psychotic disorder.

Aim To compare serum levels of vitamin D, parathyroid hormone (PTH), calcium, phosphorus and CRP levels in psychotic disorder patients and control group.

Methods A case-control study was conducted on four groups: acute phase of schizophrenia, acute manic episode of bipolar disorder, methamphetamine-induced psychotic disorder and healthy control subjects. Sample size was 45 in each group. Weekly duration of sun exposure, monthly vitamin D intake and serum levels of vitamin D, calcium, phosphorus, PTH and CRP were assessed. Brief Psychiatric Rating Scale (BPRS) was used to evaluate psychotic symptoms.

Results Duration of sun exposure and monthly vitamin D intake were comparable among groups. Serum levels of vitamin D, calcium and phosphorus were not statistically different between groups ($P = 0.463$, $P = 0.086$ and $P = 0.339$, respectively). Serum levels of PTH were significantly higher in control group ($P < 0.001$). CRP levels were significantly lower in control subjects ($P < 0.001$). The levels of serum vitamin D and CRP did not show statistically significant difference among three groups of patients.

Conclusion Acute psychotic disorders seem to be associated with higher CRP and lower PTH levels. Clinical importance of the findings

and relation of these differences to the metabolic and inflammatory bases of psychosis are not clear yet.

³ Specialized Early Psychosis Outpatient Service for Adolescents and Young Adults, Department of Psychiatry, Bruderholz, Switzerland

⁴ University of Basel Psychiatric Hospital, Department of Psychiatry, Basel, Switzerland

* Corresponding author.

Introduction In the growing research field of early psychosis detection in patients with an at risk mental state (ARMS), most studies focus on the transition to frank psychosis. However, the majority of ARMS patients do not go on to develop frank psychosis and reported transition rates are declining. Little is known about the long-term outcome of these non-transitioned patients (ARMS-NT).

Objectives To investigate in preliminary analyses the long-term outcome of ARMS-NT patients with respect to persistence of ARMS signs and symptoms and the rates of late psychotic transition.

Methods The ongoing study “FePsy-BHS-NT” follows up ARMS-NT without transition during at least the first two years for up to 15 years after their initial assessment. ARMS status is ascertained with the Basel Screening Instrument for Psychosis (BSIP). ARMS remission is defined as the absence of attenuated psychotic symptoms or brief limited intermittent psychotic symptoms for at least 12 consecutive months.

Results In this preliminary sample of 51 ARMS-NT, the majority of patients (70.6%) have remitted from their at risk mental state, 13.7% remain at risk and 15.7% have made a late psychotic transition during the course of long-term follow up (median = 5.75, range 4–11 years after initial assessment).

Conclusions The considerable rates of ARMS persistence and late psychotic transition indicate that longer follow-up durations than commonly recommended should be contemplated in ARMS patients. Potential predictors of favorable long-term clinical outcome, as well as psychosocial, neurocognitive and other outcomes of ARMS-NT patients will be further evaluated in the present study.

Acute psychotic disorders: Factors related to schizophrenia evolution

R. Ben Soussia*, A. Bouallagui, I. Marrag, S. Khoudja, S. Younes, M. Nasr

CHU Tahar Sfar, Psychiatry, Mahdia, Tunisia

* Corresponding author.

Introduction Acute psychotic disorders are described as a clinical syndrome characterized by Acuteness of the installation, the intensity and the polymorphism of delirium.

Aim Describe the demographic characteristics of a population of patients with an acute psychotic disorder and identify factors correlated with evolution to schizophrenia.

Methods This is a retrospective, descriptive and analytic study conducted on hospitalized patients in psychiatric department EPS Mahdia for acute psychotic disorder according to DSM-VI-TR criteria. A study of the recurrence time was performed by Kaplan–Meier and Cox test was used to identify factors correlated with evolution to schizophrenia.

Results One hundred and eleven patients were collected. The average age of the study population was 27 years, a male predominance was noted (59.5%), 39.6% of patients had family history of psychiatric disorders, including schizophrenic disorders and bipolar disorder were the most common with rates of 63.6 and 18.4% of cases. For our patients, 38.7% progressed to schizophrenia. Four risk factors were significantly predictive of progression to schizophrenia: male gender ($P=0.026$), subacute or progressive onset disorders ($P=0.003$), partial remission of the disorder ($P=0.023$) and the prolonged duration of untreated psychosis ($P=0.027$).

Conclusion The evolution of an acute psychotic disorder remains unpredictable. In fact, the severity is related to the risk of developing schizophrenia or mood disorder. Attention is paid in recent years to recognize and seek most precociously as possible factors associated with this evolution.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Acute psychotic disorder: Which future?

R. Ben Soussia*, A. Bouallagui, S. Younes, I. Marrag, M. Nasr
CHU Tahar Sfar, Psychiatry, Mahdia, Tunisia

* Corresponding author.

Introduction At present, in absence of reliable clinical and evolutionary data, it is difficult to determine what the consequences of an acute psychotic disorder, specifically if it is a mode of entry into schizophrenia, a mood disorder or a short-lived episode.

Aim The objective of this study was to describe the sociodemographic characteristics and evolutionary modalities of a population of patients with a first psychotic episode.

Methods This is a retrospective descriptive study, which involved patients admitted to psychiatric ward EPS Mahdia for acute psychotic disorder according to DSM-VI-TR criteria. Data collection was conducted from archived observations and through a pre-determined sheet.

Results One hundred and eleven patients were collected. The average age of the study population was 27 years, a male predominance was noted (59.5%), 52.3% were from urban, 73% of patients were single, 33.3% were from a consanguineous marriage. Among those patients with a first acute psychotic episode, 43 patients (38.7%) progressed to schizophrenia, 15.3% to bipolar disorder, 23, 4% to recovery while 22.5% were lost view.

Conclusion The long-term evolution of an acute psychotic disorder remains unpredictable. In fact, the severity is related primarily to the risk of developing a schizophrenic disorder or a mood disorder. In this context, attention is paid in recent years to recognize and seek the earliest possible factors associated with this development.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Elevated sera levels of galectin-3 in stable schizophrenia

M. Borovcanin^{1,*}, I. Jovanovic², S. Minic Janicijevic³, N. Gajovic², N. Arsenijevic², M. Lukic L.²

¹ Faculty of Medical Sciences, University of Kragujevac, Department of Psychiatry, Kragujevac, Serbia

² Faculty of Medical Sciences, University of Kragujevac, Center for Molecular Medicine and Stem Cell Research, Kragujevac, Serbia

³ Clinical Centre Kragujevac, Psychiatric Clinic, Kragujevac, Serbia

* Corresponding author.

Introduction Galectin-3 (Gal-3) is a unique member of the lectin family involved in cell proliferation, adhesion, apoptosis and immune responses. Deletion of the *Gal-3* gene reduces experimental autoimmune encephalomyelitis and variation of gene encoding for Gal-3 already showed to be related with cognitive function. Also, elevated Gal-3 sera levels were measured in patients with Alzheimer's disease.

Aims and objectives We measured the serum concentrations of Gal-3 in patients with schizophrenia in remission and try to determine possible correlation of Gal-3 sera levels with clinical parameters, especially cognitive aspects.

Methods In this pilot study were included patients with schizophrenia in remission on three months stable depot antipsychotic medication (risperidone and paliperidone) ($n=27$) and healthy controls ($n=18$). Serum levels of Gal-3 were measured using sensitive enzyme-linked immunosorbent assay (ELISA) kits, specific for humans (R&D Systems, Minneapolis). Cognition was evaluated using the Positive and Negative Syndrome Scale (PANSS) cognitive factors.

Results Higher mean values of Gal-3 were measured in patients with schizophrenia in remission compared with healthy volunteers (1389.69 vs. 994.23 pg/mL; $P=0.011$), but correlation with PANSS cognitive factor was not established ($P=0.748$).

Conclusions These findings suggest that the role of Gal-3 should be explored further, in different stages of disorder and depending on applied therapy, but also considering specific cytokine milieu.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁶ University Psychiatric Hospital Vrapce, Forensics Department, Zagreb, Croatia

* Corresponding author.

Introduction Neurocognitive impairment in schizophrenia is associated with functional disability and poorer quality of life, and is the most resistant of all schizophrenia symptoms to current psychopharmacotherapy.

Objectives To compare the differences in neurocognitive status during the acute phase of first psychotic episode and stable symptomatic remission.

Aims To investigate the pattern of neurocognitive impairment in patients with first episode psychosis during acute phase and stable remission phase.

Methods We performed a longitudinal study, including 150 patients with first episode of psychosis at two time points: during their hospitalization at Zagreb university hospital centre or university psychiatric hospital Vrapče, at acute phase of illness and after 12–18 months, during stable remission. Assessment included detailed clinical interview, clinical rating of neuropsychiatric symptoms using standardized psychiatric scales, self-assessment scales and comprehensive neurocognitive testing.

Results While our preliminary results ($n=40$) showed statistically significant improvement in various neurocognitive domains, including visuo-learning abilities, verbal learning, executive functions, attention and processing speed, initial impairment in semantic and phonetic fluency observed in acute psychosis remained unchanged in remission as well.

Conclusions Although our results showed improvement in most of cognitive domains during time, language abilities remained unchanged. This further confirms the hypothesis that language impairment is a trait marker of psychotic disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ University of Medicine, Psychiatry, Targu-Mures, Romania

⁴ Clinical Hospital, Psychiatry, Timisoara, Romania

* Corresponding author.

Introduction Current research shows that subjects with disorders belonging to the schizophrenia spectrum have a poor social functioning. There are several factors that can influence social functioning, social cognition being one of them.

Objectives Assessing the ability to identify emotions and its role in the social functioning of subjects with a schizophrenia spectrum diagnosis.

Purpose Increasing the social functioning of subjects with a schizophrenia spectrum diagnosis.

Method We evaluated 31 subjects who were at their first admission to the Timisoara psychiatric clinic and who met the diagnostic criteria for a schizophrenia spectrum disorder (a diagnosis of F20, F22 or F25 according to ICD 10). The following parameters were monitored: sociodemographic (gender, age of onset, educational level, marital and professional status), theory of mind (Reading the Mind in the Eyes Test) and social functioning (GAF Scale). The subjects were evaluated during periods of remission. The acquired data was statistically processed.

Results The results of the sociodemographic parameters analysis were similar to those in international literature. Most subjects showed a lack of theory of mind (a mean score of 18, standard deviation 5.84). All subjects experienced a decrease in social functioning (a mean score of 64.7 on the GAF Scale). There is a direct correlation between the ability to identify emotions and social functioning (Spearman $R=0.386$, $P<0.05$).

Conclusions A decreased ability to identify emotions is directly correlated with decreased social functioning in subjects with schizophrenia spectrum disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Long acting antipsychotics treatment of schizophrenia: A 24-month prospective study on patient's attitude towards treatment

E. Calderani*, F. Pietrini, I. Burian, F. Chiarello, D. Dahlke, S. Gemignani, P. Marino, G.A. Talamba, L. Poli, A. Santangelo, V. Ricca, A. Ballerini

University of Florence, Neuro. Far. Ba, University of Florence, Florence, Italy

* Corresponding author.

Introduction Long-acting injectable (LAI) second-generation antipsychotics (SGAs) are considered an alternative to oral antipsychotics for schizophrenic patients with low adherence to therapy. However, it is still a matter of debate whether LAI-SGAs are able to significantly improve patient's attitudes towards treatment (ATT) [1].

Objective To investigate the impact of LAI on ATT over 24 months.

Methods Nineteen schizophrenic patients were switched from either oral olanzapine (11) or paliperidone (8) to the corresponding LAI. Patients were assessed at baseline (T0), after 6 (T1), 12 (T2) and 24 months (T3). Drug Attitude Inventory-10 (DAI-10) [2] was used to assess ATT. Young Mania Rating Scale (YMRS), Montgomery-Asberg Depression Rating Scale (MADRS), Positive and Negative Syndrome Scale (PANSS), and Short Form Health Survey (SF-36) were used for psychopathology evaluations.

Results Eleven patients reached T3. Eight patients were excluded (4 olanzapine, 4 paliperidone): 4 required a significant change in concomitant treatment, 4 a change of antipsychotic (metabolic comorbidity). No changes in psychopathology occurred between T2 and T3, some scales improved from baseline to T2. DAI-10 mean scores were improved after 12 months, thus not significantly, and were further improved at 24 months ($P = .008$ vs baseline).

Conclusions ATT keeps improving after one year of LAI treatment, unrelated to clinical response.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Relationship between cognition and primary negative symptoms sub-domains in schizophrenia

O.O. Capatina^{1,*}, I.V. miclutia¹, A. toma²

¹ University of Medicine and Pharmacy Iuliu Hatieganu, Psychiatry, Cluj-Napoca, Romania

² Psychiatry City Hospital Tarnaveni, Psychiatry, Tarnaveni, Romania

* Corresponding author.

Introduction The relationship between negative symptoms and cognition in schizophrenia is not clear, a number of authors whom

studied this relationship came up with inconsistent findings and meta-analyses show that there is a small moderate associations between the two domains.

Objectives and aims The aim of this study was to investigate the relationship between cognition and the primary negative symptoms sub-domains.

Methods Sixty-seven female patients with schizophrenia were evaluated using PANSS and NSA-16 scales. Correlation and regression analyses were used in the present study to investigate the relationship between the primary negative symptoms sub-domains obtained by using the principal component analysis, and cognition evaluated with the PANSS using the 5 factor model as described by Lindenmayer.

Results No relationship was found between the PANSS Cognitive factor and Negative factor, but when investigating the relationship of the Cognitive PANSS factor with the negative sub-domains: diminished expression (DE) and avolition-apathy (AA), it was shown that there is a significant association between cognition and AA domain, but there was shown no association with the DE domain, and there was just a small association with the composite score of the NAS-16.

Conclusions Our study reveals the relative independence of cognitive factor from the negative domain of the psychopathology, even though the association with AA domain was clear. These findings also support the need of using appropriate assessment tools in order to get a refined understanding of the phenomenology of schizophrenia.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ Faculty of Medicine, University of Coimbra, Psychological Medicine Department, Coimbra, Portugal

* Corresponding author.

Background Suicide risk is an important variable to consider both in assessment and throughout the therapeutic process in psychotic disorders. The SRS-P is an 18-item scale computed from the patient and clinician-rated scores obtained in the CIPD. The scale comprises lifetime assessment of depressed mood, anhedonia and its current interference and severity, current and past feelings of hopelessness, suicidal ideation, 'voices' about suicide, and suicide-related behaviors.

Aims To assess reliability and convergent validity of the SRS-P in a sample of participants with psychosis.

Methods The sample comprised 22 participants (68.2% male), single (72.7%), between 19 and 47 years old ($M = 31.05$; $SD = 7.088$), with 4–17 years of education ($M = 11.77$; $SD = 3.176$), employed (50%). The most prevalent diagnosis was schizophrenia (68.2%) and the participants had a mean of 1.90 hospitalizations ($SD = 2.548$). The mean age of illness onset was 23.57 years ($SD = 5.555$). The participants were assessed with the CIPD, Depression, Anxiety and Stress Scales-21, Forms of Self-Criticism and Reassurance Scale, Self-Compassion Scale, Other as Shamer Scale and the Empowerment with Psychotic Symptoms Scales.

Results The SRS-P has shown good reliability ($\alpha = .87$) and validity in relation to depressive symptoms ($r = .67$; $P = .001$), anxiety ($r = .74$; $P < .001$), stress ($r = .59$; $P = .004$), inadequate self ($r = .43$; $P = .046$), hated self ($r = .54$; $P = .009$), reassured self ($r = -.65$; $P = .001$), self-compassion ($r = -.63$; $P = .002$), shame ($r = .46$; $P = .033$) and empowerment regarding positive symptoms ($r = -.54$; $P = .015$).

Conclusions The SRS-P presented adequate reliability and convergent-divergent validity. Further studies are planned in order to test the factorial structure of the scale and confirm the presented results in a larger sample.

Internal and external responsiveness of the personal and social performance scale in patients with schizophrenia

E.C. Chiu^{1,*}, C.L. Hsieh²

¹ National Taipei University of Nursing and Health Sciences, Department of Long-Term Care, Taipei city, Taiwan, ROC

² National Taiwan University, School of Occupational Therapy, Taipei city, Taiwan, ROC

* Corresponding author.

Introduction The Personal and Social Performance scale (PSP) is widely used to assess social functioning with 4-domain scores and a global score in patients with schizophrenia. However, internal and external responsiveness of the PSP is largely unknown limiting its use as an outcome measure.

Objectives The purpose of this study was to examine internal and external responsiveness of the PSP in inpatients with schizophrenia receiving treatments in the acute phase.

Methods Eighty patients were conducted the PSP and the Clinical Global Impression-Severity (CGI-S) at admission and at discharge. The standardized effect size (ES), the standardized response mean (SRM), and paired *t*-test were used for examining internal responsiveness. We estimated correlations between the changes in scores of the PSP and those of the CGI-S using Pearson's *r* for investigated external responsiveness.

Results For internal responsiveness, the ESs and the SRMs of the domains were 0.74–1.74 and 0.68–1.72, respectively. The values of the ES and the SRM in the global score were 1.72 and 1.74, respectively. The paired *t*-tests showed statistically significant difference ($P < 0.001$) for the score changes of the four domains and the global score. Regarding external responsiveness, fair and moderate to good correlations ($r = 0.35$ – 0.74) were found among the changes in the 4-domain scores and the global score with the those of the CGI-S.

Conclusions The PSP has sufficient internal responsiveness and substantial external responsiveness in inpatients with schizophrenia receiving treatments at the acute wards. The PSP is useful as an outcome measure for detecting changes of social functioning over time.

Cognitive outcomes of Bergamot Polyphenolic Fraction (BPF) supplementation in schizophrenia: Preliminary data

M. Crucitti*, A. Bruno, G. Pandolfo, G.M. Troili, R.A. Zoccali, M.R.A. Muscatello
University of Messina, Department of Biomedical and Dental Sciences and Morphofunctional Imaging, Messina, Italy

* Corresponding author.

Background Cognitive deficits in schizophrenia significantly affect illness and community outcomes, and quality of life. Several studies support the neuroprotective properties of polyphenolic compounds resulting in neuronal protection, suppression of neuroinflammation and the potential to promote memory, learning and cognitive functions. Bergamot differs from other citrus fruits for flavonoids and flavonoid glycosides composition (neohesperidin, neohesperidin, naringin, rutin, neodesmina, roifolina and poncirina), and for their high amount. For these features, BPF may represent a potential supplement for improving cognitive functions.

Aims The present study was aimed to explore the efficacy of BPF supplementation on clinical symptoms and cognitive functioning in a sample of schizophrenic subjects receiving atypical antipsychotics (APs).

Methods Ten schizophrenic outpatients treated with atypical APs assumed BPF at the oral daily dose of 1000 mg/day for 30 days. Brief Psychiatric Rating Scale, Wisconsin Card Sorting Test, Verbal Fluency Task-Controlled Oral Word Association Test, and Stroop Color-Word Test were administered.

Results The results obtained indicate that BPF administration substantially improved WCST performances (perseverative responses, $P = 0.008$; perseverative errors, $P = 0.012$; total errors, $P = 0.011$; categories, $P = 0.023$). Moreover, a trend for others clinical (BPRS) and cognitive variables (Verbal Fluency Task-Controlled Oral Word Association Test, and Stroop Color-Word Test) decrease was observed.

Conclusions The findings provide evidence that BPF administration may be proposed as an effective therapeutic strategy to improve cognitive outcome in schizophrenia. Further clinical trials with adequately powered and well-designed methodology are needed to better explore the BPF effectiveness on cognitive impairments in schizophrenic patients.

Neuropsychological profile of patients in the first episode of psychosis

V.P. Bozikas*, A. Dardagani, P. Athanasis, I. Gliatas, E. Ntoulos, E. Parlapani

Aristotle University of Thessaloniki, 1st Psychiatric Clinic- GH Papegeorgiou, Thessaloniki, Greece

* Corresponding author.

Neurocognitive dysfunction in patients presenting psychotic symptoms for the first time has been repeatedly noted by researchers. However, there is still much diversity in data concerning the performance of these patients in specific cognitive domains and their degree of impairment. We used the Cambridge Neuropsychological Test Automated Battery (CANTAB), in order to administer a comprehensive battery of neuropsychological tests. A series of tests was selected measuring attention, memory, planning, inhibition, shifting ability, mental flexibility, working memory and visuospatial ability. The sample comprised 64 patients (37 male) with first episode of psychosis and 14 healthy individuals (9 male). Patients' performance was lower in all cognitive domains, in relation to the performance of controls. More specifically, impairments in sustained attention ($-.6$ SD), memory ($-.7$ SD), planning ($-.6$ SD), working memory ($-.7$ SD), shifting ability ($-.6$ SD) and visuospatial ability ($-.6$ SD) were prominent. Also, patients presented a severe deficit in speed of processing ($-.7$ SD) and selective attention ($-.6$

SD). Our data confirms that patients in the first episode of psychosis present deficits in all cognitive domains. A more rigorous and thorough examination of specific subcomponents of cognitive abilities may be necessary in order to examine possible contributing factors as to specify the exact nature of cognitive deficits in first episode of psychosis.

A longitudinal evaluation of cognitive deficits in patients with first episode of psychosis

A. Dardagani*, P. Athanasis, A. Lagoudis, A. Ramnalis, E. Ntouros, V. Bozikas

Aristotle University of Thessaloniki, 1st Psychiatric Clinic–GH Papageorgiou, Thessaloniki, Greece

* Corresponding author.

It has been well documented in many studies till now that patients in their first episode of psychosis demonstrate cognitive deficits. However, it is yet to be made clear how these deficits progress. Deterioration, stability or even amelioration in some domains has been noted from researchers. The aim of this study was to examine the longitudinal course of cognitive deficits over time. We administered a comprehensive battery of neuropsychological test to a group of first psychotic episode patients at the acute phase, 6 months and 1 year later. The sample comprised of 25 patients (13 male) in the first episode of psychosis. Specific tests of the Cambridge Neuropsychological Test Automated Battery (CANTAB) were used. The cognitive domains of attention, memory, working memory, visuospatial ability and planning, mental flexibility/shifting were examined. Repeated measures ANOVA was used in order to detect changes in the patients' performance over time. According to our data, there was an improvement from baseline to 6 months in attention, planning and visual working memory. There was no change in performance in these cognitive domains from 6 months to 1 year from baseline. Memory, mental flexibility/shifting and visuospatial memory remained stable over time. Our data suggest variability concerning neuropsychological performance in specific tests examining different domains. Evaluation of cognitive function in the first episode of psychosis needs more thorough and comprehensive research, in relation to its course over time.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW0248

The relationship of emotion recognition with neuropsychological performance in patients with first episode psychosis

A. Dardagani*, E. Dandi, S. Tsotsi, M. Nazou, A. Lagoudis, V.P. Bozikas

Aristotle University of Thessaloniki, 1st Psychiatric Clinic, GH Papageorgiou, Thessaloniki, Greece

* Corresponding author.

The relationship between neuropsychological dysfunction and emotion perception has been frequently noted in various studies. Attention, for example, has been found to play an important role in emotion processing and recognition. Not many studies though, have examined this relationship in first psychotic episode patients. The aim of the present study was to explore the nature of the relation between performance in cognitive tests and a test that

measures emotion perception. In a sample of 46 first psychotic episode patients (22 male), we administered a comprehensive battery of neuropsychological non-verbal tests and an emotion recognition test. The cognitive domains of attention, memory, working memory, visuospatial ability and executive function were examined, by using specific tests of the Cambridge Neuropsychological Test Automated Battery (CANTAB). The emotion recognition assessment comprised a new test that includes 35 coloured pictures of individuals expressing six basic emotions (happiness, sadness, anger, disgust, surprise, fear) and a neutral emotion. We used partial correlation–controlling for the effect of age–and we found a statistically significant relationship between emotion recognition and overall cognitive performance. More specifically, attention, visual memory and visuospatial ability positively correlated with emotion recognition. In regard to specific cognitive domains, attention positively correlated with anger and fear, whereas visual memory correlated with happiness and fear. In conclusion, it seems that the role of underlying visual processes in emotion perception has to be further examined and evaluated in this group of patients.

No effect of cognitive performance on post-intervention improvement in emotion recognition

V.P. Bozikas^{1,*}, S. Tsotsi¹, A. Dardagani¹, E. Dandi¹, E.I. Nazlidou¹, G. Garyfallos²

¹ Aristotle University of Thessaloniki, 1st Psychiatric Clinic–GH Papageorgiou, Thessaloniki, Greece

² Aristotle University of Thessaloniki, 2nd Psychiatric Clinic, Thessaloniki, Greece

* Corresponding author.

Deficits in emotion perception in patients with first episode of psychosis have been reported by many researchers. Till now, training programs have focused mainly in patients with schizophrenia and not in first psychotic episode (FEP) patients. We used a new intervention for facial affect recognition in a group of 35 FEP patients (26 male). The emotion recognition intervention included coloured pictures of individuals expressing six basic emotions (happiness, sadness, anger, disgust, surprise, fear) and a neutral emotion. The patients were trained to detect changes in facial features, according to the emotion displayed. A comprehensive battery of neuropsychological tests was also administered, measuring attention, memory, working memory, visuospatial ability and executive function by using specific tests of the Cambridge Neuropsychological Test Automated Battery (CANTAB). We tried to explore whether cognitive performance can explain the difference noted between the original assessment of emotion recognition and the post-intervention assessment. According to our data, overall cognitive performance did not correlate with post-intervention change in emotion recognition. Specific cognitive domains did not correlate with this change, either. According the above mentioned results, no significant correlation between neuropsychological performance and post-intervention improvement in emotion recognition was noted. This finding may suggest that interventions for emotion recognition may target specific processes that underlie emotion perception and their effect can be independent of general cognitive function.

Efficacy and safety of MIN-101: A new drug for the treatment of negative symptoms in schizophrenia a 12-week randomized, double blind, placebo-controlled trial

R. Luthringer

Minerva, Neuroscience, Colamr, USA

Objective To compare the efficacy, safety, and tolerability of MIN-101, a compound with high affinities for sigma 2 and 5-HT_{2A} receptors, to placebo in treating negative symptoms, in stabilized patients with schizophrenia.

Methods This multi-national phase 2b trial enrolled 244 patients with schizophrenia who were symptomatically stable for ≥ 3 months prior to entering the trial and had scores ≥ 20 negative subscale of the PANSS. Patients were randomized to monotherapy with MIN-101 32 mg/day, MIN-101 64 mg/day or placebo in a 1:1:1 ratio. The primary endpoint was the PANSS negative symptom score based on the five factors (pentagonal) model.

Results Statistically significant reduction in the primary endpoint score was demonstrated for MIN-101 32 mg and 64 mg compared to placebo ($P \leq 0.022$, ES 0.45 and ≤ 0.003 , ES 0.58, respectively). This was supported by similar effects on most of the secondary measurements including: the PANSS three factors negative symptoms subscale, PANSS total score, CGI, BACS, CDSS, and PSP. There were no statistically significant differences in PANSS positive subscale scores between MIN-101 and placebo. No weight gain or clinically significant changes in vital signs, prolactin levels, routine laboratory values, metabolic indices and extrapyramidal symptom scores (EPS) were observed.

Conclusions Since positive symptoms and EPS did not change, the improvement in negative symptoms was not secondary to improvement in positive symptoms or EPS, suggesting that MIN-101 might be the first specific treatment to have a direct effect on negative symptoms.

Disclosure of interest I have received consultant fees from Minerva Neuroscience the sponsor of this trial and own stock of Minerva Neuroscience

The importance of family in the long-term evolution of psychoses

L. Dehelean*, C. Cornoiu, A.M. Romosan, R.S. Romosan, I. Papava
"Victor Babes" University of Medicine and Pharmacy,
Neuroscience/Psychiatry, Timisoara, Romania

* Corresponding author.

Introduction Adherence and tolerance to treatment are important factors, which may predict the long-term evolution of a psychosis. Family members may influence prognosis by modulating emotional expressivity and treatment supervision.

Objectives To assess the role of family members in the long-term evolution of psychoses.

Method The present study is retrospective, conducted on patients with psychosis. Data were obtained from psychiatric records extending for a period of four years. The following parameters were analyzed: socio-demographic data, family relationships (parents, spouses) and clinical/evolutive data (onset age for psychosis, number of recurrences).

Results We analyzed 71 patients, 42 (59.2%) women and 29 (40.8%) men with a mean age of 30.38 years ($SD = 9.33$). The subjects were diagnosed according to ICD 10 criteria with acute and transient psychotic disorder (50 patients, 70.4%), schizophrenia (13 patients, 18.3%), and schizoaffective disorder (8 patients, 11.3%). Patients who reported conflicts between parents had significantly more recurrences ($t = -2.1$, $P = 0.04$), while those who reported

satisfactory relationships in their family of origin had fewer recurrences ($t = 2.58$, $P = 0.01$) and a later onset age ($t = -2.89$, $P = 0.006$). Unmarried/single subjects had the psychosis onset at a significantly earlier age ($t = 4.72$, $P = 0.0001$). In addition, these patients had more conflicts between parents ($Z = -2.02$, $P = 0.04$) in comparison with married ones.

Conclusions Conflicts in the family of origin may predispose to a greater number of recurrences and to an earlier disorder onset. The presence of a spouse may represent a protective factor.

Classification of first-episode schizophrenia spectrum disorders and controls from whole brain white matter fractional anisotropy using machine learning

P. Mikolas^{1,*}, J. Hlinka², Z. Pitra², A. Skoch², T. Frodl¹,
F. Spaniel², T. Hajek³¹ Otto-von-Guericke University Magdeburg, Department of
Psychiatry and Psychotherapy, Magdeburg, Germany² National Institute of Mental Health, 3rd Faculty of Medicine,
Charles University, Prague, Czech Republic³ Dalhousie University, Department of Psychiatry, Halifax, Canada

* Corresponding author.

Background Schizophrenia is a chronic disorder with an early onset and high disease burden in terms of life disability. Its early recognition may delay the resulting brain structural/functional alterations and improve treatment outcomes. Unlike conventional group-statistics, machine-learning techniques made it possible to classify patients and controls based on the disease patterns on an individual level. Diagnostic classification in first-episode schizophrenia to date was mostly performed on sMRI or fMRI data. DTI modalities have not gained comparable attention.

Methods We performed the classification of 77 FES patients and 77 healthy controls matched by age and sex from fractional anisotropy data from using linear support-vector machine (SVM). We further analyzed the effect of medication and symptoms on the classification performance using standard statistical measures (t -test, linear regression) and machine learning (Kernel-Ridge regression).

Results The SVM distinguished between patients and controls with significant accuracy of 62.34% ($P = 0.005$). There was no association between the classification performance and medication nor symptoms. Group level statistical analysis yielded brain-wide significant differences in FA.

Conclusion The SVM in combination with brain white-matter fractional anisotropy might help differentiate FES from HC. The performance of our classification model was not associated with symptoms or medications and therefore reflects trait markers in the early course of the disease.

⁵ University of Warwick, Division of Mental Health and Wellbeing, Warwick Medical School, Warwick, United Kingdom

* Corresponding author.

Objectives Evidence from meta-analyses of randomised clinical trials shows interventions for young people at ultra-high risk (UHR) of developing psychosis are effective both clinically and economically. While research evidence has begun to be integrated into clinical guidelines, there is a lack of research on the implementation of these guidelines. This paper examines service provision for UHR individuals in accordance with current clinical guidelines within the National Health Service (NHS) in England.

Method A self-report online survey was completed by clinical leaders of Early Intervention in Psychosis (EIP) teams ($n = 50$) within the NHS across the UK.

Results Of the 50 EIP teams responding (from 30 NHS Trusts), 53% reported inclusion of the UHR group in their service mandate, with age range predominantly 14–5 years (81%) and service provided for at least 12 months (53%). Provision of services according to NICE clinical guidelines showed 50% of services offered cognitive behavioural therapy (CBT) for psychosis, and 42% offered family intervention. Contrary to guidelines, 50% of services offered antipsychotic medication. Around half of services provided training in assessment by CAARMS, psycho-education, CBT for psychosis, family work and treatment for anxiety and depression.

Conclusions Despite clear evidence for the benefit of early intervention in this population, current provision for UHR within EIP services in England does not match clinical guidelines. While some argue this is due to a lack of allocated funding, it is important to note the similar variable adherence to clinical guidelines in the treatment of people with established schizophrenia.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Effects of chronic antipsychotic treatment on neurophysiological correlates of the auditory oddball task in schizophrenia: A preliminary report from a multicentre study

G. Di Lorenzo^{1,*}, A. Mucci², A. Vignapiano², G. Giordano², F. Ferrentino¹, C. Niolu¹, M. Altamura³, D. Marasco³, S. Galderisi²

¹ University of Rome, Tor Vergata, Department of Systems Medicine, Rome, Italy

² University of Naples SUN, Department of Psychiatry, Naples, Italy

³ University of Foggia, Department of Clinical and Experimental Medicine, Foggia, Italy

* Corresponding author.

Introduction The effects of chronic antipsychotic administration on the human brain are debated. In particular, first-generation (FGAs) and second-generation antipsychotics (SGAs) seem to have different impacts on brain function and structure in subjects with

schizophrenia. Few studies have investigated the effect of chronic administration of FGAs and SGAs on indices of brain function, such as event-related potentials (ERP) or neuropsychological performance.

Objectives Within the Italian Network for Research on Psychoses study, subjects stabilized on FGAs or SGAs were compared on P300, an ERP component, thought to reflect attention, working memory and context integration and on neurocognitive indices.

Methods ERPs were recorded in 110 chronic, stabilized patients with Schizophrenia (28 used FGAs) during a standard auditory oddball task. P300 latency and amplitude were assessed at Pz channel. MATRICS Consensus Cognitive Battery (MCCB) was used for cognitive assessment.

Results Compared with the SGAs group, patients on FGAs showed significant increased P300 latency ($P = 0.003$; Cohen's $d = 0.67$) and significant decreased P300 amplitudes ($P = 0.023$; Cohen's $d = 0.38$). The two groups did not differ on psychopathology and MCCB scores. Multiple linear regressions revealed that "FGAs vs. SGAs" ($\beta = 0.298$, $P = 0.002$) and MCCB neurocognitive composite T-score ($\beta = -0.273$, $P = 0.004$) were independent predictors of P300 latency, whereas only age ($\beta = -0.220$, $P = 0.027$) was an independent predictor of P300 amplitude.

Conclusions FGAs seem to affect the functional brain activity more than SGAs, particularly slowing cortical processing. Our results suggest that discrepant findings concerning P300 latency in schizophrenia might be related to the type of antipsychotic treatment used. Longitudinal studies are needed to further address this issue.

Schizophrenia and major depression: Resilience, coping styles, personality traits, self-esteem and quality of life

S. Di Marco^{1,*}, A. Feggi¹, E. Cammarata¹, L. Girardi¹, F. Bert², G. Scaoli², C. Gramaglia¹, P. Zeppegno¹

¹ UPO—Università degli Studi del Piemonte Orientale—Novara, Traslational medicine, Novara, Italy

² Università degli Studi di Torino, Department of Public Health and Paediatric Sciences, Torino, Italy

* Corresponding author.

Introduction Resilience is commonly defined as positive adaptation to adverse events or as the ability to maintain or regain mental health after exposure to difficulties. According to the bio-psycho-social model, resilience is influenced by self-esteem, coping strategies and personality traits. In schizophrenic patients, resilience seems to affect real-life functioning, while in mood disorders, resilience influences the longitudinal course of the disorder, reducing the frequency of relapses and improving drugs response.

Objectives The aim of this study is to assess levels of resilience and self-esteem, coping strategies, perceived quality of life and temperament characteristics in a sample composed by patients with major depressive disorder and patients affected by schizophrenia.

Methods We collected a sample composed by 40 patients with major depressive disorder and 40 patients affected by schizophrenia patients recruited at the "Maggiore della Carità" Hospital in Novara, Italy. The assessment protocol included: Resilience Scale for Adults (RSA), Coping Orientation to Problems Experienced Inventory—Brief (BRIEF—COPE), Rosenberg Self-esteem Scale (RSES), Paykel List Of Stressful Events, Temperamental and Character Inventory (TCI) and Short form 36 (SF-36). Comparison of qualitative data was performed by means of the χ^2 , a t -test was performed for continuous normal-distribution variables otherwise a non-parametric Mann–Whitney test was performed. Statistical significance was set at $P \leq 0.05$.

Conclusions In patients with major depressive disorder resilience were associated with a good self-perception of physical and mental health, higher self-esteem levels and problem-focused/emotion focused coping strategies. In schizophrenic patients, sample there was no positive correlation between resilience and perceived quality of life. Further implications will be discussed.

Systematic evaluation of dose-escalation strategies after initial non-response to standard-dose pharmacotherapy in schizophrenia

M. Dold^{1,*}, G. Fugger¹, M. Aigner², R. Lanzenberger¹, S. Kasper¹

¹ Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria

² Karl Landsteiner University, Department of Psychiatry, Tulln, Austria

* Corresponding author.

Objectives This meta-analysis investigates if dose increase of an antipsychotic drug (high-dose treatment, dose escalation) is advantageous for schizophrenic patients who failed to respond adequately to standard-dose treatment with the same antipsychotic.

Methods Within a systematic literature survey, we identified all randomized controlled trials (RCTs) comparing a dose increase directly to standard-dose continuation treatment in schizophrenic subjects with initial non-response to prospective standard-dose pharmacotherapy with the same antipsychotic. The primary outcome was mean change in the Positive and Negative Syndrome Scale (PANSS) total score. Secondary outcomes were dichotomous response and attrition rates. Study selection and data extraction were conducted independently by two authors. We calculated effect sizes (Hedges's *g* and risks ratios) using the Mante-Haenszel random-effects model. Meta-regression analyses were performed to explore the influence of the degree of the dose increase on effect sizes.

Results Five trials ($n=348$) examining quetiapine ($n=2$, $n=191$), ziprasidone ($n=1$, $n=75$), haloperidol ($n=1$, $n=48$), and fluphenazine ($n=1$, $n=34$) were included. We found no significant between-group differences for the mean PANSS/BPRS total score change, even not when itemized according to the individual antipsychotic agents. There were no between-group differences for response and dropout rates. The non-significant meta-regressions indicate no impact of the different amounts of dose increments on effect sizes.

Conclusions We found no evidence for the efficacy of a dose escalation after initial non-response to standard-dose pharmacotherapy as general advisable treatment strategy. As the high-dose treatment was not accompanied by significant increased attrition rates, appropriate tolerability and acceptability of this pharmacological option can be assumed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cognition in schizophrenia: Selective impairment and factors that influence it

N. Petrova^{1,*}, M. Dorofeikova²

¹ Saint Petersburg State university, Medical faculty, Saint-Petersburg, Russia

² Saint-Petersburg V.M. Bekhterev psychoneurological research institute, Department of geriatric psychiatry, Saint-Petersburg, Russia
* Corresponding author.

Currently it is well known that schizophrenia is associated with cognitive impairment. Still there are many unresolved questions, such as whether cognitive deficit is total, what are the relationships of cognitive impairment with clinical features, demographic characteristics and different biomarkers, which could shed light on its pathogenesis. The aim of our study was to characterize cognitive impairment in schizophrenia and to find factors that may contribute to it. Sixty patients with paranoid schizophrenia were examined. BACS, Rey-Osterreith complex figure and correction task were used to assess cognitive functioning. Only 14.3% of patients had BACS score in the normal range. The vast majority of them showed impaired motor function, verbal and visual memory. Cognitive functioning did not worsen with time. Working memory impairment was influenced by genetic predisposition to schizophrenia and age of disease onset. Residual positive symptoms led to a decrease in the speed of skill development. Symptoms of anxiety and depression contributed to the impairment of accuracy. Hypomania was associated with impaired planning. Planning and problem-solving behavior did not correlate with other cognitive functions, which makes them isolated domains. Higher levels of NSE had been found in patients with more severe memory impairment. S100B level was associated with safer constructive abilities. In general, cognitive impairment in schizophrenia, although present in the majority of patients, varies a lot and appears selective and dependent on certain clinical features.

The study was supported by RSCF 14-50-00069 grant.

* Corresponding author.

Aim The primary purpose of this study is to evaluate the degree of impairment of decision-making capacity in schizophrenia patients compared to non-mentally-ill controls, as determined by the MacCAT-CR instrument.

Materials and methods We analyzed the results obtained from three databases: ISI Web of Science, Pubmed, and Scopus. Each database was scrutinized using the following keywords: "MacCAT-CR + schizophrenia", "decision-making capacity + schizophrenia", and "informed consent + schizophrenia."

Results and discussions We included ten studies in the analysis. Even if schizophrenia patients have a significantly decreased decision-making competence compared to non-mentally-ill controls, they should be considered as competent unless very severe changes are identified during the clinical examination. Using enhanced informed consent techniques significantly decreased the difference between schizophrenia patients and non-mentally-ill controls (except for the reasoning dimension), and should be employed whenever the investigators want to include more severe

patients in their clinical trials. Older age, an increased percentage of men gender or inpatient status tend to escalate the score difference of decision-making competence compared to non-mentally-ill subjects in various dimensions of the decision-making capacity. The main limitations of the study are: (1) a decreased number of studies included in the analysis is small (2) only three studies included data about enhanced ways of informing potential subjects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Diagnostic stability in the first episode of psychosis

M. Duarte*, A. Batista, J. Maia

Centro Hospitalar de Leiria, Psychiatry, Leiria, Portugal

* Corresponding author.

Introduction Early intervention programs in psychosis have demonstrated efficiency in reduction the duration of untreated psychosis, relapse prevention, socio-professional integration and prognosis improvement. In daily practice, it is evident the clinical heterogeneity of the first episodes of psychosis (FEP), as well as the difficulty in initially assigning a specific diagnosis, being difficult to do the differential diagnosis and verifying, during follow-up, very different clinical outcomes among patients.

Objectives/aims Two years after the start of specific consultation for FEP, the authors intended to characterize the followed patients and their evolution, comparing socio-demographic and clinical parameters, with emphasis on diagnosis at the first visit and after two years assessing their variability/stability.

Methods Data research from a 48 patients sample followed up on the FEP consultation.

Results The diagnostics on the first consultation were 79% psychosis with no other specification (NOS), followed by cannabinoids addiction in 35%. After two years, in 29% of cases, there was a diagnostic change being actually 46% Psychosis NOS, 21% cannabinoids addiction and 17% schizophrenia. Initially, only 39% did not have previous history of toxic substances use, being 75% the current percentage. Six percent abandoned the consultation.

Conclusions The authors conclude that, in this specific psychiatry consultation, it is important to initially keep an unspecified diagnostic, with further progressive evaluation allowing a more accurate diagnostic, since the initial diagnostic specification is often found to be incorrect, with adverse consequences for the patient. It would be useful to compare the results with a sample of patients under “as usual” treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Auditory verbal hallucinations in first episode psychosis – an fMRI symptom capture study

T. Dunne^{1,*}, P. Mallikarjun², M. Broome³, B. Farmah⁴, K. Heinze⁵, R. Reniers⁵, S. Wood^{5,6}, F. Oyebo², R. Upthegrove²

⁶ University of Melbourne, Department of Psychiatry, Melbourne, Australia

* Corresponding author.

Introduction Neurobiological models of auditory verbal hallucination (AVH) have been advanced by symptom capture functional magnetic resonance imaging (fMRI), where participants self-report hallucinations during scanning. To date, regions implicated are those involved with language, memory and emotion. However, previous studies focus on chronic schizophrenia, thus are limited by factors, such as medication use and illness duration. Studies also lack detailed phenomenological descriptions of AVHs. This study investigated the neural correlates of AVHs in patients with first episode psychosis (FEP) using symptom capture fMRI with a rich description of AVHs. We hypothesised that intrusive AVHs would be associated with dysfunctional salience network activity.

Methods Sixteen FEP patients with frequent AVH completed four psychometrically validated tools to provide an objective measure of the nature of their AVHs. They then underwent fMRI symptom capture, utilising general linear models analysis to compare activity during AVH to the resting brain.

Results Symptom capture of AVH was achieved in nine patients who reported intrusive, malevolent and uncontrollable AVHs. Significant activity in the right insula and superior temporal gyrus (cluster size 141 mm³), and the left parahippocampal and lingual gyri (cluster size 121 mm³), $P < 0.05$ FDR corrected, were recorded during the experience of AVHs.

Conclusions These results suggest salience network dysfunction (in the right insula) together with memory and language processing area activation in intrusive, malevolent AVHs in FEP. This finding concurs with others from chronic schizophrenia, suggesting these processes are intrinsic to psychosis itself and not related to length of illness or prolonged exposure to antipsychotic medication.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Region of Southern Denmark, Department of psychiatry, Kolding/Vejle, Denmark

⁵ Aarhus University Hospital, Skejby, Department of Cardiology, Skejby, Denmark

* Corresponding author.

Introduction Antipsychotics are associated with the polymorphic ventricular tachycardia, Torsade's de pointes, which in worst case can lead to sudden cardiac death. The QTc interval is used as a clinical proxy for Torsade's de pointes. QTc interval is prolonged by monotherapy with antipsychotic, but it is unknown if the QTc interval is prolonged further with antipsychotic polypharmacy.

Objectives To investigate the associations between QTc interval and antipsychotic mono- and polypharmaceutical treatment, respectively, in schizophrenic patients.

Aims To learn more about the impact of antipsychotics on the QTc interval.

Methods An observational cohort study of unselected patients with schizophrenia visiting outpatient facilities in the Region of Central Jutland, Denmark. Patients were enrolled from January 2013 through March 2015 with follow-up until June 2015. Data was collected from clinical interviews and clinical case records.

Results ECGs were available in 58 patients receiving antipsychotic treatment. We observed no difference in average QTc interval for the whole sample of patients receiving monotherapy or polypharmacy ($P=0.29$). However, women presented longer QTc-interval on polypharmacy than on monotherapy ($P=0.01$).

Conclusion We recommend an increased focus on monitoring the QTc interval in woman with schizophrenia receiving antipsychotics as polypharmacy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Postural control and executive functioning in patients with schizophrenia

M. Yildirim¹, A. Elvan¹, G. Ercegil^{2,*}, I.E. Simsek¹, S. Savci¹, K. Alptekin³

¹ Dokuz Eylul University, School Of Physical Therapy And Rehabilitation, Izmir, Turkey

² EGE University, Psychology Department, Izmir, Turkey

³ Dokuz Eylul University, Psychiatry Department, Izmir, Turkey

* Corresponding author.

Introduction Patients with schizophrenia commonly show deficits in executive functioning that allow a person to make plans, solve problems, do many tasks simultaneously and adapt to unexpected conditions. Executive dysfunction is associated with very simple and automatic activities, such as walking in schizophrenia patients. However, no study exists about its relation to postural control in these patients.

Aim To investigate the effect of executive functioning on postural control using dual task paradigms.

Methods Fifteen clinically stable schizophrenia outpatients and 15 healthy controls were enrolled in the study. Postural control was assessed with bilateral stance test using the Balance Master system under three different conditions with eyes open and eyes closed (EC): without a task, during a cognitive task (verbal fluency) and during a motor task (holding a cup of water).

Results Standing on a foam surface with EC resulted in higher postural sway velocities in schizophrenia patients under all conditions ($P=0.009$, $P=0.032$, $P=0.013$). During a cognitive task, both schizophrenia patients and healthy controls showed higher velocities on firm surface with EC in comparison to the condition without a task ($P=0.023$). Both schizophrenia patients and healthy controls did not show higher postural sway velocities during the motor task.

Conclusion The effect of verbal fluency on postural sway shows the relationship between executive functioning and postural control in schizophrenia patients. Foam surface also higher postural sway velocities in schizophrenia patients in EC condition suggesting the difficulties in integrating the proprioceptive information in the absence of visual input.

Keywords Executive functioning; Schizophrenia; Postural control

Patients with severe schizophrenia. functioning improvement after 7-year of comprehensive treatment

J.J. Fernandez-Miranda^{1,*}, S. Díaz-Fernández², D.F. Frías-Ortiz²

¹ SESPAsturian Mental Health Service, AGCSM-V, Gijón, Spain

² SESPAsturian Mental Health Service, AGCSM-V, Gijón, Spain

* Corresponding author.

Introduction To reach not only clinical but also rehabilitation (especially to improve psychosocial functioning) goals in people with schizophrenia is a need.

Objective To know the retention in treatment and functional outcomes of patients with severe schizophrenia enrolled in a specific and comprehensive programme for 7 years.

Method A 7-year prospective, observational study of patients with severe schizophrenia (CGI-S of 5 or over) undergoing comprehensive programme ($n=200$). Assessment included at the beginning and after 3, 6, 12, 24, 36 and 84 months: the CGI-S, the Camberwell Assessment of Needs (CAN) and the WHO-DAS. Time in treatment, reasons for discharge, laboratory tests, weight, medications, adverse effects and hospital admissions in the previous six years and during the follow-up were registered.

Results CGI at baseline was 5.9 (0.7). After seven years, 44% of patients continued under treatment (CGI=4.3 (0.8); $P<0.01$); 36% were medical discharged (CGI=3.4 (1.5); $P<0.001$); WHO-DAS decreased in the four areas ($P<0.005$) and also CAN ($P<0.01$); 8% were voluntary discharges. Ten patients dead; three of them committed suicide (1.5%). Hospital admission decreased significantly ($P<0.001$), and also antipsychotic combinations and antiparkinsonian medications. Fifty-five percent of all of them were treated with atypical long-acting antipsychotics, with good tolerability and few side effects (among them, only 4% were voluntary discharges).

Conclusion Retention of patients with schizophrenia with severe symptoms and impairment in a specific and comprehensive programme was really high. Such good treatment adherence helped to get remarkable clinical and functional improvement. Long-acting medication seemed to be useful in improving treatment adherence.

Extrapyramidal side effects and functional remission in schizophrenia

B. Ghajati^{1,*}, C. Leila², L. Raja¹, C. Majda²

¹ Razi Hospital, Psychiatry Department "C", Tunis, Tunisia

² Razi Hospital, Psychiatry Department "E", Tunis, Tunisia

* Corresponding author.

Treating patients with schizophrenia has evolved towards including, as an effective goal, their functional remission. Beyond the discrepancies in this concept definition, a plethora of studies has been conducted trying to identify predictors of functioning in schizophrenia. Among which antipsychotic prescription and related side effects.

Aim Explore extrapyramidal side effects link with functional prognosis of patients with schizophrenia spectrum disorder.

Methods We conducted a cross-sectional, retrospective and descriptive study in the psychiatry department "C", in Razi hospital (Tunis), between October 2014 and March 2015. Sixty patients suffering from schizophrenia spectrum disorder (DSM IV-R) were included. Functional status was explored with the Global Assessment of Functioning Scale (GAF), the Social and Occupational Functioning Assessment Scale (SOFAS) and the Social Autonomy Scale (EAS). Extrapyramidal side effects (EPS) were evaluated using the Simpson and Angus Rating Scale (SAS).

Results Functional remission was achieved according to GAF, SOFAS and EAS in respectively: 63,30%, 48,30% and 51,70% of the patients. SAS mean score was 0.898 ± 0.29 (0.4–2). Although SAS showed no significant association with GAF, SOFAS and EAS global scores, patient with less EPS had better autonomy in EAS' dimension "Relationship with the outside" ($P=0.048$).

Conclusion EPS may influence functional remission at several levels starting from the neurobiological to the social stigmatization and the treatment adherence levels. Further research in this matter is required.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW0265

Concomitant psychotropic medications and functional remission in schizophrenia patients

B. Ghajati^{1,*}, C. Leila², L. Raja¹, C. Majda²

¹ Razi Hospital, Psychiatry Department "C", Tunis, Tunisia

² Razi Hospital, Psychiatry Department "E", Tunis, Tunisia

* Corresponding author.

Along with the rise of symptomatic and functional remission concepts in schizophrenia, multiple aspects of the disease treatment have been explored in their link to vocational prognosis. Although antipsychotics are the corner stone treatment, monotherapy is seldom. In fact, concomitant psychotropic medications (CPM) use during treatment of schizophrenia has dramatically increased worldwide.

Aim To examine whether concomitant psychotropic medications use is associated to functional remission in schizophrenia patients.

Methods A cross-sectional, retrospective and descriptive study was conducted in the psychiatry department "C", in Razi hospital (Tunis), between October 2014 and March 2015. Sixty patients suffering from schizophrenia spectrum disorder (DSM IV-R) were included. Functional status was explored with the Global Assessment of Functioning Scale (GAF), the Social and Occupational Functioning Assessment scale and the Social Autonomy Scale (EAS). Sociodemographic and therapeutic characteristics have been collected during a semi-structured interview.

Results Rates of functional remission were respectively: 63.30% at the GAF scale, 48.30% at the SOFAS and 51.70% at the SAS. Antipsychotics were prescribed alone in more than half patients (56.70%), mood stabilizers in 40% and antidepressants in 1.7% of the cases. Benzodiazepines were prescribed in 40% of the patients. There was no association between CPM use and functional remission, using three scales (GAF: $P=0.091$; SOFAS = 0.125; EAS = 0.728).

Conclusion Largely used, concomitant psychotropic medications can increase side effects, cause drug interactions, escalate treatment costs, and lead to non-adherence. That is said, their therapeutic effectiveness should be thoroughly investigated, aiming to recovery not only symptoms control.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Functional connectivity of the ventral tegmental area and avolition in schizophrenia: A resting state functional MRI study

G.M. Giordano^{1,*}, M. Stanziano², A. Mucci¹, M. Papa²,

S. Galderisi¹

¹ University of Naples SUN, Department of Psychiatry, Largo Madonna delle Grazie, 80138, Napoli, Italy

² University of Naples SUN, Laboratory of Neuronal Networks, Department of Mental and Physical Health and Preventive Medicine, Via Luciano Armanni 5, 80138, Napoli, Italy

* Corresponding author.

Introduction Impaired motivation is considered a fundamental aspect of the Avolition domain of negative symptoms. The ventral

tegmental area (VTA) contains the highest number of DA neurons projecting to the brain areas involved in motivation-related processes.

Aim The aim of our study was to investigate by functional MRI the resting-state functional connectivity (RS-FC) of the VTA in patients with schizophrenia and its relationships with real-life motivation and avolition.

Method The RS-FC was investigated in 22 healthy controls (HC) and in 26 schizophrenia patients (SCZ) treated with second generation antipsychotics only and divided in high (HA = 13) and low avolition (LA = 13) subgroups. We used the Quality of Life Scale and the Schedule for the Deficit Syndrome to assess real-life motivation and avolition, respectively.

Results HA, as compared to LA and HC, showed a reduced RS-FC of VTA with the right ventrolateral prefrontal cortex (R VLPFC), right posterior insula (R pINS) and right lateral occipital cortex (R LOC). The RS-FC for these regions was positively correlated with motivation in the whole sample and negatively correlated with avolition in schizophrenia patients.

Conclusion Our findings demonstrate that motivational deficits in schizophrenia patients are linked to reduced functional connectivity in the DA circuit involved in retrieval of the outcome values of different actions to guide behavior. Further characterization of the factors modulating the functional connectivity in this circuit might foster the development of innovative treatments for avolition.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The impact of cannabis in the early stages of schizophrenia: A 3-year longitudinal study on cannabis influence on relapse rates

M. Gomez Revuelta^{1,*}, M. Juncal Ruiz², O. Porta Olivares², V. Gajardo Galan², G. Pardo de Santayana Jenaro², L. Sanchez Blanco², D. Abejas Diez², R. Landera Rodriguez², L. Garcia Ayala², N.I. Nuñez Morales², M. Fernandez Rodriguez²

¹ Hospital Universitario de Álava-Sede Santiago, Vitoria, Gasteiz, Psychiatry, La Penilla, Spain

² Hospital Universitario Marques de Valdecilla, Psychiatry, Santander, Spain

* Corresponding author.

Introduction The first five years after the onset of a first episode of psychosis (FEP) are crucial for long term outcome. In this period, the risk of relapse is particularly high. Consequences of relapse include an increased risk of neurotoxicity, chronicity, hospitalization, decreased response to treatment, increased economic burden and functional impairment.

Objectives To discern the influence of cannabis on relapse as it may contribute to adopt specific measures in patients during early stages of the illness.

Material and methods PAFIP is an early intervention program for patients with a FEP. Between January 2005 and January 2011, 163 patients were recruited for this study. They were followed-up during 3 years at intervals of three months. The sample was divided into three groups: (1) those non-cannabis users neither before the FEP nor during follow-up (nn), (2) consumers before the FEP and during follow-up (ss) and (3) consumers before the FEP that gave up consumption during follow-up (sn).

Results No statistically significant differences between the three groups were observed but a trend ($P=0.057$) towards a more enduring survival in Group 3 (sn). (Kaplan–Meier curve and detailed Log Rank Test results will be included in the final poster).

Conclusions Cannabis has a detrimental effect on schizophrenia. The interruption of its use could contribute to improve the outcome of the disease, as the results of our study suggest.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Diagnostic stability in first psychotic episode after 5 years follow-up

M. Mota-Oliveira¹, M.J. Peixoto¹, I. Ferraz¹, E. Pereira¹, R. Guedes^{1,*}, A. Norton², C. Silveira¹

¹ Centro Hospitalar de São João, Clínica de Psiquiatria e Saúde Mental, Porto, Portugal

² Hospital Magalhães Lemos, Hospital Magalhães Lemos, Porto, Portugal

* Corresponding author.

Introduction The diagnosis of psychosis is based on the presence or absence of characteristic symptoms. The presence of such symptoms varies during the course and treatment, raising the question of diagnostic stability after a first psychotic episode.

Aims and objectives The aim of this study is to evaluate the diagnostic stability after a first psychotic episode in the long term (five years after the first inpatient admission).

Methodology A retrospective study that included patients with first psychotic episode between 2007 and 2011 admitted to the inpatient unit of the psychiatry and mental health clinic of São João hospital center, Oporto, Portugal and re-evaluation of the diagnosis after five years.

Results We included 60 patients with a first psychosis episode, 22 of which were drop-outs after five years. Of the 38 patients evaluated, it was possible to see that after 5 years 68.4% ($n=26$) maintained the same diagnosis during follow-up. In particular, the diagnosis of schizophrenia was kept in 83.3% of patients after 5 years ($n=15$, 18 patients with the diagnosis of schizophrenia after first admission). Diagnosis of acute and transient psychotic disorder and psychosis not otherwise specified were the least stable diagnosis after 5 years.

Conclusions The diagnosis after a first psychotic episode has important therapeutic and prognostic implications. The presence of characteristic symptomatology, with periods of partial or total remission between subsequent episodes emphasizes the need for regular monitoring, since this group of patients appears to be more vulnerable to changes in diagnosis over time.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Side effects of clozapine and their relationship with clinical variables in patients with schizophrenia

G. Gürçan*, Ş. Hun Şenol, A.E. Anıl Yağcıoğlu, A. Ertuğrul Hacettepe University Faculty of Medicine, Psychiatry, Ankara, Turkey

* Corresponding author.

Introduction The side effects of clozapine may affect the treatment process negatively, and increase the disability.

Aims We aimed to assess the side effects of clozapine, and their relationship with the clinical variables in schizophrenia patients, and study the predictors of disability.

Methods Consecutive 122 outpatients who met DSM-IV criteria for schizophrenia, and were on clozapine treatment were included in the study. Information about sociodemographic characteristics, past and current clinical status were gathered through a clinical interview and review of the medical records, and physical measures and laboratory tests, including clozapine plasma levels, were recorded. The patients were assessed with SCID-I, Positive and

Negative Syndrome Scale, UKU-Side Effect Rating Scale, WHO-Disability Assessment Schedule-II.

Results Hypersalivation, weight gain, sedation and constipation were the most common side effects of clozapine. Although the mean plasma clozapine levels were high (828.11 ± 445.5 ng/mL), no significant effect of clozapine dose and plasma levels were detected on the severity of side effects, except for constipation. Metabolic syndrome prevalence was found to be 50% according to ATP IIIA criteria. Duration of clozapine treatment, clozapine dose and plasma levels were not significantly different between patients with and without metabolic syndrome. Regression analysis showed that the severity of schizophrenia psychopathology and the number of side effects predicted the severity of disability.

Conclusions Side effects of clozapine increase the disability of patients with schizophrenia and should be monitored regularly. On the other hand, clozapine dose and plasma levels do not determine the severity of most of the common side effects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Effect of clozapine on psychiatric comorbidities in patients with schizophrenia

G. Gürçan*, Ş. Hun Şenol, A.E. Anıl Yağcıoğlu, A. Ertuğrul Hacettepe University Faculty of Medicine, Psychiatry, Ankara, Turkey

* Corresponding author.

Introduction Clozapine has superior efficacy in treatment-resistant schizophrenia, and has various effects on psychiatric comorbidities, which may affect the illness course.

Aims We aimed to assess the past and current psychiatric comorbidities in schizophrenia patients treated with clozapine, and study their relationship with clinical variables.

Methods Consecutive 122 outpatients who met DSM-IV criteria for schizophrenia receiving clozapine were included. Information about past and current clinical status were gathered through a clinical interview and review of the medical records, along with laboratory test results. Patients were assessed with structured clinical interview for Axis-I Disorders for DSM-IV, Clinical Global Impression Scale, Positive and Negative Syndrome Scale (PANSS), Calgary Depression Scale, Yale-Brown Obsessive Compulsive Scale (Y-BOCS), Panic and Agoraphobia Scale (PAS), WHO-Disability Assessment Schedule-II.

Results There was a significant decrease in the diagnosis of depression, alcohol and substance use disorder, number of suicide attempts, and an increase in the diagnosis of obsessive compulsive disorder (OCD) after clozapine initiation. Clozapine related de novo OCD appeared in 48.4% of the patients, and there was a positive correlation between Y-BOCS total scores and clozapine dose and plasma levels. In the de novo OCD group, compulsion scores were higher than obsession scores with checking most prevalent among compulsions. Total PANSS, Y-BOCS, PAS scores were positively correlated with total disability score.

Conclusions Clozapine seems to decrease comorbid depression, alcohol and substance use and number of suicide attempts and increase OCD. Assessment and treatment of psychiatric comorbidities in clozapine using schizophrenia patients is vital to decrease disability.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Schizophrenia puts a significant burden on caregivers.

Objectives To explore the effects of two long-acting treatments (LAT), paliperidone palmitate 1-month and 3-month formulations on caregiver burden (CGB) in European patients with schizophrenia using the Involvement Evaluation Questionnaire (IEQ)

Aims To conduct a subgroup analysis of two randomized, double-blind studies (NCT01515423 and NCT01529515).

Methods Caregivers (≥ 1 h of contact/week with the patients) were offered to complete the IEQ (31 items, each scoring: 0–4; total score: sum of 27 items [0–108]).

Results Among 756 European caregivers (53% parents, 18% spouse/partner or girl/boyfriend, 10% sister/brother), 60% reported a CGB of ≥ 32 hours/week at open-label baseline (BL-OL). CGB reduced significantly for patients with both BL-OL and at least one double-blind IEQ sum-score ($n = 433$): mean improvement [SD] (9.9 [12.66], $P < 0.001$) from BL-OL (mean [SD] 26.0 [13.30]) to study end (16.0 [10.47]); (reduction in burden associated with worrying [2.9 points] and urging [4.3 points]). CGB significantly improved in patients on prior oral antipsychotics post-switching to LAT with less leisure days impacted and less hours spent in caregiving ($P < 0.001$). There was significant relationship between improvements and relapse status, patient age ($P < 0.001$), age at diagnosis ($P < 0.002$), and number of prior psychiatric hospitalizations in the last 24 months ($P < 0.05$). Prior use of long-acting antipsychotics other than paliperidone palmitate 1-month or 3-month formulations at BL-OL and duration of prior psychiatric hospitalizations in the last 24 months did not show significant effect on improvements.

Conclusion Switching from an oral antipsychotic to an LAT can provide a meaningful and significant improvement in caregiver burden.

Comorbidities in patients with an at-risk mental state and first episode psychosis

U. Heitz^{*}, J. Cherbuin, S. Menghini-Müller, L. Egloff, S. Ittig, K. Beck, C. Andreou, E. Studerus, A. Riecher-Rössler

University of Basel Psychiatric Hospital, Center for gender research and early detection, Basel, Switzerland

* Corresponding author.

Introduction Non-psychotic axis I diagnoses are highly prevalent in at-risk mental state (ARMS) and first episode psychosis (FEP) patients, the most common being affective and anxiety disorders.

Few studies have examined differences between ARMS and FEP patients or gender effects regarding such diagnoses.

Objective To examine current and lifetime comorbidities in ARMS and FEP patients. Furthermore, to examine gender differences, and differences between patients with (ARMS-T) and without later transition to psychosis (ARMS-NT).

Methods This study was part of the Früherkennung von Psychosen (FePsy) study. Current and lifetime axis I comorbidities were assessed using the Structured Clinical Interview for DSM-IV (SCID-I).

Results One hundred and thirty-two ARMS and 98 FEP patients were included. Current comorbidities were present in 53.1% of FEP and 64.4% of ARMS patients, the most common being affective, anxiety and substance use disorders. Current affective disorders were significantly more common in ARMS than FEP. Lifetime comorbidities were diagnosed in 58.2% of FEP and 69.7% of ARMS patients, with significantly more affective and anxiety disorders in ARMS than FEP. Male FEP patients had more current and lifetime substance use disorders (across all substances) compared to female FEP. No differences emerged between ARMS-T and ARMS-NT.

Conclusions As expected ARMS patients have many comorbidities, while clearly diagnosed FEP have less comorbidities. There were few gender differences in axis I comorbidities. Moreover, no differences between ARMS-T and NT emerged, suggesting that axis I comorbidities do not improve prediction of transition. Nevertheless, the high comorbidity prevalence is relevant for global functioning and clinical treatment.

Visual and motor functions in schizophrenia

A. Hopulele-Petri^{1,*}, M. Manea²

¹ County Emergency Hospital, Psychiatry, Cluj-Napoca, Romania

² University Of Medicine And Pharmacy "Carol Davila", Psychiatry, Bucharest, Romania

* Corresponding author.

Introduction Over the past decade, perceptual organization has gained an increasingly important role in the psychopathology of schizophrenia. With the advancements in visual neurocognitive sciences, visual processing, especially mid- and high-level processing have been linked with psychotic symptoms, as well as prodromal and ultra-high risk patients. Motor dysfunction is being seen as well as an integral element of schizophrenia, separate from the other symptoms and with possible implications for disease risk and outcome. This could illustrate two systems at work, which by either individual dysfunction or integrative disorganization help explain some the neurocognitive mechanisms in schizophrenia.

Objective and aims The current study's argument is that tests from these two domains could be used in a complementary manner to offer a neurocognitive characterization of schizophrenic patients.

Methods A total of 24 patients and 19 controls were evaluated. In order to assess mid-level visual perception the Leuven Perceptual Organization Screening Test was used, along with a scale for assessing soft neurological signs and a task for gait and motor imagery. Clinical symptoms were measured with the Positive And Negative Symptoms Scale, using the five-factor model as proposed by Lindenmayer. Data analysis involved comparison of means between patient and control groups as well as a multivariate factor analysis calculating the impact of perceptual and motor functions on clinical symptoms.

Results Consistent with previous findings, visual and motor functions would differentiate between patient and control groups. In

accordance with the study's aim, visual and motor functions had different impact on symptom dimensions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction During the last decades, the recovery from severe mental illness has shifted from a focus on reducing symptoms to a more holistic approach of emphasizing consumer-centered goals and subjective wellness (Anthony, 1993). The implementation of this controversial new model it has not had an easy path. In that sense, Ridgway (2004, 2011) developed the Recovery Enhancing Environments (REE), an instrument to gather information on personal mental health recovery and the elements that people feel are important to their recovery; staff activities and an organizational climate that encourages resilience.

Objective To present the preliminary results of the Spanish adaptation.

Method English to Spanish translation of REE was carried out. The REE interview and Euro-Qol5d, HoNOS, EEAG and CGI scales were completed by 312 patients in Mental Health Services organization of Bizkaia (Spain), 189 men and 123 women (age = 48.89). The interviewers of the REE were service users trained and hired for this task.

Results The alpha de Cronbach was .98, and for its dimensions: program performance indicators (.97), organizational climate (.92) and recovery markers (.93). The concurrent validity with others scales have resulted in correlations coefficients superiors to $r = .35$ ($P < .001$).

Discussion As the different indicators are adequate and the instrument has a similar structure to other theoretical studies, it can be concluded that Spanish REE is an appropriate measure to fill the gap between the knowledge in the recovery model and what services can do to support this model. All of this information gathered from people who receive mental health services.

Introduction There is an increasingly recognition of the concept of recovery in the treatment of mental illness. Recovery defined as living a fulfilling, rewarding life, even in the ongoing presence of a mental illness. Consequently, a number of instruments have been designed to assess recovery-oriented outcomes.

Objective The objective of the study was to conduct a systematic revision of the instruments used to assess recovery with appropriate psychometric properties.

Method A systematic review of the literature has been realized. The adequacy of the instruments utilization, the content validity and psychometrics properties were gathered and analyzed.

Results/discussion After a systematic review, it has been obtained 25 different instruments for measuring personal recovery and 17 for assessing the orientation of recovery in mental health services. As a consequence of the lack of consensus that exists in the conceptualization of recovery; several instruments have been developed and used to assess the different recovery domains. But it is essential to select scales that match with the recovery model and assess adequately the individual's recovery, and also, the recovery orientation of services. Moreover, those instruments should have appropriate psychometric properties and should be suitable to be introduced in routinely clinical settings.

⁴ Seversk Clinical Hospital, Psychiatry Department, Seversk, Russia

* Corresponding author.

Introduction The problem of mental health of synthetic ("designer") drug or "spice" users draws the increasing attention of experts of various areas in psychiatry, addiction psychiatry and psychotherapy.

Research objective To classify and describe the psychotic states arising after the use of "spice"; to define the personality changes and probable consequences of the use observed in patients in the conditions of a hospital.

Material and methods One hundred and one patients (93 men and 8 women; mean age 27.8 ± 7.6 years) with dependence on "spice" revealed between 2014 and 2015 were examined. History taking, clinical-psychopathological investigation and experimental psychological testing were used.

Results and discussion As a result of research the patients were divided into 5 groups according to criteria of ICD-10:

- group 1: acute intoxication with delirium ($n = 16$; 15.84%);
- group 2: residual and late-onset psychotic disorders like flashbacks ($n = 9$; 8.92%);
- group 3: withdrawal state with delirium ($n = 32$; 31.68%);
- group 4: psychotic disorder, mainly hallucinatory ($n = 30$; 29.70%);
- group 5: paranoid schizophrenia ($n = 14$; 13.86%).

The use of synthetic cannabinoids ("spice") can initiate transient psychotic episodes, serve as the contributing factor of development of paranoid schizophrenia, continuous type of the course, leads to "accentuation" of schizoid, paranoid and psychopathic traits of the personality. It is proposed to make up a question of the possibility

of additional use of the clarifying designation “synthetic cannabinoids/spice” at reference of patients using synthetic cannabinoids to the section of ICD-10 F12 “Mental and behavioural disorders due to use of cannabinoids” the agenda of clinicians.

Adverse childhood experiences, personality disorders and addiction: Which relationship?

F. Cerrato^{1,*}, G. Aluisio¹, P. Casadio², G. Di Girolamo¹, S. Valente¹, D. De Ronchi¹, A.R. Atti¹

¹ Psychiatry, Department of Biomedical and Neuromotor Sciences-Psychiatry, Bologna, Italy

² AUSL Romagna, Pathological Addiction Department, Faenza, Italy

* Corresponding author.

Introduction Stressful or traumatic events occurred during childhood do have a role in the genesis of personality disorders. Less is known about this remarkable association in people with addictive behaviors.

Aims This study aims to disentangle the relationship between childhood adverse experiences, personality disorders (PDs) and substance use disorders (SUDs).

Methods A cross-sectional naturalistic study of 320 consecutive SUDs outpatients attending an Italian addiction service. Participants were clinically evaluated by a semi-structured interview, the SCID-II (Structured Clinical Interview for DSM-IV Axis II PD), and the CECA-Q (Childhood Experience of Care and Abuse-questionnaire). Multivariate logistic regression analyses were used to estimate odds ratio (OR) and 95% confidence intervals (95% CI)

Results The prevalence rate of PDs in our sample of patients is 62.2%. PDs were associated with a history of physical punishment in childhood (OR = 1.82; CI 95%: 1.05–3.16; $P = 0.034$). Being exposed to three adverse events increases the risk of Cluster B PD (OR = 5.92; CI 95%: 2.21–15.92; $P < 0.001$). Heroin addiction increases the risk of Cluster B PD, both as previous (OR = 2.93; CI 95%: 1.49–5.75; $P = 0.003$) or current (OR = 4.34; CI 95%: 1.97–11.8; $P = 0.004$) consumption. Childhood institutionalization increases the probability of cluster B PD (OR: 2.15; CI 95%: 1.02–4.54; $P = 0.041$). Whereas being employed reduces the probability of both PDs and SUDs (OR = 0.54; CI 95%: 0.31–0.93; $P = 0.027$).

Conclusions PDs occurred in 62% of patients and were related to adverse childhood experiences and SUDs having detrimental effects on both social and occupational functioning. Being employed could be a protective factor on the development of PDs.

The prevalence and correlates of depression awareness in patients with alcohol use disorder

C. Charnsil*, R. Aroonrattanapong

ChiangMai University, Psychiatry, Chiang Mai, Thailand

* Corresponding author.

Introduction Alcoholic use disorder is a big problem in every country. It is the leading factor causing high disability-adjusted life year (DALYs). The National Institute of Mental Health Epidemiology Catchment Area found that 37% of people with alcoholic use disorder had comorbid along with psychiatric disorder especially depression. In order to successfully treat patients with alcoholic use disorder, we have to treat their comorbidity along as well.

Aim To examine the prevalence and correlation of depression awareness in patients with alcoholic use disorder.

Methods Inpatients and outpatients who were diagnosed with alcoholic use disorder and alcohol dependence were invited to participate in this research. Subjects who had any history of depressive disorder treatment before were excluded. The awareness of depression was determined by the Illness Perception Questionnaire-Revised, IPQ-R. Depressive disorder was determined by the Thai version of the nine-item Patient Health Questionnaire (PHQ-9).

Results Ninety subjects with alcoholic use disorder agreed to join this research. Twenty-nine of the 90 (32.2%) had depression due to the PHQ-9 scale. Twenty-three were aware that they had depression and that was related to alcohol use. Using the logistic regression analysis, there were no significant factors related to this awareness.

Conclusion There is high prevalence of depression in patients with alcoholic use disorder and most of them have awareness did not receive treatment for depression.

* Corresponding author.

Introduction Systematic reviews and meta-analyses report low-quality evidence to suggest a significant differential effectiveness between standard psychosocial interventions in reducing substance consumption. They highlight the presence of several types of treatments that usually integrate different approaches in a multimodal manner. CBT-based interventions seem to be the most effective ones in terms of dropouts and relapse prevention, particularly in cocaine addiction.

Objectives We discuss recent advances in experimental and clinical studies on cocaine addiction. We especially try to integrate emerging cognitive neuroscience evidences and results of the meta-analyses of the effectiveness of psychosocial interventions.

Aims The primary aim of this study is to explore the feasibility of a new multimodal intervention for cocaine addiction, namely MACA (Metacognitive Awareness in Cocaine Addiction). Secondary aims are to discuss: (i) rationale of integrating different approaches; (ii) preliminary results of a previous pilot-study; (iii) feasibility of present study using the RE-AIM (reach, effectiveness, adoption, implementation, and maintenance) framework.

Methods We describe and evaluate our model that comprises: – an individual short intervention based on dilemma-focused therapy; – a psycho-educational group based on standard CBT treatments; – a relapse-prevention group based on mindfulness protocols for addiction; – a follow-up online self-administered course and automatic personalized feedback.

Results Existing literature seems to support the need for new integrated programs. RE-AIM feasibility analysis shows promising results in integrating the proposed approaches in terms of symptoms reduction, relapse prevention and cost-benefit ratio.

Conclusions Preliminary evidence supports potential for the MACA program in treating cocaine addiction. The research design of a wait-list controlled trial with pre- and post-treatment assessment is discussed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ GH Lariboisière-Fernand Widal, Toxicology laboratory, Paris, France
* Corresponding author.

Introduction Addiction to psychoactive substances (PAS) can lead to cardiovascular complications. Cardiotoxicity of drugs is known but it is rarely documented by toxicology.

Objectives We conducted a prevalence study on PAS use among patients with cardiac symptoms, with an analysis of diagnosis and a description of PAS user's characteristics.

Aims To improve the therapeutic management in addictology for cardiac patients.

Methods Prospective observational study performed during 3 months. Patients admitted in cardiology had to complete a hetero-questionnaire about his PAS consumption and a qualitative toxicological research in urine and/or blood (immunochemical/GC–MS detection).

Results One hundred and sixty-one patients were included: 86% men, aged 24–68 years (Table 1). Results show a high level of PAS use in our population: 8.7%. A significant PAS use is observed among patients aged 40–70 years, with a prevalence of 22% for the 40–49, 15% for the 50–59 and 7% for the 60–69. PAS detected were mainly cannabis and cocaine. Clinical diagnoses of patients positive to PAS were acute coronary syndromes and severe cardiac arrhythmias.

Conclusions In patients admitted in cardiology, toxicological screening is rarely done. Our study shows a significant PAS use among patients aged 40–70 years. According to data of the French Health Barometer, there is regular use of cannabis and cocaine at respectively 3% and 1.1% among people aged 18–64. These results invite us to achieve a more systematic identification of PAS use among patients with cardiovascular disorders and to optimize the therapeutic management by a systematic orientation in addictology.

Table 1 Patients characteristics.

Data about patients	Total sample (N / %)	PAS positive (N / %)	PAS negative (N / %)	p-value
PATIENTS	161 (100%)	14 (8.7%)	147 (91.3%)	
Male	111 (69%)	12 (86%)	99 (87%)	p=0.17
Median age	64	50	65.4	p=0.0004
Current smoker	54 (34%)	11 (79%)	43 (29%)	p=0.0005
Cardiovascular risk factors (at least 1)	121 (75%)	9 (64%)	112 (76%)	P=0.50
Past cardiovascular history	70 (43%)	5 (36%)	65 (44%)	p=0.77
Neither past cardiovascular history, nor risk factors	33 (20%)	5 (36%)	28 (19%)	p=0.25
Previous substance use disorders	21 (13%)	5 (36%)	16 (11%)	p=0.03
Admission for acute coronary syndrome	71 (44%)	8 (57%)	63 (43%)	p=0.47

* Corresponding author.

Introduction QTc interval prolongation is considered a risk factor for fatal polymorphic ventricular tachycardia, which can result in sudden cardiac death. Most psychotropic drugs have a dose-dependent potential to prolong the QTc interval. However, other factors require appropriate consideration, including: age; gender; other medications; electrolyte abnormalities; severe comorbid conditions, such as co-occurring alcohol or substances abuse/dependence.

Objectives The objective was to study the potential mediating roles of alcohol/substances abuse on QTc prolongation.

Aims The Italian research group STAR Network, in collaboration with the Young Italian Psychiatrists Association, aimed to evaluate the frequency of QTc interval prolongation in a sample of patients under treatment with psychotropic drugs through a cross-sectional national survey.

Methods A sample of 2411 unselected patients were enrolled after performing an ECG during the recruitment period. Sociodemographic and clinical characteristics were collected from medical records. Collected data underwent statistical analysis.

Results A total of 11.2% of patients reported alcohol abuse, and only 8.9% psychotropic substances. According to the threshold, less than 20% of patients had a borderline value of QTc, and 1% a pathological value. Patients with co-occurring alcohol misuse and drug abuse were more likely to have longer QTc interval.

Conclusions The present study describes the frequency of QTc prolongation in real-world clinical practice. Before prescribing a psychotropic drug, the physician should carefully assess its risks and benefits to avoid this type of adverse reaction, particularly when additional risk factors are present. The potential role of alcohol and substances on QTc length could be particularly useful in emergency settings.

Clinical features and diagnosis of alcoholic hallucinosis

N. De Uribe-vilorio*, A. Alonso Sanchez, M. De Lorenzo Calzon, M. Gomez Garcia, A. Alvarez Astorga, H. De La Red Gallego, R. Hernandez Anton, S. Gomez Sanchez, C. Noval Canga, G. Medina Ojeda, F. De Uribe Ladron De Cegama
Hospital Clinico Universitario De Valladolid, Psychiatry, Valladolid, Spain

* Corresponding author.

Introduction Alcoholic hallucinosis is a rare complication of chronic alcohol abuse, characterized by acoustic verbal hallucinations and delusions, mainly of a menacing content, arising in clear consciousness, that appear during or shortly after a period of heavy alcohol consumption.

Objectives and aims To outline the key clinical features of alcoholic hallucinosis in order to improve differential diagnosis with other entities.

Methods We studied the evolution of an outpatient followed in a Mental Health Centre of Valladolid and compared it with present data about the condition, found in a bibliographic search of articles no older than 10 years about the topic.

Results Partial insight about the experience, along with clear consciousness, was key to discard other psychiatric diagnosis that also present acoustic hallucinations. Neuroimaging and functional tests in our patient showed moderate cognitive impairment and cortical atrophy, which contradicts other studies which claim that an acceptable level of cognition must be present in order to gain the necessary insight to meet the diagnostic criteria.

Conclusions Alcoholic hallucinosis is a rare form of subacute encephalopathy, secondary to an abrupt stop in a previously chronic and heavy alcohol consumption. Its diagnosis is mainly clinical, and neuroleptics are the most used drug, being abstinence essential for an adequate evolution. The course is usually benign, although the acoustic phenomena may not disappear completely.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Resilience and psychological correlates in a group of patients affected by dual diagnosis

C. Delicato*, E. Gattoni, S. Di Marco, C. Vecchi, A. Venesia, P. Zeppegno, C. Gramaglia
Università degli Studi del Piemonte Orientale "A. Avogadro", Translational Medicine, Novara, Italy

* Corresponding author.

Introduction Although several authors found a strong association between childhood trauma and substance abuse disorder, many other suggest that specific personological aspects and resilience may contribute to the development of this disease.

Objectives To compare the characteristics of psychiatric patients with and without dual diagnosis assessing differences in psycho-

logical correlates, such as resilience, coping strategies, self-esteem, temperament, character traits and childhood trauma.

Methods From November 2015 to May 2016, we recruited all patients aged between 18 to 65 years referred to the Psychiatry Ward of "Maggiore della Carità" Hospital in Novara, Italy. Diagnosis of psychiatric disorder was made according to DSM-5 diagnostic criteria. Exclusion criteria were: inability to express a valid informed consent, a personality disorder or mental retardation diagnosis. We administered to each patient: Resilience Scale for Adult (RSA), Brief Cope, Rosenberg Self-esteem Scale (RSES), Childhood Trauma Questionnaire (CTQ), Temperament and Character Inventory (TCI). Patients were subdivided for the analysis into two groups: dual diagnosis and no dual diagnosis (or single diagnosis) group.

Results Data show that dual-diagnosis patients ($n = 40$) had lower global levels of resilience (RSA) and cooperativeness (TCI). Higher novelty seeking and reward dependence traits (TCI) were found as well. Moreover, the lower Cope-Avoidance (Brief Cope) was statistically different among patients with dual diagnosis compared to single diagnosis ones.

Conclusions Identified differences between these two groups could suggest targets to manage during the treatments in order to optimise dual diagnosis patients' outcomes.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Recovery orientation as a key element in addiction treatment: Preliminary results of a patient's survey

G. Eikmeier*, R. von Heugel, A. Lacroix, I. Molkenin, T. Rosenbrock, R. Böttcher, A. Paul, J. Nachtigall
Psychiatry, Klinikum Bremerhaven, Bremerhaven, Germany

* Corresponding author.

"Recovery" in addiction treatment goes far beyond abstinence, but means a self-determined and meaningful life. Although this approach has been implemented in a number of programs, only little research has been carried out on this issue. Within the context of focusing our treatment program for addictive disorders more strongly according to recovery principles, we studied the baseline situation with the Bremerhavener Questionnaire of Treatment Satisfaction (BFPZ). Sixteen items cover different aspects of our traditional qualified inpatient detoxification program as well as recovery principles. Each item can be rated from 0 (strongly disagree) to 3 (strongly agree). Between December 1st 2015 and March 31st 2016, all in house patients with a substance abuse treated for more than 24 hours in the psychiatric department of Klinikum Bremerhaven Reinkenheide were asked to fill in the questionnaire ($n = 201$). Response rate was 35% ($n = 70$). Overall treatment satisfaction was high (mean: $2,57 \pm 0,65$). On the single item level, aspects of empathy and openness were rated best (mean $> 2,3$), while special aspects of personal recovery (choice, hope, life goals, diversity of treatment options) were rated worst (mean $< 2,3$). Eighty-nine percent of the patients wanted to stop their alcohol consumption completely, 2% wanted to break their consumption temporarily and 9% wanted to consume less. Thirty-four percent were interested in additional therapy offers for controlled substance use. The results will be presented in detail and discussed with regard to the implications for recovery-oriented addiction treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Substance-induced psychotic disorders in an emergency department

A. Fernandez-Quintana*, A. Novo-Ponte, C. Quiroga-Fernandez, M.D.C. Garcia-Mahia

Psychiatry, Clinical University Hospital of La Coruña, La Coruña, Spain

* Corresponding author.

Introduction Substance abuse has been correlated with psychotic disorders albeit more accurate details on causality remain to be assessed. Furthermore, the prevalence and prognosis of substance-induced psychotic disorders have not been clearly established.

Method Retrospective study performed in 124 patients assessed in an Emergency Department (ED) due to psychotic symptoms over a 6-month period. Medical records were reviewed to obtain clinical and socio-demographic variables.

Objectives (1) To analyse substance abuse patterns among ED psychotic patients; (2) to estimate the prevalence of substance-induced psychotic disorders in ED; (3) to underpin the socio-demographic and clinical variables associated.

Results Personal history of substance abuse: THC 31.5%, alcohol 29%, cocaine 18.5%, benzodiazepines 18.5%, opiates 6.5%, MDMA 4%, amphetamines 3.2%, hallucinogens 2.4%. Accumulated time interval of substance abuse prior to psychotic onset: 0–5 years 15% (3.9% developed psychosis during the first year of cannabis use), 5–10 years 9.2%, more than 10 years 20.8%. Urine testing for drug misuse undertaken in 80.6% of cases: positives 53%, negatives 47%. Among positive urine test results: THC 16.5%, benzodiazepines 16.5%, cocaine 6.1%, opiates 5.1%, alcohol 0.9%, amphetamines 0.8%, hallucinogens 0.8%. Substance-induced psychotic disorder (F19.15) was diagnosed among 20.4% of patients. This diagnosis was 1.5 times more prevalent among males. Forty-eight percent of patients were single, 36% married, 12% divorced, 4% widowers. Habitat: 68% urban, 34% rural. Highest prevalence group 36 – 50 year olds.

Conclusions Both substance abuse and substance-induced psychotic disorders are highly prevalent in our sample. Their socio-demographic and clinical profile is similar to that found in schizophrenia. Further refinements of these findings are warranted.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cannabis-induced psychotic disorders and THC use among patients with psychotic symptoms

A. Fernandez-Quintana*, C. Quiroga-Fernandez, A. Novo-Ponte, M.D.C. Garcia-Mahia

Psychiatry, Clinical University Hospital of La Coruña, La Coruña, Spain

* Corresponding author.

Introduction Causality between THC and psychotic symptoms has been outlined in several studies and a potential role for THC in the development of Schizophrenia remains to be assessed.

Methods Retrospective study undertaken in a sample of 124 patients assessed in an Emergency Department (ED) due to psychotic symptoms. Medical records were reviewed to obtain clinical and sociodemographic variables.

Objectives (1) To analyse the prevalence of THC consumption among psychotic patients in ED; (2) to establish the prevalence of cannabis-induced psychotic disorder; (3) to underpin the socio-demographic and clinical variables associated with cannabis-induced psychosis.

Results Personal history of cannabis use 31.5% (6.5% as a single drug.) Accumulated time interval of cannabis use prior to the first

psychotic episode: 0 – 5 years 15% (3.9% developed psychosis during the first year of cannabis use), 5 – 10 years 9.2%, more than 10 years 20.8%. Cannabis-induced psychotic disorder (F12.5) was diagnosed in 3.3% of the sample. The prevalence of this diagnosis was the same among male and female patients. The highest prevalence of cannabis-induced psychosis was found among 36–50 years old patients (50%). All patients with a diagnosis of Cannabis-induced psychotic disorder had a personal history of THC use and urine tests had been positive for THC in 75% of the cases. Habitat: 75% urban, 25% rural. Marital status: 50% single, 50% married.

Conclusions Cannabis use is highly prevalent among patients who present with psychotic symptoms in ED and THC is correlated with psychotic episodes. The prevalence of cannabis-induced psychosis has also increased. Further studies comprising larger samples are warranted.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Evolutionary aspects of psychotic disorders induced by cannabis

F. Guermazi*, R. Ennaoui, N. Halouani, S. Chouayakh, J. Aloulou, O. Amami

Psychiatry, Hedi Chaker university hospital, Sfax, Tunisia

* Corresponding author.

Introduction Cannabis is increasingly used by young people. Its several noxious effects on mental health have become a matter of preoccupation. Although cannabis use may be involved in the etiology of acute psychosis, there has been considerable debate about the association observed with chronic psychosis.

Aims (1) To describe the profile of patients with cannabis use disorders (CUD); (2) to determine the evolutionary aspects.

Methods We proceed with a retrospective and descriptive study conducted among 16 male patients with CUD and hospitalised for the first time in the psychiatric department at the University Hospital Hedi Chaker during the period from 1 January 2012 to 31 December 2014.

Results An overwhelming majority of the subjects were single and unemployed. One-third of the users had a stay abroad, the half was incarcerated at least once and one patient was implicated in illegal drugs trade. CUD were associated with specific personality disorders: borderline (18.8%) and antisocial (6.3%) personality. Into at least the 2 years of follow-up, different evolutionary aspects were distinguished. Many of the patients were lost to follow (18.8%). A total restitution of symptoms or a recurrence of the same disorders were observed in 25% of cases. About 56.3% of subjects had a change in diagnosis to either schizophrenia (43.3%) or affective disorder (12.5%).

Conclusion This study showed that cannabis use can be a cause of the emergence of chronic psychosis. This emphasizes the importance of early screening of the vulnerability to psychotic disorder and identify more effective strategies to improve intervention.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Video and Internet gaming addiction among young adults

F. Guermazi*, N. Halouani, K. Yaich, R. Ennaoui, S. Chouayakh, J. Aloulou, O. Amami

Psychiatry, Hedi chaker university hospital, Sfax, Tunisia

* Corresponding author.

Introduction With the popularity of high-tech devices and Internet use in recent years, playing online or offline games has become

a popular activity, among young adults (YA). However, research suggests that excessive engagement may in extreme cases lead to symptoms commonly experienced by substance addicts.

Aims Estimate the prevalence of problematic use of video and Internet games (PUVIG) among YA. Determine the factors associated with it.

Methods A cross-sectional study was carried out during the first half of September 2016. A sample of 69 YA with a high education's level was randomly selected from the general population. Data were collected through a global questionnaire consisted of a sociodemographic part, the Young Internet Addiction Test, the Problem Video Game playing questionnaire, online network game scale and the Perceived Stress Scale.

Results The average age was 27.6 years. The majority (70%) reported using video or Internet games. The risk of dependency to online network games involved 10% of game players while the presence of video games use consequences concerning 16%. Gaming addiction was significantly more likely in boys ($P=0.001$). The students had more PUVIG than employees ($P=0.036$). A link was highlighted with a problematic Internet use ($P=0.008$), a facebook addiction ($P=0.001$) and high perceived stress level (0.014).

Conclusions Playing video and Internet games is a widespread activity among YA. The factors potentially involved are inevitably multiple and complex. It supports the need to carefully explore these emerging practices among this vulnerable population and suggest the establishment of better prevention and better tracking of video gaming.

Does adolescents' depressive symptoms increase the possibility of addictive Internet gaming?: 1-year follow up study in Korea

S.J. Jo^{1,*}, H.W. Yim¹, J. Hyunsuk¹, K. Eunjin¹, S. Hye-Jung¹, L. Hae Koo²

¹ Department of Preventive Medicine, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

* Corresponding author.

Introduction Adolescents' Internet gaming disorders might influence on their social and psychological developmental tasks and physical health negatively. Depression is the commonly co-existed conditions with addictive Internet gaming, but not much research has been reported whether depressive symptoms would precede the addictive Internet gaming in this population.

Objectives This prospective observation study was performed to make clear whether adolescents' depressive symptoms precede their addictive Internet gaming.

Aims Adolescents' 1-year incidence of the addictive Internet gaming was calculated, and test their depressive symptoms increase the incidence.

Methods In Korea, whole students of the 1st grade in three middle schools were participated in this study. Baseline assessment of 508 students was performed via standardized self-reported questionnaire on May–June, 2015. Internet game use-elicited symptom screen (IGUESS) was used to addictive Internet gaming conditions. IGUESS is the 9-itemed DSM-5 diagnostic criteria-based instrument to screen high risk of Internet gaming disorders. Depressive symptoms was measured by Child Depression Inventory (CDI) group. One year after the baseline assessment, follow-up assessment was performed. Four hundred and forty-eight students have been par-

ticipated in the 1-year check up without addictive Internet gaming at baseline.

Results In total, 4.7% of subjects had depressive symptoms at baseline, and incidence of addictive Internet gaming was 9.2%. After adjusted by sex, Internet game use per week, and self-control status, depressive symptoms of baseline increased the 1-year incidence of addictive Internet gaming significantly (OR=3.5, $P=0.034$).

Conclusions Depressive adolescents have higher possibility they could experience the addictive Internet gaming.

² Health Sciences Research, Mayo Clinic, Rochester, USA

³ Psychiatry and Psychology, Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic, Rochester, USA

⁴ Health Sciences Research, Psychiatry and Psychology, Mayo Clinic, Rochester, USA

* Corresponding author.

Background Psychiatric co-morbidities and alcohol craving are known contributors to differences in alcohol consumption patterns.

Methods Univariate and multivariable linear regression models were used to examine the association and interactions between the Inventory of Drug Taking Situations (IDTS) negative, positive and temptation sub-scale scores, sex, as well as co-morbid depression and anxiety determined by Psychiatric Research Interview of Substance and Mood Disorders (PRISM) with alcohol consumption measured by Time Line Follow Back (TLFB) during preceding 90 days in 287 males and 156 females meeting DSM-IV criteria for alcohol dependence.

Results IDTS positive, negative and temptation scores were strongly associated with increased alcohol consumption measures including the number of drinks per day and number of drinking days per week ($P<0.0001$). Male sex was associated with higher amount of alcohol consumption per drinking day ($P<0.001$), but not with the number of drinking days per week ($P>0.05$). In men, lifetime history of depression was associated with fewer drinking days ($P=0.0084$) and fewer hazardous drinking days ($P=0.0214$) but not with differences in daily alcohol consumption. In women, depression history was not significantly associated with alcohol consumption measures. Post-hoc sex-stratified analyses suggested that the association of the negative IDTS score with total amount of alcohol consumed by men may be modified (decreased) by lifetime depression history. We found no associations of alcohol consumption measures with anxiety or substance-induced depression.

Discussion Decreased frequency of drinking in male alcoholics with lifetime depression history is unexpected. This finding emphasizes the complex relationships between alcoholism and depression, which require further investigation.

FKBP5 modulates the effects of nicotine on hpa axis activity in females

A. Koopmann*, F. Kiefer

Department of Addictive Behaviour and Addiction Medicine
Mannheim, Central Institute of Mental health, Mannheim, Germany

* Corresponding author.

Background FK506 binding protein 51 is a modulator of the hypothalamic-pituitary-adrenal axis activity. Its function is modulated by the single nucleotide polymorphism rs 1360780. Females often use smoking to cope with stress. The aim of this study was to investigate if the influence of nicotine consumption on cortisol plasma levels is modified by the polymorphism of rs 1360780 in females.

Methods Two hundred and ninety-six female smokers were genotyped for the SNP rs1360780 of FKBP5 protein. Cortisol plasma concentrations were measured in blood plasma drawn three hours after smoking. Severity of tobacco addiction was assessed based on the Fagerström Test for Nicotine Dependence (FTND).

Results Thirty-six participants were TT-homozygotes and 260 were C allele carriers. In TT homozygotes, we found a significant negative correlation between the FTND sum score and the cortisol plasma concentrations. In a linear regression analysis, the FTND sum score accounts for 12.4% of the variance of cortisol plasma levels. By contrast, we could not find such an association in C allele carriers.

Conclusions Our results suggest that nicotine is an important confounder in the modulation of HPA axis activity by FKBP5. In the light of these findings, future studies on FKBP5 should include nicotine consumption as a confounder.

Influence of impulsivity during decision-making in regular cannabis users

V. Laprevote^{1,*}, A.L. Devin², B. Blanc³, R. Schwan¹

¹ Psychiatric University Clinic of Grand Nancy, CPN Nancy, Laxou, France

² Université de Lorraine, EPSaM- EA4360 APEMAC, Metz, France

³ Addiction Medicine Department, CH Jury, Metz, France

* Corresponding author.

Introduction Regular cannabis use is associated with cognitive impairments, including impaired decision making measured by the Iowa Gambling Task. The question remains whether the impulsivity measured in regular cannabis users may participate to impaired decision making. Interestingly, the Cambridge Gambling Task (CGT) is a computerized gambling task allows to differentiate risk taking and impulsivity when making a decision.

Aims This study aims at separately exploring the impact of regular cannabis use on risk taking and impulsivity during decision making process.

Objectives To do so, we compared the performance of regular cannabis users and healthy controls during the CGT.

Methods Forty-three regular cannabis users (>7 units/week) with a cannabis use disorder (CUD), 8 non-CUD regular cannabis users and 30 healthy controls were recruited. Decision-making was assessed using the CGT. The following outcomes were considered: Delay aversion score, Overall proportion bet, quality of decision making, risk taking and risk adjustment.

Results The analysis on delay aversion score showed a group effect ($F=3.839$, $P=0.026$) but no effect on other CGT variables. This effect was explained by the fact that cannabis CUD users had

a higher delay aversion score than healthy controls and non-CUD cannabis users.

Conclusions In this study, CUD cannabis users had an increased impulsivity but no increase of risk taking and quality of decision-making. Future work should include the CGT with a clinical scale to evaluate impulsivity and a motor inhibition task to understand if the impairment observed relates to cognitive or motor abilities.

⁶ Orthopaedic Research Unit, Odense University Hospital, Odense, Denmark

* Corresponding author.

Introduction Exercise addiction is characterized by compulsive and excessive exercise patterns that eventually can lead to musculoskeletal injury. While exercise leads to increased self-esteem and is a useful tool for emotional regulation, the level of psychosocial distress may be negatively affected by such injuries.

Objectives The prevalence proportions of post-injury depression and emotional stress in athletes with exercise addiction have not previously been explored and compared to non-addicted athletes.

Aims We wanted to test the hypothesis that athletes with addiction profiles react to injury with higher levels of emotional and social distress compared to athletes without addiction.

Methods A cross-sectional survey was employed and a total of 1167 athletes (673 with diagnosed musculoskeletal injuries and 494 without present injury) responded to the following questionnaires: The Exercise Addiction Inventory, The Major Depression Inventory, The Perceived Stress Scale and EQ-5D to assess quality of life.

Results We found that 26% of the injured athletes with exercise addiction had symptoms of major depression and 53% reported emotional distress. These proportions were significantly greater compared with the injured non-addicted athletes where 11% had symptoms of major depression and 28% reported stress. Quality of life was also significantly reduced in the addiction group.

Conclusions Injured athletes with exercise addiction report more post-injury psychosocial distress compared with injured non-addicted exercisers. Future trials need to investigate the effect of emotional assessment and support as a complement intervention to somatic injury treatment. Injured athletes should be examined for exercise addiction as they are at risk of depression.

Use of novel psychoactive substances and induced psychiatric symptoms: Outcomes from the Eivissa Project

G. Martinotti^{1,*}, C. Montemitto¹, M. Corbo¹, F. Sarchione¹, E. Cinosi¹, A. Pasquini¹, V. Mancini¹, C. Merino del Villar²

¹ Neuroscience and Imaging, University G. d'Annunzio, Chieti, Italy

² Department of Psychiatry, Hospital Can Misses, Ibiza, Spain

* Corresponding author.

Introduction Polydrug abuse seems to be especially popular in Ibiza, an important market for new psychoactive substances (NPS). The misuse of psychoactive substances can lead to serious psychiatric symptoms.

Aims To evaluate symptoms induced by NPSs and other club drugs, correlating with the main classes of drugs.

Methods Ninety subjects (M/F 59/31) admitted in the Psychiatric Unit of Can Misses Hospital (Ibiza) referring a recent intake of substances were enrolled. The following scales were administered: TLFB (Timeline follow-back); Positive and Negative Symptoms Scale (PANSS); Symptom checklist-90 (SCL-90); Young Mania Rating Scale (YMRS); Hamilton Depression Scale (HAM-D); Hamilton Anxiety Scale (HAM-A); Modified Overt Aggression Scale (MOAS); Columbia Suicide Severity Rating Scale (C-SSRS).

Results Polydrug abuse was reported by 67.4% of the sample; the sample was grouped by the main preferred substance in THC-, stimulants-, and depressors-users. The majority of patients reported a previous psychiatric history. Positive symptoms resulted to be higher among THC-users ($P < .05$). Anxiety evaluated by SCL-90 was prevalent in the group of Depressors-users ($P < .05$). The scores of MOAS and SCL-90 subscale for hostility/aggression resulted to be significantly ($P < .01$) greater in the THC-users group.

Conclusions Some specific psychiatric symptoms are characteristic of some classes of substances and may help to identify them when a urine sample is not available. The possibility to develop psychiatric symptoms after a recent drug use is more common in two situations: (1) patients with a previous psychiatric history; (2) subjects with a history of very strong substance use.

* Corresponding author.

Introduction After analysis of biological and pharmacological data, we formulated the hypothesis that the factors involved in

trafficking of stem cells could be engaged in aetiology of bipolar disorder (BP).

Aims In this study, we considered the role of complement cascade proteins, stromal derived factor-1 (SDF-1), and sphingosine-1-phosphate (S1P) in long-term treated BP.

Methods A group of 30 patients with BP, without the history of lithium treatment, was examined in remission and compared with a group of 30 healthy volunteers. In peripheral blood, we have analysed the concentration of stromal derived factor-1 (SDF-1), sphingosine-1-phosphate (S1P), and some proteins of the complement cascade (C3a, C5a, C5b-9).

Results Peripheral blood concentration of C3a, C5a, C5b-9 and SDF-1 was significantly higher in BP group compared to control group. The concentration of S1P does not distinguish BP patients from controls.

Conclusion Our results suggest the possible role of the regeneration system in aetiology of BP.

Five-year course of bipolar disorder following treatment of first manic episode with risperidone versus olanzapine: A retrospective review

K. Kulkarni*, G. Devasthali, A. Purty, M. Kesavan, J. Reddy, S. Jain

Psychiatry, National Institute of Mental Health & Neurosciences, Bangalore, India

* Corresponding author.

Objective Contemporary treatment guidelines recommend use of second-generation antipsychotics (SGAs) either as mono therapy or in combination with mood stabilizers as first-line treatment. While these drugs have been established to have superior efficacy compared to placebo, there is very less data comparing these antipsychotics with one another. We sought to study differences in the five-year outcome of first episode of mania (FEM) treated with olanzapine or risperidone, either alone or in combination with mood stabilizer.

Methods We conducted a retrospective chart review of patients diagnosed with FEM (ICD-10) in the year 2008 ($n = 88$) at our centre. We selected the data of patients prescribed either olanzapine or risperidone for the purpose of this analysis. We extracted data about time to recovery and recurrence after FEM, total episodes, drug compliance and response, and number of follow-up visits from 2008 to 2013. The study was approved by the Institute Ethics Committee.

Results A total of 88 patients received diagnosis of FEM in the year 2008, of which 50 (56.8%) received risperidone and 35 (39.8%) received olanzapine. The two groups were comparable in socio-demographic and clinical symptomatology of FEM (all $P > 0.08$). Complete recovery was significantly more in the olanzapine group than the risperidone group ($\chi^2 = 4.84$, $P < 0.05$).

Conclusion Our study indicates that risperidone and olanzapine, either alone or in combination with mood stabilizers have a similar impact on the five-year course of BD following a first manic episode. However, olanzapine is associated with more complete recovery from FEM than risperidone.

Bipolar disorder, obesity and cognitive impairment

M. La Montagna^{1,*}, E. Stella¹, F. Ricci¹, L. Borraccino¹, A.I. Triggiani², F. Panza³, D. Seripa³, G. Miscio³, A. Bellomo¹, M. Lozupone¹

¹ University of Foggia, Department of Mental Health, Foggia, Italy

² Laboratory of Physiology- University of Foggia, Department of Clinical and Experimental Medicine, Foggia, Italy

³ IRCCS Casa Sollievo della Sofferenza, Department of Medical Sciences, San Giovanni Rotondo, Italy

* Corresponding author.

Introduction According to scientific literature, cognitive impairment is a disabling feature of the bipolar disorder (BD), present in all the phases of the disease. Obesity and metabolic disorders represent another risk factor for cognitive dysfunctions in BD, since the excess of weight could adversely influence several cognitive domains.

Objective To highlight the presence of impairment of cognitive functions in a sample of subjects suffering from BD and obesity.

Aims Evaluation of the cognitive performance in a sample of BD patients, considering their anthropometric measures (height and weight) and body mass index (BMI).

Methods The neuropsychological battery MATRICS Consensus Cognitive Battery (MCCB) was administered by trained physicians for the evaluation of seven different cognitive domains in 46 patients (mean age: 43.17 years old; 39.13% male), affected by BD enrolled in the psychiatric unit of Azienda Sanitaria Locale and University of Foggia. In particular, cognitive functions assessed were speed of processing, attention/vigilance, working memory, verbal learning, visual learning, reasoning and problem solving, and social cognition. BMI was calculated, and patients were divided into a group of normal weight and another one of overweight or obese, on the base of BMI value (BMI cut-off = 25).

Results The obese patients amounted at 56.52%. We have found the presence of cognitive deficits in two of the seven domains assessed, that are speed of processing ($P < 0.01$) and reasoning and problem solving ($P < 0.05$) in the sample of overweight patients.

Conclusions Cognitive deficits are clearly revealed in BD patients during the euthymic phase of the disorder. The obesity in BD could contribute to increase dysfunctions in cognitive domains.

Concordance and discrepancy between subjective and objective cognitive assessment in bipolar disorder: What is influencing this discrepancy?

F. Lima^{1,*}, T. Cardoso¹, C. Bonnin², A. Martinez-Aran², E. Vieta², A. Rosa³

¹ Universidade Federal do Rio Grande do Sul, Postgraduate Program in Psychiatry and Behavioral Sciences, Porto Alegre, Brazil

² University of Barcelona, Bipolar Disorders Program, Barcelona, Spain

³ Universidade Federal do Rio Grande do Sul, Department of Pharmacology, Porto Alegre, Brazil

* Corresponding author.

Introduction Evidence has shown that some patients with bipolar disorder have a relatively accurate sense of their cognitive abilities, whereas others may overreported or underreported cognitive difficulties, which causes a discrepancy in this measures.

Objectives To investigate concordance and discrepancy between subjective and objective cognitive measures, as well as to identify factors that could influence this discrepancy.

Methods Patients who met DSM IV-TR criteria for bipolar disorder in partial or full remission (HDRS-17 score ≤ 12 ; YMRS score ≤ 7) were recruited from outpatient clinic at Barcelona and Porto Alegre. Objective cognitive assessment was performed by the Letter-Number Sequencing (LNS-WAIS III). Cognitive Complaints in Bipolar Disorder Rating Scale (COBRA) was used as a subjective cognitive measure.

Results Were included 179 patients. We found a concordance between COBRA and LNS in 62 cases, and discrepancy in 117 cases (Fig. 1). The incongruent group (COBRA-and LNS+) have less years of study (8.10 ± 4.01) than the incongruent group (COBRA+ and LNS-) (13.44 ± 4.05 , $P = 0.001$), and than congruent group (COBRA-and LNS-) (13.75 ± 4.04 , $P = 0.003$). Finally, the congruent group (COBRA+ and LNS+) was the group with higher functioning impairment.

Conclusions A few number of false-negative cases were detected, suggesting that COBRA can be used as a screening instrument. A special attention should be provided for subjects with a few years of study, because possibly these subjects presents more difficulty in express its cognitive difficulties.

Figure 1 Concordance and discrepancy between subjective and objective assessment in bipolar disorder. Legend: LNS: Letter-number sequencing; COBRA: Cognitive Complaints in Bipolar Disorder Rating Scale; FAST: Functional Assessment Short Test. *Difference is statistically significant for the comparison between COBRA+ LNS+ and COBRA-LNS+ ($P = 0.011$), for the comparison between COBRA+ LNS+ and COBRA-LNS- ($P = 0.004$), and for the comparison between COBRA+ LNS- and COBRA-LNS- ($P = 0.039$).

Typical and atypical antipsychotics in acute mania: Comparison of effectiveness

C.R. Medici^{1,2,3,*}, L.M. Kai², S.B. Kristensen⁴, C. Kirkedal^{1,2}, S.P.V. Straszek¹

¹ Aarhus University Hospital, Department of Affective Disorders, Aarhus, Denmark

² Aarhus University Hospital, Psychiatric Research Academy, Department of Affective Disorders, Aarhus, Denmark

³ Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus, Denmark

⁴ Aarhus University, Section of Biostatistics, Aarhus, Denmark

* Corresponding author.

Introduction Mania is challenging to treat. Typical antipsychotics may be more efficient compared with atypical antipsychotics, however, with unfavourable side effects.

Objectives To help the clinician choose between typical and atypical antipsychotics.

Aims To investigate the correlation between change in severity of mania and the corresponding day to day use of typical and atypical antipsychotics.

Methods This retrospective case record study included patients admitted with mania (International Classification of Diseases 10th revision code F30, F31.0, F31.1, F31.2 or F31.6) at the Department of Affective Disorders, Aarhus University Hospital, Denmark, between January 2013, and December 2015. The dose of typical and atypical antipsychotics was standardized as defined daily dose according to the World Health Organization's guidelines. The severity of mania was measured daily with the Modified Bech-Rafaelsen Mania Scale (MAS-M), a validated, nurse administered scale (MAS-M). We applied a linear regression in a mixed model approach to compare the Mas-M score over time under the influence of typical and atypical antipsychotics, respectively, adjusted for baseline characteristics.

Results We included 43 patients. Patients receiving typical antipsychotics had more recent hospital admissions, a higher dosage antipsychotics and more constraint. The baseline MAS-M score was higher in patients receiving typical antipsychotics. The daily change in MAS-M score was -0.25 for typical antipsychotics and -0.23 for atypical antipsychotics with a difference of 0.02 (95% CI $0.008-0.039$).

Conclusions The rate of improvement of mania may be independent of baseline illness or type of antipsychotic medication. This may be confounded by indication.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Neuropsychological differences between bipolar and borderline personality disorder patients

I. Michopoulos^{1,*}, K. Tournikioti¹, R. Gournellis¹, P. Ferentinos¹, K. Vassilopoulou¹, A. Karavia¹, M. Papadopoulou², A. Douzenis¹

¹ National and Kapodistrian University of Athens, Medical School, 2nd Department of Psychiatry, "Attikon" Hospital, Athens, Greece

² Ygeias Melathron" Hospital, Department of Neurology, Athens, Greece

* Corresponding author.

Introduction There is a continuing debate about the differences and similarities between bipolar disorder (BD) and borderline personality disorder (BPD).

Objectives Only few studies have focused on the neuropsychological profile of these two disorders.

Aims We studied the differences on memory, executive function and inhibitory control between BD and BPD patients.

Methods Twenty-nine patients with BD in euthymia, 27 patients with BPD and 22 healthy controls matched for age and education were included in the study. All of them were female. BD patients who could also be diagnosed with BPD were excluded from the study. Participants were administered a series of tests from the Cambridge Neuropsychological Test Automated Battery (CANTAB), assessing memory, executive function and inhibitory control.

Results BD and BPD patients performed worse than controls in general. Significant differences were found in the PAL test; BD patients had 46.71, BPD patients had 36.56 and controls had 15.77 errors ($P=0.004$). BPD patients performed worse in the IE/ED set-shifting test; they made 48.16 errors while BD patients made 23.64 and controls 16.14 ($P=0.001$). BPD patients performed better in the

problem-solving task (SOC), they solved 10.0, BD patients 6.32 and controls 8.32 problems ($P<0.001$).

BD and BPD patients had similar performance in the SST inhibition task but worse than controls ($P=0.03$).

Conclusions BD and BPD seem to have differences in neuropsychological performance. BD patients show more deficits in memory learning and problem solving while BPD patients show more deficits in set shifting.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ School of Medicine, Department of Pathophysiology, Kragujevac, Serbia

* Corresponding author.

Introduction Immune parameters are frequently associated with mood disorders and affective temperaments. In our study, we investigate the role of soluble intercellular adhesion molecule-1 (sICAM-1) in affective temperaments and mood symptoms in healthy adults.

Methods Healthy adults were screened for psychiatric disorders using the non-patient version of the Structured Clinical Interview for DSM-IV-I and II. Affective temperaments were evaluated with Temperament Evaluation of Memphis, Pisa, Paris and San Diego-Autoquestionnaire (TEMPA). State mood symptoms were assessed using the Young Mania Rating Scale (YMRS) and Montgomery-Åsberg Depression Rating Scale (MADRS). Serum sICAM-1 levels were measured using enzyme-linked immunosorbent assay.

Results We identified no association between sICAM-1 levels and affective temperament scores. We identified correlation between sICAM-1 levels and manic symptoms measured by YMRS. Furthermore, sICAM-1 was a significant predictor of manic symptoms in a linear regression model with age, gender, BMI and smoking habits as confounding variables.

Conclusions Our findings suggest that sICAM-1 could be a relevant immune factor for severity of state affective symptoms and could contribute to better understanding of complexity of affective disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The association between school achievement and subsequent development of bipolar disorder

S.D. Pedersen^{1,*}, L. Petersen², O. Mors¹, S.D. Østergaard¹

¹ Aarhus University Hospital, Department of Clinical Medicine-Psychosis Research Unit, Risskov, Denmark

² National Centre for Register-based Research, Department of Economics and Business Economics, Aarhus BSS, Aarhus, Denmark

* Corresponding author.

Introduction Prior studies have indicated that both high and low school achievement are associated with development of bipolar disorder (BD). We believe that the latter association may be due to the confounding effect of family history of mental disorder.

Objective To further investigate the association between school achievement and subsequent development of BD by adding adjustment for family history of mental disorder.

Methods We are conducting a historical prospective cohort study based on data from nationwide Danish registers. The cohort consists of all individuals born in Denmark 1986–97 of Danish-born parents, who were alive and living in Denmark at age 16 years, and who have completed final examinations in 9th grade between 2002 and 2014 ($n = 578,247$). The cohort members will be followed until death, emigration, development of bipolar disorder, or end of study, whichever comes first. Hazard rate ratios for bipolar disorder will be calculated in a Cox model using the z-score for examination grades as unit of exposure. The regression analyses will be adjusted for a series of potential confounders including family history of mental disorder.

Results We expect to find a positive association between high school achievement and development of BD. In contrast, we expect to demonstrate that the association between low school achievement and BD detected in prior studies is due to confounding by family history of mental disorder. The results will be shown at the conference.

Conclusions By further testing the potential link between emigration and BD, we hope to contribute to a more balanced perception of BD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Emotional deficits in remitted bipolar and schizoaffective patients

R.S. Romosan*, A.M. Romosan, L.M. Ienciu, L. Dehelean, A.C. Bredicean

“Victor Babes” University of Medicine and Pharmacy, Neuroscience, Timisoara, Romania

* Corresponding author.

Introduction Both bipolar and schizoaffective patients have deficient social skills persisting even during the remission of the clinical symptoms. These deficits may represent impediments for the social reintegration and recovery of these patients.

Objectives The purpose of the study was to assess and compare emotion recognition abilities of schizoaffective and bipolar patients during remission.

Methods The study was conducted between 2014 and 2016 on remitted outpatients, diagnosed with either bipolar disorder ($n = 38$) or schizoaffective disorder ($n = 32$), according to ICD 10 criteria, and a healthy control group ($n = 65$). In order to evaluate patients' ability of understanding the emotional expressions of other people, we used the revised version of the “Reading the Mind in the Eyes” test (“Eyes test”).

Results The patient group consisted of 41 (58.6%) women and 29 (41.4%) men, with a mean age of 43.57 years ($SD = 10.56$). The control group was comprised of 25 males (38.5%) and 40 females (61.5%), with a mean age of 42.03 years ($SD = 11.07$). We found statistically significant differences ($P = 0.003$) between the patient groups and the control group regarding emotion recognition abilities (poorer emotion recognition skills than the control group in both bipolar and schizoaffective patients). Patients with schizoaffective disorder gave significantly more incorrect answers in the “Eyes test” than bipolar patients ($P = 0.015$). Although not statistically significant, women had better emotion recognition abilities than men, both in the patient sample and the control group.

Conclusions Schizoaffective patients have more severe emotional deficits than bipolar patients during euthymic periods.

Lurasidone adjunctive to lithium or valproate for prevention of recurrence in patients with bipolar I disorder

J. Calabrese¹, A. Pikalov^{2,*}, J. Cucchiario², Y. Mao², A. Loebel²

¹ Case Western Reserve University, University Hospitals Case Medical Center, Cleveland, USA

² Sunovion Pharmaceuticals Inc., Medical Affairs, Fort Lee, USA

* Corresponding author.

Introduction Information is not available on the maintenance efficacy of lurasidone in bipolar disorder.

Objectives/aims To evaluate the recurrence prevention efficacy of lurasidone plus lithium (Li) or valproate (VPA) for the maintenance treatment of bipolar disorder.

Methods Patients with bipolar I disorder received up to 20 weeks of open-label lurasidone (20–80 mg/d) plus Li or VPA. Patients who achieved consistent clinical stability were randomized to 28 weeks of double-blind treatment with lurasidone (20–80 mg/d) or placebo, plus Li or VPA.

Results A total of 496 patients met stabilization criteria and were randomized to adjunctive lurasidone vs. placebo. Fewer patients in the lurasidone group had recurrence of any mood episode compared with the placebo group, with a hazard ratio of 0.71 ($P = 0.078$). In pre-planned secondary analyses, recurrence rates were significantly lower for the lurasidone group treated with a modal open-label dose of 80 mg/d (hazard ratio [HR], 0.35; $P = 0.020$); when patients presented with an index episode of depression (HR = 0.57; $P = 0.039$); and when outcome was time-to-all-cause discontinuation (HR = 0.72; $P = 0.034$), or time-to-recurrence based on symptom severity criteria (HR = 0.53; $P = 0.025$).

Conclusions In patients stabilized on lurasidone plus Li or VPA, continued treatment was associated with non-significant reduction in risk of recurrence of any mood disorder (primary). Consistent with dose-response effects observed during acute treatment of bipolar depression, risk of recurrence on lurasidone was significantly reduced after open-label treatment with the 80 mg/d dose, and in the 20–80 mg/d dose in patients presenting with an index episode of depression.

Clinicaltrials.gov: NCT01358357.

Exploring the complex association between affective temperaments and suicidal behaviour

G. Serafini^{1,*}, G. Canepa¹, G. Adavastro¹, M. Pompili², P. Girardi³, M. Amore¹

¹ University of Genoa, Neuroscience DINOGMI, Genoa, Italy

² Sant'Andrea Hospital- Suicide Prevention Center, Sapienza University of Rome, Neurosciences, Rome, Italy

³ Sant'Andrea Hospital, Sapienza University of Rome, Neurosciences, Rome, Italy

* Corresponding author.

Introduction Suicidal behaviour is one of the most relevant public health problems and it is associated with a significant disability and psychosocial impairment. Affective temperaments, hopelessness, suicidal ideation, and suicide intent may be significantly involved in suicidal behaviour.

Objectives The present study explored the complex relation between these clinical variables and suicide.

Aims We aimed to evaluate the specific role of affective temperaments and other risk factors as potential predictors of suicide risk.

Methods The sample included 276 patients (19.9% men, 81.1% women; mean age: 48.1 years, SD:16.9), of which most with major affective disorders, who were admitted at the Psychiatric Unit of the University of Genoa (Italy). All participants have been evaluated using the Temperament Evaluation of Memphis, Pisa and San Diego Auto-questionnaire (TEMPS-a), Beck Hopelessness scale (BHS), Scale for Suicide Ideation (SSI), and Intent Score Scale (ISS).

Results Patients with anxious temperament significantly differ in terms of residual interepisodic symptoms, substances abuse, adherence to treatment, and current episode duration when compared with those having other affective temperaments. Only suicidal ideation and irritable temperament resulted significant predictors of suicide preparation. In addition, suicidal ideation and prior suicide attempts represent significant predictors of suicide intent.

Conclusions The present findings suggest the importance of systematic evaluation for suicidal behaviour that may allow clinicians to identify patients at higher suicide risk. As these data may be influenced by the severity of the psychopathological conditions and psychiatric medications, which were used during admission by our patients, further additional studies are needed to test these preliminary findings.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Childhood traumatic experiences and coping strategies: Correlations with quality of life

G. Serafini^{1,*}, C. Conigliaro¹, F. Pittaluga¹, M. Pompili², P. Girardi³, M. Amore¹

¹ University of Genoa, Neuroscience DINOGMI, Genoa, Italy

² Sant'Andrea Hospital, Suicide Prevention Center, Sapienza University of Rome, Neurosciences, Rome, Italy

³ Sant'Andrea Hospital, Sapienza University of Rome, Neurosciences, Rome, Italy

* Corresponding author.

Introduction Individuals with a history of childhood traumatic experiences may exert maladaptive coping strategies and impaired adult quality of life.

Objectives The present study explored the association between childhood traumatic experiences, coping strategies, and quality of life.

Aims We aimed to evaluate whether childhood traumatic experiences or specific coping strategies may significantly predict quality of life.

Methods This is a cross-sectional study including 276 patients (19.9% men, 81.1% women; mean age: 48.1 years, SD: 16.9), of which most with major affective disorders, who were recruited at the psychiatric unit of the university of Genoa (Italy). All participants were assessed using the Childhood Trauma Questionnaire (CTQ), Coping Orientation to Problems Experienced (COPE), and Short Form 12 Health Survey version 2 (SF-12).

Results Subjects with a history of emotional abuse were more likely to have an earlier age of onset of their psychiatric conditions, an earlier age of their first treatment/hospitalization, higher recurrent episodes and days of hospitalization, longer illness duration and non-psychiatric treatments at intake when compared with those who did not present any history of abuse. Based on regression analyses, only positive reinterpretation and growth, focus on and venting of emotions, and substance abuse, but not childhood traumatic experiences, resulted positive predictors of physical quality of life. Moreover, focus on and venting of emotions was able to predict mental quality of life.

Conclusions While traumatic experiences did not predict quality of life, specific coping strategies were significant predictors of quality of life. Further studies are requested to test these preliminary results.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Platelet and plasmatic lipidic profile as potential marker of bipolar disorders: Preliminary findings

L. Sideli^{1,*}, A. Mule¹, F. Damiani¹, M. Corso¹, S. Montana¹, M. Caprin¹, G. Colli¹, S. Di Giacomo¹, D. Catalano², M. Greco², F. Di Gaudio², D. La Barbera¹

² Medical Biotechnologies and Legal Medicine, University of Palermo, Palermo, Italy

* Corresponding author.

Introduction Although the diagnosis of bipolar disorder is currently based on clinical criteria, preliminary studies showed that palmitic and arachidonic acid levels are able to discriminate adult patients with major depressive disorder (MDD) from those with bipolar disorder (BD).

Objectives To replicate and to expand previous findings by investigating the relation between mood disorders and platelet and plasmatic fatty levels.

Aims To compare the lipidic profile of individuals with different mood disorder (MDD vs. BD) and to investigate the relation with specific clinical features (duration of illness, attempted suicide, psychotic symptoms).

Methods Potential participants were recruited from the outpatient and inpatient psychiatric units of the university hospital of Palermo (Italy). Diagnosis of DSM IV mood disorders was made using the MINI. Symptom severity was assessed using the HAM-D rating scale and the YMRS. Fatty acid profile was analyzed using mass spectrometry.

Results Preliminary analyses were performed on 8 patients with MDD and 6 with BD. Groups were similar in terms of demographic variables. Patients with MDD showed highest levels of platelet palmitic acid, stearic acid, and arachidonic acid. Furthermore, plasmatic docosahexaenoic acid was negatively related with manic symptoms severity ($Rho = -0.697$; $P = 0.025$) and platelet alpha linolenic acid was positively related with illness duration ($Rho = 0.845$; $P = 0.040$).

Conclusions These preliminary findings suggest that platelet fatty acids may be possible biological markers to improve the diagnosis of BD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Bipolar disorder in epilepsy

N. Sivakova^{1,*}, G. Mazo², L. Lipatova¹

¹ St. Petersburg Psychoneurological Research Institute named after V.M. Bekhterev, the Department of epilepsy, Saint Petersburg, Russia

² St. Petersburg Psychoneurological Research Institute named after V.M. Bekhterev, the Department psychopharmacology and pharmacotherapy of patients with resistant conditions with a group of endocrinology Psychiatry, Saint Petersburg, Russia

* Corresponding author.

Introduction Bipolar disorder (BD) and epilepsy are the chronic recurrent diseases with several similarities in pathogenic mechanisms. There are high prevalence of comorbidity between affective disorders and epilepsy. However, most recent studies focused on association epilepsy with depression, while lack of scientific data about relationship between epilepsy and BD.

Objectives This study examined the frequency of bipolar disorder in epileptic patients.

Aims To improve the diagnostic tool for BD in epileptic patients.

Materials and methods We observed 50 patients with epilepsy (PE). In this study, the symptoms of BD were measured by the Hypomania Checklist-32 (HCL-32).

Results The mean age of the entire cohort was 40 (SD=19.2) years. The proportion of females were 62%. The mean score using HCL-32 were 11.1 (SD=4.5, range: 3–20) with 17 (34%) scoring above 14, the cut-off points for the basic version of the HCL-32. Among of high score subgroup there were 6 men and 11 women, maximum age was 74 and minimum 19, the mean age of the subgroup were 37 years. The patients 8 out of 17 (47%) received a score of 20 or more (maximum of 37) on the bipolar index that corresponds to $\geq 20\%$ probability BD.

Conclusion The results of the study observed a high prevalence of BD in PE. Future research addressing (1) using of psychiatric examination instruments to assess affective symptoms among PE and (2) treatment management of affective symptoms by antiepileptic drugs might result in better treatment outcomes among patient with comorbidities of BD and PE.

Introduction Age of onset of illness may be useful in explaining the heterogeneity among older bipolar patients.

Objective To examine the relationship of age of onset with clinical, demographic and behavioral variables, in older patients with bipolar disorder.

Methods This was a cross-sectional, descriptive and analytical study, including 24 patients suffering from bipolar disorders, aged 65 years or more and followed-up in outpatient psychiatry unit

at Hedi Chaker university hospital in Sfax in Tunisia. We used a standardized questionnaire including socio-demographic, behavioral and clinical data. Age of onset was split at age 40 years into early-onset (<40 years; $n = 12$) and late-onset (≥ 40 years; $n = 12$) groups.

Results The mean age for the entire sample was 68.95 years. The mean age of onset was 39.95 years. The majority (60%) of patients were diagnosed with bipolar I. Few meaningful differences emerged between early-onset and late-onset groups, except that tobacco use was significantly higher in the late-onset group (66.6% vs. 16.6%; $P = 0.027$). No significant differences between the early-onset and late-onset groups were seen on demographic variables, family history and number of medical diagnoses or presence of psychotic features.

Conclusion Our study found few meaningful behavioral differences between early versus late age at onset in older adults with bipolar disorder.

Cultural variations in bipolar disorders in non-clinical samples

H. Aldos, H. Meray, A. Soliman*

Qatar University, Social Sciences Department, Doha, Qatar

* Corresponding author.

Introduction The prevalence of bipolar disorder (BD) is continuously increasing worldwide. Based on pathophysiological prospective, BD is related to the change in neural circuitry involved in the regulation of emotion. Since there is a cultural variation in emotion expression, it is expected that BD is subject to cultural differences. The literature suggests that the prevalence of BD is influenced by gender, region and ethnicity.

Objectives Exploring the pervasiveness of BD in the Arab cultures. **Aims** – exploring the pervasiveness of BD in six different but related Arab cultures;

– examining the gender differences in BD in the Arab cultural context.

Methods This study used 327 freshmen university students (42% males and 58% females) from six different Arab universities and administered the Mood Disorder Questionnaire (MDQ). The validity and reliability of the MDQ was measured on 220 Qatari university students.

Results The results showed that BD was positively related to age and that males exhibited greater BD symptoms than females. The MDQ scores varied between the Arab subcultures. Sudanese subjects scored the highest on the MDQ, and therefore showed the highest numbers of BD characteristics, followed by Palestinians, Egyptians, Yemenis, Qataris, Jordanians and Tunisians. The Tunisians exhibited the lowest BD symptoms among six Arab cultures.

Conclusions The findings suggested that it is arguable that BD is sensitive to cultural variations in the Arab world, with males showing a higher number of bipolar symptoms. It is arguable that BD is influenced by cultural openness and socioeconomic status.

³ IRCCS Casa Sollievo della Sofferenza, Department of Medical Sciences, San Giovanni Rotondo, Italy

* Corresponding author.

Introduction Cognitive dysfunctions concerning working memory, attention, psychomotor speed, and verbal memory are a disabling feature of the bipolar disorder (BD). According to scientific literature, cognitive disturbances are present not only in depressive and manic phases of BD, but also during the euthymic period, without regard to whether or not drugs are assumed.

Objective To determine the presence of one or more dysfunctions in cognitive domains in a sample of subjects suffering from BD, in euthymic phase, compared with healthy controls.

Aims Evaluation of the following cognitive performances in subjects affected by BD: speed of processing, attention/vigilance, working memory, verbal learning, visual learning, reasoning and problem solving, and social cognition.

Methods Forty-six patients affected by BD in the euthymic phase (mean age: 43.17 years old; 39.13% male), and 58 healthy controls (mean age: 39.21 years old; 51.72% male) were enrolled in the psychiatric unit of Azienda Sanitaria Locale, Foggia. The neuropsychological battery MATRICS Consensus Cognitive Battery (MCCB) was administered by trained psychiatrists.

Results We found the presence of cognitive impairment, affecting six out of seven of cognitive functions assessed ($P < 0.001$): speed of processing, attention/vigilance, working memory, verbal learning, visual learning, reasoning and problem solving.

Conclusions These preliminary results from our case-control study show that cognitive deficits are clearly present also during the euthymic phases of subjects with bipolar disorder (mainly pertaining attention/vigilance domain). These cognitive abnormalities may represent a biomarker of bipolar disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Patterns of impairment in executive functions within unipolar and bipolar depression

B. Suci^{1,*}, R. Paunescu², I. Miclutia²

¹ Children's Emergency Hospital, Psychiatry Clinic, Cluj-Napoca, Romania

² Iuliu Hatieganu University of Medicine and Pharmacy, Department of Neurosciences, Cluj-Napoca, Romania

* Corresponding author.

Introduction The majority of studies revealed that cognitive deficits are an important aspect in many psychiatric illnesses, such as bipolar disorder and major depressive disorder. In the past, cognitive impairment was considered part of depression and it was expected to diminish as other mood symptoms improved with treatment.

Method This study is based on the review of recent literature, performed in order to understand the dimension of executive impairment in unipolar and bipolar depression.

Results Both unipolar and bipolar depressed patients display cognitive deficits in several cognitive domains within executive functions. Different subcomponents of executive functions are altered in both types of patients, but impairments in sustained attention appear specific in bipolar depression while dysfunctional divided attention is reported in unipolar disorder. Studies describe deficits in planning strategies and monitoring processes that are characteristically impaired in unipolar depressed patients. Also these subjects tend to make more perseverative responses suggesting set shifting deficits and moreover they require longer time and more cognitive effort in order to accomplish tasks involving inhibitory control or cognitive flexibility. Other findings suggest that bipolar I depressed patients perform worse than bipolar II depressed patients and unipolar depressed patients across all executive functions especially in the decision making process that is considered to be a trait marker for bipolar disorder with no differences between the two types of bipolar subjects.

Conclusions Executive functions represent a term that includes a higher order of cognitive abilities with deficits that are present in both disorders but display slightly different patterns of impairment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Objective quantification of psychomotor dynamics during pharmacological treatment of bipolar depression

P. Terziivanova*, S. Haralanov, E. Haralanova, G. Dzhupanov
Medical University, Psychiatry and Medical Psychology, Sofia, Bulgaria

* Corresponding author.

Introduction Psychomotor disturbances are among the core symptoms of endogenous depression. They reflect the underlying pathophysiology of the depressive episode and are sensitive to the neurobiological effects of its pharmacological treatment. Being objectively manifested, the psychomotor functions and dysfunctions are technically recordable and measurable by the available motion analysis systems.

Aims To objectively record and measure the psychomotor dysfunctions in bipolar depression and their dynamics during pharmacological treatment.

Methods We introduced an original (internationally patented) equilibrium method for objective and quantitative recording of psychomotor dysfunctions during stepping locomotion in 37 hospitalized patients with bipolar depression and 30 well-matched healthy controls. Two separable psychomotor functions were analyzed in parallel: conscious (voluntary) activity and subconscious (automatic) reactivity. Both patients and controls were examined twice in order to quantify their psychomotor dynamics. Patients were examined at the first day of their hospitalisation and the day before their discharge. The two consecutive examinations of the controls were with equivalent time intervals.

Results There was no significant psychomotor dynamics ($P > 0.05$) in the healthy controls between their first and second equilibrium recording. Psychomotor activity and/or reactivity of the patients were relatively slower at their first recording and significantly accelerated ($P < 0.05$) at their second recording after effective pharmacological treatment.

Conclusions Objective recording and quantitative assessment of psychomotor dynamics in patients with bipolar depression during the pharmacological treatment of their current episode could be a sensitive measure of their improvement and might be used as a surrogate pharmacodynamic biomarker for objective treatment monitoring.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ National & Kapodistrian University of Athens, Medical School, Mental Health Care Unit, Evgenidion Hospital, Athens, Greece

* Corresponding author.

Introduction Bipolar disorder (BD) is frequently associated with cognitive deficits in attention, verbal memory and executive functions that have been related to various clinical characteristics of the disorder.

Objectives However, few studies have examined the effect of gender on cognition despite its clinical relevance.

Aims The aim of our study was to investigate potential diagnosis-specific gender effects on visual memory/learning and executive functions in BD.

Methods Cognitive performance of 60 bipolar-I patients and 30 healthy controls was evaluated by using CANTAB battery tasks targeting spatial memory (SRM), paired associative learning (PAL), executive functions (ID/ED, SOC). A multivariate analysis of covariance (MANCOVA) of neuropsychological parameters was performed with gender and diagnosis as fixed effects and age and education as covariates. Following univariate analyses of covariance (ANCOVA) were undertaken to examine the effect of gender on each neuropsychological task.

Results Bipolar patients showed significantly poorer performance in paired associative learning (PAL), set shifting (ID/ED) and planning (SOC). Moreover, a diagnosis specific gender effect was observed for cognitive functioning in BD (gender × diagnosis interaction $P=0.029$). Specifically, male healthy controls outperformed healthy females in tasks of visual memory/learning but this pattern was not sustained (SRM) or was even reversed (PAL) in BD patients.

Conclusions The present study is one of the few studies that have examined the effect of gender on neurocognitive function in BD. Our findings indicate that the gender-related variation observed in healthy subjects is disrupted in BD. Moreover, they suggest that gender may modulate the degree of frontotemporal dysregulation observed in BD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Features of emotional intelligence and its connection with level of social functioning in patients with depressive-paranoid symptoms

O. Zubatiuk

Shupyk National Medical Academy of postgraduate education, Psychiatry, Kyiv, Ukraine

Introduction The problem of social functioning of psychiatric patients is one of the most relevant these days.

Objectives Studying characteristics of emotional intelligence parameters in patients with depressive-paranoid symptoms in psychotic disorders in the structure of F 20.0, F25.1 and F33.3.

Participants Study involved 40 patients divided into three groups according to nosology:

– Group 1: F 20.0;

– Group 2: F 25.1;

– Group 3: F 33.3.

Methods MSCEIT (Russian version of the adapted version of Sergienko O.O., Vetrova I.I.), the scale of PANSS and PSP.

Results The highest rates are in the group F25.1, except for the scale D. In group F 20.0 compared to other scales reduced scale index N. In group F 33.3 reduced compared to the scales A and E are indicators of scales D and H. 2. The observed negative correlation scale D performance of N5, G1, G5, G8, G14 (PANSS) in group F 20.0 and positive correlation in group F 33.3 of G6. E indicators scales show positive correlation with G3, group F20.0, and F33.3. Also was found a negative correlation with the performance scale O13 H group F20.0. 3. The positive correlation between the level of social functioning and performance scale H group F20.0 scales and indicators in the group D F33.3.

Conclusion The findings are the “resource area”, which have become “target” of rehabilitation programs for this group of patients.

Some personality traits in patients with bipolar II disorder

M. Zuljan Cvitanovic (Psychiatrist)*, I. Stipetic (Psychologist), D. Lasic (Psychiatrist)

Department of Psychiatry, University Hospital Centre Split, Split, Croatia

* Corresponding author.

Introduction Bipolar I disorder (BD I) is characterised by at least one full-manic episode. In bipolar II disorder (BD II), all upswings are hypomanic, which means they never reach full-blown mania. Therefore, BD II evolves into BD I, but BD I can never evolve into BD II. Differential diagnosis of patients evaluated for BD II should include BD I, major depressive disorder (MDD) and borderline personality disorder (BPD). Patients with BPD often have the same type of severely disrupted life as well as patients with BD II because of the multiple episodes of significant mood disorder symptoms.

Objectives Establishing some personality traits in patients suffering from BD II, their relationship and predictability.

Methods The test group was formed out of 55 patients diagnosed with BD II in remission phase from 2012 until 2015. Three measuring instruments were used: Eysenck's Personality Questionnaire (EPQ), Self-destruction Scale (SAD) and Beck Depression Inventory (BDI).

Results We calculated the prevalence of personality traits (neuroticism, psychoticism, elements of borderline personality Disorder), their correlation and predictive validity.

Conclusion We established the prevalence of neuroticism, elements of Borderline Personality Disorder and their significant predictability in patients with BD II in remission.

Disclosure of interest The authors have not supplied their declaration of competing interest.

An embodied approach to understand behavioural characteristics in subjects with autism spectrum disorders

M. Kékes Szabó

University of Szeged, Department of Applied Pedagogy and Psychology, Szeged, Hungary

There are three main areas of impairment in autism: social interaction, communication and repetitive-stereotyped behaviors. While over a long time orthodox cognitive psychology tried to explain the background of these symptoms, nowadays embodiment theories also seem to be useful tools to grasp the real nature of the disease and get a coherent picture about it. The significance of body states, the perceiver's experiences, dynamic interaction between the organism and its environment, and the emergent nature of the connected processes have increased. This study focused on the autistic children's cognitive development and aimed to explore several aspects of it. Accordingly, the sensory-perceptual processes and the participating children's object use were investigated. The main research methods were questionnaires that were filled in by the parents, participant observation via object play and eye-movement analysis during static and dynamic stimuli. The results confirmed different behavioral patterns by children with autism. Thus, for example, hyper-/hyposensitivity, a reduced rate of creative/pretend activities and a lower level of the preference of social effects could be explored in the autistic group more often than it was found in the case of individuals with typical development. In this way, more aspects of the disease could be clearly interpreted using an embodied approach to the behavioural characteristics, although further studies are required to explore these phenomena in a wider range.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

The effects of high exposure to smartphone from ages 3 to 5 years on children's behaviors

S.J. Kim*, S.M. Cho, K.Y. Lim

Ajou university hospital, Psychiatry, Suwon, Republic of Korea

* Corresponding author.

Introduction Smartphones are becoming widely popular and the number of users is significantly increasing, reaching over 65% in South Korea in 2013 and the children begin to use a smartphone at earlier age. Earlier and higher exposure of multimedia is known to have negative effects on children's physical and mental status.

Objectives The aim of the present study was to examine young children's exposure to smartphone and identify the effects of high exposure of smartphone on children's behaviors among Korean children from ages 3–5 years.

Methods In 2014–2015, the parents of 400 children aged 3–5 years (207 boys and 193 girls) were surveyed using a questionnaire on the use of smartphone, children's behaviors, temperaments, social and language development at 3 community-based children's mental health centers.

Results Many children used televisions (95.5%), computers (37.3%) or tablet PC (36.2%), and smartphones (84.6%). Most (74.2%) started using mobile medias before age 2. Parents gave children devices like smartphones to keep them calm (60.8%), when being busy doing something (52.2%), and at playtime (34.3%). The chil-

dren's age at first smartphone use and the frequency were not associated with children's behaviors and temperaments. Higher use group (>2 h/d) show more somatic symptoms (OR 8.97, $P < .001$), more attention problem (OR 4.43, $P < .001$), more aggressive symptoms (OR 1.30, $P < .001$) and more withdrawal symptoms (OR 1.22, $P < .001$) than lower use group.

Conclusions Young children in Korean urban communities had almost universal exposure to mobile devices, especially smartphone. Early and severe exposure of smartphone by young children aged 3–5 years is highly associated with children's behaviour problems like both internalising and externalising problems.

Handedness in children with autism spectrum disorders

L. Kobylinska*, C.G. Anghel, I. Mihailescu, F. Rad, I. Dobrescu

"Prof. Dr. Al. Obregia" Clinical Psychiatry Hospital, Child and Adolescent Psychiatry, Bucharest, Romania

* Corresponding author.

Children with autism spectrum disorders (ASD) have a less definitive hand preference for certain actions as opposed to neurotypical children. Moreover, left-handedness in children with ASD has been associated with more echolalia. The objective was to conduct a screening of potential risk and associated features for autism spectrum disorders, among which the hand preference of the child. The current aim is to compare the perceived handedness of children with autism spectrum disorders with that of children with other psychiatric pathologies.

Methods Eight hundred and forty-two parents completed our risk and associated features screening questionnaire. Out of these, 494 answered the question regarding handedness (209 had children diagnosed with ASD). This asked the parents to state how they perceived their child's handedness. An ADOS assessment has been conducted for 170 of the children whose parents were included in the study, based on clinical relevance for the case. The data were analysed using Excel and SPSS 22.0. For the comparisons, Chi² and the Kruskal–Wallis test were used.

Results Children with ASD had more left-handedness ($\chi^2(2) = 12.54$, $P = 0.002$). There were no differences between boys and girls in terms of perceived handedness in any of the groups. There were no differences in the ADOS scores according to the perceived hand laterality ($\chi^2(2) = 0.58$, $P = 0.74$).

Conclusion Rightward-asymmetry in regions of corpus callosum has been reported to correlate with symptoms severity in ASD. The finding of different perceived handedness in children with ASD versus children with other psychiatric pathologies is useful for designing appropriate, individualized training programs for motor therapy.

Prevention of conduct disorders at the community level

J. Kostić*, M. Stanković, L. Milosavljević

Health center-Nis, Department for Child and adolescent psychiatry, Nis, Serbia

* Corresponding author.

Introduction Epidemiological data indicate that 30% to 50% of young people contact the child psychiatrist for behavioral disorders problems. Protective factors research that reduce the risk of conduct disorders are just as important as the research of risk fac-

tors. The aim of this work is to introduce the preventive factors in the reduction of conduct disorders, including 4 domains: individual, family, school and community. The emphasis is placed on preventive factors at the community level, which are covered by the national, state and local policies that support programs oriented towards children and young people. Good infrastructural community support enable young people to participate in activities where they have opportunities to make choices, make decisions and share responsibility. These experiences help young people to develop new skills, increase their self-confidence and make the difference, while such programs help adults to create a basis for understanding and working together with young and engaged people.

Conclusion The interest in the behavior of young people and their perspective creates a culture of care for young people instead of a culture of ignoring or even marking behavior among young people as deviant and antagonistic, which has a significant preventive effect on the development of behavior disorder.

Evaluation of stress and support to parents of children with developmental disabilities—Our experience

J. Kostić*, L. Milosavljević, M. Stanković

Health center-Nis, Department for Child and adolescent psychiatry, Nis, Serbia

* Corresponding author.

Introduction Stress is an integral part of parenting. The stress of parenting is especially increased at parents of children with developmental disabilities, which can have negative effects on the health of the parents, the relationship with the child and total parental behavior. The objective of this work is to assess the level of stress of parenting among parents of children with developmental disabilities. Parents were involved in workshops support within a regional project. The workshops were conducted twice a month, in the duration of two hours, during the one-year period. The workshops were led by experts in various fields, and work with parents was psycho-educational and supportive. The assessment was made using the questionnaire Parenting Stress Index-Short Form, within the two time frames, at the beginning of the project and after 12 months. The results showed that nearly two-thirds of parents of children with disabilities were under clinically significant stress at the beginning of the service. By retesting after twelve months, it was found that parental stress decreased, and the decrease is particularly evident in the parental competence experience. Although stress is reduced to some extent by the way the parent is experiencing emotional exchange with the child, its level still remains high.

Conclusion Our experience shows that supportive workshops, which we participated in significantly, but insufficiently contributed to the stress reduction among parents. This paper discusses other possible interventions, which would specifically be aimed at developing strategies for reductions of clinically high level of parental stress.

The impact of psychopedagogical intervention on quality of life in adolescents with attention deficit

hyperactivity disorder (ADHD) treated with psychostimulant medication

C. Lima*, D. Rodrigues, M. Silva, S. Rego

ForAll, Desenvolvimento Pessoal e Bem-Estar, Unipessoal, Lda., Psicologia, Paredes de Coura, Portugal

* Corresponding author.

Several studies have shown that ADHD has a significant negative impact on multiple domains of quality of life of children and adolescents, particularly in terms of behavioral, emotional and psychosocial quality of life. The psychopedagogical intervention can be therapeutic, preventive and promote educational inclusion. Moreover, it aims to address the learning process, how it is developed and how the individual relates himself to learning, both in the cognitive, social and emotional domains. Our purpose was to understand whether the psychopedagogical intervention influences the quality of life of adolescents with ADHD considering their pharmacological plans. The aim of this study was to evaluate the impact of a psychopedagogical intervention on quality of life of a sample of adolescents with ADHD taking into account their pharmacological plans (rubifen, ritalin, and concerta). We used quantitative and qualitative assessment measures: the KIDSCREEN-10, to measure the quality of life of these adolescents, and a semi-structured interview to assess the impact of a psychopedagogical intervention in the lives of these adolescents and their parents, respectively. The results showed that psychopedagogical intervention has a positive impact on the quality of life of adolescents with ADHD, as well as in the family dynamics. Due to the demands of school work (homework) and their negative impact on the family dynamics and consequently in the quality of life, the results corroborate the relevance of a psychopedagogical intervention to improve these areas. Thus, it appears that this type of intervention is very useful for adolescents with ADHD.

Faux pas: Assessing theory of superior mind. A control-case study

E. Magallón-Neri^{1,*}, J. Figueras², C. Amat³, M. Benages³

¹ University of Barcelona, Faculty of Psychology, IR3c, Clinical Psychology and Psychobiology, Barcelona, Spain

² University of Barcelona, Clinical Psychology and Psychobiology, Barcelona, Spain

³ Federació Espectre Autista, Asperger de Catalunya, Clinical Assistance, Barcelona, Spain

* Corresponding author.

Often, children with autism spectrum disorder (ASD) can present deficits for acquiring superior level of theory of mind (ToM) in the detection of false beliefs or blunder situations. The objective of this study is to assess 51 subjects with a primary education level (18 with ASD compared to 33 control subjects) comparing ToM level by using the test of Faux Pas test by Baron-Cohen et al. (1999) in two groups divided in 2 layers by age of 7 and 11 years. Results showed significant differences in this construct (ToM) between control group and ASD group only at the age of 11 years (z -score = 2.26; P = .023), but not at the age of 7 years (z -score = 1.89; P = .062). This suggests that ToM's superior capacity acquires greater expression and maturity towards late childhood, just before transition to adolescence stage.

³ Mental Health Research Institute, Tomsk National Research Medical Center of RAS, addictive disorders, Tomsk, Russia

* Corresponding author.

Introduction Cognitive and behavioural problems usually accompany isolated clefts of the lip and/or the palate (ICLP) [1].

Aims To investigate cognitive, emotional and personal features of children with ICLP in comparison with non-cleft children from complete families and non-cleft orphans.

Methods The ICLP group consisted of 29 children (age 14.2 ± 0.7). The first comparison group (1CG) consisted of 34 non-cleft children (age 14.1 ± 0.5). The second comparison group (2CG) consisted of 30 non-cleft orphans (age 13.8 ± 0.8). Drawing tests "House-Tree-Person" have been selected to evaluate the level of children's development, emotional and personal features in all three groups. M. Luscher Color test was chosen to figure out the children's psychological state, regardless of education level.

Results The most characteristic features of the ICLP children and 2CG were similar. They included infantilism (69%; 43.3%), low self-control (65.5%; 56.7%), demonstrative demeanor (62%; 36.7%), escape from reality into fantasy (93%; 76.7%), anxiety (69%; 63.3%). ICLP children compared with the 1CG has shown significantly higher level of aggression (79.3% vs. 4.2%), increased self-esteem (59.6 vs. 4.2%), impulsiveness (51.7% vs. 16.7%), the importance of other people's opinions (59.6% vs. 29.2%). Contrary, the feelings of lack of emotional warmth, the need for protection were observed in 1CG more frequently—70.8% vs 55.2% in ICLP and 60% in 2CG.

Conclusions Psychological correction in children with ICLP should be aimed at increasing the adaptive functions, facilitating communication with peers, search the area for self-realization.

* Corresponding author.

Introduction Autism spectrum disorders (ASD) are complex psychiatric disorders, with both genetic and environmental factors

implicated in their etiology. Recent studies suggest the prenatal and early postnatal genesis of ASD, therefore, understanding the effect of environmental risk factors could be important for prevention and treatment of ASD.

Aims The aim of this study was to determine the association of prenatal factors and perinatal complications with ASD.

Methods Our study included 102 subjects with ASD (80% boys) aged 9.35 ± 5.85, and 107 age and sex matched healthy controls (77% boys). For the diagnosis of ASD, we used the ICD-10 criteria and Autism Diagnostic Interview-Revised (ADI-R). A questionnaire regarding prenatal and perinatal factors/complications was administered to all subjects.

Results Logistic regression model of having autism vs. being a control subject included gender, age, maternal and paternal age at birth, pregnancy order, smoking in pregnancy, number of medication during pregnancy (mostly tocolytics, antihypertensives, antiarrhythmics), and early postnatal complications (mostly prematurity, low birth weight, hyperbilirubinaemia). The model was significant, explaining about the third of variance, with number of medication during pregnancy and having an early postnatal complication as significant predictors.

Conclusions Our study has shown a significant association of specific prenatal and perinatal factors and ASD, even after controlling for other potential confounding variables. Identifying specific risk factors is important for prevention of ASD. It is also the first step in defining basis of the gene–environment interaction mechanism, which might enable development of an individualised therapeutic approach for this group of disorders.

Sensory processing disorders and psychopathology

J. Mesquita Reis^{*}, L. Queiróga, R. Velasco Rodrigues, B. Pinto Ferreira, F. Padez Vieira, M. Farinha, P. Caldeira da Silva
Dona Estefânia Hospital, Child and Adolescent Psychiatry, Lisboa, Portugal

* Corresponding author.

Introduction Sensory processing is the individual's ability to receive, process and integrate sensory information from the environment and body movement in the central nervous system, in order to produce adaptive responses. Sensory processing disorders (SPD) are associated to difficulties in regulating emotions and behaviours as well as motor abilities in response to sensory stimulation that lead to impairment in development and functioning. It is estimated that SPD affect 5–16% of school-aged children. Although these diseases constitute a primary diagnostic category in the Diagnostic Classification of Mental Health and Development Disorders of Infancy and Early Childhood: DC0-3, they have not yet been validated by the Diagnostic and Statistical Manual of Mental Disorders-DSM. In the latest edition of DSM, SPD were only included as one of the diagnostic criteria of autism-spectrum disorders. However, several studies have suggested that SPD may present themselves solely or coexist with other clinical conditions.

Objective The aim of this study was to review systematically the relationship between SPD and psychopathology.

Methodology Articles indexed in the Pubmed database were analyzed.

Results/conclusion Although sensory processing problems are well known to occur in association with autism, their relationship with other mental disorders is not a well studied area. Some studies have related them with ADHD, behavioural disorders and learning disorders. Some studies also comproved that SPD are a valid diagnosis and that there are individuals with SPD who do not meet the criteria for other known disorder. One study found an abnormal

white matter microstructure in children with SPD. Despite these findings SPD need to be further studied.

Altered puberty timing in recent decades: Implications for adolescence-onset conduct disorder

P. Michielsen*, M. Nuijten

Mental Health Western Northern Brabant, General Adult Psychiatry, Halsteren, The Netherlands

* Corresponding author.

Introduction In industrialised countries, the age of puberty onset has substantially diminished over the last 150 years. Several factors, like improved nutrition and health care have contributed to this, but there are concerns about other factors, like obesity, levels of divorce and chemicals. There is an association between early puberty and externalizing disorders in both girls and boys.

Aim To describe trends in advanced puberty timing and adolescence-onset conduct disorder (CD), analyse if an association exists between both and evaluate which measures can be taken to prevent youth from antisocial activities during adolescence.

Method A systematic literature review using Medline, Embase and Psycinfo Databases.

Results Family break-up and increased stress are risk factors for adolescence-onset conduct disorder. Obesity is associated with low SES families, so prevention campaigns giving advice on healthy nutrition may be beneficial. On the general level, there is no clear positive correlation between adolescence-onset CD and early puberty over the last decades as numbers of CD are decreasing.

Conclusion Potential mental health gains can be obtained to focus on children with multiple risk factors for early puberty. More research is needed to assess, which interventions (diet, advice on body changes, social expectations, etc.) are most useful.

Onset paranoid symptoms in depressive and non-depressive middle adolescence sample: School-based preliminary study from Croatia

S. Krnic*, D. Britvic, M. Milanovic

University Hospital Center Split, Department of Psychiatry, Split, Croatia

* Corresponding author.

Introduction There is a lack of epidemiological evidence on the prevalence and incidence of mental health disorders in adolescence in Croatia. Depressive disorder and paranoid symptoms have been demonstrated to be closely related in adult community samples or patients with adult depression. The present study used a cross-sectional design to evaluate a sample of Croatian adolescents.

Objectives Examine the prevalence of paranoid symptoms in adolescents attending grammar school as a preliminary study of clinical characteristic of depression in adolescence.

Methods A sample of 450 individuals, average age 15.7 (SD=0.45); female 232 (51.6%), male 218 (48.4%). The screening was followed by the use of a structured psychiatric interview (HAMD-21), which was administered to confirm the presence or absence of depression disorder. Item paranoid symptoms were administered to evaluate the level OD symptoms (0–none;

1–suspicious; 2–ideas of reference; 3–delusions of reference and persecutions).

Results A total of 450 participants were screened, using HAMD-21, paranoid symptoms occurred (44.9%). Depressed adolescents: moderate, severe and very severe, defined as more than 14 points in HAMD-21 presented paranoid symptoms 68.1%, and non-depressed 32.2%.

Conclusion The depressive group displayed more frequent and intense paranoid symptoms than the control group ($P < 0.001$). Among non-depressed the incidence of paranoid symptoms is a surprisingly high. This could be the consequences of the war in Croatia, transition, as well as the influence of social networks on adolescent communication. This requires future studies.

Relationship between early maladaptive schemes and traumatic childhood experiences with suicidal behavior in adults

L. Montes Reula*, H. Saiz García, A. Portilla Fernández

Biomedical Research Center CIB, Psychiatric, Pamplona, Spain

* Corresponding author.

Exposure to traumatic events in childhood is associated with suicidal behavior in adulthood, in the form of ideas, attempted or completed suicide. The abuse causes impaired cognitive schemes in the attachment figure, abandonment, mistrust and vulnerability to damage. The literature has demonstrated the dose–response relationship between a traumatic event in childhood and the development of mental disorders and the possibility of suicidal behavior. In addition, abuse is transmitted through the generations along with another factor of suicidal vulnerability (family history of suicide). Abuse in childhood is associated with depression, anxiety, antisocial behavior or substance. In fact, in investigations is suggested the vulnerability to any psychopathological disease. A history of suicidal behavior increases the risk for these children. Since child abuse increases suicidal behavior, we can find families in which coexists history of suicidal behavior and child abuse. The high prevalence of abuse and vulnerability neurodevelopmental leads us to consider a plan of action for this population. Rejection and/or contempt suffered in a developing brain might be related to subsequent alterations in emotional regulation or impulsivity. For these associations should conduct a more thorough screening in children's consultations to address this issue. It is very important to approach about cognitive schemes that subsequently repeated dysfunctional acts. Impulsive or unstable behavior could be reduced. This would decrease the consequences that these children have in adulthood.

Executive functioning impairments in adolescents with early diagnosis of obsessive compulsive disorder

N. Nazarboland

Shahid Beheshti University, Psychology, Tehran, Iran

Despite the neuropsychology literature provide reliable evidence of impaired executive functions in obsessive-compulsive disorder (OCD), it has not been determined whether these deficits are prior to onset of the disorder or they begin to appear as consequence. To investigate whether recent onset of OCD in ado-

lescence is characterized by executive functioning difficulties in behavioral inhibition, attentional flexibility, and decision-making. Executive functions were compared in adolescents with recent (past year) appearance of OCD symptoms ($n=40$) and control group ($n=40$). Three computerized tests within the CANTAB battery were completed by all subjects (the Affective Go/No Go task, the Intra-Dimensional, Extra-Dimensional Set-Shifting task, and the Decision-Making task). Using one-way ANOVA showed that compared with control group, the OCD adolescents displayed a bias towards negative stimuli with less errors on sad and hopeless words on the Affective Go/No Go task. They also made faster decisions while they bet more of their available points compared to controls, in the Decision-Making task. Adolescents with recent OCD diagnosis (less than one year) showed greater attention towards sad and hopeless stimuli and more impulsive behavior when making decisions. However, they were able to switch attentional set to neutral stimuli. These findings suggest that executive functioning impairments can characterize adolescence OCD from early beginning of the disorder.

Learning disabilities and attention deficit disorder with hyperactivity of important issues should be considered in elementary school students. The aim of this study was comparison learning disorders, reading, spelling, math and achievement among students in elementary school grades in Bandar Abbas. For this purpose, 384 students were randomly selected. Instruments for gathering data were:

- k-Math test;
- test spelling disorder (Fallahchai test);
- reading test (Baezat test);
- CSI-4.

Factor analysis of variance test was used to analyze of data. The results showed that in the scale of dyslexia, there were more disorders in the children with attention deficit disorder in reading errors, comprehension and reading speed than normal group. In mathematical disorder scale, there were significant difference between the two groups of children with attention deficit disorder with hyperactivity and normal children. Then, the children with attention deficit disorder had higher disorders in operations math, mathematical concepts, mathematical applications, and general score math. The scale of the problem dictates there were significant difference between the two groups of children with attention deficit disorder with hyperactivity and normal children. Then, the children with attention deficit disorder had higher disorders in problem dictates. In academic achievement, the children with attention deficit disorder had lower mean in academic achievement. Finally, the results showed that age, gender, and their interaction had no significant impact on learning disorders, based on attention deficit disorder and normal groups.

* Corresponding author.

According to Boesch et al., people with autism spectrum disorder (ASD) are at a greater risk of developing harmful behaviors, such as self-aggression and other challenging behaviors than individuals with normal development do not exhibit. The method of approach that is supported by scientific evidence for interventional procedures is applied behavior analysis, reported by Carr et al. [1].

Aim In order to provide evidence-based intervention for autism from this approach in practice.

Method In reference to a longitudinal approach, an intervention program was designed and implemented to serve 40 children with ASD, who were treated for one (1) year at the Victory BRT Institute in Florida, US. The behaviors targeted for reduction (excess behavioral), are the following: physical aggression, self-aggression and non-compliance. The program began with a baseline (12 consecutive days) with observations at home and others different natural contexts. The last three (3) months of the year consisted of monthly follow-up sessions to monitor the treatment implemented. The results were analyzed by repeated measures, ANOVA Sig ($P=0.003$) ($F=8$). Analyses show that the critical level associated with the effect of time-content interaction is strong, so the treatment generated a positive effect by reducing the behaviors targeted in time.

Conclusions These results provide evidence that interventions from applied behavior analysis are effective.

* Corresponding author.

Risperidone, atypical antipsychotics, was approved for irritability in autistic disorder. However, some patients had minimal improvement or no response to this treatment. The purpose of this study was to evaluate the association of pharmacogenomics factors and clinical outcomes in autistic children and adolescence who treated with risperidone for long periods. Sixty-seven autistic subjects diagnosed with DSM-IV criteria and treated with risperidone more than 1 year were evaluated clinical symptom by CGI, aggressive, over activity, and repetitive score. Polymorphisms of ABCB1, CYP2D6, DRD2, DRD3, and HTR2A were analyzed. Almost patients showed stable symptom on aggressive (91.04%), over activity (73.13%), repetitive (68.25%) behavior, and all clinical symptoms (82.09%). Only 4.48% of patients showed minimally worse on CGI-I score. Patients in non-stable of all symptom group had DRD2 Taq1A non-wildtype (TT and CT) frequencies higher than clinical stable group ($P=0.046$), whereas other genes polymorphism showed no significant association. Interestingly, there was no patient with HTR2A-1438G > A wildtype in all non-stable symptoms. However, there was no significant association due to small sample sizes. Drug levels (RIS, 90H-RIS, and active moiety) did not show the association with any clinical outcome. Increased appetite was the common ADRs, which associated with high body weight, whereas there was not significantly associated with genetic variations and non-genetic information. In conclusion, risperidone showed efficacy to control autism, especially aggressive symptom in long-term treatment. However, dopamine 2 gene variation affect to non-stable in risperidone treated patients. This study supports pharmacogenomics testing for personalized therapeutics of risperidone in autistic disorder.

Aims/method Publications and studies have shown that the existence of serious mental disorders in parents is a risk in the development of children and is more common the existence of mental illness in them than in the general pediatric population. This work aims to reflect in depth on the study of the influence of psychotic parents on child development through a review of a clinical study. We present the case of 14 years old adolescent who is being treated in a mental health center, whose parents suffers from a severe mental illness. We also defend the importance of a preventive approach or treatment that impinges on the child and family environment.

Results/conclusions A way of community work, in coordination with the different teams (social services, educational services, etc.)

allows more efficient and appropriate treatment, using various resources. When risk factors for developing mental health problems in childhood, family history and especially the existence of one or both parents of mentally pathology type schizophrenia or other psychoses are studied become important. It seems essential to address as a priority to the social group have called “high-risk group of psychosis”, and in particular to the “sons of patients diagnosed with psychosis”, both for its size and the severity and chronicity of psychopathology if developing means for early psychosocial care does not occur.

Introduction The determination of IQ is essential in the assessment and diagnosis of children. There are multitude of tests, one of the most used are the Wechsler Scales.

Aims Hypothesis: Assessment of IQ is equivalent using the Wechsler Intelligence Scale for Children-Revised (WISCr) and Kaufman intelligence brief test (KBIT).

Subjects Children undergoing treatment at Unit Child and Adolescent Mental Health of Talavera with determination IQ at some point in the intervention: 39 pairings determination of IQ subjects attended: 20 males and 19 females, aged between 4 and 14 years.

Material Subjects are evaluated with KBIT and WISCr tests.

Methods Design: Quasi-experimental with two conditions. Independent variables: IQ Total WISCr and age management KBIT (for eight years application of the full test, under this age not full test).

Dependent variable: IQ KBIT.

Analysis Calculation of correlation between IQ by non-parametric test. Comparison between groups using non-parametric test for dependent data (sign test). Rejecting null hypothesis for alpha significance $P < 0.05$.

Results Partial KBIT; 21 comments, 11 males, 10 females; Spearman $r = .714$ ($P < .001$); average estimate of 12.71 points higher in KBIT, Dt 18.07, sign test $Z = -2.012$ ($P < .041$).

Full KBIT 18 observations, 9 males, 9 females; Spearman $r = .739$ ($P < .001$); lower average estimate of 3.44 points in KBIT, Dt 12.43, sign test $Z = -.236$ ($P < .815$).

Conclusions The results support high validity regardless of age management KBIT, although IQ scores obtained before 8 years should be considered with caution. The KBIT has the advantage of its shorter evaluation, however the information obtained from WISCr is wider.

* Corresponding author.

Introduction Although prenatal maternal smoking is an established risk factor for offspring's attention deficit hyperactivity disorder (ADHD), the studies of association between paternal smoking and childhood ADHD have produced inconsistent results. **Objective** The objective of the present study was to determine whether paternal smoking during early developmental period is associated with an increased risk of offspring's ADHD.

Methods We conducted hospital-based case-control study with 107 medically diagnosed ADHD cases and 205 controls (aged 6–12 years). The diagnoses of ADHD were assessed with DSM-IV based semi-structured diagnostic interviews. Paternal smoking behavior was assessed with spouse-report questionnaire. The association between exposure to paternal smoking and ADHD were analyzed using multivariate logistic regression analysis. The primary outcome of interest was an odds ratio (ORs) reflecting the risk of offspring's ADHD incidence associated with father's smoking during the index pregnancy, up to one year after birth, and current smoking status. Control variables in our regression model were age, sex, financial status, parents' education levels, low birth weight, and premature birth.

Results Our final regression model revealed that paternal smoking during pregnancy (OR = 1.68, 95% CI = 1.03–2.76) and up to one year after birth (OR = 1.69, 95% CI = 1.04–2.77) were significantly related to their offspring's ADHD.

Conclusions The current results suggest that exposure to paternal smoking during the fetal and newborn period is associated with increased risk of ADHD. This study warrants public health policies to reduce children's exposure to secondhand smoke and their risk of ADHD.

* Corresponding author.

Background The association between parental severe mental illness (SMI) and depression in offspring may be due to genetic liability or adverse environments. We investigated the effect of parental SMI, SES, and adversity on depression in a sample of youth enriched for familial risk of mental illness.

Method We assessed 217 youth (mean age 11.95, SD 4.14, range 6–24), including 167 (77%) offspring of parents with SMI. We measured exposure to childhood maltreatment and bullying with the

Juvenile Victimization Questionnaire (JVQ) and Childhood Experiences of Care and Abuse (CECA) interview.

Results In total, 13.36% participants reported significant bullying and 40.76% had a history of childhood maltreatment. Rates of bullying and maltreatment were similar in offspring of parents with and without SMI. Maltreatment likelihood increased with decreasing socioeconomic status. Exposure to bullying (OR = 3.11, 95% CI 1.08–8.88, $P = 0.03$) predicted depression in offspring more strongly than family history of SMI in parents.

Conclusions Adversity, such as maltreatment and bullying, has a stronger impact on the risk of developing depression than family history of mental illness in parents. These adverse experiences are associated with socioeconomic status rather than parental mental illness.

Paradigm shift in the educational system of adolescents with disabilities

S. Paulino^{*}, C. Almeida, M. Croca, N. Santos

Hospital Santa Maria, Psychiatry Service, Lisbon, Portugal

* Corresponding author.

Introduction In the last years, there has been a paradigm shift in the educational system of young people with disabilities. Regular schools associated with specific support plans have become the destination of choice for these adolescents, instead of schools with special education. This integrated teaching seeks to reduce stigma and to promote tolerance but frequently these students become easy targets of psychological and physical violence or discrimination.

Objective To evaluate the integration of adolescents with disabilities in mainstream education compared to special teaching.

Methods Analysis of 32 patients with disabilities from the adolescence consultation of the psychiatry service of hospital de Santa Maria, between January 2015 and September 2016.

Results About 30% of the adolescents with disabilities who attend regular schools with special support complains of poor adjustment associated with some kind of mistreatment by peers.

Conclusion Violence among students in school is a current problem very difficult to fight. Young people with disabilities often find themselves in a significant minority presenting less efficient defense mechanisms. If unprotected, they may easily develop school phobia or refusal. These situations must be identified and avoided to prevent the associated suffering.

* Corresponding author.

Introduction Irritability is the most frequently reported symptom in child and adolescent depression. The association of both has been linked with high rates of chronicity, comorbidity and impairment.

Objectives To study the association between irritability and depressive symptoms in children and adolescents.

Methods We have studied 857 participants recruited from the only child and adolescent mental health clinic in a catchment area of 122,968 people under 18 (2004–2010). A sample of 857 participants (112 controls and 745 patients) was included to carry out a cross-sectional study. Irritability was measured by a Visual Analog Scale (VAS irritability)–scored from 0 to 10–, and depressive symptoms by the Children's Depression Inventory (CDI). The participants were categorized into controls and patients, and according to their irritability (≤ 4 [I], 5 [II] and ≥ 6 [III]). The mean of CDI score was calculated for each of the groups, adjusted by sex and age, and analyzed by ANCOVA.

Results The following means were obtained from the controls: 13,71 (group I), 9,82 (group II) and 17,45 (group III). Regarding to the patients: 13,92 (group I), 11,54 (group II) and 15,64 (group III). A quadratic association ($P < 0.0015$) was found between VAS irritability score and CDI score.

Conclusions There is not a linear association between irritability and depressive symptoms in children and adolescent. High rates of depressive symptoms were associated both with high and low rates of irritability. Several questions remain unexplained about the status of irritability in psychiatry, as Stringaris group has been pointed out.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Negative psychotic symptoms in 22q11.2 deletion and their association with neuropsychological profile

M. Pontillo^{1,*}, A. Lin², M. Armando¹, D. Menghini¹, G. Alvares², S. Vicari¹

¹ Children Hospital Bambino Gesù, Neuroscience and Neurorehabilitation, Rome, Italy

² Thelethon Kids Institute, Thelethon Kids Institute, Perth, Australia

* Corresponding author.

22q11.2 deletion syndrome (22q11.2 DS) is associated with a markedly elevated risk for schizophrenia spectrum disorders. The role of negative symptoms in the pathogenesis of schizophrenia in this population and their link to role, social and cognitive functioning is still unclear. Aims of this study were investigate the association between negative symptoms, social and role functioning and neurocognitive performance in the sample of individuals with 22q11.2DS and compare them to healthy controls. The study was conducted on a sample of 60 individuals with 22q11.2DS (mean age = 14.8; SD = 4.8) and 56 healthy control (HC) participants (mean age = 13.8; SD = 5.4). Individuals with 22q11.2DS and high level of negative symptoms showed significantly higher level of impairment in several neurocognitive domain (i.e. visuospatial abilities, verbal response inhibition) compared with individuals with 22q11.2DS and low level of negative symptoms and healthy controls. They showed also lower global functioning, specifically role functioning and not social functioning. Negative symptoms are frequent in 22q11.2DS and are associated with specific cognitive deficit and low role functioning. These results suggest that negative symptoms should be considered an important target in the assessment of risk of conversion to full-blown psychosis and in planning of psychological interventions for this population.

From assortative mating theory to genetic background, several ethipathogenic hypotheses in ASD deal with the traits of parents. Background several ethipathogenic hypotheses in ASD deal with the traits of parents. The objectives of our study were to measure the ADHD and autism spectrum disorder quotients in parents of children diagnosed with ASD comorbid with ADHD and to correlate the measurements for the tests in parents with those in their children. The specific aim was to identify whether any significant correlations exist.

Method Fifty-two pairs of parents of children with autism spectrum disorders and ADHD were included in this study, based on informed consent and the ethical committee's approval. The child's diagnosis was established by a specialist in child and adolescent psychiatry, based on the child's clinical symptoms and on specific diagnostic scales, such as the ADOS and ADHD-rating scale. The parents completed an Autism Spectrum Quotient Scale (ASQS) and an adult ADHD scale. The data were analyzed using SPSS 22.0 and Excel. The correlations were verified using Spearman's non-parametric correlation test.

Results There was a strong correlation between the parents' ADHD scores ($r = 0.5$, $P < 0.001$), and a reverse medium correlation between the mother's ADHD score and the child's ADOS score ($r = -0.32$, $P = 0.02$). The father's ASQS and ADHD scores correlated between each other ($r = 0.31$, $P = 0.02$). There were no correlations between the parents' and the child's ADHD score, nor between the child's ADOS score and the parents' ASQS scores.

Conclusion Our results suggest that ADHD symptoms in parents of children with autism spectrum disorders comorbid with ADHD might be predictors for the child's prognosis.

⁴ Clinic for mental disorders "Dr Laza Lazarevic", Daily hospital, Belgrade, Serbia

* Corresponding author.

Introduction The phenomenon of non-suicidal self-injury (NSSI) as an act of deliberate destruction of body tissue without suicidal intent is common in adolescence. NSSI and suicide attempts (SA), although distinct behaviors differing in intent, form and function, often co-occur in the same individual.

Objective and aims Recent studies investigate the association between SA and NSSI among adolescent, as well as risk factors associated with these phenomenon. We investigated the co-occurrence of NSSI and SA among adolescents treated in hospital during the previous year.

Method We conducted a cross-sectional study among hospitalized adolescents in the Clinic for mental disorder “Dr Laza Lazarevic”, aged 14 to 18 years, in the period from 01.01.2015 to 01.01.2016. The data were obtained from clinical interviews of patients.

Results Study included 146 adolescents, 51.4% male and 48.6% female, average age 15.5. We found a statistically significant difference of NSSI ($c^2 = 9.951, P = 0.002, \phi = 0.276$) and SA ($c^2 = 4.517, P = 0.034, \phi = 0.192$) among female adolescent. The co-occurrence of NSSI and SA was found in 4.8% of adolescents, which does not indicate a statistically significant difference ($c^2 = 1.009, P = 0.315, \phi = -0.101$) compared to the total population of hospitalized adolescents.

Conclusion Although our study did not confirmed a higher incidence of SA in adolescent with NSSI, understanding of what percentage of those engaging in NSSI also make SA, and how they are related have great significance in their prevention taking into account the dangerousness and lethality of those behavior.

Untreated remission of adolescents' mental health problems: Challenging the treatment gap?

D. Raven^{1,2,*}, F. Jörg^{1,2}, R.A. Schoevers¹, A.J. Oldehinkel¹

¹ UMCG, Psychiatry, GRONINGEN, The Netherlands

² Friesland Mental Health Services, Research and Education, Leeuwarden, The Netherlands

* Corresponding author.

Introduction Mental health problems are highly prevalent and are associated with a high burden, but such problems are often left untreated. This is referred to as the “treatment gap”. The question of who is most likely to remit from their mental health problems without treatment has received surprisingly little attention. A few studies do suggest that untreated remission is common in the general population, but these are in particular limited by short follow-up times.

Objectives The aims of this study are to describe untreated remission of mental health problems in adolescence, and to assess the extent to which mental health problems recur after untreated remission.

Methods Data from the Dutch community-based cohort study TRacking Adolescents' Individual Lives Survey (TRAILS) were used. Depressive and anxiety problems were assessed using the Youth Self-Report at ages 11, 13, and 16, and the Adult Self-Report at ages 19 and 22.

Results Preliminary analyses show high rates of untreated remission (approximately 80% over all waves). However, a substantial proportion of remitted cases still report sub clinical levels of mental health problems at follow-up. More elaborate analyses are ongoing, and will be presented at the conference.

Conclusions First results suggest that untreated remission is common in adolescents. The presence of residual symptoms may point towards an elevated risk of recurrence in adolescents who remit without treatment. Further knowledge about untreated remission is of vital importance for an accurate assessment of the treatment gap, and for prevention and early intervention programmes.

Self-harm and attachment in adolescents: What is the role of emotion dysregulation?

G. Rogier^{1,*}, C. Petrocchi², M. D'aguanno², P. Velotti³

¹ La Sapienza, Psicologia clinica e dinamica, Roma, Italy

² University of Rome, La Sapienza, Department of Dynamic and Clinical Psychology, Roma, Italy

³ University of Genoa, Educational Sciences, Psychology Unit, Genoa, Italy

* Corresponding author.

Introduction Self-harm typically occurs in adolescence and has been conceptualized as a dysfunctional strategy to regulate intense negative emotions. Furthermore, empirical literature outlines that self-harmers are more prone to have an insecure attachment style. Moreover, the link between quality of attachment and capacity to regulate emotions has been theoretically and empirically supported.

Objective To examine the associations between attachment style, self-harm behaviors and emotion dysregulation among a sample of adolescents. The sample consisted of 740 adolescents aged between 13 and 19 years (mean age = 16.70, SD = 0.91).

Aims To explore the nature of different pathways by which insecure attachment leads to self-harm behaviors.

Results As expected, insecure attachment and emotion dysregulation were positively associated with self-harm behaviors. Moreover, emotion dysregulation mediated the link between attachment styles and self-harm. Specific pathways between types of insecure attachment dimension of emotion dysregulation and self-harm behaviors emerged.

Conclusions Such results confirm the theorization of self-harm behaviors as a dysfunctional strategy to regulate emotions. Moreover, such emotion dysregulation in self-harmers seem to be connected to insecure attachment. Depending on the subtype of insecure attachment, specific dimensions of emotion dysregulation seem to be involved in self-harm behavior, suggesting interesting clinical implications.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A population service evaluation of the ADHD pathway of children and young people's services, Malta

A. Saliba*, D. Agius, E. Sciberras, N. Camilleri
Mount Carmel Hospital, Malta, Psychiatry, Attard, Malta

* Corresponding author.

Introduction ADHD is the commonest neurodevelopmental disorder in young people (YP) aged 5–18 years. YP with untreated ADHD are 5 times more likely to develop co-morbid psychiatric disorders.

Objectives To carry out a population service evaluation of the assessment process and management of YP with ADHD at Child and Young People's Service (CYPS), Malta age 0–16 years for 2014.

Aims To describe the service input, assessment and treatment of YP attending CYPS and compare to ADHD NICE guidelines 2008.

Methods All patients diagnosed with ADHD at CYPS throughout 2014 were included. The incidence of YP with ADHD on treatment age 3–16 years in Malta was calculated. Information was collected from; (i) retrospective case file review and (ii) methylphenidate and atomoxetine registry and compared with NICE guidelines.

Results One hundred and thirty-six YP were diagnosed with ADHD. The minimum 12-month incidence of ADHD on treatment (3–16 years) in Malta was 553 per 100,000. Pre-diagnosis assessments were more frequently performed by other YP services ($n = 97$,

71.3%, $P \leq 0.01$). A psychiatrist or paediatrician confirmed the diagnosis in 113 (83.1%). Sixty-two (45.3%) of YP were prescribed medication, 50 (36.8%) were referred for parental skills course and 55 (40.4%) psychotherapy. Mean waiting time for first appointment was 187.6 days ($CI \pm 26.9$, 0–720), and first specialist review was 301.0 days ($CI \pm 34.4$, 0–800) (Tables 1–3).

Conclusions The incidence for YP (3–16 years) with ADHD on treatment was lower than the US. Since most pre-diagnostic assessments were carried out by other services, this raised the question about the reliability and validity. We recommend a diagnostic MDT meeting following the multimodal assessment to diagnose ADHD. Medication prescribing followed NICE overall, standardising non-pharmacological management is required.

Table 1 Assessment available at intake multidisciplinary team meeting.

Table 2 Young people prescribed medication.

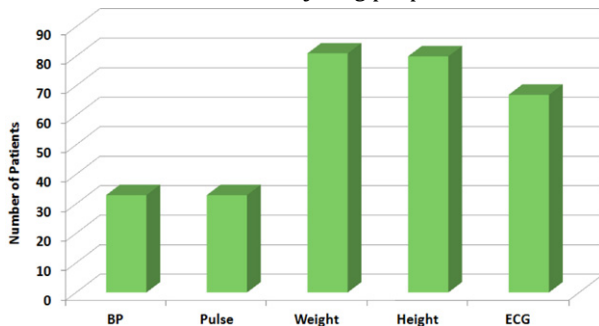

Table 3 Medical assessment for young people on treatment.

³ Helsinki University Central Hospital and University of Helsinki, Forensic Psychiatry, Helsinki, Finland

* Corresponding author.

Introduction Structured self-reports, such as Beck's Depression Inventory (BDI) are widely used in assessing adolescents' psychological wellbeing.

Objectives To investigate what factors are associated with discrepancies between BDI scores and diagnostic assessment in adolescent psychiatric patients and general population.

Aims To recognize what factors may contribute to high BDI scores besides depressive symptoms.

Methods The study population consisted of 206 adolescents (13–17 years old) who were hospitalised for the first time in adolescent psychiatry and 203 age and gender matched adolescents recruited from schools in the same region. Study subjects filled self-reports on depression symptoms (BDI-21), substance misuse (AUDIT), psychiatric symptoms (SCL-90), defense styles (DSQ-40) and self-image (OSIQ). Diagnostics was based on K-SADS-PL interview, and/or clinical interview and clinical records when available. Information on background and life events was gathered from study subjects.

Results We compared subjects who scored in BDI-21 either 0–15 points or 16–63 points firstly among subjects who did not fill diagnostic criteria for current unipolar depression and secondly among those who did fulfill the diagnostic criteria. High BDI-21 scores in subjects without depression diagnosis were associated with female sex, older age, several adverse life events, higher psychiatric comorbidity, worse self-image and more immature, neurotic and image-distorting defense styles (and less mature defense style). Low BDI-21 scores among subjects with depression diagnosis were associated with male sex, more positive self-image and less immature defense style.

Conclusions High BDI-21 scores may reflect a broad range of challenges in an adolescent's psychological development even in the absence of depression.

Disclosure of interest The authors have not supplied their declaration of competing interest.

School violence: Characterization of occurrence's records of a public high school institution

E. Scherer^{1,*}, Z. Scherer², L. Cavalin², J. Rodrigues²

¹ Ribeirão Preto Medical School Hospital of the University of São Paulo, Neurosciences and Behavioral Sciences, Ribeirão Preto, Brazil

² University of São Paulo at Ribeirão Preto College of Nursing, Psychiatric Nursing and Human Sciences, Ribeirão Preto-São Paulo, Brazil

* Corresponding author.

Introduction Acts of indiscipline, incivility and violence are common in the school environment and reflect on physical and mental health of those involved.

Objective To characterize conflict records made by students, teachers/others and parents/guardians in a Brazilian high school institution.

Method Qualitative research, exploratory documental. Studied 113 records from 2014 to 2016.

Results “Indiscipline and Incivility”–75 records (66 by teachers/others and 9 by students) of students: improper use of clothes and accessories, cell phone use in class, not bringing material, dating in school, conversations during class, do not respect the timetables, inappropriate jokes, disrupting activities, theft of materials and disrespect toward authority figures. “School violence”–22 records (12 by students, 9 by teachers/others and 1 by parent/guardian) of school violence: physical violence between students, psychological/verbal between students/teachers/others, and a match of sexual abuse. Three records (by teachers/others) of violence against the school: students destroyed teaching and cleaning materials and caused damage to the patrimony. Fifteen records (12 by students, 2 by parents/guardians and 1 by teacher) of school’s violence: teachers’ harassment (excessive rigor in regard to school performance, clutter in the ratings, refusal to clarify doubts and inappropriate criticism on student’s behavior) and institutional negligence (teachers’ delay, lack of clarification on teaching organization and supervision in practical activities).

Conclusion Some students’ acts of indiscipline and incivility can be protests against the social control of the school. Assistance in case of conflicts and violence as well as preventive measures must be based on interdisciplinary and inter-sectorial articulation practice.

Mothers mental health of children with attention deficit/hyperactivity disorder (ADHD)

Z. Sepehrmanesh

Kashan University of Medical Sciences, psychiatry department-medical faculty, Kashan, Iran

Background Attention deficit hyperactivity disorder (ADHD) is the most common neuropsychiatric disorder in pediatric populations with an early onset. Mental health of mother can effect on child mental health and relation between mother and child is very important. The aim of this study was investigation about mental health of mothers with children suffering from attention deficit/hyperactivity disorder.

Materials and methods This cross sectional study was carried out on 100 mothers of children with ADHD diagnosis (Kashan, Iran). The data collection instruments included the Goldberg’s General Health Questionnaire, and the questionnaire form includes the personal information and the variables associated to mental health.

Results The total means score of GHQ in the mothers’ was $26/6 \pm 11/78$. Fifty-eight percent of the mothers have mental health problem. The highest mean score in the sub scales was related to the anxiety subscale (7.73) and the most common mental health problem in these mothers was anxiety problems (11%). Mental health problem is most common in mothers with low socio-economic status, younger age than 30 years old, education lower than diploma degree, householder mothers, single, having boy child with ADHD, having child more than 9 years old.

Conclusion According to the results of this study, 58% of the mothers have mental health problem. So with screening and on time diagnosis and treatment, we can prevent disadvantage effects of these problems on social and mental health of their children.

Factors associated with depression severity in adolescence

G. Serra^{1,*}, M.P. Casini¹, V. Maggiore¹, R.J. Baldessarini², S. Vicari¹

¹ Pediatric Hospital Bambino Gesù, Department of Neuroscience, Roma, Italy

² Harvard Medical School, Department of Psychiatry, Boston, USA

* Corresponding author.

Introduction Severe depression is greatly impairing during adolescence and involves a high risk for suicidal behaviors.

Objectives and aims Identify clinical and demographic factors associated with severity of depression in adolescents diagnosed with a major mood disorder so as to improve clinical treatment and prevent suicidal behaviors.

Methods We analyzed factors associated with depression severity in 145 severely ill adolescents diagnosed with a major affective disorder using the K-SADS (Kiddie-Schedule for Affective Disorders and Schizophrenia) at the Mood Disorder Outpatient Program of Bambino Gesù Children’s Hospital (Rome). Depressive and manic symptoms were rated with the CDRS-R (Children’s Depression Rating Scale-Revised) and K-SADS-MRS (Mania Rating Scale), respectively. Bivariate comparisons were followed by multivariable linear regression modeling.

Results Depression severity was greater among females than males (mean CDRS scores: 53.0 vs. 42.8; $P < 0.0001$) and with major depressive versus bipolar disorder diagnosis (50.4 vs. 45.4; $P = 0.001$). Manic symptoms, including irritability, mood lability, crowded thoughts, delusions, and insomnia, were more likely with more severe depression; their number and severity correlated with CDRS-R total score (respectively, $\beta = 1.53$ and 5.44 ; both $P < 0.0001$). Factors independently and significantly associated with CDRS-R depression score in multivariate modeling were:

- presence of suicidal ideation;
- absence of ADHD;
- female sex;
- greater number of manic symptoms.

Conclusions Severe depression was associated with manic symptoms and with suicidal ideation among adolescents diagnosed with either bipolar or major depressive disorders. This relationship should be considered in treatment planning and suicide prevention, including consideration of mood-stabilizing and antimanic agents in the treatment of severe adolescent depression.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Pediatric bipolar disorder (BD) is a highly morbid pediatric psychiatric disease, consistently associated with family psychiatric history of mood disorders, with high levels of morbidity and disability and with a great risk of suicide.

Objectives While there is a general consensus on the symptomatology of depression in childhood, the phenomenology of pediatric mania is still highly debated and the course and long-term outcome of pediatric BD still need to be clarified.

Aims To assess the prevalence, demographics, clinical correlates and course of these euphoric versus irritable pediatric mania.

Methods Systematic review of the available studies assessing the phenomenology, course and outcome of pediatric mania.

Results Eighteen studies reported the number of subjects presenting with either irritable or elated mood during mania. Irritability has been reported to be the most frequent clinical feature of pediatric mania reaching a sensitivity of 95–100% in several samples. Only half the studies reviewed reported on number of episodes or cycling patterns and the described course was mostly chronic and ultra-rapid whereas the classical episodic presentation was less common. Few long-term outcome studies have reported a diagnostic stability of mania from childhood to young adult age.

Conclusions Severe irritability is the most common presentation of abnormal mood described in children with bipolar disorder. Longitudinal studies of samples with irritable versus elated mood presentation and chronic versus episodic course may help clarify whether these are factors predicting different long-term course, treatment-response and outcome of pediatric onset bipolar disorder.

Pretreatment predictors of early response revealed by quantitative cerebral blood flow in major depressive disorder

Z. Hou^{1,*}, Z. Wang², W. Jiang¹, Y. Yin¹, Y. Yue¹, Y. Zhang¹, Y. Yuan¹

¹ Zhongda Hospital, Medical School of Southeast University, Department of Psychosomatics and Psychiatry, Nanjing, China

² Zhongda Hospital, Medical School of Southeast University, Department of Neurology, Nanjing, China

* Corresponding author.

Objective The potential pattern of regional cerebral blood flow (rCBF) in major depressive disorder (MDD) underlies different response to antidepressants medication remain unclear. This study aimed to investigate the differences of rCBF between patients with different treatment response.

Methods Eighty MDD patients [(44 treatment-responsive depression (RD) and 36 non-responding depression (NRD)] and 42 healthy controls (HC) underwent pulsed arterial spin labeling (PASL) scans in magnetic resonance imaging and clinical estimates. The exact rCBF values of each groups were obtained via quantification evaluation.

Results Compared to NRD, the RD patients showed decreased rCBF values in frontal sensorimotor network (i.e. left paracentral lobule, left medial frontal gyrus, right superior frontal gyrus and right middle frontal gyrus), and further receiver operating curve (ROC) analyses demonstrated that the altered rCBF in these four regions exhibited outstanding performance on distinguishing NRD from RD. The NRD also exhibited reduced rCBF in bilateral cerebellum posterior lobe and right middle occipital gyrus and elevated rCBF in right postcentral gyrus and right middle frontal gyrus as compared to HC.

Conclusions The decreased rCBF in frontal sensorimotor network appeared to be distinct characteristics for NRD, and might be severed as promising neuroimaging markers to differentiate

depressed patients with weak early response to antidepressant medication. These findings expand our understanding of neural substrate underlying the antidepressant efficacy.

Review of Othello syndrome and its relationship with neurological disorders

P. Michielsen^{1,*}, L. De Jonge², S. Petrykiv³, M. Arts⁴

¹ Mental Health Western Northern Brabant, General Adult Psychiatry, Halsteren, The Netherlands

² Mental Health Western Northern Brabant, Department of Neuropsychiatry and Geriatric Psychiatry, Halsteren, The Netherlands

* Corresponding author.

Introduction Othello syndrome is a psychotic disorder characterized by delusion of infidelity or jealousy. It predominantly occurs in the context of specific psychiatric or neurological disorders. Othello syndrome is associated with mental changes including excessive aggression, hostility, and irritability. Patients with Othello syndrome misinterpret the behaviour of the spouse or sexual partner to provide evidence for their false perception.

Objectives and aims The purpose of this paper is to examine the phenomenon of Othello syndrome as a result of specific neurological diseases.

Methods The study design was a retrospective case series of patients with Othello syndrome. We searched the electronic databases PubMed and Embase for review articles and original research using the search terms 'Othello syndrome, Morbid Jealousy, Pathological Jealousy, Delusional Jealousy, Delusions and Infidelity, Delusions of Jealousy or Infidelity'.

Results In the present study of 95 case reports, the relationship between Othello syndrome and a neurological pathology was described. This syndrome was most commonly associated with neurodegenerative diseases (59%), followed by medication induced Othello syndrome (13.7%) and vascular dementia (8.4%). Lesions particularly in the right (dorsolateral) frontal lobes were associated with this syndrome.

Conclusion This study demonstrates that Othello syndrome occurs most frequently in patients with right frontal lobe dysfunction. It is predominantly related with Lewy Body Disease and Alzheimer's disease. Clinicians should keep an "index of suspicion" regarding dementia when Othello syndrome presents in elderly persons.

Reward learning and dopamine release in adults with 22q11DS

E. Van Duin¹, Z. Kasanova², M. Beck¹, D. Hernaes¹,

I. Myin-Germeys², T. van Amelsvoort^{1,*}

¹ Maastricht University, Psychiatry, Maastricht, The Netherlands

² KU Leuven, Psychiatry, Leuven, Belgium

* Corresponding author.

Background 22q11.2 deletion syndrome (22q11DS) is a genetic disorder caused by a microdeletion on chromosome 22q11.2 and

associated with an increased risk for psychosis. A dysfunctional motivational reward system is thought to be one of the salient features in psychosis caused by abnormal dopamine functioning. It is unknown whether patients with 22q11DS have a dysfunctional reward system.

Methods This study aims to investigate reward learning in 22q11DS. The study included 10 adults with 22q11DS (age: 33.1 years, 60% female) and 10 age-gender-matched healthy controls (HC, age: 39.7 years, 60% female). A single infusion 18F-fallypride PET scan was acquired during which all subjects performed a version of the learning phase of the Probabilistic Stimulus Selection Task for reward learning (RL), modified to deliver social feedback. **Results** IQ-scores were significantly lower in the 22q11DS group ($P < .001$) compared to HC. The 22q11DS group both earned significantly less money ($P < .05$) and performed worse during the RL-task ($P < .05$) than HC. However, the learning curve for the RL-task was the same for both groups. IQ-scores were a significant positive predictor for earnings ($P < .05$) and performance ($P < .05$), but not for the learning curve.

Conclusions These preliminary results indicate that people with 22q11DS are capable of learning at the same speed as HC, however they are less susceptible for reward than HC because their overall performance during RL is worse than HC. This lower reward sensitivity could be a result of haplo-insufficiency of COMT in 22q11DS and consequently abnormal prefrontal dopamine functioning.

Alexithymia and coping strategies: Predictors of hopelessness?

G. Serafini^{1,*}, L. Capobianco¹, M. Pompili², P. Girardi³, M. Amore¹

¹ *Neuroscience Dinogmi, University of Genoa, Genoa, Italy*

² *Neurosciences, Sapienza University of Rome, Sant'Andrea Hospital, Suicide Prevention Center, Rome, Italy*

³ *Neurosciences, Sapienza University of Rome, Sant'Andrea Hospital, Rome, Italy*

* *Corresponding author.*

Introduction Alexithymic traits and coping strategies may affect the onset and course of many psychiatric conditions. However, their role in determining hopelessness and suicide risk has been not still elucidated.

Objectives The present study analyzed the correlations between alexithymia, coping strategies, and hopelessness.

Aims We aimed to evaluate whether specific coping strategies and alexithymia may predict hopelessness which is widely considered an independent risk factor for suicide.

Methods This is a cross-sectional study conducted on 276 patients (19.9% men, 81.1% women; mean age: 48.1 years, SD: 16.9), of which most with major affective disorders, who were admitted at the Psychiatric Unit of the University of Genoa (Italy). All participants were assessed using the Beck Hopelessness Scale (BHS), Coping Orientations to Problems Experienced (COPE), and Toronto Alexithymia Scale (TAS-20).

Results Alexithymic subjects significantly differ from non-alexithymic individuals in terms of substance abuse ($\chi^2 = 23.1$; $P = .027$). According to bivariate analyses, we found a significant correlation between hopelessness and suicidal thoughts/wishes ($r = .34$; $P = .01$), humor ($r = -.24$; $P = .05$), and behavioural disengagement ($r = .205$; $P = .05$). Behavioural disengagement is also a positive predictor of hopelessness (OR = 1.25; 95% CI: 1.03–1.52) while humour is a negative predictor of hopelessness (OR = 0.85; 95% CI: 0.73–0.99).

Conclusions Behavioural disengagement needs to be considered a risk factor while humor is a protective factor for suicide. Surpris-

ingly, we found no significant association between alexithymia and hopelessness. Further additional studies are requested to test these exploratory findings in order to more deeply elucidate the role of both alexithymia and coping strategies in suicidal behaviour.

Clinical high risk symptoms and criteria in the community: Prevalence, clinical significance and risk factors for their occurrence

F. Schultze-Lutter^{1,*}, C. Michel¹, B.G. Schimmelmann¹, S. Ruhrmann²

¹ *University of Bern, University Hospital of Child and Adolescent Psychiatry and Psychotherapy, Bern 60, Switzerland*

² *Department of Psychiatry and Psychotherapy, University of Cologne, Cologne, Germany*

* *Corresponding author.*

Introduction In clinical samples, symptomatic ultra-high risk (UHR) criteria and the basic symptom criterion "cognitive disturbances" perform well in predicting psychosis, and best when both approaches are combined.

Objective However, little-to-nothing is known about clinical high risk (CHR) and their constituent symptoms in the community.

Aims We studied the prevalence, clinical relevance, and moderators of CHR criteria and symptoms in the community.

Method Regression analyses involved 2683 community participants (age 16–40 years; response rate: 63.4%). Semi-structured telephone interviews were performed by well-trained psychologists.

Results Lifetime and current CHR symptoms were reported by 21.1% and 13.8% of interviewees. Frequency of symptoms was mostly low, only 2.4% met any CHR criterion. A stepwise relationship underlay the association of the two types of CHR symptoms and criteria with the presence of mental disorders and functional deficits, with odds ratios being highest (7.4–31.8) when UHR and basic symptoms occurred together. Report of a family history of mental disorder generally increased risk for CHR symptoms. While younger age increased risk for basic symptoms, lifetime substance misuse and trauma increased risk for UHR symptoms.

Conclusions Prevalence of CHR criteria was within the to-be-expected range from prevalence rates of psychoses. Clinical relevance of both CHR symptoms and criteria increased in a stepwise manner from basic symptoms via UHR symptoms to their combined presence, reinforcing the clinical utility of their combined use. The risk factors selectively associated with basic and UHR symptoms support developmental models relating basic symptoms to neurobiological and UHR symptoms to psychological factors.

Two-step cluster analysis application to a sample of psychiatric inpatients at psychiatric service of diagnosis and care

F. Ambrosini^{1,*}, M. Benassi¹, R.P. Sant'Angelo², R. Raggini², L. Mandolesi¹, G. Piraccini²

¹ *Department of Psychology, University of Bologna, Bologna, Italy*

² *U.O. Servizio Psichiatrico di Diagnosi e Cura, Istituto AUSL della Romagna - Cesena, Cesena, Italy*

* *Corresponding author.*

Introduction Recent findings demonstrated significant overlaps among major psychiatric disorders on multiple neurocognitive domains. However, it is not clear which are the cognitive functions that contribute to this phenomenon.

Objectives To find the optimal clustering solution using the two-step cluster analysis on a sample of psychiatric patients.

Aims To classify into subgroups a cross-diagnostic sample of psychiatric inpatients on the basis of their neurocognitive profiles.

Methods Seventy-one patients with psychotic, bipolar, depressive and personality disorders hospitalised at Psychiatric Diagnosis and Care Service of Bufalini Hospital of Cesena participated in the study. The symptomatology was assessed using Health of the Nation Outcome Scales-Roma and Brief Psychiatric Rating Scale. Cognitive functions were evaluated using Tower of London, Modified Wisconsin Card Sorting Test, Judgment and Verbal Abstract Tasks test, Raven matrices, Attentional Matrices, Stroop Test and Mini Mental State Examination. Two-step cluster analysis was conducted using the standardized scores of each neurocognitive test.

Results Two groups were obtained: – group 1, with good cognitive performances; – group 2, with almost all subjects having impaired cognitive performances.

Executive functions and attention are the major determinants of the cluster solution. The clusters did not differ on socio-demographic correlates. Different diagnoses were equally distributed amongst the clusters.

Conclusions Two-step cluster analysis was useful in identifying subgroups of psychiatric inpatients with different cognitive functioning, overcoming other cluster techniques limitations. According to former literature, these results confirm a continuum of severity in cognitive impairment across different psychiatric disorders.

⁴ Department of psychology, Virginia Commonwealth University, Richmond, USA

⁵ Department of mental health and substance abuse, World Health Organization, Geneva, Switzerland

* Corresponding author.

Introduction One of the WHO's innovations for improving the ICD-11 chapter Mental and Behavioral Disorders was the creation of the Global Clinical Practice Network (GCPN), an international network of more than 12,000 mental health and primary care professionals from 144 countries.

Aims and objectives In order to evaluate perceived clinical utility of the ICD-11 guidelines, the case-controlled field studies that involved the application of the proposed diagnostic guidelines to standardized case material were implemented via the Internet in different languages.

Method Two hundred and seventy-eight Russian mental health care professionals, the GCPN members, have participated in case controlled Internet study for the chapter “Schizophrenia and

Other Primary Psychotic Disorders”. Russian participants were represented by psychiatrists mostly (89%) and much less by psychologists (8%) which corresponds with the general situation in the Russian mental health care system.

Results Russian clinicians have used the proposed ICD-11 diagnostic guidelines successfully to assess delusional disorder as well as schizophrenia. But there were certain categories (schizoaffective disorder, subthreshold delusions) with which the participants seemed to struggle. The critical comments were focused on opposing so called syndrome-based assessment and nosological diagnostics. Most concerns were about elimination of Schizophrenia subtypes.

Conclusion Russian mental health care professionals proved to be interested in ICD revision process and demonstrated their special diagnostics opinion based on rich clinical traditions and psychopathological approach. In order to use ICD-11 guidelines in clinical practice more efficiently supplementary appropriate training would be needed.

Exploring maternal mental health in Syrian refugee women

A. Bowen^{1,*}, A. Ahmed², C. Feng²

¹ Nursing, University of Saskatchewan, Saskatoon, Canada

² School of Public Health, University of Saskatchewan, Saskatoon, Canada

* Corresponding author.

Introduction There has been a rapid influx of 30,000 Syrian refugees in Canada, many are women of childbearing age, and most have young children. The literature reports that refugee women are almost 5 times more likely to develop postpartum depression than Canadian-born women. However, little is known about the experiences that the Syrian refugee women have encountered pre- and post-resettlement and their perceptions of mental health issues in general, and of maternal depression in particular. Thus, there is an urgent need to understand the refugee women's experiences of having a baby in Canada from a mental health perspective.

Methods Participants include Syrian refugee women who migrated to Saskatoon Canada in 2015–16 and who were either pregnant or up to one year postpartum. Qualitative data was collected via a focus group with thematic analysis, while depression with Edinburgh Postnatal Depression Scale (EPDS) and PTSD screening and sociodemographic descriptive data were collected from a structured questionnaire to provide context for the qualitative analysis.

Results Twelve women participated in the focus group, despite smiling often, 58% of them screened as probable depression (EPDS > 10), 25% screened positive for depression (> 12 on EPDS), and 17% screened positive for PTSD. None of the women indicated intimate partner violence or suicidal thoughts. All participants indicated social support, mostly partner, and 25% had a history of depression. Thematic analysis will be shared.

Conclusions Perinatal Depression is a serious problem for refugee women that deserve more in-depth study to ensure optimal outcomes and to develop services and programs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Validation and test-retest reliability of facial expressions basic emotions of baby stimulus

M. Donadon^{1,*}, R. Martin Santos², F. De Lima Osório³

¹ *Neuroscience and Behavior, Medical School at Ribeirao Preto, Ribeirao Preto, Brazil*

² *Universidade Autonoma de Barcelona, Barcelona, Spain*

³ *Neurociências e Ciências do comportamento, Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto, Brazil*

* Corresponding author.

Introduction Emotional facial expression paradigms of adults have been very used in the literature; however, studies with baby's emotional faces are very few.

Objectives To study the psychometric validity and reliability of a series of basic emotions faces of babies stimuli.

Methods We used 72 photographs of 12 baby faces (6–12 months), both sex and different ethnic groups, expressing basic emotions (happiness, sadness, fear, anger, surprise and neutral) elicited in the laboratory by pre-task defined. A total of 119 subjects of both sexes (63% women) in different age groups (18–65 years) and ethnicities, were invited to evaluate the facial emotional stimuli presented by the computer program SuperLab. They should choose the emotion represented by the photograph. Furthermore, 31 subjects were randomly selected to perform a test-retest assessment after an interval of 20 days.

Results It was observed that 35 stimuli presented hit rate exceeding 70% and 11 between 60% and 50%. The facial emotion of happiness was the most easily recognized, while fear was associated with the lower success rates. Only seven stimuli presented a hit rate lower than 20% (fear). All stimuli, except for one, showed a good reliability test/retest (McNemar test > 0.05).

Conclusion The study offers a series of baby emotional facial stimuli with good validity and reliability for research setting. However, the 30% of stimuli without satisfactory success rate may be problems with stimuli or stimulating task, as it becomes difficult to distinguish the emotion face on the baby.

EW0360

Does hikikomori exist in Ukraine?

I. Frankova

Psychosomatic medicine and psychotherapy, Bogomolets National Medical University, Kyiv, Ukraine

Introduction The term “Hikikomori” refer to the modern phenomenon—severe (acute, prolonged) social withdrawal (SSW). Recently, there have been increasing reports of Hikikomori around the globe, Ukraine is not an exception.

Objectives To describe epidemiological and psychopathological features of Hikikomori from Ukraine.

Methods Hikikomori was defined as a six-month or longer period of spending almost all time at home, avoiding social situations, social relationships, associated with significant distress/impairment. Lifetime history of psychiatric diagnosis was determined by the M.I.N.I. 7.0. Additional measures was Alexithymia Scale (TAS-20), Life experience questionnaire (LEQ), Buss-Durkee Hostility Inventory (BDHI), Chaban quality of life scale (CQLS).

Results In total, 65.4% of Hikikomori group (HG, $n=26$) had at least one psychiatric diagnosis, 34.6% had not. Personality disorders (15.4%), PTSD (11%), MDD (7.7%), SAD (7.7%), OCD (7.7%), bulimia nervosa (3.8%) were the most common. Onset of SSW in 41.7% started before 18 y.o. Healthy individuals formed the control group (CG, $n=25$). Individuals with Hikikomori had high

level of alexithymia (TAS-20 $M=71$, $SD=11.6$ vs. $M=60.8$ $SD=13.8$, $P=0.006$). Childhood trauma was reported by 31.8% of CG vs. 52% of HG. Hikikomori had higher trauma index (LEQ $M=3.03$, $SD=0.98$ vs. 2.31 , $SD=1.1$, $P=0.019$), larger number of lifespan traumatic events (LEQ 95%CI 4.57–7.35 vs. 2.8–5.28, $P=0.039$); higher levels of irritability, resentment, suspiciousness, higher aggressiveness (BDHI $M=23$, $SD=6.4$ vs. $M=16.6$, $SD=6$, $P=0.001$), low quality of life (CQLS $M=12.4$, $SD=3.3$, $P\leq 0.001$).

Conclusion Hikikomori exist in Ukraine, SSW quantitatively and qualitatively related to childhood trauma, manifests in adolescence, can be characterized by defined psychopathological features and affects quality of life.

Analysis of the factors affecting stigmatization and attitudes toward depression in young and elderly patients

G.Z. Kamyş^{1,*}, O. Erden Aki¹, İ. Yıldız², A. Dolgun³

¹ *Hacettepe University, Department of Psychiatry, Ankara, Turkey*

² *Private Madalyon Psychiatry Outpatient Clinics, Psychiatry, Ankara, Turkey*

³ *Hacettepe University, Department of Biostatistics, Ankara, Turkey*

* Corresponding author.

Objectives Depression is a frequently seen but under-recognized and under-treated syndrome in community. Stigmatization is an important barrier for care-seeking and treatment.

Aims In this study, we aimed to investigate the relationship of sociodemographic factors and attitudes towards depression between young and old age groups in a clinical population.

Method A total of 133 patients (18–88 years old, $n=37$ old-age group, $n=96$ young-age group) with a diagnosis of depression were recruited in this study. All the patients were evaluated with a semi-structured clinical interview and using stigmatization scales.

Results As young and old age groups compared, RHIDO total scores, RHIDO alienation sub-scale scores, social withdrawal subscale scores, and resistance to stigmatization subscale scores were found to be higher in young-age group than old-age group. Except working status, other sociodemographic factors were not found to have any effect on the scores of stigmatization scales.

Regarding the clinical features; number of episodes, comorbid physical disorders and time since first admission had an effect on RHIDO total and subscale scores. Negative attitudes towards depression were seen to be common in all the subjects, but no statistically significant difference was found between young and old age groups.

Conclusion Stigmatization is very common also for depression, and it is found to be related to different features including age, working status, and time since first admission. In order to help for decreasing the negative attitudes and increasing the help seeking behavior, some interventions should be conducted both in psychiatry clinics and society.

Using culture to enhance mental health in a northern Canadian aboriginal population

B. Mainguy^{*1}, L. Mehl-Madrona²

¹ *Coyote Institute, Education, Orono, USA*

² Eastern Maine Medical Center, Family Medicine Residency, Bangor, USA

* Corresponding author.

Introduction We present three community case studies for how community development and cultural enhancement affected mental health as an epiphenomenon.

Methods An initiative was undertaken in 3 Northern Canadian aboriginal communities to enhance spiritual and cultural fluency and to provide opportunities to healthy interaction among community members. We began each process with a narrative investigation of the community by eliciting stories about perceived problems in the community. We collected further narratives at the end of the intervention about how it had affected people personally. We reviewed the narratives for commonalities and themes using modified grounded theory and dimensional analysis. We measured numbers of patients presenting to behavioral health services with mental health diagnoses, number of people sent to hospital for mental health treatment, and number of suicide attempts. We collected quality of life data using the My Medical Outcome Profile 2.

Results Community development and cultural enhancement efforts reduced all of the variables we were tracking. Follow-up interviews revealed common themes of people becoming more present-centered, feeling higher quality in their relationships; feeling more connected to god, creator, nature, or higher power; feeling more peaceful; feeling more accepting of death and change; and having a greater sense of meaning and purpose. As an interesting side effect, people began to eat more traditional diets and to be more active.

Conclusions Creating opportunities for community interaction and shared community projects and enhancing interactions with spiritual elders resulted in improvement in indices of mental health in three indigenous communities in Northern Canada.

Female genital mutilation [FGM] and emotional support: A research study exploring the value and sustainability of offering emotional support to women exposed to FGM

S. McAndrew*, T. Warne, P. Mulongo

University of Salford, School of Nursing Midwifery Social Work & Social Science, Salford, United Kingdom

* Corresponding author.

Introduction Global estimates suggest over 130 million girls and women have undergone FGM. While practiced in Africa, Asia and the Middle East, due to immigration trends it is now prominent in Western society. While studies have focused on physical health consequences, post-2000 a small but growing number of studies have reported on the psychological impact of FGM. This paper reports on a project exploring the mental health consequences of FGM, the effectiveness of therapeutic support, and the sustainability of a new service through training peer mentors.

Objectives To establish and evaluate 3 drop-in clinics, offering emotional support to women who have experienced FGM. Build capacity through training peer mentors to continue the work of supporting women.

Method Community-based participatory research (CBPR) was used for this two-part project. In part 1, 30 women participated, data being collected via the Warwick-Edinburgh Mental Well-being Scale (WEMWS) and follow-up interviews. Part 2 involved the training of 12 peer mentors. Data was analysed using descriptive statistics and thematic analysis and evaluation respectively.

Results Improvement was found in the women's mental well-being, with themes (1) Speaking the unspoken (2) Emancipation of emotion (3) Harnessing hope, being identified. Of the 12 peer mentors successfully completing the course, 9 are now volunteering.

Conclusion Mental health professionals are best placed to enable women to address FGM traumas and improve their mental well-being. Additionally, they can raise public and professional awareness and, through research, can help develop more appropriate and sensitive services for migrant women from practicing communities.

Korean public knowledge and perceptions about treatment of attention-deficit hyperactivity disorder

I. Shon^{1,*}, B. Nam²

¹ Keyo Hospital, psychiatry, Uiwang, Republic of Korea

² Konkuk University, Psychiatry, Chungju, Republic of Korea

* Corresponding author.

Objective The aim of this study was to examine (1) public knowledge and perceptions about attention-deficit hyperactivity disorder (ADHD) and (2) factors influencing the public's decisions to adhere to ADHD pharmacotherapy.

Methods In this study, 396 participants responded to the Internet survey regarding their experiences, beliefs and treatment preferences about ADHD.

Results Two hundred and fifty-two respondents (63.6%) were reluctant to pharmacological treatment of ADHD. The respondents chose the functional impairment of the brain as the main cause of ADHD were favorable to pharmacological treatment and scored significantly high on the ADHD Knowledge Questionnaire. On the other hand, the respondents who regarded ADHD as an overly active personality rather than a disease were skeptical to pharmacotherapy and scored significantly low. The respondents who were acquainted with someone who had been diagnosed with ADHD perceived themselves relatively well informed about ADHD. However, the subjective perception of the degree of knowledge of ADHD was not correlated with the objective score of the ADHD Knowledge Questionnaire.

Conclusion The Korean public is not well informed about ADHD and its treatments. Culturally appropriate psychoeducational strategies based on the media and the Internet are needed. Providing biomedical conceptualization of ADHD to the public may aid with treatment decisions and promote adherence to pharmacological treatment.

A systematic review and case report of the Koro syndrome in an intellectually disabled Caucasian patient

A. Pastor Romero*, E. Guillot de Mergelina, L. Borredá Belda, J.F. Pérez Prieto

Hospital Clínico Universitario de Valencia, Psychiatry department, Valencia, Spain

* Corresponding author.

Introduction Koro syndrome has traditionally been considered a culturally bound syndrome, characterized by the delusional belief that one's genitalia are retracting and the anxiety caused by the

perception of imminent death. Although it is widely regarded as an epidemic in South-east Asia, there are some isolated cases in other cultures as well.

Objectives We present a Koro case study and a systematic review, focusing on the presentation and its treatment, in order to make visible this syndrome to Western culture and provide the tools to identify it.

Aims To provide an overview of Koro's presentation, phenomenology and treatment. We also want to clarify the nosology classification of this syndrome and its influence in the reported cases.

Methods We begin describing a new case of Koro syndrome: a Spanish male presented an acute psychosis, the patient had an intellectual disability and a family history of mental illness. A systematic review was done based on articles published in Pubmed following the PRISMA guidelines.

Results From 117 studies, only 29 met the inclusion criteria. Data were analyzed on several epidemiological and clinical characteristics. We found that Koro syndrome is more often presented as a result of intoxication or as a part of a previous known psychotic disorder. Cases involving patients sharing their delusion have been only reported in Asia.

Conclusion No specific data could be obtained about epidemiology and pathogenesis, as our conclusion about Koro syndrome was based mainly on few case studies. Pharmacotherapy and social support may be effective in ameliorating the symptoms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Describing and comparing quality in psychiatric care across the globe with the QPC-Instrument

A. Schröder*, L.O. Lundqvist

Faculty of Medicine and Health, University Health Care Research Center, Örebro, Sweden

* Corresponding author.

Introduction There is a lack of cross-cultural comparison of patients and staff perceptions of quality of care in the psychiatric care. One reason is the absence of standardized instruments.

Objectives The international research programme "Quality in Psychiatric Care" aims at adapting the instrument QPC versions for patients and staff to different international settings.

Aims The aims are to test the psychometric properties and equivalence of dimensionality of the different language versions of QPC and also to describe and compare the quality of inpatient, outpatient and forensic in-patient psychiatric care across different countries.

Methods The QPC is a family of self-reported instruments from the patients' perspective. In this programme, we used different languages versions in three areas for patient and staff; inpatient (QPC-IP/IPS), outpatient (QPC-OP/OPS) and forensic inpatient care (QPC-FIP/FIPS).

Results The Danish versions for QPC-FIP and QPC-FIPS show that the confirmatory factor analysis revealed that the factor structure was equivalent to the original Swedish version. Patients rated the quality of care generally lower than staff and lowest in the participation dimension. The Indonesian version of QPC-IP is under analysis. The first result show that patients rated the quality of care lower than Swedish inpatients and lowest in the discharge dimension. Several studies in Indonesia are still ongoing as well as in Brazil and Spain.

Conclusions There are few standardized instruments for measuring quality of care in the psychiatric care. Therefore, QPC is expected to make an important contribution to the development in this field.

Emotional expression and culture: Implications from nine Arab countries

B. Abu-Hamda, A. Soliman*, A. Babekr, T. Bellaj
Qatar University, Social Sciences Psychology, Doha, Qatar

* Corresponding author.

Introduction There is a notion that emotional expression is universal, yet it is subject to cultural variations. Research in this field has studied cultural extremes in European, American and East Asian cultures. However, very little is known about the differences in emotional expression in the Arab subcultures.

Objective Exploring the differences between the emotional reactions among the nine Arab subcultures.

Aims (1) Examining the cultural differences in emotional reactions; (2) examining the differences between Muslim and non-Muslim individuals; (3) exploring the differences between Arabs and non-Arabs.

Methods Several real life scenarios including 15 different stressful situations and 15 non-stressful situations were presented to 40 individuals from the nine Arab subcultures. The participants were aged between 18 to 40 years of age. The subjects were randomly classified into groups depending on whether they were Arabs or non-Arabs and according to whether they were Muslims or non-Muslims. The subjects' emotional reactions were measured by means of Likert-like items.

Results The results showed that there were no significant differences among the nine Arab subcultures in their emotional reactions to the non-stressful situations. However, there were significant differences among the Arab subcultures in the stressful situations. Moreover, both religion and ethics were strong predictors of the differences in the emotional reactions that varied between subjects in their cultural group. The Arab Muslims tended to express more anger but the Arab non-Muslims expressed more sadness.

Conclusions Emotional expression is impacted by ones' cultural background and is particularly influenced by religion and ethics. Although Arab countries share the same language, they express emotions differently.

The improvement of mental health competences and skills on a Brazilian Federal University

D. Soria^{1,*}, J.D. Cabrial¹, B.C. Marinho¹, N. Romeiro¹,
A. Mendes², R. Mello¹, T.V.C. Vernaglia¹

¹ Federal University of State of Rio de Janeiro, Nursing Medical Surgical, Rio de Janeiro, Brazil

² Nise da Silveira Psychiatric Institution, Culture Point Madness on the street Loucura Suburbana, Rio de Janeiro, Brazil

* Corresponding author.

Background The extension project "UNIRIO is madness: the improvement of mental health competences and skills." work since 2015 with "Ponto de Cultura Loucura Suburbana" on the promotion of mental health and culture style in Brazil. The project work on the development of psychosocial rehabilitation for psychiatric patients, their families and the community.

Aims Participate on the production and execution on the artistic/therapeutic workshop that demystify the social stigmatizing vision about psychiatric patients.

Methods The activities developed are: administrative actions; institutional strengthening for social inclusion initiative through work; and the Carnival Block organization.

Results This study work on constituting a social inclusion initiative through workshop that generate employment, e.g.: sale material production, financial management, material replacement. Although we do all the preparative to the Carnival Block–“Loucura Suburbana”.

Conclusion The relationship with the psychiatric patients shows that social inclusion through carnival workshop practice is the primary means for the identity of people suffering from mental disorders and contribute to reduce community social stigma.

Differences in baseline demographics, presentation, pathways to care and duration of untreated psychosis (DUP) in the ethnically diverse population of Lancashire, UK

V. Damle^{1,*}, D.N. Husain²

¹ Lancashire Care NHS Foundation Trust, Psychiatry, Bolton, United Kingdom

² Lancashire Care NHS Foundation Trust, Psychiatry, Manchester, United Kingdom

* Corresponding author.

Introduction DUP is the time from the emergence of first psychotic symptom to the commencement of adequate antipsychotic treatment. Psychopathological and sociocultural factors influence patient's treatment seeking behavior. Better understanding of DUP could help in development of improved therapeutic strategies and public health initiatives. Emphasis on early detection of psychosis and reduction of DUP has led to a huge interest in pathways to care. **Objectives** To understand the differences in baseline demographics, presentation, care-pathways and DUP in ethnically diverse population of Lancashire, UK.

Methods Our cross-sectional study involved a subset analysis of National EDEN data for Blackburn and Preston in Lancashire.

Results Of the 183 patients, 78% were Whites and rest belonged to BME population. Median DUP was 188 days. Whites were significantly younger at onset of both non-specific symptoms and psychosis and at acceptance into EIS. Whites were significantly less likely than non-whites to be married, more likely to be in paid work and to have used illicit drugs. There were no significant differences with respect to other demographics/delays in help seeking or DUP. Non-White group had shorter DUP of 95 days (but not statistically significant, $P=0.060$).

Conclusions Better understanding of mental illness and local services in White patients could have led to early help seeking. Having a supportive family may have promoted early help seeking and thus shorter DUP in BME group. Further studies are needed exploring socioenvironmental variables, substance misuse and knowledge of local psychiatric services amongst the BME population and the influence of these variables on DUP.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Somatoform symptoms' influence on the rubber hand illusion: Additional analysis

O. Perepelkina*, G. Arina, M. Boboleva, V. Nikolaeva
Lomonosov Moscow State University, Department of psychology,
Moscow, Russia

* Corresponding author.

Introduction In the rubber hand illusion (RHI) [1], sense of body ownership is changed by synchronous touches to the hidden participant's hand and a visible rubber hand. It was previously shown [2] that medically unexplained symptoms were associated with the weaker RHI ($n=40$).

Objectives We used data from our previous research [3] and supplementary questionnaires to test the hypothesis that somatoform symptoms would be associated with the decreased response to RHI. **Methods** Subjects ($n=78$) voluntarily undergo the following procedures: RHI experiment with measurement of proprioceptive drift and self-reports, Screening for Somatoform Disorders (SOMS-2) and Symptom Check List-90-Revised (the “somatization scale”).

Results Robust regression was used to evaluate predictors influence: Drift/Self-reports~SOMS-2 + somatization. SOMS-2 was a significant predictor for proprioceptive drift with positive coefficient ($P<0.05$, adjusted), both predictors were insignificant for self-reports.

Conclusions Thus, the results of [2] were not reproduced. We demonstrated on the larger sample, that the higher somatoform symptoms (scores of SOMS-2) predicted the stronger RHI. Since our research and [2] had been conducted on non-clinical groups, it is necessary to conduct the critical experiment on the clinical population.

The reported study was funded by RFBR according to the research project No.16-36-00394.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction There is a limited amount of data regarding the relationship between epilepsy and psychiatric symptoms and quality of life (QoL) in children and adolescents.

Objectives The aim of this study was to determine the levels of depression, anxiety and attention-deficit hyperactivity disorder symptoms and health-related quality of life (HRQL) in children and adolescents with epilepsy.

Methods The sample consisted of 75 children with epilepsy and 50 healthy controls aged 8–18 years. Questionnaires were used to evaluate the psychiatric status and HRQL of the patients.

Results Patients had lower child-rated psychosocial and total area HRQL scores, and lower parent-rated psychosocial, physical and total area HRQL scores than the controls did. Inattention scores of the epilepsy group were significantly higher compared to controls. No significant differences were found between patients and controls in terms of anxiety and depression scores. Regarding determinants of HRQL, severity of depression and anxiety had a decreasing effect on child-rated HRQL total scores; and severity of anxiety had a decreasing effect on parent-rated HRQL total scores.

Conclusions Epilepsy is associated with poor QoL in childhood and severity of depression and anxiety are among the determinants of QoL. Clinicians should be more aware of accompanying psychiatric symptoms in epileptic patients and take the necessary precautions in the early period of the illness in an effort to improve QoL.

The new great imitator – neuropsychiatric symptoms of Lyme disease

M.C. Cochat Costa Rodrigues^{1,*}, I. Moreira², M.J. Peixoto³, C. Silveira³

¹ Magalhães Lemos Hospital, Psychiatry, Porto, Portugal

² Hospital D.^a Estefânia, Centro Hospitalar de Lisboa Central, Department of Child and Adolescent Psychiatry, Lisboa, Portugal

³ Centro Hospitalar de São João, Clinic of Psychiatry and Mental Health, Porto, Portugal

* Corresponding author.

Introduction Lyme disease, caused by the spirochete *Borrelia burgdorferi* as recognized as a possible cause of multisystemic signals and symptoms, including symptomatology of the central as well as the peripheral nervous system.

Objectives Identification of neuropsychiatric symptoms associated with Lyme disease.

Methods Literature review in the light of researched articles published in Pubmed/Medline as well as related bibliography.

Results Since the identification of the etiology of syphilis in the early twentieth century, mental health professionals consider the fact that serious psychiatric symptoms can be caused by infections of the central nervous system and that early antibiotic treatment can prevent permanent neurological/psychiatric damage. Syphilis was known as “the great imitator” because its multiple manifestations mimic other known diseases. In recent years, a new epidemic, also with multiple manifestations emerged—Lyme disease, also known as the “new great imitator”. Like syphilis, Lyme disease may be associated with neuropsychiatric symptoms, which means that often these cases are initially referred for psychiatric services, before another diagnosis is made. The incorrect assessment of these patients as individuals with functional psychiatric disease can result in a delay in the start of antibiotic treatment and may cause serious neurological and psychiatric damage.

Conclusions According to the review, the authors propose that in the evaluation of acute psychiatric disease or atypical chronic disease, with poor therapeutic response, Lyme disease should be considered and ruled out, especially if there is epidemiological context and absence of psychiatric family antecedents.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW0373

Attention, vigilance and visuospatial functioning in hospitalised elderly medical inpatients – relationship to delirium syndromal status and motor subtype profile

C. Daly

University of Limerick, psychiatry, limerick, Ireland

Objective The early and efficacious detection of neurocognitive disorders poses a key diagnostic challenge. We examined how bedside cognitive tests perform across the spectrum of delirium and motor subtypes.

Methods The performance on a battery of bedside cognitive tests were compared in elderly medical inpatients with DSM-IV delirium, subsyndromal delirium, and no neuro cognitive disorder and in motor subtypes.

Results One hundred and ninety-eight patients (mean age 79.14 ± 8.26) were assessed with no delirium ($n=43$), subsyndromal delirium ($n=45$), and full syndromal delirium ($n=110$). The ability to meaningfully engage with the tests varied from 59% for vigilance B test to 85% for Spatial Span forward test and was found to be least in the full syndromal delirium group. The no delirium group was distinguished from the delirium groups for all the tests and from the full syndromal delirium group for the vigilance B test and global visuospatial function test. The subsyndromal delirium group differed from the full syndromal delirium group in respect of global visuospatial function test, spatial span backwards and vigilance A tests. Patients with full syndromal delirium were best identified using the interlocking pentagons test and clock drawing test whereas those with subsyndromal delirium were best identified using interlocking pentagons test and months backwards test. Those with subsyndromal delirium were significantly better in their ability to engage than those with full syndromal delirium.

Conclusions Simple bedside tests of attention, vigilance, and visuospatial ability are useful to help to distinguish neurocognitive disorders namely subsyndromal delirium from other presentations.

The effects of bariatric surgery on pharmacokinetics of antidepressants: A systematic review

L. de Jonge^{1,*}, S. Petrykiv², J. Fennema³, M. Arts⁴

¹ Leonardo Scientific Research Institute, Geriatric Psychiatry, Bergen op Zoom, The Netherlands

² University of Groningen, University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands

³ GGZ Friesland, Geriatric Psychiatry, Leeuwarden, The Netherlands

⁴ University of Groningen, University Medical Center Groningen, Department of Old Age Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction Morbid obesity (BMI ≥ 35) has been associated with mood and anxiety disorders. Regular use of antidepressants is common among patients who are candidate for bariatric surgery. The Roux-en-Y gastric bypass (RYGB) is one of the most common techniques used in bariatric surgery for reducing nutrient absorption. This type of surgery may however result in major changes in drug absorption.

Objectives and aims To report and discuss the consequences of bariatric surgery on changes in antidepressant drug absorption.

Methods We present all published in vitro and in vivo studies on antidepressant drug absorption after bariatric surgery.

Results In vitro studies showed that only bupropion had a significantly increased dissolution in a post-RYGB environment; venlafaxine and citalopram showed no alteration of dissolution; fluoxetine, paroxetine, sertraline, and amitriptyline had a significantly decreased dissolution in a post RYGB environment. Some in-vivo studies reported that only citalopram and escitalopram had an increased dissolution.

Conclusion After bariatric surgery, special caution is required in patients using antidepressant medication because of the expected changes in drug absorption, nutritional status, and electrolyte balance.

⁴ Campus Psychiatric Hospital St.-Norbertus, University Psychiatric Department, Duffel, Belgium

* Corresponding author.

Objective There is a large consensus concerning the important aetiological role of childhood trauma in chronic fatigue syndrome (CFS). In the current study, we examine the differential effect of childhood trauma subtypes on fatigue and physical functioning in patients with CFS.

Methods One hundred and fifty-five participants receiving treatment at the outpatient clinic for CFS of the Antwerp University Hospital in Belgium were included in this study. Stepwise regression analyses were conducted with the outcomes of the total score of the Checklist Individual Strength (CIS) measuring fatigue and the physical functioning subscale of the medical outcomes short form-36 health status survey (SF-36) as the dependent variables, and the scores on the five Traumatic Experiences Checklist (TEC) subscales as the independent variables.

Results Fatigue and physical functioning scores in CFS patients were significantly predicted by sexual harassment only. A significant effect of emotional neglect, emotional abuse and bodily threat during childhood on elevated fatigue or reduced physical functioning levels could not be found.

Conclusion There is a differential effect of childhood trauma subtypes on fatigue and physical functioning in CFS patients. Sexual harassment emerged as the most important predictor variable. Therefore, childhood (sexual) trauma has to be taken into account in assessment and treatment of chronic fatigue syndrome.

Joint hypermobility syndrome and anxiety disorder: Structural brain correlates

J. Eccles^{1,2,*}, J. Tung¹, N. Harrison^{1,2}, C. Mathias^{3,4}, H. Critchley^{1,2,5}

¹ Brighton and Sussex Medical School, Neuroscience, Brighton, United Kingdom

² Sussex Partnership NHS Foundation Trust, Psychiatry, Worthing, United Kingdom

³ Hospital of St John and St Elizabeth, Autonomic & Neurovascular Medicine Unit, London, United Kingdom

⁴ Institute of Neurology, University College London, London, United Kingdom

⁵ University of Sussex, Sackler Centre for Consciousness Science, Falmer, United Kingdom

* Corresponding author.

Introduction Joint hypermobility syndrome/Ehlers Danlos III (JHS/EDS III) is a common, connective tissue condition. This group is over-represented in panic/anxiety disorders and exhibits autonomic abnormalities and heightened interoceptive sensibility. Previous neuroimaging in healthy volunteers with hypermobility has observed differences in key emotional brain regions, notably amygdala and insula.

Aims and objective To explore, in a clinical population, the structural brain correlates underpinning the association between JHS/EDS III and anxiety.

Method Seventy participants were divided into four experimental groups: (2 × 2 factor design: presence/absence of hypermobility; presence/absence of anxiety). Hypermobility was assessed using Brighton Criteria. All participants underwent brief tests of autonomic function and interoception. Structural images were obtained using a 1.5T MRI scanner. Results are reported at whole brain uncorrected significance threshold of $P < 0.001$.

Results Comparison of grey matter volume revealed increased insular volume in anxious patients with JHS/EDS-III compared to anxious patients without (Fig. 1A, B), correlating with initial peak heart rate on standing. Additionally, amygdala volume correlated with hypermobility score in anxious patients, but not in non-anxious individuals (Fig. 1C, D). Amygdala volume correlated with interoceptive accuracy.

Conclusions This data implicates amygdala and insula as likely neural substrates mediating clinical relationships between hypermobility syndrome and anxiety, demonstrating the relevance of autonomic and interoceptive influences on this relationship. Further work hopes to explore functional and structural connectivity between these regions in JHS/EDS-III.

Figure 1 Structural neuroimaging of the relationship between joint hypermobility and anxiety. A. Insula structural differences in anxiety disorder in those with hypermobility syndrome compared to those without. B. Plot showing differences in insula volume. C. Amygdala structural differences, demonstrating significant interaction between anxiety status and degree of hypermobility. D. Plot showing interaction between anxiety on the relationship between amygdala volume and hypermobility source.

Psychiatry and primary care: A global medical care

B. Gelas-Ample^{1,*}, L. Fau¹, A. Bailly², F. Pillot-meunier²

¹ Centre hospitalier Le Vinatier, Pôle Ouest, Bron, France

² Centre hospitalier Le Vinatier, Pôle Mopha, Bron, France

* Corresponding author.

Patients suffering from psychiatric disorders have a decrease in life expectancy of 15 years compared to the general population. This excess mortality is not related predominantly to suicide but mostly to a higher frequency of somatic diseases, such as cardiovascular, neoplastic, metabolic diseases. Their high prevalence and their low diagnoses are related to a poorer access to screening, prevention and somatic care than in the general population. Indeed, we estimated that more than 60% of patients treated in public psychiatry do not have a general practitioner (GP) in France. The GP has a role in the coordination, prevention and management of patient health care circuit. To allow a better access to general practitioner, a consultation and a somatic network have been created in Lyon. The purpose is to bring the user back into the primary care system, to ensure a durable monitoring, and a better prevention of avoidable diseases. Patients without GP are oriented to the consultation by their referent psychiatry team. During three consultations with a doctor and a nurse, an assessment of the patient's overall health is realized as well as a synthesis and a redirection to the city network. This reinstatement also allows a better communication between somatic and psychiatric care, to insure a more global view of the patient. A work around the re-empowerment and social rehabilitation is carried out to re-anchor the person in the city and in the care, which every citizen is entitled.

Efficacy and safety of antidepressants as analgesics in chronic pain: A review

J. Fennema^{1,*}, S. Petrykiv², L. de Jonge³, M. Arts⁴

¹ GGZ Friesland, Geriatric Psychiatry, Leeuwarden, The Netherlands

² University of Groningen, University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands

³ Leonardo Scientific Research Institute, Department of Geriatric Psychiatry, Groningen, The Netherlands

⁴ University of Groningen, University Medical Center Groningen, Department of Old Age Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction Due to the aging population worldwide, chronic pain is becoming an important public health concern. Chronic pain is bidirectional associated with psychiatric disorders including depression and anxiety. Antidepressants are widely used as adjunct therapy for the treatment of chronic pain for many disorders. **Objectives and aims** To review available literature on the efficacy and safety of antidepressants for the treatment of chronic pain, including neuropathic pain, fibromyalgia, low back pain, and chronic headache or migraine.

Methods We performed a detailed literature review through PubMed, EMBASE and Cochrane's Library to assess the efficacy and safety of antidepressants in chronic pain conditions.

Results In neuropathic pain, fibromyalgia, low back pain, and chronic headaches/migraine, tricyclic antidepressants (TCAs) showed a significant analgesic effect. Selective serotonin reuptake inhibitors (SSRIs) are not effective for the treatment of low back pain and headaches or migraine. Venlafaxine, a serotonin norepinephrine reuptake inhibitor (SNRI) showed significant improvement of fibromyalgia and neuropathic pain. Duloxetine (SNRI) also reduced the pain in fibromyalgia.

Conclusion TCAs are the 'gold standard' antidepressant analgesics. However, an electrocardiogram and postural blood pressure should be implemented prior to TCA treatment and TCAs should be initiated at low dosages and subsequently increased to the maximum tolerated dose. One should pay attention to their cardiotoxic potential, especially in the older population. For the treatment of neuropathic pain, SNRIs are second-line agents. Although better tolerated, in most types of chronic pain conditions, the effectiveness of SSRIs is limited. To conclude: start low, go slow, and prescribe with caution.

Exploring the correlation between perceived attachment security and levels of GH hormone in a sample of children with non-organic failure to thrive: Preliminary findings

M. Fojanesi¹, M. Gallo¹, F. Russo¹, M. Valentini¹, M. Spaziani², A. Radicioni², F.S. Bersani^{1,*}, M. Biondi¹

¹ Sapienza University of Rome, Department of Psychiatry, Rome, Italy

² Sapienza University of Rome, Department of Endocrinology, Rome, Italy

* Corresponding author.

Introduction Short stature caused by growth hormone (GH) deficiency is one of the causes of the "Failure to Thrive" (FTT) condition. In absence of clear organic causes, several different psychosocial conditions may play a role in explaining the FTT phenotype. Advances in developmental psychology have highlighted the role of emotions and caregiving behaviors in the organization of child's personality and psychobiology, with the mother-son attachment

bond being considered a fundamental developmental experience. The objective of the present preliminary study was to assess whether there are significant correlations between attachment styles and GH levels in a sample of subjects with non-organic FTT.

Methods We enrolled 27 children (mean age: 9.49 ± 2.63) with non-organic FTT. Perceived attachment security was assessed through the Security Scale (SS) and its subscales focused on maternal and paternal security. Pearson partial correlation was used to test associations between GH levels and SS measures adjusting for confounding factors (i.e. age, gender and BMI).

Results Across all subjects, GH was significantly positively correlated with general security ($r=0.425$; $P=0.038$) and maternal security (SSM) ($r=-0.451$; $P=0.027$) and not significantly correlated with paternal security (SSP) ($r=0.237$; $P=0.264$).

Discussion These findings preliminarily suggest that perceived attachment security may play a role in the etiopathogenesis of non-organic GH deficiencies and add to the accumulating evidence that attachment styles are associated with specific psychoendocrine underpinnings.

Multifactor risk for coronary heart disease (CHD) development is associated with susceptibility and depressive reaction to stressful situations that causes search for ways of optimization of integrative assistance to CHD patients with depressive disorders.

Objective To carry out comparative analysis of dynamics of mental and physical state in CHD patients.

Material and methods Two hundred and eighty (57.74 ± 5.59 years) CHD patients with grade II–III angina pectoris were examined. Psychopathological method, Center of Epidemiological Studies-Depression scale (CES-D) were used.

Results Ninety patients (32.1%) had depressive disorders within depressive episode, dysthymia, adjustment disorder. The level of depression according to CES-D varied from 19 to 28 points. Comparative analysis of two groups of patients showed that CHD patients with depression had more severe grade III angina (22.1% vs. 11.6%; $P=0.036$) more frequently. Differences regarding frequency of arterial hypertension (AH) (91.1% vs. 63.2%; $P=0.0002$), type 2 diabetes mellitus (DM) (26.8% vs. 17.5%; $P=0.038$), obesity (30.7 ± 3.9 vs. 29.5 ± 4.5 ; $P=0.015$), arrhythmias (34.4% vs. 25.2%; $P=0.015$); cases of myocardial infarction (47.8% vs. 17.9%; $P=0.0001$) were revealed. Among patients with depressive disorders persons with experience of surgical myocardial revascularization ($P=0.004$), degree II–III of disability (23.3% vs. 11.6%; $P=0.0118$) were present more frequently. Patients with depression were characterized by low economic status (64.4% vs. 23.7%; $P=0.0001$); absence of social

support (34.4% vs. 12.6%; $P=0.0001$); frequent stress situations in personal history (71.1% vs. 32.6%; $P=0.0002$).

Conclusions Depressive disorders caused by psychosocial stress influence negatively CHD course that requires complex approach to therapy of comorbid pathology.

Introduction Ulcerative colitis and Crohn's disease is characterized from a complicated therapeutic management, with bodily and psychological impact to the family.

Objectives This study examined the coping strategies among families with a child or adolescent with IBD.

Aim The aim was to investigate possible sex differences with respect to coping strategies of the parents would correlated to overall coping strategies.

Method The participants were biological parents of patients diagnosed with IBD. The total sample included 61 parents with a mean age 46.2 (SD = 7.4). The parents completed:

- the Family Crisis Oriented Personal Scales;
- the Other As Shamer Scale;
- the Experiences of Shame Scale (ESS);
- questionnaire concerning socio-demographic information.

Results Mother reported higher levels of social support, accept help, passive appraisal, and overall strategies compared to fathers. The strongest difference was found in accept help ($P<0.001$). The feelings of shame of the mothers and fathers of the IBD families were very similar, without statistically significant differences between the groups. The results of the MLR, after controlling for adolescents age, sex and illness duration, revealed that the older age, being a mother, being married and being employment had direct positive associations with the overall coping strategies, while ESS had direct negative associations with the overall coping strategies. The model with all seven predictors explained 68% of the total variance ($R^2 = 0.68$, $F = 6.409$, $P < 0.001$).

Conclusions Our findings provide more detailed information on the coping strategies of Greek families with a child or adolescence with IBD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Objective To examine the risk of depression and anxiety in MS patients in the post-diagnostic period by using clinical screening instruments and a diagnostic structured clinical interview.

Method A population of 134 MS patients was examined for the risk of depression and anxiety in the post-diagnostic period of MS using the clinical screening instruments Beck Depression Inventory (BDI) and Hospital Anxiety and Depression Scale (HADS). Within six weeks of diagnosis, patients with cut-off > 12 for BDI and > 7 for HADS were offered a clinical structured interview using the Schedules for Clinical Assessment in Neuropsychiatry/SCAN Version 2.1.

Results The prevalence of depressive symptoms and depression in the post-diagnostic period of MS was 49.2% when using the screening instruments, but only 15.2% when using the SCAN interview. For anxiety, the prevalence was 3.4% for both the screening instruments and the SCAN interview in the post-diagnostic period of MS.

Conclusion MS patients have a risk of depression and anxiety in the post-diagnostic period of MS, but it is crucial to consider which tools to use in a clinical setting to investigate depression and anxiety in MS patients.

Keywords Multiple sclerosis; Psychiatric co-morbidity; Depression; Anxiety; HADS; BDI-II; Diagnostic interview

Psychosis induced by interferon- α —A limitation of treatment

M. Marinho^{1,*}, M. Mota-Oliveira¹, J. Marques², M. Bragança¹

¹ São João Hospital Centre, Clinic of Psychiatry and Mental Health, Porto, Portugal

² Local Healthcare Unit of Matosinhos, Clinic of Psychiatry, Matosinhos, Portugal

* Corresponding author.

Introduction Psychosis is an uncommon but serious complication of treatment with interferon- α , a cytokine frequently used to treat several infectious and malignant diseases.

Objectives To provide an overview of interferon- α -induced psychosis.

Methods Literature review based on PubMed/MEDLINE, using the keywords “interferon- α ” and “psychosis”.

Results Psychotic symptoms usually emerge between 6 to 46 weeks and on average 3 months after the start of interferon- α treatment, occurring most frequently in the form of persecutory, guilt or grandeur delusions and auditory hallucinations. Often they are accompanied by mood symptoms, anxiety, attention disturbances and insomnia. Many factors are known to increase the risk of psychiatric effects as a whole associated with interferon- α . Pathogenesis of interferon-induced psychosis remains unclear, however several theories have been discussed, namely the overlap influence of biological vulnerability and the cytokine's action on the brain. Dopaminergic, opioid, serotonergic and glutamin-

ergic pathways as well as hypothalamic-pituitary-adrenal axis hypersensitivity are some of the hypotheses raised about the underlying cause of that susceptibility. Psychosis management usually includes stopping interferon- α and introducing antipsychotics with minimal antidopaminergic effects and at the lowest possible dose, due to the increased risk of extrapyramidal reactions in these patients.

Conclusion The decision to use interferon-based treatments in psychiatric patients should be highly individualized. Early recognition and adequate treatment of interferon-induced psychosis might prevent subsequent emergence of serious debilitating symptoms. Thus, it is very important that medical and psychiatric treatment teams work closely together and are familiar with this important subject.

Depression among cancer patients—A reality where therapeutic nihilism cannot be accepted

M. Marinho^{1,*}, J. Marques², M. Bragança¹

¹ São João Hospital Centre, Clinic of Psychiatry and Mental Health, Porto, Portugal

² Local Healthcare Unit of Matosinhos, Clinic of Psychiatry, Matosinhos, Portugal

* Corresponding author.

Introduction Cancer is a life-threatening disease, characterized by a great deal of uncertainty and unpredictability. Thus, several stressors and emotional upheavals pervade the everyday life of cancer patients and can lead to the development of depression.

Objectives To review the recent research related to depression in cancer patients.

Methods Literature review based on PubMed/MEDLINE, using the keywords “cancer” and “depression”.

Results It is estimated that 20–25% of cancer patients meet the criteria for major depressive syndrome at some point in their illness. Depression is associated with a negative impact on treatment adhesion, cancer progression and quality of life, besides increasing suicide risk. However, it is often unrecognized and untreated. Importantly, the mistaken belief that depressive symptoms are expected in this group, the overlap between the neurovegetative symptoms of depression, the somatic symptoms of cancer and its treatment, as well as the effects of comorbid diseases make the diagnosis of major depression so complex in these patients. Some of the most helpful diagnostic indicators are feelings of hopelessness, worthlessness, excessive guilt, loss of self-esteem, and wishes to die. The several risk factors for the development of depression in cancer patients can be divided into four broad categories, namely cancer-related factors, cancer treatment-related factors, psychiatric history, and social factors. Effective management of depression consists in a combination of psychotherapy and psychopharmacology.

Conclusion Depression in cancer patients has serious consequences, however appropriate psychiatric intervention can do it over. Thus, its early recognition and appropriate management is imperative.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Efavirenz and neuropsychiatric effects—When the treatment complicates matter further

M. Marinho^{1,*}, C. Novais¹, J. Marques², M. Bragança¹¹ São João Hospital Centre, Clinic of Psychiatry and Mental Health, Porto, Portugal² Local Healthcare Unit of Matosinhos, Clinic of Psychiatry, Matosinhos, Portugal

* Corresponding author.

Introduction Efavirenz, a non-nucleoside analogue inhibitor of the reverse transcriptase, has become commonly used in the treatment of HIV infection. Although highly effective, efavirenz is associated with causing neuropsychiatric side effects in approximately 50% of patients.

Objectives To provide an overview of efavirenz-induced neuropsychiatric effects.

Methods Literature review based on PubMed/Medline.

Results The neuropsychiatric side effects of efavirenz usually begin quickly, commonly peak in the first two weeks after the start of therapy, and can include depression, anxiety, sleep disturbances, impaired concentration, aggressive behavior, paranoia, psychosis. Generally, these events are mild to moderate in severity and time limited, however, in a small number of cases, are late, persistent or intolerable. They are often associated with a negative impact on treatment adherence. Some factors are known to increase the risk of neuropsychiatric effects in HIV-positive patients. The behavioral effects of efavirenz appear to be dose-dependent and mediated predominately by the 5-HT_{2A} receptor, a primary site of action of lysergic acid diethylamine (LSD). Importantly, the efavirenz-induced neuropsychiatric effects may be difficult to distinguish from HIV-related neuropsychiatric symptoms, preexisting mental disorder or substance use. The neuropsychiatric effects should be treated with non-pharmacologic or pharmacologic interventions, according to severity. The psychiatric status of patients should be closely monitored for at least the first 6 to 12 months of treatment.

Conclusion Taking into account the high rates of neuropsychiatric side effects, it is crucial that the physicians are familiar with this important subject, and the decision to initiate efavirenz in psychiatric patients is individualized.

Disclosure of interest The authors have not supplied their declaration of competing interest.

HIV/AIDS “worried well”—When the “virus” leads to a significant illness, even in its absence

M. Marinho^{1,*}, V. Covelo¹, J. Marques², M. Bragança¹¹ São João Hospital Centre, Clinic of Psychiatry and Mental Health, Porto, Portugal² Local Healthcare Unit of Matosinhos, Clinic of Psychiatry, Matosinhos, Portugal

* Corresponding author.

Introduction Management of HIV/AIDS “worried well” people is among the most complex and challenging psychiatric problems in HIV care.

Objectives To provide an overview of HIV/AIDS “worried well”.

Methods Literature review based on PubMed/Medline, using the keywords “HIV” and “worried well”.

Results The HIV/AIDS “worried well” are those individuals who are intensely worried about being infected with HIV, despite overwhelming evidence to the contrary. Indeed, they will rapidly return with the renewed conviction that the physician has “got it wrong” or “missed something”. So, they tend to over-utilize

health care services. Seven HIV/AIDS “worried well” sub-groups have been identified: those with past sex or drug use history; those with relationship problems; the partners/spouse of those at risk; couples in individual or family life transitions; past history of psychological problems; misunderstanding of health education material; and pseudo and factitious AIDS. These patients have several striking consistencies in their presenting phenomenology and background features and usually have psychiatric problems associated. The authors will analyze all these aspects. Currently there are no guidelines to deal with this clinical condition, however cognitive-behavioral therapy along with selective serotonin reuptake inhibitors has been an effective approach. It is also important to ensure follow-up discussion to these patients, especially where unresolved life issues may cause future vulnerability in absence of intervention.

Conclusions Patients may express their concerns about HIV infection by several ways, directly or indirectly, and psychiatrists need to be aware of this reality, which causes much suffering as well as severe monetary loss.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Brain-derived neurotrophic factor (BDNF) levels and delirium

D. Adamis^{1,*}, J. Williams², K. Finn³, V. Melvin¹, D. Meagher⁴, G. McCarthy¹¹ Sligo Mental Health Services, Psychiatry, Sligo, Ireland² Sligo University Hospital, Pathology Department, Sligo, Ireland³ School of Biological Science, Cork Institute of Technology, Cork, Ireland⁴ Graduate-Entry Medical School University of Limerick, Psychiatry, Limerick, Ireland

* Corresponding author.

Introduction Studies of the association between blood BDNF levels and delirium are very few and have yielded mixed results.

Objectives To investigate the blood BDNF levels in the occurrence and recovery of delirium.

Methods Prospective, longitudinal study. Participants were assessed twice weekly with MoCA, DRS-R98, APACHE-II. BDNF levels of the same were estimated with ELISA method. Delirium has been defined as per DRS-98R (cut-off > 16) and recovery of delirium as at least two consequent assessments without delirium prior to discharge.

Results No differences in the levels of BDNF between those with delirium and those who never developed it. Excluding those who never developed delirium ($n=140$), we analysed the effects of BDNF and the other variables on delirium resolution and recovery. Of the 58 remained with delirium in the subsequently observations ($\max=8$) some of them continue to be delirious until discharge or death ($n=39$) while others recovered ($n=19$). BDNF levels and MoCA scores were significantly associated with both delirium cases who became non-delirious (resolution) during the assessments and with overall recovery. BDNF (Wald $\chi^2=11.652$, df: 1 $P=.001$), for resolution. For recovery Wald $\chi^2=7.155$; df: 1, $P=.007$. No significant association was found for the other variables (APACHE-II, history of dementia, age or gender).

Conclusions BDNF do not have a direct effect in the occurrence of delirium but for those delirious of whom the levels are increased during the hospitalisation they are more likely to recover from delirium.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Genetic variants in the *ABCB1* gene determine bioavailability of antidepressants in the brain

E. Holsboer-Trachsler^{1,*}, B. Breitenstein², T. Kirmeier², F. Holsboer²

¹ Psychiatric Clinics UPK of the University of Basel, Center for Affective, Stress and Sleep Disorders, Basel, Switzerland

² HMNC Brain Health, None, Munich, Germany

* Corresponding author.

Introduction Antidepressants are the first-line treatment of major depressive disorder, but response rates following the first antidepressant medication are moderate.

Objectives Clinical efficacy requires to overcome the blood-brain barrier where p-gp molecules are located. If they recognize and bind an antidepressant, they pump it back into the circulation. If the antidepressant is not recognized, the passage is not impaired by p-glycoproteins.

Aims We studied whether variants in the *ABCB1* gene that encodes the p-glycoprotein have an effect on blood-brain passage of antidepressants and as consequence on their clinical benefit.

Methods *ABCB1* gene variants were determined with sequencing (Illumina Bead), substrate property analysis employed mice with deletion of *ABCB1*-analog genes. Clinical protocols followed those of the MARS-project.

Results – The SNPs rs2032583 and rs2235015 provide the best clinical information about blood-brain-penetrance, with CC/CT and TT/GT being the favourable gene variants whereas TT and GG are less favourable. This distinction holds only true if antidepressants are p-glycoprotein substrates;

– in the presence of the favourable gene-variant patients treated with an antidepressant that is a p-glycoprotein substrate are more likely to remit in shorter time;

– in the presence of the less favourable gene-variant treatment with a substrate, higher dosages and augmentation strategies, or switch to non-substrates are recommended.

Conclusion From these data, a treatment algorithm was developed that maximizes treatment benefit and minimizes adverse effects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Self-stigma and quality of life in outpatients with depressive disorder – a cross-sectional study

M. Holubova^{1,2,*}, J. Prasko¹, M. Ociskova¹, M. Marackova¹, A. Grambal¹, M. Slepecky³

¹ University of Palacky Olomouc, Department of Psychiatry, Olomouc, Czech Republic

² Regional Hospital Liberec, Department of Psychiatry, Liberec, Czech Republic

³ Constantine the Philosopher University in Nitra, Department of Psychology Sciences, Nitra, Slovak Republic

* Corresponding author.

Background Self-stigma is a maladaptive psychosocial phenomenon that may disturb many areas of patient's life and have the negative impact on their quality of life. The present study explored the association between self-stigma, quality of life, demographic data, and the severity of symptoms in patients with depressive disorder.

Method Patients, who met ICD-10 research criteria for depressive disorder, were enrolled in the cross-sectional study. All probands completed these measurements: the Quality of Life Satisfaction and Enjoyment Questionnaire (Q-LES-Q), the Internalised Stigma of Mental Illness Scale (ISMI), demographic questionnaire, and the severity of the disorder measured by objective and subjective Clinical Global Impression severity scales (CGI).

Results Eighty-one depressive patients (with persistent affective disorder – dysthymia, major depressive disorder or recurrent depressive disorder) and 43 healthy controls contributed to the study. Comparing with the healthy control group, there was a lower quality of life in patients with depression. The level of self-stigma correlated positively with total symptom severity score and negatively with the quality of life. Multiple regression analysis discovered that the overall rating of objective symptoms severity and self-stigma were significantly associated with the quality of life.

Conclusions Present study suggests the lower quality of life in outpatients with depressive disorder in comparison with healthy controls, and the negative impact of self-stigma level on quality of life in patients suffering from depressive disorders.

Connection between coping strategies and quality of life in outpatient with depression – cross-sectional study

M. Holubova^{1,2,*}, J. Prasko¹¹ University of Palacky Olomouc, Department of Psychiatry, Olomouc, Czech Republic² Regional Hospital Liberec, Department of Psychiatry, Liberec, Czech Republic

* Corresponding author.

Background The quality of life is a multidimensional phenomenon which represents all aspects of patient's well-being and various areas of the patient's life. Specific coping strategies may be connected with the quality of life and also with the severity of the disorder. The objective of this study was to explore the relationship between the coping strategies and quality of life in outpatients with depressive disorder.

Methods Eighty-two outpatients, who met ICD-10 criteria for depressive disorders, were enrolled in the cross-sectional study. Data on sociodemographic and clinical variables were recorded. Individuals with depression filled out the standardized measures: The Stress Coping Style Questionnaire (SVF-78), The Quality of Life Satisfaction and Enjoyment Questionnaire (Q-LES-Q), and The Clinical Global Impression (CGI).

Results The patients overuse negative coping strategies, especially, escape tendency and resignation. Using of positive coping is in average level (the strategy Positive self-instruction is little used). Coping strategies are significantly associated with quality of life. Higher using of positive coping has a positive association with QoL. The main factors related to QoL are the subjective severity of the disorder, employment and positive coping strategies according to regression analysis.

Conclusions This study revealed the connection between coping strategies and quality of life in patients with depressive disorders. Strengthening the use of positive coping strategies may have a positive effect on the quality of life, mental conditions and treatment of patients with depression.

Features of formation and system of psychoprophylaxis of suicidal behavior in young patients with depression

H. Kozhyna*, V. Mykhaylov, K. Zelenskay

Kharkiv National Medical University, Psychiatry, Narcology and medical psychology, Kharkiv, Ukraine

* Corresponding author.

The work covers the study of the formation of suicidal behavior in young adults with depressive disorders and developing of pathogenetic based system of its prevention. There were clinical and psychopathological signs of depressive disorders in young patients analyzed. Anxiety, asthenia, asthenic-apathetic and melancholy variants of depressive disorders in young patients with suicidal behavior were highlighted. In this study, there were the markers of suicide risk for young patients with depressive disorders determined: high suicide risk, low death self-consciousness, high anhedonia level, clinical manifestations of anxiety and depression by the hospital anxiety and depression scale, severe anxiety and depression by the Hamilton anxiety rating scale, major depressive episode by the Montgomery-Asberg depression rating scale. It has been proved that in observed young patients with depressive disorders with suicide behavior increased concentrations of serotonin, cortisol, noradrenaline and decreased levels of adrenaline

and melatonin in plasma were observed. These changes were determined as neurohormonal background for depletion of adaptation resource in stress situations. There were approaches to differentiated prevention of suicidal behavior in depressive disorders in young people validated that include pharmacotherapy (selective SSRI, melatonin, serotonin and norepinephrine), psychotherapy and psychoeducation. Psychotherapeutic complex in patients with depressive episode must include personality-oriented psychotherapy, cognitive behavioral therapy, family therapy and autogenous training; in disorders of adaptation – rational psychotherapy, cognitive-behavioral analytic psychotherapy, family therapy, autogenic training. Psychoeducation should be carried out using information modules, training a positive self-image, improved compliance; formation of communication skills, problem solving, interpersonal interaction and problem-oriented discussions.

Case report: Three years of refractory atypical depression successfully treated with “old school” moclobemide (maoi-r)

S. Latorre^{1,*}, I. Moreno¹, M.J. Gordillo²¹ Àrea de Salut d'Eivissa i Formentera, Community Mental Health Team, Eivissa, Spain² Àrea de Salut d'Eivissa i Formentera, Psychiatry, Eivissa, Spain

* Corresponding author.

Background Atypical depression is linked to bipolarity and specific response to mono amino oxidase inhibitors (MAOI), treatments not commonly used due to their complex handling. We describe a successfully treated case.

Methodology Clinical description. Depression severity is assessed with Montgomery Asberg depression rating scale (MADRS).

Clinical case Female, 54-year-old. Major depression, since 2011, refractory to venlafaxine/aripiprazol and escitalopram 20 mg/day. Manic episode with psychotic symptoms after potentiation with duloxetine. Diagnose of schizoaffective disorder was made, treated with aripiprazol 10 mg/day, with established chronic depressive symptoms, despite addition of valproate and venlafaxine, and partial response to pramipexole up to 1 mg/day.

– Decision of cleaning up aripiprazol during 8 days and switch to moclobemide monotherapy was made due to atypical features. Baseline MADRS: 31. At week 2, there is change in mood, expression, psychomotor features and speech formal and content alterations. At week 4, activity increases, and biorythms normalize. At week 8 (with 600 mg/day increased dose), full response is obtained, including drive, and anxiety, with MADRS 12.

– After one year of treatment, she has kept stability with no manic or psychotic symptoms emergence. Reduction in dose are linked to depression relapses. She still struggles with psychosocial recovery.

– Tolerance has been good in all moment, except for headache crisis, not linked to high blood pressure or diet.

Conclusions MAOI still has a role in affective disorders treatment, given its effectiveness, unique mechanism of action and good tolerability. Targeted psychopharmacological and phenomenology knowledge can be the key to a recovery.

Differences in perceived reasons for and barriers to, seeking help for depression between people with and without heightened depressive symptomatology

B. Lienemann^{1,*}, S.T. Jason²¹ University of Southern California, Department of Preventive Medicine, Los Angeles, USA² Claremont Graduate University, Department of Behavioral and Organizational Sciences, Claremont, USA

* Corresponding author.

Introduction Depression is treatable, but many people with depression do not seek help. When studies are conducted assessing barriers to and reasons for help seeking, it is common to combine responses from people with and without depressive symptomatology.

Objectives/aims The goal of the current study was to assess if people with and without heightened levels of depressive symptomatology perceive reasons/barriers similarly.

Methods Prior to the main study, two pilot studies were conducted which resulted in sets of 10 reasons and barriers rated as those participants were most aware of as influencing their decision to seek help for depression. Participants ($n=520$) rated the importance of these reasons/barriers to their decision regarding help seeking. Two groups were created based on their Beck depression inventory-II score: no to minimal and mild to severe depressive symptomatology.

Results Although, the order across the reasons/barriers varied between the groups, the most important reason for both groups was seeking help to enjoy life again, while the most important barrier for both groups was negative side effects of depression medication. The no to minimal group rated reasons to seek help as significantly more important to their help seeking decision process than the mild to severe group, while the mild to severe group rated barriers to seeking help significantly more important to their help seeking decision process than the no to minimal group.

Conclusions Greater importance of barriers to seeking help could partially explain why help seeking decreases as depressive symptomatology increases. Interventions should increase the importance of reasons to seek help.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Correlation between chronic somatic co-morbidities and prognosis of major depressive disorder

N. Lucev^{1,*}, A. Vuk¹, I. Simunovic Filipcic², I. Filipcic¹¹ Psychiatric hospital Sveti Ivan, Department of psychiatry, Zagreb, Croatia² The University Hospital Centre Zagreb KBC Zagreb, Department of Psychological Medicine, Zagreb, Croatia

* Corresponding author.

Introduction Depression and somatic disorders are closely inter-related. Depressed mood is recognized to contribute to the development and progression of wide range of somatic diseases, while at the same time somatic diseases may increase the risk of depression. Co-morbidity research still represents huge research and clinical challenge to contemporary psychiatry and medicine.

Objectives To check whether the correlation of NSC and poor prognosis of MDD treatment is merely the consequence of age and duration of illness.

Methods We investigated a cross-sectional sample consisting of 290 psychiatric diagnosed with MDD. Outcome was the number of psychiatric rehospitalizations (NPR) since the first diagnosis of MDD treatment success. Predictor was NSC. Covariates controlled were sex, age, BMI, marital status, number of household members, education, work status, duration of MDD, CGI-severity of MDD at diagnosis, treatment with antidepressants and anti-psychotics.

Results After adjustment for all confounders, mediation analysis revealed insignificant indirect effects of NSC on NPR through patient's age ($P=0.296$) and duration of MDD ($P=0.180$). Direct effect of NSC was significant and clinically relevant ($P<0.001$). Effect of NSC was significantly moderated by duration of MDD ($P=0.019$). NSC and NPR were not significantly associated if MDD lasted for less than a year. The more MDD lasted the stronger was correlation of NSC and NPR.

Conclusion Correlation of NSC and poor prognosis of MDD is not a mere consequence of patient's age and duration of illness. To treat MDD effectively we have to treat simultaneously somatic co-morbidities.

Disclosure of interest The authors have not supplied their declaration of competing interest.

From pilot project to RCT – Music intervention to improve sleep quality in depressed patients: A mixed methods study

H.N. Lund*, A. Heyman-Shlaczinska, I.N. Pedersen

Aalborg Psychiatric Hospital, Klinik Syd, Aalborg, Denmark

* Corresponding author.

Introduction Insomnia is a common sleep disorder for patients with depression. This has a major impact on the quality of life for the individual. A randomized controlled trial (RCT) will address the use of music as a non-pharmacological treatment to reduce insomnia in depression.

Objectives and method The aim is to investigate, whether music listening is effective to:

- improve sleep quality;
- reduce symptoms of depression;
- improve quality of life;
- limit or replace medication.

A RCT will address the use of music as a treatment modality in depression using an explanatory mixed methods design. In the first phase of the study, patient data is collected from 3D accelerometer, log files from a new app for iPad called 'the music star' and questionnaires (MDI, HAM, PSQI and WHO-QOL). 'The music star' is an app for iPad used to select music from special designed playlists developed by Danish music therapists in psychiatry. An exploratory follow-up (semi-structured interviews) aims to explain quantitative results from accelerometer and 'the music star' log files. Participants enrolled are registered at the clinic for unipolar and bipolar affective disorders at Aalborg University Hospital – Psychiatry. The participants test whether a sound pillow and special designed playlists is effective to reduce insomnia in depression in a 4 week period.

Results and conclusions A feasibility study has been conducted on 11 participants showing positive results in terms of participation and sleep quality.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Confirmatory factor analysis of the postpartum depression screening scale-21 in a sample of Portuguese women

C. Marques*, S. Xavier, J. Azevedo, M. Marques, M.J. Soares, A. Macedo, A. Oliveira, A.T. Pereira

Faculty of Medicine, University of Coimbra, Department of Psychological Medicine, Coimbra, Portugal

* Corresponding author.

Introduction The postpartum depression screening scale (PDSS; Beck & Gable, 2002) is a widely used measure to assess women's depressive symptoms after their children's birth. Pereira et al. adapted, validated and developed a short-version of PDSS for Portuguese women (PDSS-21).

Objective To examine the factor structure of the PDSS-21, using confirmatory factor analysis (CFA) in a sample of Portuguese women in the postpartum period.

Methods The sample was composed of 208 women (mean age = 32.72; SD = 4.49) who completed the PDSS-21 approximately at the 6th week postpartum. CFA was used to test the model suggested by prior exploratory factor analyses of PDSS-21. AMOS software was used.

Results After two items were deleted and some errors were correlated, CFA indicated a good fit for the second-order factor ($\chi^2/df=1.793$; CFI=0.957; GFI=0.889, rmsea=0.062; P [rmsea \leq 0.05] < 0.056). The 19-item PDSS showed excellent internal consistency ($\alpha=0.92$) and the four dimensions presented Cronbach's alphas ranging between good ($\alpha=0.83$) and excellent ($\alpha=0.93$).

Conclusions These findings suggest that the 19-item PDSS obtained through CFA is a reliable and valid measure to assess depressive symptoms among women in the postpartum period.

The paradoxical effect of two different emotion regulation processes in the association between shame and depression

A.L. Mendes, C. Ferreira, J. Marta-Simões*

Faculty of Psychology and Education Sciences, university of Coimbra, CINEICC, Cognitive-Behavioral Center for Research and Intervention, Coimbra, Portugal

* Corresponding author.

Experiential avoidance, considered a main process of psychological inflexibility, has been defined as the unwillingness to be in contact with particular unwanted inner experiences and the effort to control or avoid its form, frequency and the context in which they occur. On the other hand, decentering, conceptualized as the ability to deal with feelings, thoughts and emotions as subjective and ephemeral events, which occur in the mind, is considered an important protective process against psychopathology. The present study aimed to explore the moderator effect of two different emotional regulation processes, decentering and experiential avoidance, on the association between external shame and depression. The sample comprised 421 participants (131 males and 290 females), aged between 18 and 34-year-old. Results from two independent path analysis revealed that decentering abilities and experiential avoidance showed a significant moderator effect on the association between external shame and symptoms of depression. In fact, these findings allow to verify that decentering abilities were negatively linked to symptoms of depression. Through a path analysis,

the buffer effect of decentering was confirmed. On the contrary, performed tests demonstrated that experiential avoidance exacerbates shame's impact on the severity of depressive symptoms. Taken together, these findings emphasize the importance of targeting maladaptive emotion regulation processes (such as experiential avoidance), and developing adaptive strategies (e.g., decentering abilities), as strategies to diminish depressive symptomatology in prevention and intervention programs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Shame and depression: The roles of self-reassurance and social safeness

J. Marta-Simões*, C. Ferreira, A.L. Mendes

Faculty of Psychology and Education Sciences, University of Coimbra, CINEICC, Cognitive Behavioural Centre for Research and Intervention, Coimbra, Portugal

* Corresponding author.

Self-reassurance and social safeness are both positive factors linked with a lighter experience of shame and depression symptoms. Self-reassurance is defined as an adaptive emotion regulation process, and social safeness as an emotion experience related to feelings of being safe around others, accepted by others, and connected to one's social world. Nevertheless, data about how self-reassurance and social safeness and pleasure operate in the association between external shame and depression is still scarce. A path model which hypothesised that self-reassurance and social safeness and pleasure may act as mediators on the association between shame and depressive symptomatology was tested. This study's sample consisted of adult men ($n=54$) and women ($n=125$), from the Portuguese general population. Results indicated that self-reassurance and social safeness act as mediators in the relationship between shame and depression symptoms. Specifically, a higher report of shame seems to explain higher levels of depressive symptomatology, via lower tendency for self-reassurance and poorer experience of social safeness. The tested model explained 45% of the variance of depressive symptomatology and was revealed to be invariant between men and women. This study's results underline the profound impact of the experience of comfort within secure and warm social relationships, but mostly the importance of self-soothing and self-compassion abilities which associate with greater social functioning. Moreover, in practical terms, these findings reinforce the pertinence of cultivating self-compassion, which has proven to be particularly relevant when intervening with high levels of shame, and in the prevention of depression.

* Corresponding author.

Background Despite its high effectiveness, electroconvulsive therapy (ECT) is not a widely used method to treat depression. One of the reasons for this could be the fear of cognitive side effects. The aim of this study was to investigate effects of ECT on cognitive function.

Methods We conducted a prospective study with a sample size of 23 patients (10 male), who met the criteria of treatment-resistant depression according to ICD-10 and gave their informed consent for ECT treatment. Before and after ECT, the following investigations have been performed: Beck depression inventory (BDI), Montgomery-Asberg depression rating scale (MADRS), Mehrfachwahl-Wortschatz-Intelligenztest (MWT-B), trail making test (TMT) A and B, stroop-test, mini mental state examination (MMSE) and the German version of the California verbal learning test (MGT).

Results After ECT treatment, we found highly significant changes of depression-scales BDI ($P=0.028$) and MADRS ($P=0.001$). IQ as measured by the MWT-B ($P=0.851$), executive functions as measured by trail making test A ($P=0.568$) and B ($P=0.372$) and stroop-test, memory functions as measured by the MGT ($P=0.565$) (Figure 1) and MMSE ($P=0.678$) did not differ significantly after ECT treatment.

Conclusion There were no significant differences in cognitive function before and after ECT treatment. To confirm these findings, it would be necessary to perform larger studies.

* Corresponding author.

Objectives To examine 5 years trajectories of secondary-treated late-life major depressive disorder (MDD), and evaluate whether pre-existing cerebrovascular disease and related risk factors are associated with more severe trajectories of late-life MDD.

Methods Data were obtained from Danish registers. The sample included 11,184 adults ≥ 60 at index MDD diagnosis. Trajectories of in or outpatient contact at psychiatric hospitals for MDD over the 5 years period following index MDD diagnosis were modeled using latent class growth analysis. Risk factors included cerebrovascular disease, cardiovascular disease, hypertension, diabetes, and vascular dementia defined based on hospital diagnoses and prescription medications, demographic characteristics and characteristics of the index MDD diagnosis.

Results The final model included classes with consistently low (66%), high decreasing (19%), consistently high (9%) and moderate

fluctuating (6%) probabilities of contact at a psychiatric hospital for MDD during the 5 year period following the index MDD diagnosis (Fig. 1). Older age, greater severity, inpatient treatment and > 12 antidepressant prescriptions within 5 years of the index MDD diagnosis predicted membership in more severe trajectory classes. Cerebrovascular disease and related risk factors were not associated with trajectory class membership.

Conclusions A substantial proportion (34%) of individuals diagnosed with MDD in late-life require specialized psychiatric treatment for extended periods of time. We found no evidence that cerebrovascular disease or related risk factors predicted course trajectories in secondary-treated late-life MDD.

Fig. 1 Trajectories of late-life MDD.

² Clinical center Nis, Clinic for protection of mental health, The Faculty of Medicine, University of Nis, psychiatry, Niš, Serbia

* Corresponding author.

Introduction It is known that there is a cognitive decline in major depressive disorder. Most studies were performed on patients whose sum on a Montgomery and Asberg depression rating scale was greater than 30.

Objectives In our work, we concentrated on mild and moderate depression, MADRS > 30 was not criteria. Patients included were diagnosed with mild to moderate depressive episode.

Aims To determine how depressive episodes affect cognition.

Methods We included 30 patients diagnosed at the clinic for psychiatry in Nis. We covered the age group between 20 and 40 years, regardless of the gender and educational level. For the assessment of cognition, we used digital symbol substitution test (DSST), Rey audio verbal learning test (RAVLT), trail making test (TMT), stroop color naming test (Stroop), and patients were evaluated with Montgomery and Asberg depression rating scale (MADRS). Tests were conducted on the first visit to a psychiatrist. Patients were compared with the results of the healthy population with the same characteristics, and in the same period (August 2016). Mean values were compared and groups were compared by Student's t-test.

Results There was a statistically significant difference in all of the tests, and all of the parts of tests conducted on the patients and the control group.

Conclusions There is a statistically significant cognitive decline in patients with mild and moderate depression.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Emotional schemas: A new cognitive perspective for the distinction between unipolar depression and bipolar disorder

O. Onur

Istanbul Bakırköy Research and Training Hospital for psychiatry neurology and ne, Psychiatry, Istanbul, Turkey

Introduction Clinicians need to make the differential diagnosis between unipolar depression and bipolar disorder to guide their treatment choices. Looking at the differences observed in the emotional schemas might help with this differentiation. This study is an exploratory investigation of schema theory's Leahy's emotional schemas among individuals diagnosed with bipolar disorder and unipolar depression.

Methods Three groups of subjects 56 unipolar depression in the remission period, 70 bipolar eutimic and 58 healthy controls were asked to fill out the Leahy Emotional Schema Scale (LESS). The clinicians diagnosed the participants according to the criteria of DSM-IV-TR with SCID-I, and rated the moods of the subjects with the Beck Depression Scale, and the Young Mania Rating Scale (YMRS). Statistical analyses were undertaken to identify the group differences on LESS.

Results The bipolar eutimic and unipolar depression patients' scores on the LESS dimensions were significantly different from the healthy participants in the areas of control, consensus, acceptance of feelings, dissimilarity and simplistic view of emotions.

Conclusions These results suggest that the metacognitive model of unipolar depression might be extrapolated for patients with bipolar disorder. Bipolar disorder may be associated with a general activation of the emotional schemas.

Introduction COPD is a common disease, has an impact not only on physical but also on psychological well-being. Anxiety, stress, depression are common co-morbidities for COPD patients.

Objectives This paper proposes to study from a qualitative point of view the effect of depression on COPD patients.

Aims A qualitative methodology was chosen in order to explore 75 (male $n=69$, female $n=6$) COPD patients' symptoms and signs of anxiety, stress and depression.

Methods Data were collected through semi-structured interviews. All patients also completed the Beck Inventory and the GDS

15 questionnaires. The interviews were conducted both in the general university hospital of Larissa and in patients' homes.

Results We enrolled 75 patients (15: normal, 17: mild depression, 7: moderate and 1 severe). Persistent low mood and lack of interest was expressed by most of the participants. "Before I get this thing, I was in a good mood, but not now". Poor self-management was associated with anxiety disorders and high temper: "I withdrew, due to my health". .."I was really stressed, and depressed, and quick-tempered". COPD diagnosis was difficult for some patients: "At the beginning, I wasn't in the mood for anything, just sleeping and more of watching TV". Other patients seemed to be in a good mood: "I was never scared of anything, I am happy".

Conclusions This research shows that depressive and anxiety symptoms are common among COPD patients. Depression has a significant impact on the daily life of patients while breathlessness made patients feel housebound and social isolated.

⁴ *COS and Associates Ltd., Data Science, Hong Kong S.A.R.*

⁵ *UH Case Medical Center, Psychiatry, Cleveland, USA*

* *Corresponding author.*

Background This post-hoc analysis evaluated whether the efficacy of lurasidone in major depressive disorder (MDD) with mixed features is moderated by the number and characteristics of manic symptoms present at study baseline.

Methods Patients meeting DSM-IV-TR criteria for MDD who presented with two or three manic symptoms (consistent with the DSM-5 mixed features specifier) were randomly assigned to 6 weeks of double-blind treatment with either lurasidone 20–60 mg/d ($n=109$) or placebo ($n=100$). Finite mixture models were applied to identify latent class patterns of the 10 baseline manic symptoms.

Results Three latent class profiles were identified: 105 (50.5%) patients had manic symptom profile 1 (MIX 1) with mean MADRS 33.0, mean YMRS 9.2, mean number of manic symptoms 3.8; 63 (30.3%) patients had manic symptom profile 2 (MIX 2) with similar baseline mean MADRS (32.4) and YMRS (9.3) and lower number of manic symptoms 3.5; 40 patients had manic symptom profile 3 (MIX 3) with significantly higher severity scores in MADRS (35) and YMRS (14.9) and mean number of manic symptoms 4.6. A significant moderating effect on change in YMRS score was observed for the "decreased need for sleep" symptom, with greater lurasidone effect size (vs. Placebo) found in patients without vs. With this symptom ($P<0.05$).

Conclusions In this post-hoc analysis of a placebo-controlled trial involving MDD patients with mixed features, absence of "decreased need for sleep" was found to be significantly associated with improvement in manic and depressive symptoms and to moderate the treatment effect on manic symptoms.

² Department of Psychiatry, Hospital Liberec, Liberec, Czech Republic

³ Faculty of Social Science and Health Care, Constantine the Philosopher University in Nitra, Department of Psychology Sciences, Nitra, Slovak Republic

* Corresponding author.

Objective The goal of this study was to examine the influence of dissociation, hope, personality trait and selected demographic factors in treatment response of this group of patients.

Methods Pharmacoresistant depressive inpatients completed clinical global impression – both objective and subjective form, Beck depression inventory, and Beck anxiety inventory at baseline and after six weeks of combined pharmacotherapy and psychotherapy (group cognitive behavioral or group psychodynamic). The Internalized Stigma Of Mental Illness Scale, Dissociative Experience Scale Adult Dispositional Hope Scale, and temperament and character inventory were completed at the start of the treatment with the intention to find predictors of treatment efficacy.

Results The study included 72 patients hospitalized for the pharmacoresistant major depression, 63 of them finished the study. The mean scores of BDI-II, BAI, subjCGI, and objCGI significantly decreased during the treatment. BDI-II relative change statistically significantly correlated with the total ISMI score, discrimination experience (ISMI subscale), and harm avoidance (TCI-R personality trait). According to stepwise regression, the strongest factors connected to BDI-II relative change were the duration of the disorder and discrimination experience (ISMI). ObjCGI relative change significantly correlated with the level of dissociation, the total ISMI score, and hope in ADHS total score, and self-directedness. According to stepwise regression, the strongest factor connected to objCGI relative change was discrimination experience (ISMI).

Conclusions According to our results, the patients with pharmacoresistant depressive disorders, who have had more experience with discrimination because of their mental struggles, showed a poorer response to treatment.

The major depressive disorder hierarchy: Rasch analysis of 6 items of the Hamilton depression scale covering the continuum of depressive syndrome

L. Primo de Carvalho Alves^{1,*}, M. Pio de Almeida Fleck¹, A. Boni², N. Sica da Rocha¹

¹ Universidade Federal do Rio Grande do Sul, Programa de Pós-graduação em Psiquiatria e Ciências do Comportamento, Porto Alegre, Brazil

² Universidade Federal do Rio Grande do Sul, Faculdade de Medicina, Porto Alegre, Brazil

* Corresponding author.

Objectives Melancholic features of depression (MFD) seem to be a unidimensional group of signs and symptoms. However, little

importance has been given to the evaluation of what features are related to a more severe disorder. That is, what are the MFD that appear only in the most depressed patients. We aim to demonstrate how each MFD is related to the severity of the major depressive disorder.

Methods We evaluated both the Hamilton depression rating scale (HDRS-17) and its 6-item melancholic subscale (HAM-D6) in 291 depressed inpatients using Rasch analysis, which computes the severity of each MFD. Overall measures of model fit were mean (\pm SD) of items and persons residual = 0 (\pm 1); low χ^2 value; $P > 0.01$.

Results For the HDRS-17 model fit, mean (\pm SD) of item residuals = 0.35 (\pm 1.4); mean (\pm SD) of person residuals = -0.15 (\pm 1.09); $\chi^2 = 309.74$; $P < 0.00001$. For the HAM-D6 model fit, mean (\pm SD) of item residuals = 0.5 (\pm 0.86); mean (\pm SD) of person residuals = 0.15 (\pm 0.91); $\chi^2 = 56.13$; $P = 0.196$. MFD ordered by crescent severity were depressed mood, work and activities, somatic symptoms, psychic anxiety, guilt feelings, and psychomotor retardation.

Conclusions Depressed mood is less severe, while guilt feelings and psychomotor retardation are more severe MFD in a psychiatric hospitalization. Understanding depression, as a continuum of symptoms can improve the understanding of the disorder and may improve its perspective of treatment.

Depression among Tunisian young mothers

O. Zerriaa*, O. Moula, S. Ben Saadi, S. Chebli, R. Ghachem Razi Hospital, B, Mannouba, Tunisia

* Corresponding author.

Introduction In the Tunisian cultural context, the mother is in charge of childcare, housekeeping and the well-being of the whole family, which can lead to exhaustion and depression.

Objective To estimate the frequency of depression among mothers aged between 20 and 40 years, its consequences and the possible solutions.

Method Transversal study using an anonymous questionnaire of 26 questions published through social media sites to mother with young aged children.

Results Three hundred and twenty-seven mothers participated in the study: 20% of them aged between 20 and 30 years and 80% between 30 and 40. Ninety-seven percent of the participants were married; 96% of them had university education. Seventy-nine percent of them were working mothers and 50% of them did not get any help in childcare. Forty-two percent of the participants had only 1 child, 49% had 2 children, 8% 3 children and only 1 mother had 4 children. Depressive symptoms were present in 73% of the participants and were significantly higher among mothers aged between 30 and 40. However, depression was certain in only 36% of them and there was no significant difference between the two age groups. Eighteen percent of the participants noticed an increase in consumption of cigarettes, 31% resorted to tranquilizers, 25% needed sick leaves, and 2% resorted to alcohol use. Less working hours was suggested as a solution in 36% cases, sharing house chores in 30% cases.

Conclusion Depression among young mother is a public health problem in Tunisia. It is underestimated and not always treated, which can have a serious impact on the whole family well-being.

The dietary status of adults with ADHD

J.N. Kjaer^{1,*}, L. Jakobsen², M. Lasgaard²,
P. Munk-Jørgensen³

¹ Aarhus University Hospital, Department of Affective Disorders, Risskov, Denmark

² Public Health and Quality Improvement, Central Region Denmark, Aarhus, Denmark

³ Psychiatric Research Academy, Aarhus University Hospital, Århus, Denmark

* Corresponding author.

Objective The aim was to investigate the dietary status of adults with ADHD. Furthermore, we compared the group with a representative sample of a healthy adult Danish population.

Method Data were collected from the ADHD database operated by the ADHD outpatient clinic at Aarhus university hospital. We used data from newly referred patients in a seven months period from April 2014 through October 2014. The collected data include weight, height, blood pressure, somatic or psychiatric comorbidity, blood sample, physical activity scale. Concerning the diagnosis of ADHD: DIVA, ASRS, BRIEF-V. Inter99 was used to assess the dietary status. The representative sample was obtained as a part of a public health survey from 2010 called “how are you” conducted in the same region of Denmark as the location of the psychiatric hospital. Preliminary results, one hundred and forty-three patients were included in the study, 52% males. The mean age was 30.9 years. A larger proportion of ADHD patients fall in the category “unhealthy dietary pattern” compared to the representative sample population (26% vs. 12%), while the proportion in the “healthy dietary pattern” category is markedly lower (14% vs. 24%). The differences seem to be explained by lower than recommended intakes of fruits and vegetables.

Conclusion Our findings suggest a general shift towards more unhealthy dietary patterns among patients with ADHD. This exposes them to higher risk of somatic diseases, notably diabetes mellitus and cardiovascular disease. Lifestyle interventions could be a necessary part of standard treatment for patients with ADHD.

Mental health stigma: What's been done? Where to go?

P. Macedo*, M. Silva, A. Fornelos, A.R. Figueiredo, S. Nunes
CHTMAD, Departamento de Psiquiatria e Saúde Mental, Vila Real, Portugal

* Corresponding author.

Introduction Negative attitudes towards psychiatric patients still exist in our society. Persons suffering from mental illness frequently encounter public stigma and may internalize it leading to self-stigma. Discrimination occurs across many aspects of economic and social existence. It may represent a barrier for patients to receive appropriate care. Many anti-stigma campaigns have been taken to decrease people's prejudice, but its effects are not well documented.

Objectives To characterize anti-stigma initiatives and its effects on diminishing negative consequences of stigma.

Methods Bibliographical research using PubMed using the keywords “stigma” and “mental illness”.

Results Despite several approaches to eradicate stigma, it shows a surprising consistency in population levels. It was expected that focus on education would decrease stigma levels. The same

was expected following concentration on the genetic causation of pathology. Most studies have revealed that education has little value and endorsing genetic attributions has led to a greater pessimism on the efficacy of mental health services, sense of permanence and guilty feelings within the family.

Conclusion Public stigma has had a major impact on many people with mental illness, especially when leading to self-stigma, interfering with various aspects in life, including work, housing, health care, social life and self-esteem. As Goffman elucidated, stigma is fundamentally a social phenomenon rooted in social relationships and shaped by the culture and structure of society. Social inclusion has been pointed as a potential direction of change.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Mental health conditions and co-morbidities among internally displaced populations (IDPs) in Ukraine

N. Makhshvili^{1,*}, J. Javakhishvili², I. Pinchuk³, B. Roberts⁴

¹ Ilia State University, Mental Health Resource Centre, Tbilisi, Georgia

² Ilia State University, Institute of Addictology, Tbilisi, Georgia

³ Ukrainian Institute of General and Forensic Psychiatry, General and Forensic Psychiatry, Kiev, Ukraine

⁴ London School of Hygiene and Tropical Medicine, epidemiology and public health, London, United Kingdom

* Corresponding author.

Reliable epidemiological data on the burden of mental health conditions and key risk factors is crucial in helping to design appropriate trauma-informed mental health and psychosocial support responses for the estimated 1.4 million IDPs in Ukraine. The aim of the proposed study is to collect evidence on mental health and psychosocial support needs among IDPs in order to help inform mental health policy in Ukraine.

The specific objectives were to:

- measure the prevalence of mental health conditions of post-traumatic stress disorder (PTSD), depression, anxiety, and their co-morbidity;
- examine the characteristics associated with the mental disorders (e.g. gender, age, trauma exposure, socio-economic stressors);
- draft evidence-based recommendations for mental health and psychosocial support to relevant governmental and professional bodies in Ukraine.

The study used a cross-sectional survey conducted throughout Ukraine in 2016 with 2203 IDPs aged 18 years and over. Descriptive and multivariate regression analyses were used. PTSD prevalence was 32% (22% men; 36% women), depression–22% (16% men; 25% women), and anxiety prevalence was 17% (13% men; 20% women). There were also high levels of co-morbidity between PTSD, anxiety and depression. Key factors statistically significantly associated with mental disorders included female gender, older age, cumulative trauma exposure, more recent displacement and a bad household economic situation. The findings provided sufficient evidence to draft the trauma-informed mental health policy recommendations to key policy-makers in Ukraine.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Substance use disorder in the offspring of antenatally depressed mothers in the Northern Finland 1966 birth cohort: Relationship to parental history of severe mental disorder

P. Mäki^{1,*}, T. Taka-Eilola², J. Veijola¹

¹ University of Oulu and Oulu University Hospital, Psychiatry, University of Oulu, Finland

² University of Oulu, Psychiatry, University of Oulu, Finland

* Corresponding author.

Introduction Maternal depression during pregnancy is common. However, reports of the adult offspring with maternal antenatal depression are scarce.

Objectives Our aim was to study whether offspring of antenatally depressed mothers have increased risk for substance use disorder when taking account parental mental disorder.

Methods In the Northern Finland 1966 Birth Cohort, the mothers of 12,058 children were asked at the antenatal clinic if they felt depressed. The offspring were followed for over 40 years. Substance use disorders were detected using the Finnish Care Register for Health Care, which was also used for identifying severe mental disorders in the parents till 1984.

Results Of the mothers, 14% had rated themselves as depressed during pregnancy. Of the parents, 10% had had a hospital-treated mental disorder. The risk for substance use disorder was slightly increased in the offspring of antenatally depressed mothers (crude OR 1.6; 95% CI 1.2–2.1), when compared with the cohort members without maternal antenatal depression. The risk for substance use disorder was higher in the offspring with both maternal antenatal depression and parental mental disorder (2.8; 1.7–4.7) than in those with maternal depression but without parental mental disorder (1.4; 1.1–2.0) or those without maternal depression and with parental mental disorder (1.5; 1.1–2.2). The reference group was cohort members without maternal antenatal depression and without parental mental disorder. The association remained significant after adjustment [1].

Conclusions Offspring with both maternal depression during pregnancy and parental severe mental disorder have elevated risk for substance use disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Does substance abuse mediate or moderate the relationship between childhood trauma and the experience of persecutory delusions in people with schizophrenia in South Africa?

S. Mall

University of the Witwatersrand, Division of Epidemiology and Biostatistics, School of Public Health, Faculty of Health Sciences, Johannesburg, South Africa

Background Persecutory delusions, a key symptom of schizophrenia, may be associated with the experience of early childhood trauma as well as with cannabis dependence. Little research has, however, addressed these associations in people with schizophrenia on the African continent. We examined if persecutory delusions were significantly associated with childhood trauma in people with schizophrenia from South Africa, and we investigated whether cannabis dependence mediates or moderates this association.

Methods Seven hundred and twenty-eight people with schizophrenia completed several scales including the childhood trauma questionnaire (CTQ) which captures several domains of childhood trauma. Logistic regression and structural equation modelling methods were employed to examine the relationship between persecutory delusions and specific experiences of childhood trauma, and to determine if cannabis dependence is mediating or moderating this relationship.

Results Preliminary results suggest that of the various childhood traumas, the strongest predictor of the presence of persecutory delusions was emotional abuse [OR: 1.02 (0.94–1.08)]. There was no evidence of mediation by cannabis dependence. However, all experiences of childhood trauma, measured by the CTQ (with the exception of physical neglect) interacted with cannabis dependence to increase the risk of the onset of persecutory delusions ($P < 0.001$).

Conclusions These results are consistent with previous data in demonstrating that both childhood trauma and cannabis dependence are associated with persecutory delusions in schizophrenia. These findings suggest that it is important to examine the role of early childhood trauma as well as substance use in predicting the onset of psychosis to inform treatment strategies.

Objective To determine trends and impact on outcomes of atrial fibrillation (AF) in patients with pre-existing major depressive disorder (MDD).

Background While post-AF MDD has been extensively studied, contemporary studies including temporal trends on impact of pre-AF MDD on AF and post-AF outcomes are lacking.

Methods We used Nationwide Inpatient Sample (NIS) from Healthcare Cost and Utilization Project (HCUP) from 2002 to 2012. We identified AF and MDD as primary and secondary diagnosis respectively using validated International Classification of Diseases, 9th Revision, and Clinical Modification (ICD9CM) codes, and used Cochrane-Armitage trend test and multivariate regression to generate adjusted odds ratios (aOR).

Results We analyzed total of 3,887,827 AF hospital admissions from 2002 to 2012 of which 6.78% had MDD. Proportion of hospitalizations with MDD increased from 4.93% to 14.19% (P -trend < 0.001). Utilization of atrial cardioversion was lower in patients with MDD (34.37% vs. 40.52%, $P < 0.001$). In-hospital mortality was significantly lower in patients with MDD (aOR 0.749; 95% CI 0.664–0.846; $P < 0.001$) but discharge to specialty care was higher

(aOR 1.695; 95%CI 1.650–1.741; $P < 0.001$). In addition, median length of hospitalization (2.5 vs. 2.13 days; $P < 0.001$) and median cost of hospitalization (28,246 vs. 22,663; $P < 0.001$) was higher in hospitalizations with MDD.

Conclusions Our study displayed an increasing proportion of patients with MDD admitted due to AF in the last decade with lower mortality but higher morbidity post-AF. In addition, there was significantly less utilization of atrial cardioversion in this population along with higher median length and cost of hospitalization. There is a need to explore the reasons behind this disparity in outcomes and atrial cardioversion utilization in order to improve post-AF outcomes in this vulnerable population.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Objective To determine temporal trends, invasive treatment utilization and impact on outcomes of pre-infarction drug abuse (DA) on acute myocardial infarction (AMI) in adults.

Background DA is important risk factor for AMI. However, temporal trends in drug abuse on AMI hospitalization outcomes in adults are lacking.

Methods We used Nationwide Inpatient Sample (NIS) from Healthcare Cost and Utilization Project (HCUP) from 2002 to 2012. We identified AMI and DA as primary and secondary diagnosis respectively using validated International Classification of Diseases, 9th Revision, and Clinical Modification (ICD9CM) codes, and used the Cochrane Armitage trend test and multivariate regression to generate adjusted odds ratios (aOR).

Results We analyzed total of 7,174,274 AMI hospital admissions from 2002 to 2012 of which 1.67% had DA. Proportion of hospitalizations with DA increased from 5.63% to 12.08% (P trend < 0.001). Utilization of coronary artery bypass grafting (CABG) was lower in patients with DA (7.83% vs. 9.18%, $P < 0.001$). In-hospital mortality was significantly lower in patients with DA (aOR 0.811; 95% CI 0.693–0.735; $P < 0.001$) but discharge to specialty care was higher (aOR 1.076; 95% CI 1.025–1.128; $P < 0.001$). The median cost of hospitalization (40,834 vs. 37,253; $P < 0.001$) was higher in hospitalizations with DA.

Conclusions We demonstrate an increasing proportion of adults admitted with AMI have DA over the decade. However, DA has paradoxical association with mortality in adults. DA is associated with lower CABG utilization and higher discharge to specialty care, with a higher mean cost of hospitalization. The reasons for the paradoxical association of DA with mortality and worse morbidity outcomes need to be explored in greater detail.

* Corresponding author.

Objective To determine trends and impact on outcomes of acute myocardial infarction (AMI) in patients with pre-existing psychosis.

Background While post-AMI psychosis has been extensively studied, contemporary studies including temporal trends on impact of pre-AMI Psychosis on AMI and post-AMI outcomes are lacking.

Methods We used Nationwide Inpatient Sample (NIS) from Healthcare Cost and Utilization Project (HCUP) from 2002 to 2012. We identified AMI and psychosis as primary and secondary diagnosis respectively using validated International Classification of Diseases, 9th Revision, and Clinical Modification (ICD9CM) codes, and Cochrane-Armitage trend test and multivariate regression to generate adjusted odds ratios (aOR).

Results We analyzed total of 7,174,274 AMI hospital admissions from 2002 to 2012 of which 1.77% had psychosis. Proportion of hospitalizations with psychosis increased from 6.94% to 11.85% (P -trend < 0.001). Utilization of percutaneous coronary intervention (PCI) was lower in patients with psychosis (29.98% vs. 40.36%, $P < 0.001$). Utilization of coronary artery bypass grafting (CABG) was lower in patients with psychosis (8.01% vs. 9.18%, $P < 0.001$). In-hospital mortality was significantly lower in patients with psychosis (aOR 0.677; 95% CI 0.630–0.727; $P < 0.001$) but discharge to specialty care higher (aOR 1.870; 95% CI 1.786–1.958; $P < 0.001$). In addition, median length of hospitalization (3.77 vs. 2.90 days; $P < 0.001$) was higher in hospitalizations with psychosis.

Conclusions Our study displayed increasing proportion of patients with psychosis admitted due to AMI in last decade with lower mortality but higher morbidity post-infarction, and significantly less utilization of PCI and CABG. There was also increased length of stay patients with MDD. There is need to explore reasons behind this disparity in outcomes and PCI and CABG utilization to improve post-AMI outcomes in this vulnerable population.

Prevalence of Internet addiction: A pilot study in a group of Italian students

D. Marazziti, F. Mucci*, F. Vanelli, N. Renda, S. Baroni, A. Piccinni

Università di Pisa, Dipartimento di Medicina Clinica e Sperimentale, Pisa, Italy

* Corresponding author.

Introduction Internet addiction (IA) is considered part of the so-called “new technologies addictions” group, that in turn belongs to a wider, novel group of abnormal behaviors defined “no-drug addictions” or “behavioral addictions”. Similarly to substance abuse, there is the risk either to arouse symptoms like craving, tolerance and habituation either to develop a full-fledged addiction to the Internet.

Aim The aim of this study is to examine the current pattern of Internet use and eventually of IA, as well as their main characteristics, in a group of high-school students from Calabria, a Southern Italian region.

Methods Five hundred high-school students (42% boys, 58% girls, mean age $SD \pm 16.23$ years) volunteered for this study. A specific questionnaire of 45 items with 5 possible answers ranging between “never” and “very often” on a Likert scale was developed.

Results Most of the young subjects interviewed owned a smartphone with Internet, and claimed to spend more time online than at the beginning. Nearly everybody had an active account in at least one social network. A small withdrawal from social relationships and from sport activities emerged in this group.

Conclusions Although about 10% of examined students presented IA symptoms, our findings cannot be considered representative of the total high-school population, these results underline the need of further investigation and awareness. In fact, many underestimated, vague, and other unspecific neuropsychiatric symptoms, such as alterations of sleep-wake pattern, chronic fatigue, headache, visual problems, carpal tunnel syndrome and eventually anxiety or depression may be underlying to an unrecognized condition of IA.

Intensive case management (ICM) project in eastern lower Austria: A description

M. Ramirez Gaite^{1,*}, E. Gundendorfer-Mag, FH², Dr. W. Hrubos²

¹ Psychosoziale Zentren GmbH, PSD Tulln, Tulln, Austria

² Psychosoziale Zentren GmbH, Fachbereichsleitung, Stockerau, Austria

* Corresponding author.

Introduction Our ICM Project was implemented in 2012, with the primary objective of preventing hospitalizations and unburdening services. Here, we present a description.

Objectives ICM is a type of multi-professional assertive community treatment (ACT) and case management, although our concept has a stronger focus on social work than ACT and uses less resources. It aims at patient's stabilization at home, better life quality, less inpatient/residential treatments, and more access to crisis intervention.

Methods Presently we have 118 spots. Target groups are persons with severe psychiatric conditions at high risk for institutionalization or already institutionalized, including heavy users of mental health services. An initial eligibility assessment is required. At least 3 workers are providing a minimum of 2 h face-to-face contact per week per person. Care is offered predominantly at home

environment and anchored in: careful distance-closeness ratio, structured and restructuring, autonomy enhancing, respectful, non-judgmental, confidential, regularity and commitment. Each treatment plan is individualized and based on two axes: intensive assistance and day-structure. It comprises comprehensive psychiatric treatment, counselling, assistance in everyday life, support groups, crisis management and interdisciplinary organizational meetings.

Results The program was evaluated in 2014 using the CANSAS and FLZ scales and its effectiveness was validated. Most significant improvements were found in day-structure, housing, social contacts and performance, nutrition, and psycho-education. Life satisfaction improvement was found mostly in areas of general health, performance, relaxation and autonomy.

Conclusions Since its implementation ICM has steadily expanded. Further research tools are currently being developed. Results will be presented in future publications.

Attention deficit hyperactivity disorder and scientific school performances among Moroccan children

F.Z. Rouim^{1,*}, F.Z. Azzaoui², A.O.T. Ahami¹

¹ Faculty of Science Ibn tofail, Biology, Kenitra, Morocco

² Faculty of science Ben M'sik, Biology, Casablanca, Morocco

* Corresponding author.

Background and aim Attention deficit hyperactivity disorder (ADHD) is classified as neurodevelopmental disorders. ADHD is one of the major problems in childhood encountered most often in schools. A study realized by Platt in 2011 show that children with ADHD often experience difficulties in mathematics. The aim of this study is to assess whether there is a relationship between school performance in scientific subjects (mathematics and natural science) and attention deficit hyperactivity disorder.

Methods The study was realized among 239 children studying in a urban school in Kenitra city (North-West of Morocco), and aged from 6 to 16 years. To evaluate the relationship between ADHD and the average class results of mathematics and natural science, Conners rating scale (parent and teacher short version) and the academic transcripts are used.

Results The results show that there is a significant correlation ($P < 0.05$, $P < 0.01$) between the average class results in each natural science and mathematics and three components of Conners rating scales (parent's version), which are behavioral difficulties, learning difficulties and hyperactivity/impulsivity. Furthermore, the Conners rating scale (teacher's version) show, also, that there is a significant correlation ($P < 0.05$, $P < 0.01$) between behavioral difficulties, hyperactivity/impulsivity and inattention passivity and the average class results in natural science and in mathematics.

Conclusion As known, children with ADHD are not less intelligent than other children, although our study show that children with ADHD represent low marks in natural science and in mathematics. In fact, deeper investigations are needed to study the possible factors that could affect ADHD children's school performance.

EW0419

A study of patient's perspective of schizophrenia using emic perspectiveD. Sanyal^{1,*}, D. Das²¹ KPC Medical College, Jadavpur, Psychiatry, Kolkata, India² Manasi Mental Health Service Centre-Nanda-Singur, Psychiatry, Hoogly, India

* Corresponding author.

Introduction Knowledge about how patients perceive mental illness and how it possibly influences help seeking behaviour is important in development of proper plan for mental health reform. **Objective** This study planned to study disease related perception, first help seeking behaviour and stigma among schizophrenia patients admitted at a hospital.

Aims (1) To know about patient's view regarding the problems; (2) attempt to predict help seeking behaviour.

Methods Fifty-one patients suffering from schizophrenia according to DSM-5 and fit to be interviewed were assessed using EMIC (Explanatory Model Interview Catalogue) to get emic (insider or person's own cultural) perspective of disease related perception, help seeking behaviour and stigma.

Results Terms used to describe their illness included "depression" (21.6%), "mental" (17.6%) "matha kharap" (9.8%). Most common perceived cause was stress (25.5%) and sorcery (23.5%). Mental health specialist was visited by 27.5% Faith healer consultation was high (29.4%). Stigma score was higher with marriage related issues and social isolation. Using exhaustive CHAID analysis, it was found that patients with negative themes as disease name like "matha kharap" (loosely meaning crazy) are more likely to visit faith healers, while patients naming the condition with some medical related term like depression were more likely to visit mental health specialist.

Conclusion Clearly perception of patients regarding mental illness and its causation varies greatly from the way psychiatrists' viewpoint and this perception is likely to influence help seeking behaviour. Understanding these issues is likely to enable better patient awareness and proper formulation of plans to address mental health issues.

Neighbourhood ethnic density and incidence of psychosis – First and second generation migrants comparedP. Schofield^{1,*}, J. Das-Munshi², L. Becares³, E. Agerbo⁴¹ King's College London, Division of Health & Social Care Research, London, United Kingdom² King's College London, Health Service & Population Research Department, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom³ The University of Manchester, Centre on Dynamics of Ethnicity, Manchester, United Kingdom⁴ Aarhus University, CIRRAU, Centre for Integrated Register-based Research, Aarhus, Denmark

* Corresponding author.

Introduction Living in an area with few people from the same ethnic background has been associated with increased incidence of psychosis (the ethnic density effect).

Objectives Compare associations between neighbourhood ethnic density and incidence of non-affective psychosis for first and second generation migrants.

Methods Population based cohort (2.2 million) of all those born 1st January 1965 or later and living in Denmark on their 15th birth-

day. We looked at a total of 106,000 migrants, including 62% first generation migrants. Ethnic density was determined at age 15 and we adjusted for age, gender, calendar period, parental psychiatric history and parental income at age 15.

Results For the first generation, we found no evidence that rates of non-affective psychosis were related to neighbourhood ethnic density for migrants from Africa (comparing lowest and highest quintiles): IRR 1.02 (95% CI 0.6–1.73), and the Middle East: IRR 0.96 (CI 0.68–1.35) and only weak evidence for migrants from Europe (excluding Scandinavia): IRR 1.35 (CI 0.98–1.84). Conversely, for the second generation rates of non-affective psychosis were increased for migrants from Africa in lower ethnic density neighbourhoods (comparing lowest and highest quintiles): IRR 3.97 (95% CI 1.81–8.69), Europe (excluding Scandinavia): IRR 1.82 (CI 1.28–2.59) and the Middle East: IRR 2.42 (CI 1.18–4.99).

Conclusions There is strong evidence for an area ethnic density effect on psychosis incidence for second generation migrants, but not for first generation migrants. This could reflect a greater resilience among the latter group to the adverse effects of minority status.

Disclosure of interest The authors have not supplied their declaration of competing interest.

What is the prevailing diagnosis on admission into adult psychiatric wards? A meta-analysis of trends in the United KingdomA. Shoka^{1,*}, C. Lazzari², Katherine Gower^{1,2}¹ School of Health and Social Care, University of Essex, Colchester, United Kingdom² General Adult Psychiatry, North Essex NHS University Foundation Trust, Colchester, United Kingdom

* Corresponding author.

Introduction There seems to be an upsurge in psychiatric admissions related to female patients with borderline personality disorder. Does this reflect the actual trend?

Objectives Study of the typology of admission into acute psychiatric wards for an adult population.

Aims To understand the trend of actual psychopathology in the general population admitted into psychiatric wards.

Methods A total population of 197 psychiatric admissions was diagnosed in the period March 2015–March 2016 in a general psychiatric ward in the United Kingdom. The four major diagnostic categories were: personality disorder (mostly inclusive of borderline p.d.) ($n=77$), paranoid schizophrenia ($n=24$), schizoaffective ($n=11$) and other ($n=82$). Meta-analysis of the population analyzed the results. Gender was divided into 82 male and 125 female admissions, with 181 informal admissions, 68 under Sections of the Mental Health Act, and 5 under recall from Community Treatment Order.

Results Meta-analysis (Fig. 1) of the whole study showed a statistically significant heterogeneity in results with Tau squared $t^2=0.031$, Cochran's Q ($df=3$)= 141.90 , $P<.001$, and $I^2=97.87$, a prevalence of borderline personality disorder over other diagnoses; a prevalence of female over male admissions, ($t^2=.02$, Q ($df=1$)= 18.67 , $P<.001$, $I^2=94.64$), and a prevalence of patients admitted informally ($t^2=0.131$, Q ($df=2$)= 586.366 , $P<.001$, $I^2=99.65$).

Conclusions The prevailing population of acute psychiatric wards for the general adult population is females who are admitted informally with diagnosis of borderline personality disorder.

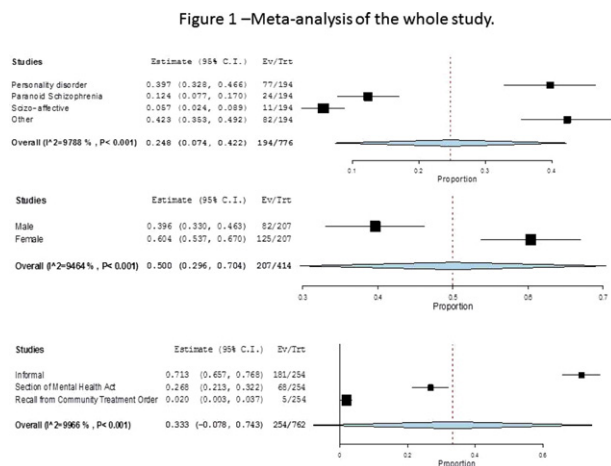

Fig. 1 Meta-analysis of the whole study.

Length of admission into psychiatric hospitals according to diagnoses

A. Shoka^{1,*}, C. Lazzari², Katherine Gower^{1,2}

¹ University of Essex, School of Health and Social Care, University of Essex, Colchester, United Kingdom

² North Essex NHS University Foundation Trust, United Kingdom, General Adult Psychiatry, Colchester, United Kingdom

* Corresponding author.

Introduction In recent years, psychiatry in the United Kingdom has faced an important challenge due to the shortage of beds for patients with increased lengths of stay. Available resources have been saturated due to the reduced capability of psychiatric hospitals to provide spaces for patients needing access to psychiatric care.

Objectives This research provides a figure of length of stay linked to psychiatric pathology at discharge.

Aim To establish the length of admission of psychiatric patients.

Methods The sample comprised 137 discharges from a general adult psychiatric ward distributed over the first 8 months of 2016. Results were analyzed by descriptive statistics and meta-analysis.

Results Overall, longer periods of admission were recorded for psychoses and shorter periods for adjustment disorders. Psychoses had a median length of admission of 28 days (range = 3–374); borderline personality disorders, 10 days (range = 1–249); mood disorders, 14 days (range = 2–74); drug addictions, 6 days (range = 1–222); and adjustment disorders, 5 days (range = 1–55). Meta-analysis (Fig. 1) provided a confidence interval estimate for the whole model of 24.314 days (95% CI = 13.00–35.621) with $P < .001$. Meta-analysis results also provided $t^2 = 101.061$, Cochrane's Q ($df = 4$) = 14.327, $I^2 = 72.081$, with $P = .006$.

Conclusions Psychoses are conditions that require longer admissions, whereas adjustment disorders are more transient pathologies. Borderline personality disorder is somewhat of a hybrid condition. Overall, patients remain in hospital for about a month (24 days).

Fig. 1 Meta-analysis of length of admission in hospital according to diagnoses.

Analysis of hospital admissions for psychiatric care in Portugal: Results from the SMAILE study

M. Silva^{1,*}, A. Antunes¹, A. Loureiro², P. Santana², J. Caldas-de-Almeida¹, G. Cardoso¹

¹ Chronic Diseases Research Center CEDOC, NOVA Medical School, Lisboa, Portugal

² CEGOT, Centre of Studies on Geography and Spatial Planning, Department of Geography, University of Coimbra, Coimbra, Portugal

* Corresponding author.

Introduction Evidence shows that the prevalence and severity of mental disorders and the need for psychiatric admission is influenced by socio-demographic and contextual factors.

Objectives To characterize the severity of hospital admissions for psychiatric care due to common mental disorders and psychosis in Portugal.

Aims This retrospective study analyses all acute psychiatric admissions for common mental disorders and psychosis in four Portuguese departments of psychiatry in the metropolitan areas of Lisbon and Porto, and investigates the association of their severity with socio-demographic and clinical factors.

Methods Socio-demographic and clinical variables were obtained from the clinical charts of psychiatric admissions in 2002, 2007 and 2012 ($n = 2621$). The number of hospital admissions per year (>1) and the length of hospital stay (31 days) were defined as measures of hospital admission severity. Logistic regression analysis was used to assess which socio-demographic and clinical factors were associated with both hospital admission severity outcomes.

Results Results showed different predictors for each outcome. Being widowed, low level of education, being retired, having psychiatric co-morbidity, and a compulsory admission were statistically associated ($P < 0.05$) with a higher number of hospital admissions. Being single or widowed, being retired, a diagnosis of psychosis, and a compulsory admission were associated with higher length of hospital stay, while having suicidal ideation was associated with a lower length of hospital stay.

Conclusions Socio-demographic and clinical characteristics of the patients are determinants of hospital admissions for psychiatric care and of their severity.

Funding Fundação para a Ciência e Tecnologia (FCT), Portugal.

Study on female refugees – A representative research study on refugee women in Germany

E. Sönmez^{1,*}, J. Jesuthasan², I. Abels³, R. Nassar², C. Kurmeyer⁴, M. Schouler-Ocak²

¹ Marmara University Pendik Training and Research Hospital, Psychiatry, Istanbul, Turkey

² Psychiatrische Universitätsklinik der Charité Campus Mitte im St. Hedwig Krankenhaus, Psychiatry, Berlin, Germany

³ Charité Universitätsmedizin Berlin, Mentoring Competence Centers, Berlin, Germany

⁴ Charité Universitätsmedizin Berlin, Zentrale Frauen- und Gleichstellungsbeauftragte, Berlin, Germany

* Corresponding author.

Introduction Germany is one of the European countries that receive the highest number of refugees for the last years, with around 468 thousand asylum seekers in the first half of 2016. However, the increase in the speed of short-term procedures regarding refugees may at the same time overlook the risks regarding specific populations. Moreover, women and children constitute the most vulnerable groups during war and conflicts and the worst effects, in terms of physical, mental and social consequences, develop on these groups.

Objectives To understand deeply the psychosocial situation of female refugees that have arrived in Federal German Republic, to assess their challenges and resources before, during and after the displacement and to propose recommendations for policy changes.

Methods The study consists of two modules, taking place in five states in Federal German Republic, including Berlin, Mecklenburg-Vorpommern, Bayern, Hessen und Mainz. In the first step, a representative stratified sample of female refugees from Syria, Iraq, Iran, Afghanistan, Somali and Eritrea are recruited. The quantitative study instrument include a socio-demographic question form and HSCL-Hopkins checklist, Harvard Trauma questionnaire, Beck depressions inventory, EUROHIS-QOL and SCL-14. In the second step, a qualitative in-depth analysis of focus group meetings is conducted.

Results and conclusions There is an urgent need to take action for the mental health problems of refugees. This study constitutes one of the most extensive researches, especially on a subpopulation of refugees that requires specific attention. Challenges faced throughout the protocol and detailed results will be shared as presentation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Pharmacological issues in cancer patients

M. Alves^{1,*}, A. Tavares²

¹ Hospital de Magalhães Lemos, Serviço C, Porto, Portugal

² Instituto Português de Oncologia do Porto, Serviço de Psico-Oncologia, Porto, Portugal

* Corresponding author.

Introduction Depression and anxiety are the main causes of psychiatric disorder in cancer patients, associated with a decreased tolerance and adherence to cancer treatment, longer hospital stays,

decreased quality of life and possibly influence prognosis and mortality.

Objectives This review will address psychopharmacological options in cancer patients, side effects and possible drug interactions between psychotropic drugs and chemotherapy, either by toxicity, to which these patients are more sensitive, or a reduction in efficacy in anti-tumor treatment.

Methods Non systematic literature review through the Medline and clinical key databases, with time constraints.

Results Selective Serotonin Reuptake Inhibitors are the first line treatment for depression, because of their tolerability and safety profile. Venlafaxine is the safer choice for the treatment of depression and hot flushes in women with breast cancer undergoing chemotherapy with tamoxifen. Tricyclic antidepressants are used in patients with neuropathic pain, due to its analgesic properties. Haloperidol is the safest antipsychotic, with less drug interactions and lower metabolic risk. Benzodiazepines are used in anxiety states for short periods. Psychostimulants are an option in patients with depression and life expectancy of less than one month. Mood stabilizers are recommended to treat mania, commonly induced by corticosteroids.

Conclusions Treatment of psychiatric disease in cancer patients leads to an increased adherence to anti-tumoral treatment and improves quality of life. Regardless of the cancer stage there is indication to start treatment. We must, however, take into account possible side effects and drug interactions between psychotropic drugs and chemotherapy, through toxicity or diminished efficacy, when combined with anti-tumoral treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cancer survivor – What comes next?

M. Alves^{1,*}, A. Tavares²

¹ Hospital de Magalhães Lemos, Serviço C, Porto, Portugal

² Instituto Português de Oncologia do Porto, Serviço de Psico-Oncologia, Porto, Portugal

* Corresponding author.

Introduction The number of long term cancer survivors (more than 5 years after diagnosis) are nowadays increasing because of advances in cancer screening, early detection, treatment strategies and management of acute treatment toxicities.

Objectives We aim to highlight the long-term psychological responses or late effect of cancer diagnosis and treatment.

Methods Non systematic literature review through the Medline and clinical key databases, with time constraints.

Results There are physical and functional difficulties that may not be solved with the conclusion of treatment or can become problematic in survivors of cancer.

Long-term refers to psychological or emotional responses that emerge after cancer diagnosis and treatment and persist for at least 5 years. Late effects of cancer refer to psychological or emotional responses that emerge after treatment completion. Risk factors to its development depends on the diagnosis, type of treatment, age at treatment, time since treatment, genetic vulnerability, psychological, social and environmental factors.

Specific deficits are more prevalent in survivors than in healthy adults of the same age. Fatigue, sexual dysfunction, cognitive impairment and musculoskeletal symptoms are common. Functional limitations that induce restricted physical and social activities may happen in survivors. Physical function and late complications can be influenced by lifestyle, socio-economic and biologic factors.

Conclusions Cancer survivors face short-term and long-term challenges to physical and mental health and they need to be addressed in the active treatment and throughout the continuum

of survivorship care. Screening for mental health morbidity should be better integrated into active cancer treatment and survivorship and it should be provided mental health later interventions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The impact of the type of surgical treatment on the quality of life of Portuguese women with breast cancer

H. Pereira*, R. Castelo

University of Beira Interior, Psychology and Education, Covilhã, Portugal

* Corresponding author.

Introduction Breast cancer significantly impacts dimensions of quality of life such as mental health, one's level of activity, family well-being, physical concerns (symptoms and pain), treatment satisfaction, emotional well-being, sexual intimacy, and social functioning.

Aim The aim of this study is to evaluate the impact of the type of surgery on the quality of life of women being treated for breast cancer, based on the comparison of samples of women who have undergone different types of surgery.

Method Our sample consists of 90 Portuguese women divided into three groups of 30 participants each. The first group underwent radical surgery in order to treat their breast cancer. The second group of women had conservative surgery as a breast cancer treatment. Finally, the last group of women did not have any type of surgical intervention. We use a socio-demographic questionnaire and the Portuguese version of the EORTC QLQ-30 as measurement instruments. The sample consists of patients from a central hospital in Lisbon, Portugal, and the data were collected anonymously.

Results We find that in all dimensions of quality of life measured, including general health, physical functioning, social roles, and all emotional, cognitive, and social dimensions, the group of women who underwent radical surgery shows lower scores when compared to the other two groups. This indicates that this group has lower levels of quality of life.

Conclusion The use of surgery for the treatment of breast cancer leads to a diminished quality of life following surgical intervention.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Background Mindfulness based interventions (MBIs) have shown efficacy in improving psychological symptoms including depression and anxiety in cancer patients (pts). The study aimed to explore feasibility and reproducibility of MBIs in an Italian Cancer Centre measuring biochemical and psychological parameters.

Methods In this pilot prospective case-control study, we recruited newly diagnosed pts receiving adjuvant chemotherapy (CT). A MBIs program was designed consisting of 2.5 hours weekly for 8 weeks and, including meditation, yoga and body scan. Material for 45 minutes (mn) home daily practice was provided. Primary endpoint was to evaluate feasibility. Secondary endpoints were assessment of quality of life (QoL), psychological and biochemical outcomes of stress, tested at baseline (W0), W4, W8, W24, W48. PSS (Perceived Stress Reduction), POMS (profile of mood states scores), EuroQoL (EQ-5D-3L) were administered.

Results Ten pts underwent MBIs program arm. We present preliminary results, while data of control arm are being collected. All pts were female, two pts (20%) dropped out. Median age was 56 years. All received adjuvant CT, 5/8 received radiotherapy and hormone therapy. Mean of sessions attending was 6.8 (76%). Median daily practice was 30 mn. EQ-5D item for depression and anxiety showed decreasing trend in mean score from moderate to light ($P=0.15$) and significant improvement of auto-perceived QoL was observed comparing W0 and W8 ($P=0.02$)

Conclusions In a sensitive setting such as start CT, we found high pts compliance to MBIs. Improvement in self-perceived QoL after starting program was found and comparing anxious-depressive symptoms outcomes with control arm is still needed.

Psychosocial interventions to improve the quality of life for men with prostate cancer: A network meta-analysis of 31 randomized controlled trials

S. Qiu^{1,*}, D. Linghui²

¹ West China Hospital Sichuan University, Urology, Chengdu, China

² Stroke Clinical Research Unit, Department of Neurology, West China Hospital, Sichuan University, Chengdu–Sichuan, China, Department of Neurology, Chengdu, China

* Corresponding author.

Background The treatment of prostate cancer (PCa) can trigger a sequence of life-altering decisions that can induce depression and effects on health-related quality of life. We aimed to simultaneously compare all available psychosocial interventions using both direct and indirect data.

Methods In this systematic review and network meta-analysis, we searched the Embase, Medline, PsycINFO, and the Cochrane central register of controlled trials for randomized controlled trials (RCT) published before Oct, 2016, that compared active treatments dealing with psychosocial problems in PCa patients after treatment. The primary outcome was health-related quality of life improvement as measured by the 36-Item Short-Form Health Survey (SF-36). Psychological morbidity was assessed with the Hospital Anxiety and Depression Scale (HADS). This study is registered with PROSPERO, number CRD42016049621.

Results We screened 113 potentially eligible studies and identified 31 RCTs, that examined 7 psychosocial interventions in 3643 PCa participants. In terms of SF-36, cognitive behavioral therapy [standard mean difference (SMD) 2.48, credible interval [CrI] 0.23

to 4.46], group based counseling (SMD 1.36, CrI 0.40 to 3.17) had significantly greater effects than usual care. Participants assigned to all assessed interventions had a significantly improvement in depression compared with usual care, except for those assigned to psychoeducational therapy (SMD 0.02, 95% CrI -0.11 to 0.15).

Conclusion This review shows that cognitive behavioral therapy, group based counseling and exercise may have significant beneficial effects considering SF-36 and HADS when compared with usual care. However, additional well-done research studies are necessary to establish the role of psychosocial interventions in men with PCa.

Suicides and cancer mortality in Russia: A comparative analysis of trends

Y. Razvodovsky

Grodno State Medical University, Pathological Physiology, Grodno, Belarus

Introduction The association between suicide and cancer is complex. Hopelessness and depression are the common risk factors for both suicide and cancer. There is also evidence that suicide rate in cancer patients are higher than in the general population. However, the real occurrence of suicide in cancer patients is considered to be underreported. This is a good reason to expect a positive relationship between cancer mortality and suicide rates at the population level.

Aims The present study aims to test the hypothesis of the close aggregate level link between cancer mortality and the suicide rates in Russia.

Methods Trends in sex-specific cancer mortality and the suicide rates from 1956 to 2010 were analyzed employing a distributed lags analysis.

Results The results of analysis indicate the presence of a statistically significant association between trends in suicides and cancer of the upper digestive tract (mouth, oral cavity and pharynx), larynx, bronchus and lungs, stomach, colorectal, ureter and leukemia for male. There is also a statistically significant association between trends in suicides and cancer of the upper digestive tract (mouth, oral cavity and pharynx), larynx, bronchus and lungs, stomach, colorectal, ureter, breast, cervix, uterus and leukemia for female.

Conclusions Common confounding variables, including binge drinking and psychosocial distress, may explain positive aggregate-level association between the cancer mortality and suicides time series in Russia.

Clinical and psychological confirmation of stabilizing effect of neurofeedback in migraine

O. Dobrushina^{1,*}, G. Arina², E. Osina², G. Aziatskaya¹

¹ International Institute of Psychosomatic Health, Department of neurorehabilitation, Moscow, Russia

² Lomonosov Moscow State University, Department of psychology, Moscow, Russia

* Corresponding author.

Introduction Neurofeedback in migraine aims to improve neurophysiological state, which is linked to psychosomatic, emotional and cognitive regulation. Objective and complex evaluation of neurofeedback effects is feasible.

Methods A single case design cross-over placebo-controlled study with blinded evaluator included 3 females with frequent migraine (N., E., T.), 1 of whom (T.) also had TTH. Study had 4 phases: evaluation (≥ 2 weeks), treatment 1 (5 weeks), treatment 2 (5 weeks), evaluation (≥ 2 weeks). Treatment 1 and 2 included 10 infra-low frequency neurofeedback and 10 sham-neurofeedback sessions at T3T4 site in randomized order. Detailed psychological assessment was performed a baseline, at phase switch and in the end. Every day participants filled a computerized diary about pain, aura, mood, stress, copings. Before each session they received questionnaires "well-being, activity, mood" (rating of the current state between antonym adjectives, in Russian).

Results The main finding was reduction of migraine (but not TTH) frequency during real, but not sham neurofeedback phase: 11% vs. 31% days in N. ($P=0.1$), 15% vs. 30% days in E. ($P=0.046$), T. After the start of neurofeedback had only TTH. Another detected phenomena was reduction of day-to-day shifts in cognitive function domains of "well-being, activity, mood" (easy/difficult to think, attentive/distracted). In N. and E these domains had co-dynamic with mood (good/bad mood, happy/sad), while in T. – with anxiety (tensed/relaxed, nervous/calm).

Conclusion Infra-low frequency neurofeedback from interhemispheric site resulted in decrease in migraine frequency and in reduction of shifts in psychological state. Thus, the treatment had multimodal stabilizing effect.

Sham-neurofeedback as an intervention: Placebo or nocebo?

G. Arina^{1,*}, E. Osina¹, O. Dobrushina², G. Aziatskaya²

¹ Lomonosov Moscow State University, Department of psychology, Moscow, Russia

² International Institute of Psychosomatic Health, Department of neurorehabilitation, Moscow, Russia

* Corresponding author.

Introduction Sham-controlled studies of neurofeedback are aimed to provide evidence-based data regarding its efficacy. However, a sophisticated sham procedure may turn out to be an intervention rather than a neutral control.

Methods Data from a single-case cross-over sham-controlled study of NF in migraine were analyzed to access the effects of sham-NF. The study included 5 females with chronic migraine and was divided into 4 phases: pre-evaluation (≥ 2 weeks), treatment 1 (5 weeks), treatment 2 (5 weeks), post-evaluation (≥ 2 weeks), where treatment 1 and 2 included 10 infra-low frequency NF and 10 sham-NF sessions at T3T4 site in randomized order. Participants filled out a computerized diary about headache and emotions.

Results Sham-NF resulted in some reduction of the level of tension (0.8 ± 0.7 vs. 1.1 ± 0.5 , $P=0.1$) and anxiety (0.56 ± 0.5 vs. 0.95 ± 0.4 , $P=0.07$) as measured by the mean value in the diary (rating from 0 - no emotion, to 3 - very intense). While the total frequency of headache was not influenced by sham-NF ($40 \pm 11\%$ vs. $40 \pm 7\%$ days, $P=1$), a tendency towards an increase in quantity of severe headaches ($42 \pm 18\%$ vs. $20 \pm 18\%$ days, $P=0.07$) and in the need for drug intake ($74 \pm 27\%$ vs. $44 \pm 30\%$ days, $P=0.07$) was observed. We supposed that expectation of feedback and failure to receive it during sham sessions may have possible negative effects, while frequent visits to the clinic and contact with the therapist may explain reduction in anxiety.

Conclusion Sham-NF seems to have both placebo and nocebo effects, which should be considered during interpretation of results of the studies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Pain perception in children with autism (prospective study of 40 cases)

A. Kachouchi^{1,*}, S. Said (Dr)¹, P.O.N. Fadoua², P.A. Benali², P.A. Imane¹, P.M. Fatiha¹, P.A. Fatima¹

¹ University hospital Mohammed VI, Department Of Psychiatry, Marrakech, Morocco

² Avicenne military hospital, Child and adolescent psychiatry service, Marrakech, Morocco

* Corresponding author.

Introduction Recent studies show a different mode of expression of pain associated with disorders of verbal and nonverbal communication, body schema and some cognitive impairment in autistic children.

The aim of our study was to evaluate the reactivity of an autistic child in a slightly painful stimulation in a standardized situation where there is a dual relationship with an adult.

Methods We conducted a study, on 40 children with autism. The diagnosis of autism was established following a multidisciplinary assessment including scale ADIR (Autism Diagnostic Interview Revised) and ADOS (Autism Diagnostic Observation Schedule). Severity of autism was assessed by the CARS (Childhood Autism Rating Scale). All subjects were submitted to a pinch with a clothespin camouflaged by the palm of the hand of the examiner. The reactivity to pain was assessed by the NCCPC (Non-communicating children's pain checklist).

Results All children have responded to pain, 57.5% had moderate to severe pain and 42.5% had mild pain. The evaluation of the expression of pain according to the items of the NCCPC showed that 95% of children responded with motor responses, 90% responded with vocal productions, only half of the children (55%) presented facial expressions and 12.5% of the children showed physiological indices. The analysis of the type of motor and vocal reactions was not moving toward pain in almost all children (removal or protection of the area of the body affected, the precise location of the painful area are almost absent in our sample).

Conclusion These results are in favor of a different mode of expression of pain in children with autism.

Mental disorders in patients with temporomandibular pain-dysfunction syndrome

V. Medvedev*, V. Frolova, Y. Fofanova
PFUR University, Chair of Psychiatry- Psychotherapy and Psychosomatic Pathology, Moscow, Russia

* Corresponding author.

Introduction Maxillofacial surgeons and dentists often deal with the phenomenon of temporomandibular pain-dysfunction syndrome—painful condition of maxillofacial area without clear organic pathology. Psychiatric studies of this disorder are almost lacking. The aim of this study was to determine the prevalence of psychiatric disorders in patients with temporomandibular pain-dysfunction syndrome and to define the psychiatric diagnosis (ICD-10).

Methods Study sample consists of 57 patients (44 women and 13 men) with temporomandibular pain-dysfunction syndrome aged older than 18 years, who gave inform consent. The study used clin-

ical psychopathological, psychometric (HADS, HDRS, State-Trait Anxiety Inventory, Hypochondria Whitley Index, Visual Analog Scale for Pain).

Results Psychiatric disorders were revealed in 48 patients (84.2%) with temporomandibular pain-dysfunction syndrome—39 women and 9 men aged 18–65 years (mean age 39.6 ± 15.4 years). Affective disorders were diagnosed in 56.3%, personality disorders in 20.8%, schizotypal personality disorder in 12.5% and schizophrenia in 10.4%. Among affective pathology mild and moderate depressive episodes prevailed (59.3%). The severity of pain (VAS) in patients with affective disorders was higher than in patients with other psychiatric conditions.

Conclusion This study shows high prevalence of psychiatric disorders in patients with temporomandibular pain-dysfunction syndrome and proves the feasibility of a psychiatrist participate in the complex treatment of these patients. The use of psychometric method allows to improve the timeliness of the detection of patients who require further clinical psychopathological examination in order to determine the need of pharmacotherapy.

Burning mouth syndrome: Problem in the mouth?

S. Petrykiv^{1,*}, L. de Jonge², M. Arts³

¹ University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands

² Leonardo Scientific Research Institute, Department of Geriatric Psychiatry, Groningen, The Netherlands

³ University Medical Center Groningen, Department of Old Age Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction Burning mouth syndrome (BMS) is characterized by an intraoral burning sensation for which no medical or dental cause can be found. Sporadic evidence suggests that drug induced conditions may evoke BMS. Intriguingly, we observed a patient who developed BMS after induction of citalopram.

Objectives & aims A case report of patient with BMS from our psychiatric ward will be presented here, followed by a literature review on drugs induced BMS.

Methods Based on a recent literature search, we present a first case report of BMS that was apparently induced in patient shortly after beginning of citalopram. We performed a systematic search through PubMed, EMBASE and Cochrane's Library to find more cases of psychotropic induced BMS.

Results Ms. A. was a 72-year old woman meeting DSM-IV diagnostic criteria for melancholic depression, who was observed in a clinical setting. We started citalopram 10 mg. 1dd1, with 10 mg. 1dd1 increase over 7 days to 20 mg, 1dd1. The following day, she displayed a persistent burning painful sensation in the mouth. Other than BMS oropharyngological syndromes were excluded after consultation with qualified medical specialists. Citalopram therapy was discontinued, and nortriphen treatment was initiated. BMS symptoms resolved over four days. Twelve case reports have linked BMS to the use antidepressants and anxiolytics.

Conclusion Contrasting the statement that no medical cause can be found for BMS, we found that psychotropics may evoke the syndrome. Compared to other psychotropic drugs, antidepressant medication has the strongest association with BMS.

Validation of the Arabic version of the oxford happiness inventory among undergraduates in Kuwait

B. Alansari*, T. AlAli

Kuwait University, Faculty of Social Sciences, Psychology, Kaifan, Kuwait

* Corresponding author.

Introduction The Oxford Happiness Inventory (OHI) 29-Item, each involving the selection of four options that are different for each item. Although there is an Arabic version, it is not identical to the original version in terms of the number of items and response.

Objectives to evaluate the psychometric properties of the Arabic adaptation OHI and its factorial structure in undergraduate sample.

Methods The participants were 720 first year undergraduate Kuwaitis: 360 males mean age = 20.38 ± 1.60 and 360 females; mean age = 19.71 ± 1.39 (t=5.87, P<0.001). The Arabic version of OHI (Argyle, Martin, & Crossland) was administered to participants. The internal consistency reliability, factor structure, and convergent validity of the OHI with Life Orientation Test (LOT-R, Adult Hope Scale (AHS), Satisfaction With Life Scale (SWLS) were assessed as well as divergent validity of the OHI with Beck Depression Inventory-II (BDI-II)

Results Internal consistency was satisfactory for the OHI (Cronbach's alpha = 0.87) for males and (Cronbach's alpha = 0.86) for females. The results revealed no significant gender differences on happiness (F = 1.77, P>0.05). Principal component analyses (PCA) showed that a seven-component solution explains %50.50 of the total variance for males and 51.47% for females. The OHI positively correlates with the following variables: SWLS (r = .52), LOT-R (r = 0.56) AHS (r = .48) while the OHI correlates negatively with BDI-II (r = -.54).

Conclusions Findings confirm that the OHI provides satisfactory validation, and thus it can be recommended as a measure of happiness among Arab samples.

Portuguese validation of the Perfectionism Self Presentation Scale

A.T. Pereira¹, C. Marques¹, M.J. Martins¹, A.I. Araújo^{2,*}, C. Cabaços³, M.J. Brito³, L. Mendonça³, A. Macedo¹¹ Faculty of Medicine, University of Coimbra, Department of Psychological Medicine, Coimbra, Portugal² Faculty of Medicine, University of Coimbra, Department of Psychological Medicine, Macieira de Cambra, Portugal³ Faculty of Medicine, University of Coimbra, Coimbra, Portugal

* Corresponding author.

Introduction Perfectionist Self Presentation represents the interpersonal expression of perfectionism wherein individuals engage in strategies that promote their supposed perfection and conceal their perceived imperfections (Hewitt et al., 2003).

Objective To investigate the psychometric properties of the Portuguese version of the Perfectionist Self Presentation Scale/PSPS.

Methods Two hundred and eighty-six university students (69.2% females; mean age = 21.09 ± 2.133) answered the Portuguese preliminary version of the PSPS, and the Portuguese validated versions of: Multidimensional Perfectionism Scales, Dirty Dozen and Depression Anxiety and Stress Scale. To study the temporal

stability, 30 participants (66.7% females) answered the PSPS again after six weeks. SPSS and Mplus were used.

Results The PSPS Cronbach alpha was .91. The test-retest correlation coefficient was .66 (P < .01). Exploratory factor analysis resulted in a three dimension's model ($\chi^2 = 1974.015$, P < .01; RMSEA = 0.079, 90% CI = 0.069–0.088; CFI = 0.869; TLI = 0.812; SRMR = 0.046). The three factors presented good internal consistency: F1 Perfectionist self-presentation (PSPS; a = .85), F2 Interpersonal Concern over mistakes (ICM; a = .79); F3 Perfectionist image (PI; a = .70).

PSP and ICM (and PI with fewer significant coefficients and lower magnitudes) were moderately to highly correlate with personal standards, concern over mistakes, doubts about action, self-oriented perfectionism and social prescribed perfectionism ($\geq .40$). Correlations with narcissism and machiavellianism, anxiety and stress were moderate (r = .30) (all P < .01).

Conclusions The Portuguese version of PSPS has good reliability and validity, with the factorial model presenting an acceptable fit (Hair et al., 2004). It could be very useful both in clinical and research contexts, namely in an ongoing research project on the relationship between perfectionism and interpersonal functioning.

Confirmatory factor analysis of NEO-FFI-20 in a Portuguese sample

J.F. Dourado¹, A.T. Pereira², C. Marques², J. Azevedo^{2,*}, V. Nogueira², A. Macedo², A.M.C. Bastos Silva¹, A.J.M. Seco¹¹ Faculty of Sciences and Technology - University of Coimbra, CITTA, Coimbra, Portugal² Faculty of Medicine - University of Coimbra, Department of Psychological Medicine, Coimbra, Portugal

* Corresponding author.

Introduction The Five-Factor Model organizes human personality traits under a comprehensive framework of five dimensions—neuroticism, extraversion, openness to experience, agreeableness and conscientiousness. The dimensions are empirical generalizations of enduring differences in behavioural, emotional and cognitive patterns between individuals. The Portuguese version of the NEO-Five Factor Inventory (NEO-FFI-20) is increasingly used as it is the shortest version to evaluate the "Big 5".

Objective To investigate the reliability and the validity of the Portuguese version of NEO-FFI-20-item (Bertoquini & Pais Ribeiro) in a Portuguese sample, using exploratory and confirmatory factor analysis (EFA and CFA).

Methods 747 participants [417 (55.8%) women; mean age = 42.13 ± 12.349 years] answered an online survey which included the NEO-FFI-20 and socio-demographic questions. The total sample was randomly divided in two sub-samples (sample A, n = 373; sample B, n = 374). Sample A was used to EFA and sample B was used to CFA.

Results The Portuguese version of NEO-FFI-20, excluding items 14 and 16, had an acceptable fit to the data ($\chi^2/df = 2.28$; TLI = .88; CFI = .90; RMSEA = .06; P = .059). The internal consistency analysis resulted in: Neuroticism, $\alpha = .68$; Extraversion, $\alpha = .62$; Openness to Experience, $\alpha = .74$; Agreeableness, $\alpha = .70$; and Conscientiousness, $\alpha = .74$.

Conclusions The NEO-FFI-20 can be used to reliably and validly evaluate the BIG FIVE in an ongoing research project on traffic psychology to better understand and respond to risky behaviours on the road.

The Situational Dysphoria Scale (SITDS): development and validation of a self-report questionnaire for assessing situational dysphoria in borderline patients

A. D'Agostino^{1,*}, A. Aportone¹, M. Rossi Monti¹, V. Starcevic²

¹ University of Urbino Italy, Humanistic Studies, Urbino, Italy

² University of Sydney, Discipline of Psychiatry- Sydney Medical School, Sydney, Australia

* Corresponding author.

Introduction According to contemporary phenomenological literature, dysphoria is the background mood characterizing patients with borderline personality disorders (BPD). In particular circumstances, it can take the form of a state of pressure, urge to act, and quasi-explosion, which is very dependent on situational triggers. There are currently no instruments able to measure this situational form of dysphoria.

Objectives To develop and analyze psychometric properties of the Situational Dysphoria Scale (SITDS), a self-report questionnaire that measures situational dysphoria.

Aims To validate the SITDS for a future use in routine clinical practice and, more generally, to assess different forms of dysphoria in BPD in a more precise way.

Methods The preliminary 58-item SITDS was administered to 105 BPD patients, along with other conceptually similar (Nepean Dysphoria Scale) and conceptually distinct (Cynical Distrust Scale, Inventory of Interpersonal Problems-47, empathy quotient, and borderline personality severity Index-IV) instruments. The psychometric characteristics (reliability, internal structure, convergent and divergent validity) of the SITDS were then examined.

Results The final 24-item SITDS (with each item rated on three subscales: internal pressure, urge to act, and quasi-explosion) demonstrated excellent internal consistency ($\alpha = .91$). A three-cluster solution was found, with clusters pertaining to personal events, interpersonal events, and environmental events. There were medium to strong correlations with NDS, and weaker but still significant correlations with CynDis, IIP-47, EQ, and BPDSI-IV.

Conclusions The SITDS is a useful and easy-to-handle instrument for measuring situational dysphoria. Further research in clinical samples is needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Are patients with emotionally unstable personality disorder overmedicated?

E. Dobrzynska

Cygnets Health Care, Cygnets Hospital Kewstoke, Weston-super-Mare, United Kingdom

Emotionally Unstable Personality Disorder (EUPD) is often considered as treatment resistant clinical challenge. While effectiveness of psychological therapies for EUPD is widely acknowledged, there is less supportive evidence for pharmacotherapy use and patients with EUPD are perceived as overmedicated.

Objectives and aims The purpose of the study was to review prescribing guidelines and clinical practices for EUPD.

Methods MEDLINE and PsycINFO were searched for all English-language articles published 2000–2016 and containing the keywords “emotionally unstable personality disorder”, “borderline personality disorder”, “pharmacotherapy”, “drug treatment” and “treatment guidelines”.

Results NICE guidelines (2009) recommend pharmacotherapy should not be used for EUPD but for comorbid conditions only. In line with the American Psychiatric Association practice guideline, the Dutch and German guidelines recommend antipsychotics for cognitive-perceptual symptoms. However, in contrary to mood stabilisers they question the efficacy of antidepressants on impulsivity and affective dysregulation.

Studies on clinical practice showed 68% of borderline patients without comorbid disorder in UK were using antidepressants, 59% antipsychotics, 59% sedatives and 23% mood stabilizers. Similar results reported Paolini et al with polypharmacy in 83.5% of cases.

Conclusions All international guidelines recommend psychological therapies as the first-choice in EUPD treatment but diverge with respect to pharmacotherapy use. NICE and Australian guidelines abstain from psychotropics what may prevent to some degree counterproductive polypharmacy, but also can refrain from temporary pharmacological support when needed. More RCTs for pharmacotherapy use in EUPD are needed but meanwhile using pharmacotherapeutic algorithms for specific symptom domains might be the way forward.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

The purpose of this research was standardizing the questionnaire of personality disorder cluster A

N. Farrokhi^{1,*}, S. Ghahari²

¹ Young researchers club Of Islamic Azad University - Roudehen Branch, Clinical Psychology, Tehran, Iran

² Assistant professor of Mental Health- Iran University of Medical Sciences IUMS. Center of Excellence in psychiatry- School of Behavioral Sciences and Mental Health-, clinical psychology, Tehran, Iran

* Corresponding author.

Introduction As more or less stable personality traits of the person, temperament, intellect and body is what makes an individual unique compatibility with the environment.

Objective The purpose of this research was standardizing the questionnaire of personality disorder cluster A. On the basis of realizing criterion standard, DSM- 5.

Method 1303 people from universities of Tehran and Alborz provinces (753 females and 550 males) were examined by using the randomized sampling method. The questions of the questionnaire were conformed Dr. ShahramVaziri on the basis of Iran s population and culture. Then the reliability was tested and accomplished simultaneously Millon(MCMI-III) questionnaire.

Result After computing the correlation scales of Millon test with each of the questions, 20 questions that showed the highest correlation and diagnosis coefficient were chosen and scored again in next stage.

Conclusions Investigating the psychometric component of three scales (Paranoid 60%, Schizoid 66%, Schizotypal 59%) shows that they are reliable and defensibly valid. It can be said that questions related to all three measures paranoid, schizoid and schizotypal of acceptable psychometric properties and reliability are desirable.

Narcissism in Bulgarian adultsS. Stoyanova^{1,*}, V. Giannouli²¹ South-West University “Neofit Rilski”, Department of Psychology, Blagoevgrad, Bulgaria² Aristotle University of Thessaloniki, School of Medicine, Drama, Greece

* Corresponding author.

Introduction Narcissistic personality disorder influences relationships and beliefs in different life spheres.**Objective** We aimed to measure narcissism among Bulgarian adults by establishing validity of two scales measuring narcissism, specifying some social and demographic factors and differentiating narcissistic features.**Method** One hundred and thirty-four Bulgarians (17–62 years old, $M = 31$; $SD = 11$) were examined with two scales measuring narcissism. Higher score on Narcissistic personality disorder scale from the Personality Diagnostic Questionnaire-4 correlated positively ($r = .346$; $P < .001$) with higher score on A. T. Beck and J. S. Beck's scale measuring Narcissistic beliefs from Personality Belief Questionnaire that indicated their validity.**Results** No significant gender differences in narcissism were found, with female participants prevailing in the sample ($n = 118$). Family status ($F_{PDQ-4(4,128)} = 0.593$; $p_{PDQ-4} = .569$; $F_{PBQ(4,128)} = 0.295$; $p_{PBQ} = .881$), occupational status – student, employed or unemployed ($F_{PDQ-4(4,128)} = 0.593$; $p_{PDQ-4} = .569$; $F_{PBQ(4,128)} = 0.295$; $p_{PBQ} = .881$), secondary or university education ($t_{PDQ-4(112)} = 1.809$; $p_{PDQ-4} = .073$; $t_{PBQ(112)} = 1.338$; $p_{PBQ} = .184$), and the length of work experience did not differentiate narcissism ($R_{PDQ-4} = .168$; $t_{PDQ-4} = -1.853$; $p_{PDQ-4} = .066$; $R_{PBQ} = .063$; $t_{PBQ} = -0.681$; $p_{PBQ} = .497$). Advance in age was related to diminished levels of narcissism ($R_{PDQ-4} = .21$; $R^2_{PDQ-4} = .044$; $B_{PDQ-4} = -0.034$; $t_{PDQ-4} = -2.463$; $p_{PDQ-4} = .015$). Higher narcissism was related to the belief of being a special person (70.8%) and to the perceptions of other people as being envy of one's personality-own achievements (60.9%).**Conclusions** Narcissistic personality disorder is rare in the studied Bulgarian adult population – 4.5% of the subjects ($n = 6$) had the highest levels of narcissism on both scales that corresponded to the proportion of 6% prevalence of lifetime narcissism in USA, according to Stinson et al.**Disclosure of interest** The authors have not supplied their declaration of competing interest.<http://dx.doi.org/10.1016/j.eurpsy.2017.02.056>

Introduction H&F Multidimensional Perfectionism Scale is a widely used measure of perfectionism developed to measure Self-oriented perfectionism (SOP), Socially-prescribed perfectionism (SPP) and Other-oriented perfectionism (OOP) dimensions. The original scale comprises 45-likert items. We have previously developed a short version of The H&F-MPS, with 13 items, showing adequate validity in a sample of university students, using principal component analyses method with factors varimax rotation.**Objective** To examine the factor structure of the H&F-MPS13 with confirmatory factor analysis (CFA), using a different sample of Portuguese university students.**Methods** The sample comprises 245 university students (68.9% females), with a mean age of 20.95 years ($SD = 2.19$; $range = 17-33$) who completed the H&F-MPS13. CFA was used to test the model suggested by prior exploratory factor analyses of H&F-MPS13.**Results** After correlated errors, we obtained a good fit for the second-order factor ($X^2/d = 2.577$; $CFI = 0.928$; $GFI = 0.915$, $RMSEA = 0.080$; $P[rmsea \leq 0.05] = 0.001$). The H&F-MPS13 showed acceptable internal consistency ($\alpha = 0.77$) and the three dimensions presented Cronbach's alphas ranging between acceptable and good ($\alpha_{OOP} = 0.67$; $SPP = 0.73$; $SOP = 0.89$).**Conclusions** The H&F-MPS13 obtained through CFA is a reliable and valid measure to assess perfectionism in Portuguese university students.**Disclosure of interest** The authors have not supplied their declaration of competing interest.<http://dx.doi.org/10.1016/j.eurpsy.2017.02.057>

* Corresponding author.

Aim The purpose of this study was to investigate relationship between personality traits and mental health in athlete students. This study was a descriptive and correlation design.**Method** Sixty athletes students were randomly selected and responded to NEO-PIR inventory and General Health Questionnaire (GHQ 28). NEO assesses five personality traits: Neuroticism (N), Extroversion (E), Agreeableness (A), Openness to new experience (O) and Conscientiousness (C), and GHQ assesses four dimensions: Somatic symptoms (A), Anxiety (B), Social withdrawal (C) and Depression (D). NEO assesses five personality traits: Neuroticism, Extroversion, Agreeableness, Conscientiousness, Openness to experience. The data were analyzed with Pearson correlation test. **Results** The findings showed that there was positive significant correlation between neuroticism with somatic symptoms and depression, and negative significant correlation between extroversion, agreeableness, openness to new experience and conscientiousness with depression.**Conclusion** Based on findings, it is concluded that physical exercises and sport plans have positive effects on mood and affect of students, and decrease physical and mental diseases in athletes students.**Disclosure of interest** The authors have not supplied their declaration of competing interest.<http://dx.doi.org/10.1016/j.eurpsy.2017.02.058>

Dissociative symptoms in borderline personality disorder

A. Nivoli*, L.F. Nivoli, M. Antonioli, L. Floris, L. Folini, P. Milia, L.I. Vento, C. Depalmas, L. Lorettu
 University of Sassari, Department of Psychiatry, Sassari, Italy
 * Corresponding author.

Objective To study the association of dissociative symptoms and specific psychopathological dimensions in a sample of patients with Borderline Personality Disorder (BPD).

Methods An observational analytic study was conducted. Patients with BPD were administered the Diagnostic Interview for Borderline (DIB-R) and Dissociative Experience Scale (DES-II).

Results Participants were 34 adult patients with BPD. The majority presented with dissociative symptoms (65.6%; $n=21$). A statistical significant correlation was found between DES total score and DIB-R subscales: depression ($P=0.04$), feeling of loneliness and emptiness ($P=0.005$), sexual deviation ($P=0.002$) and intolerance to loneliness ($P=0.01$). Furthermore, depersonalization was statistically correlated with the severity of borderline psychopathology (DIB-R total score- $P=0.04$), suicidal behavior ($P=0.001$) and interpersonal problems ($P=0.04$). Derealization was significantly correlated with cognition ($P=0.02$), psychotic thought ($P=0.004$) and intolerance to loneliness ($P=0.02$).

Conclusions Dissociative symptoms are not easy to detect in the clinical daily work. More than a half of patients with BPD presented with dissociative symptoms detected with a specific rating scale. Particularly, only some specific psychopathological dimensions are correlated with dissociation and need to be assessed in patients with BPD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Personality traits and disorders among adult ADHD Patients: Is borderline personality disorder as common as we expect?

F. Oliva^{1,*}, S. Bramante², A. Portigliatti Pomeri², C. Carezana², G. Nibbio¹, C. Mangiapane¹, G. Maina²

¹ University of Turin, Department of Biological and Clinical Sciences, Orbassano TO, Italy

² University of Turin, Department of Neurosciences "Rita Levi Montalcini", Orbassano TO, Italy

* Corresponding author.

Introduction Patients with Attention Deficit/Hyperactivity Disorder (ADHD) have shown a high risk to develop a DSM cluster B (i.e., Borderline, OR=13.16; Antisocial, OR=3.03; Narcissistic, OR=8.69) and DSM Avoidant personality disorder (OR=9.77). Similarly, higher rates of DSM cluster B personality disorder were found among adult ADHD patients (6-25%) than general population. Although some authors investigated the prevalence of personality traits and disorders among adult ADHD patients, no studies have been yet reported about the assessment of Millon's Evolution-Based Personality profiles in adult ADHD patients.

Aims To explore the prevalence of personality traits and disorders among adult ADHD patients.

Methods Millon's personality traits and disorders were assessed in a consecutive sample of 35 adult ADHD outpatients accessing the Service for Adult ADHD of the AOU San Luigi Gonzaga (Orbassano, TO) using the Millon Clinical Multiaxial Inventory-III (MCMI-III).

Results According to the MCMI-III manual, ADHD patients in our sample showed more frequently both Cluster C and Cluster A traits and disorders, with a high prevalence of avoidant/depressive (8.6%/14.3%) and negativistic/self-defeating (20%/5.7%) personality

disorders. Conversely, we found a low prevalence of Narcissistic (5.7%) and Histrionic (5.7%) traits, and no patient showed Borderline personality traits or disorder.

Conclusions Unexpectedly, the dimensional assessment of adult ADHD personality reveals a high prevalence of cluster C and cluster A personality traits and disorders, and a low prevalence of cluster B personality disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The relation between parent personality traits and children psychopathology: A pilot study

L.A. Oliveira^{1,2,*}, T. Cartaxo³, J. Ferreira³, M. Marques³, S. Neiva³, D. Cardoso³, C. Ferreira³, R. Gonçalves³, M. Laureano³, C. Araújo³, A.T. Pereira², A. Macedo²

¹ Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

² Faculty of Medicine of the University of Coimbra, Department of Medical Psychology, Coimbra, Portugal

³ Coimbra Hospital and University Centre, Child and Adolescent Psychiatry, Coimbra, Portugal

* Corresponding author.

Introduction Personality plays a crucial role in a person's behavior, emotions and cognitive patterns and shows an important relationship with several variables such as marital status, mental disorders or parenting models. However, little is known about the relation between the parental Big Five personality traits (Neuroticism, Extraversion, Openness, Conscientiousness and Agreeableness) and children psychopathology regardless of the diagnostic of their offspring.

Objectives To analyze the correlation between parents' Big Five personality traits and their children categorical diagnosis and psychopathology score.

Methods The authors recruited 105 children in the outpatient unit of the child and adolescent psychiatry department of the pediatric hospital of Coimbra and their 117 parents. Parents were assessed using the Portuguese version of *Neo Five-Factor Inventory* and children psychopathology scores were rated by child and adolescent psychiatrists using the *Brief Psychiatric Rating Scale for Children*.

Results Forty-nine children (46.7%) were male and 56 (53.3%) were female, with a mean age of 12.5 ± 3.2 and 13.6 ± 2.9 , respectively. Twenty parents (17.1%) were male and 97 (82.9%) were female, with a mean age of 45.8 ± 4.1 and 41.2 ± 5.4 , respectively. After excluding children diagnosed with Schizophrenia, bipolar disorder, autism spectrum disorders and intellectual developmental disorder, Pearson's correlation coefficients were significant between: parents' neuroticism and children Uncooperativeness (0.211), Manipulativeness (0.238), Hallucinations (0.257), Sleep difficulties (0.296) and Disorientation (0.204); parents' agreeableness and children hostility (-0.228); and parent's conscientiousness and children disorientation (-0.231), all $P < 0.05$.

Conclusions These preliminary results suggest that parental personality traits may influence psychopathological outcomes in their children. Data are still being collected to clarify the nature of this relationship.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Overweight/obese patient referrals to plastic surgery: Temperamental and personality traits

C. Pavan^{1,*}, F. Bassetto², V. Vindigni²¹ University of Padova, Department of Medicine, Padova, Italy² University of Padova, Department of Neurosciences, Padova, Italy

* Corresponding author.

Introduction Correlations between psychiatric disorders and overweight/obesity are reported in the literature. The study aimed at detecting correlations between psychiatric disorders, temperamental traits and body image perception in overweight and obese patients who seek surgical lipostructuring treatments.

Methods 28 overweight/obese patients (age 18–60 yrs, BMI 25 to 34.9 at recruitment) were enrolled in the period March 2008–June 2011 between those referring to the outpatient service for Obesity-related lipodystrophisms of the Institute of Plastic Surgery. Presence of psychiatric disorders, temperamental traits and body image perception were evaluated, and compared to a control group ($n=25$) from general population sharing clinical/demographic features. Psychiatric evaluation was based on acquisition of clinical history, Mini-International Neuropsychiatric Interview, Beck Depression Inventory, Yale Brown Scale (YBOCS), Paykel Life Events Scale, NEO Five Factor Inventory, Tridimensional Personality Questionnaire (TPQ), Body Shape Questionnaire (BSQ).

Results The patients group presented higher scoring in lifetime depression and BSQ with moderate/mild concern with body shapes. With regard to personality traits, TPQ revealed higher score in subscale RD4 (dependence/independence) in the patients, while controls scored higher in “openness to experience” NEO-FFI subscale. At YBOCS obese patients presented higher prevalence of obsessive characters.

Conclusion The affective sphere is a relevant feature in obese patients, but also obsessive traits, as negative body shape perception and temperamental and personality characteristics appear to be involved in leading patients to seek surgical consultation. These aspects are implicated in medical/surgical outcome and compliance to treatments.

Psychological defense mechanisms in patients with different forms of essential hypertension

E. Pervichko*, Y. Zinchenko

Lomonosov Moscow State University, Faculty of Psychology, Moscow, Russia

* Corresponding author.

Introduction Essential hypertension (EH) is one of the most common diseases of the cardiovascular system. Today scientists discover more and more patients whose blood pressure values during work appear to be higher than those values during free time. This form of EH is called “hypertension at work”.

Objectives To indicate psychological defense mechanisms in patients with “hypertension at work”, as compared with ‘classical’ EH and healthy individuals.

Materials and methods Defense mechanisms were evaluated by the survey “The Life Style Index”. Eighty-five patients with ‘Hypertension at work’ (mean age was 45.9 ± 2.8) and 85 patients with ‘classical’ EH (mean age was 47.4 ± 4.5 years) took part in the study.

Results The results showed the dominance of low level psychological defences. The most common mechanisms were denial, projection and regression. More mature defense processes included

reaction formation and rationalization. The patients with ‘Hypertension at work’ significantly ($P < 0.05$) differs from second group by more frequent representation of displacement, denial, projection and reaction formation. Comprehensive interpretation of our findings suggested that affection of EH patients (specifically ‘Hypertension at work’) can be characterized by dominance of negative emotions and aggressive tendencies which would be projected, denied or suppressed. Such a complex of defense mechanisms is typical for those, who knows, based on own experience, that uncontrolled negative emotional reactions could be unsafe in social environment.

Conclusions Our findings can be considered as a basis to define a “risk group” amongst EH patients by an attribute of “emotional well-being” disorder and to develop psychological recommendations for them.

The factor structure of the Portuguese version of the personality inventory for DSM-5 (PID-5)

R. Pires^{1,*}, A. Sousa Ferreira², B. Gonçalves¹¹ Universidade de Lisboa, Faculdade de Psicologia, Lisboa, Portugal² Universidade de Lisboa, Instituto Universitário de Lisboa, Business Research Unit BRU-IUL, Faculdade de Psicologia, Lisboa, Portugal

* Corresponding author.

Introduction The DSM-5 Section III proposes a dimensional-categorical model of conceptualizing personality and its disorders, which includes assessment of impairments in personality functioning (criterion A) and maladaptive personality traits (criterion B). The Personality Inventory for DSM-5 (PID-5) is a self-report, composed of 220 items, organized into 25 facets nested in five domains of personality differences, and was developed to operationalize criterion B.

Objectives This study explores the factor structure of the Portuguese adaptation of the PID-5.

Aims The five-factor structure that has emerged in previous studies with the PID-5 (cf. Krueger & Markon) is expected to be replicated in the current study.

Methods Exploratory factor analyses with varimax oblique rotation were conducted on a sample of Portuguese adults from the general population ($n = 379$, $M_{age} = 31.49$, $SD = 14.16$, 25.3% males, 74.7% females).

Results A six factor structure was retained in which the first 5 factors resemble the PID-5 domains. The model showed good fit indices ($KMO = 0.897$). The total explained variance was 68.25%. All the facets but four had primary loadings on the expected factor.

Conclusions The similarity of results across studies and nationalities contributes to the validation of the Portuguese translation of the PID-5 and highlights the structural resemblance among the DSM-5 model and the five factor model (FFM) and the personality psychopathology-five model (PSY-5), drawing attention to the relevance of these models for the diagnosis of Personality Disorders.

Real life consequences of stigmatization, misdiagnosis, misunderstanding, and mistreatment of borderline personality disorder

V. Porr

TARA for Borderline Personality Disorder TARA4BPD, Exec Director, NYC, USA

Undiagnosed and untreated people with Borderline Personality Disorder (BPD) create a public health drain on mental health treatment. BPD underlies major public health problems including high incidence of substance abuse, alcoholism, domestic violence, impulse control disorders, incarceration, high utilization of emergency rooms and inpatient hospitalizations. Although BPD has a prevalence rate between 2–5.9%, it generally goes misdiagnosed, undiagnosed, stigmatized and mistreated. Amongst American veterans who are suicide attempters and completers, a recent study found 94% meet criteria for BPD. There is rampant professional stigma exists against BPD patients, seen as patients to be “avoided”, “treatment refractory,” “untreatable” and a “liability” due to increased risk of self-injurious and suicidal behavior. This is a contributing factor to misdiagnosis that is the usual experience for BPD patients, resulting in wasted years, hopelessness, chaos, family crises, and severe personal and economic consequences for patients and families. The need for assessing with validated diagnostic instruments to rule out or diagnose BPD, Bipolar Disorder, ADHD, substance abuse and other co-morbid diagnoses as well as the need to diagnosis children and adolescents at the time symptoms first appear will be discussed. Presentation of the shockingly few studies on BPD versus Bipolar will be presented and the consequences of failing to diagnose will be highlighted. Findings from an on-line survey from TARA4BPD, an American education and advocacy organization, will demonstrate the need for clinical education in evidence based BPD treatments, training, and supervision as well as patient and family psycho-education so as to improve outcome will be presented.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Personality disorders and temperament traits in patients with breast disease: Preliminary results

V. Prisco^{1,*}, T. Iannaccone¹, G. Di Grezia²

¹ University of Naples SUN, Department of Psychiatry, Naples, Italy

² University of Naples SUN, Department of Radiology, Naples, Italy

* Corresponding author.

Aim of the study was to identify individual characteristics in patients with a benign or malignant breast disease diagnosis. The role of specific personality traits has been considered in the assessment of temperament and character as a predictor of a certain psychopathological state in patients with breast disease diagnosis. Participants were interviewed using a structured clinical test (SCID-II, version 2.0) disorders, and the Italian version of Akiskal's semi-structured clinical interview for temperamental profiles (TEMPS-1) after clinical breast exams and ultrasonography. All patients presented different personality disorders and heterogeneity in temperamental profiles. Of 29 patients with benign breast disease diagnosis, twelve presented histrionic, seven narcissistic, five dependent, four obsessive, two borderline, one antisocial and one paranoid personality disorder. The histrionic-narcissistic disorder is associated with benign breast disease. The three patients with malignant diagnosis presented the same temperamental profile: depressive temperament was associated with malignant breast disease diagnosis. According to recent literature personality disorders cannot influence breast cancer or its prognosis. However, a psychological consultation represent a very important step to pre-dispose specific interventions, treating psychiatric reactive co-morbidities. The study shows the relevance of psychiatric counselling in breast units in the diagnostic cluster detection. Future purpose is to extend the sample and to add a follow-up evaluation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Hyperprolactinemia phenomenon in neurotic and personality disorders and changes in prolactin level after the psychotherapy

K. Rutkowski*, E. Dembinska, J. Sobanski, K. Cyranka, A. Citkowska-Kisielewska, M. Mielimaka
Jagiellonian University Medical College, Department of Psychotherapy, Krakow, Poland

* Corresponding author.

Introduction Hyperprolactinemia is a common endocrinological disorder. Some data suggest that psychological factors (e.g. personality traits) may play a role in hyperprolactinemia genesis.

Objectives Increased prolactin level (PRL) is described as clinical observations in some patients, usually with a diagnosis of borderline personality disorder. In the international literature there is lack of broader description and information of clinical implications of this phenomenon.

Aim The aim of the study is to evaluate the prevalence of hyperprolactinemia in patients with diagnoses F40-F69 according to ICD-10 and an evaluation of the changes in PRL after psychotherapy.

Methods The study population comprised 64 patients, mainly females (73%), with primary diagnosis of neurotic or personality disorder. Prolactin level was measured during the first and last week of the psychotherapy. Between the measurements patients underwent intensive short-term (12 weeks) group psychotherapy in a day hospital for neurotic and behavioural disorders.

Results Hyperprolactinemia was found in 41% of males and 42.4% of females in the study group. After psychotherapy significant reduction in prolactin level was observed in 80% of woman with hyperprolactinemia.

Conclusions Hyperprolactinemia is observed in almost 40% of patients with neurotic and personality disorders. Psychodynamic psychotherapy can be a significant factor improving PRL level in patients with neurotic and personality disorders, specifically women.

Disclosure of interest The authors have not supplied their declaration of competing interest.

DBT for co-morbid borderline personality disorder and substance use disorder without drug replacement in Egyptian outpatient settings: A non-randomized trial

A. Abdelkarim^{1,*}, T. Molokhia¹, A. Rady¹, A. Ivanoff²

¹ Alexandria Faculty of Medicine, Neuropsychiatry, Alexandria, Egypt

² Columbia University, School of Social Work, New York, USA

* Corresponding author.

Background Dialectical behavior therapy has demonstrated effectiveness for patients suffering from co-morbid borderline personality and substance use disorder. The current study tries to

replicate results of previous studies in a mixed gender sample of Egyptian outpatients.

Aim The aim of the current study was to examine the effectiveness of DBT without drug replacement relative to treatment as usual “TAU” in improving behavioral outcomes related to SUD and BPD, and improving emotional regulation.

Methods Forty outpatients with co-morbid BPD and SUD in Alexandria and Cairo were assigned for one year either to comprehensive DBT program (20 patients), or TAU defined as ongoing outpatient psychotherapeutic treatment from referring center (20 patients). Patients were assessed at baseline and follow up assessment at 4, 8, 12 and 16 months was done using Arabic version of Difficulties in Emotion Regulation Scale (DERS), urine multidrug screen and time line follow-back method for assessment of alcohol and substance use history.

Results Following one year of treatment, DBT group showed significantly lower doses of drugs used, DERS score, rates of hospital admission, ER visits, suicidal attempts and episodes of NSSI. Also, DBT patients showed markedly increased retention in treatment and longer duration of total alcohol abstinence and other drugs of abuse. Positive outcomes were maintained for four months post-treatment.

Conclusion DBT demonstrated superior efficacy in comparison to TAU for treatment of Egyptian patients suffering from co-morbid borderline personality and substance use disorder across behavioral domains of SUD, BPD and reduction hospital admission, emergency room visits and DERS score.

Empirical redundancy of burnout and depression: Evidence from time-standardized measures

R. Bianchi*, A. Lichtenthäler

University of Neuchâtel, Institute of Work and Organizational Psychology, Neuchâtel, Switzerland

* Corresponding author.

Introduction Burnout and depression are ordinarily assessed within different time frames. Burnout is most frequently assessed on an annual or a monthly basis whereas depression is generally assessed over a one- or two-week period. This state of affairs may have partly obscured the burnout-depression relationship in past research and contributed to an underestimation of burnout-depression overlap.

Objectives We investigated burnout-depression overlap using time-standardized measures of the two constructs. We additionally examined whether burnout and depression were differently associated with work-related effort and reward, occupational social support, and intention to quit the job.

Methods We enrolled 257 Swiss schoolteachers (76% female; mean age: 45). Burnout was assessed with the Shirom-Melamed Burnout Measure and depression with a dedicated module of the Patient Health Questionnaire. Work-related effort and reward were measured with a short version of the Effort-Reward Imbalance Scale and occupational social support with a subscale of the Job Content Questionnaire. Intention to quit the job was assessed with 3 generic items (e.g., “I plan on leaving my job within the next year”).

Results We observed a raw correlation of .82 and a disattenuated correlation of .91 between burnout and depression. Burnout’s dimensions (physical fatigue; cognitive weariness; emotional exhaustion) did not correlate more strongly with each other (mean $r = .63$) than with depression (mean $r = .69$). Burnout and depression showed similar associations with the job-related factors under scrutiny.

Conclusions Burnout and depression may be empirically-redundant constructs. Measurement artifacts probably contributed to an underestimation of burnout-depression overlap in many studies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ University of Basel, Department of Sport and Psychosocial Health, Basel, Switzerland

⁵ Psychiatric University Hospital, Center for Affective Stress and Sleep Disorders, Basel, Switzerland

* Corresponding author.

Introduction The concept of the Dark Triad (DT) consists of the dimensions of Machiavellianism, narcissism, and psychopathy, and has gained increased interest within the last 15 years for its predictive power to explain success in the fields of economy, politics, and professional sport. However, recent research suggests that the associations between DT and behavior are not as uniform as expected. **Aims** Investigating the associations between DT traits and vulnerable narcissism, mental toughness, sleep quality, and stress perception.

Methods A total of 720 participants between 18 and 28 years took part in the study. The sample consisted of military cadres in the US ($n = 238$), Switzerland ($n = 220$), and of students from the university of Basel ($n = 262$). Participants completed self-rating questionnaires covering DT traits, mental toughness, vulnerable narcissism, sleep quality, and perceived stress.

Results Irrespective of the sample, participants scoring high on vulnerable narcissism also reported higher DT traits, lower mental toughness, poor sleep quality, and higher scores on perceived stress.

Conclusions The present pattern of results suggests a more fine-grained association between DT traits and further behavior, calling into question to what extent DT traits might be a predictor for greater success in the fields of economy, politics or elite sports. Specifically, vulnerable narcissism seems to be key for more unfavourable behavior.

Associations between chronotype and schizotypy in healthy adults

A. Chrobak^{1,*}, A. Tereszko¹, A. Arciszewska², M. Siwek², D. Dudek²

¹ Jagiellonian University Collegium Medicum, Faculty of Medicine, Cracow, Poland

² Jagiellonian University Collegium Medicum, Department of Affective Disorders, Cracow, Poland

* Corresponding author.

Chronotype is defined as individual circadian preference, most often represented on the continuum between two extremes: morningness and eveningness. Growing number of studies show associations between circadian preference and various psychopathological symptoms. Eveningness has been shown to be related with depressiveness in non-clinical population, while morningness has been presented as protective factor. Schizotypy is a schizophrenic-spectrum personality trait linked with a tendency to eccentricity, magical thinking and unusual experiences. Features of schizotypy has been identified in patients with mood disorders i.e bipolar disorder. While there is growing number of studies evaluating associations between chronotype and affective symptoms, to our best knowledge there are no studies addressing the issue of association between schizotypy and circadian preferences. A total of 887 healthy individuals took part in the web-based study. Chronotype has been assessed with the use of Composite Scale of Morningness. Schizotypy has been measured with the use of the enlarged version of The Oxford–Liverpool Inventory of Feelings and Experiences (O-LIFE). Analysis revealed significant positive correlations between cognitive disorganization, introverted/anhedonia, implusiveness/nonconformity and eveningness. To our best knowledge, results indicate for the first time relationship between eveningness and schizotypy, measured by O-LIFE.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Systemic lupus erythematosus is a chronic inflammatory disease of the multimedia system that appear on renal involvement, cortical-mucous, bloody, and neurotic.

Aim The target of this study is to examine the effect of treatment recognition based on mental conscious on decreasing depression intensity on lupus disease and three month follow up.

Method The method of study is semi test by targeted random selection in access in which we have used of pre-test by observe group. Volume of sample includes 200 women afflicted by lupus and among them about 20 ones were ready to cooperate and in study duration were in related improvement situation and has been evaluated. They have been grouped in the two test group (ten persons) and observe one (10 persons) in which two persons has been excluded from test group and we have excluded two persons from observe group, too. Test group have received eight MBCT treatment sessions but observe group has not received any treatment. Beck depression questionnaire (BDI-II) and brief signs of psychology questionnaire (BSI-53) has been performed as pre-test and after clinical test, post-test and three-month-follow up has been done. We have used of descriptive statics and co-variance for analysis.

Results Findings has shown that treatment recognition based on mental consciousness, meaningfully have an effect on decreasing remained signs of depression.

Conclusion Three-month-follow up has shown that treatment recognition based on mental consciousness, had an effect on depression disorder, anxiety disorder, and lupus patients.

Keywords Treatment recognition based on mental consciousness; Depression; Erytmatosus systematic Lupus

The effectiveness of multi-systemic family therapy in bullying behavior of adolescents

D. Gashi Bytyçi

Community Based Mental Health Center and House for Integration, Child and Adolescent Mental Health Unit, Prizren, Kosovo

Introduction Multi-systemic family therapy is a type of psychotherapy that base on the assumption that all kinds of difficulties in individuals are at least partly explained by dysfunctions in the family system and other systems to which the individual belongs.

Objectives This study examined associations between bullying behavior and family ethos, and provides data for changes after treatment with Multi-systemic family therapy-Integrative model, as a culturally sensitive approach.

Methods Thirty-six adolescents with bullying behavior and their families were evaluated. Participants were randomly assigned into two groups: Family therapy group (FT-G) and Control group (CG). The FT-G was treated with integrative model for 6 months; the focus of FT sessions was on proximity-control goals and plans, bugs in the plans, emotive, and types of relations between family members programs. The CG was treated with the same frequency as the FT-G, but with interventions consisting of a detailed survey of their mental health, adolescents' feelings, daily routines and life events. Every month, data were collected through interviews, questionnaires, observation facilitating techniques and observations of a family play therapy.

Results In the study participated 36 outpatient adolescents ages 14–16. Seventeen adolescents were male and 19 female (Fig. 1).

Conclusions At baseline, 70 percent of participants met criteria for more than one of the following disorders, by ICD-10: conduct disorder, substance use, bulimia, borderline personality disorder, and attention deficit/hyperactivity disorder. Six months after the baseline measurement, there was a significant decrease in bullying behavior, substance use, smoking, excessive social media use, and anger control for the FT-G compared with the CG.

Figure 1. Groups by gender in variable: How often does your parent tell you to do something, with an irritated or angry tone of voice?

Adult attention-deficit hyperactivity disorder (ADHD) in parents of ADHD children

E. Kolat*, U. Kolat

Çanakkale State Hospital, Psychiatry, Çanakkale, Turkey

* Corresponding author.

Objective ADHD is one of the most common mental disorders of childhood and adolescence, and characterized by inattention, hyperactivity, and impulsivity symptomatology. The objective of this study is to find out the difference between ADHD prevalence in parents of children with or without ADHD.

Method A total of 132 parents of 90 ADHD children; aged between 6 and 12, and 67 parents of 45 non-ADHD children were recruited in the study. Control parents were matched to ADHD children parents according to age, gender and educational status.

Results Rate of childhood ADHD were significantly higher among parents of ADHD children compared to the parents of control group ($P=0.039$). Rate of adult ADHD ($P=0.076$) was not significantly but higher among parents of ADHD children compared to the parents of control group.

Conclusion In our study, we found the prevalence of childhood ADHD in parents of children with ADHD, similar to those reported by published studies but the prevalence of adult ADHD is lower than most of the previous studies. There may be several reasons for us to find a relatively low rate of adult ADHD. Firstly, in our study only parents of ADHD children are investigated, but in the previous studies not only parents but also siblings of ADHD children are investigated. Secondly, in the previous studies adult ADHD is diagnosed according to DSM-III; not DSM-IV. Under the highlight of our findings, assessing adult ADHD in patients with having a child with ADHD is important for treatment and prognosis.

Effectiveness of psychoanalysis and long-term psychodynamic psychotherapy 10 years after start of treatmentO. Lindfors^{1,*}, P. Knekt¹, J. Lehtonen², E. Virtala¹¹ National Institute for Health and Welfare, Health Department, Helsinki, Finland² National Institute for Health and Welfare & University of Eastern Finland, Health Department, Helsinki, Finland

* Corresponding author.

Introduction The evidence of potentially greater long-term benefits of psychoanalysis (PA) in comparison to long-term psychodynamic psychotherapy (LPP) is scarce.

Aims This study aimed to compare the effectiveness of PA and LPP on different aspects of functioning and wellbeing during a 10-year follow-up from the beginning of the treatments.

Methods Altogether 169 patients were included in the study: 41 patients self-selected for PA and 128 patients assigned to LPP in the Helsinki Psychotherapy Study. The eligible patients were 20–45 years of age and had a long-standing anxiety or mood disorder causing work dysfunction. Potential confounding factors were assessed at baseline and acknowledged in analyzing outcomes in personality (LPO, IIP-64, DSQ, SASB) and social functioning (SAS-SR, SOC, Perceived competence, LSS), psychiatric diagnoses (DSM-IV), symptoms (SCL-90, HDRS, HARS), work ability (SAS-work, WAI, PPF, GAF, work status), and remission, including the use of additional psychiatric treatment, measured 5 to 14 times during the 10-year follow-up.

Results From the 5-year to the 7-year follow-up personality and social functioning improved significantly more in the PA than in the LPP group. In the domain of psychiatric symptoms and work ability practically no differences were found beyond the 5-year follow-up and at the final 10-year measurement, when psychiatric and work status was relatively good in both treatment groups.

Conclusions PA may give additional benefits especially when personality-related long-term aims are essential and less intensive treatments are not considered to be sufficient.

Association between ADHD and psychopathology among prison inmates

A. Machado*, D. Rafaela, T. Silva, J. Cerejeira

Centro Hospitalar e Universitário de Coimbra, Centro de Responsabilidade Integrada, Psiquiatria, Coimbra, Portugal

* Corresponding author.

Introduction Several studies showed that among people with ADHD, the prevalence of psychiatric co-morbidities is the rule, both in general population and in perpetrators.

Objectives To analyze the relationship between ADHD and other psychiatric symptoms among prison inmates from a high security male prison in Portugal.

Methods A total of 101 subjects aged 18–65, with at least 4 years of formal education, were interviewed for socio-demographic data and completed the ASRS-v1.1 (Adult ADHD Self-Report Scale) and the BSI (Brief Symptom Inventory). Subjects were divided into ADHD positive or negative according to their score on ASRS-v1.1, and then compared regarding BSI scores using Student's t-test.

Results Seventeen subjects scored positive for ADHD. They significantly differed from the non-ADHD group in the total BSI score ($t=-4.27, P<0.001$). When looking into the different subscales of BSI, the groups differed in the subscales of obsessions/compulsions ($t=-4.05, P<0.001$), interpersonal sensibility ($t=-3.47, P 0.001$), hostility ($t=-6.71, P<0.001$), paranoia ($t=-3.17, P 0.002$) and psychotism ($t=-3.20, P 0.002$), with the ADHD group scoring higher in all the mentioned subscales. No significant differences were found between the groups in the subscales regarding anxiety, depression or somatization.

Conclusions In line with previous work, our study showed a higher prevalence of psychopathology in prison inmates with ADHD, then in non-ADHD subjects. However, while higher prevalence of depressive and anxiety symptoms in ADHD subjects is mentioned in other studies, we found no differences between the two groups concerning those subscales. The subscales that significantly differed, point to higher prevalence of dysfunctional relationships and a higher tendency for violent behaviour in the ADHD group.

Factors underlying distressful and recurrent hallucinations, perceptual distortions, dissociations and impulses associated with playing video games

A. Ortiz de Gortari

University of Liege, Psychology and Neuroscience of Cognition Research Unit, Liege, Belgium

Introduction Failures in cognitive and behavioural inhibition are the core of mental disorders, but they are also part of everyday life. Research on Game Transfer Phenomena (GTP) has shown that images, sounds and thoughts from the game manifest, and involuntary actions toward game-related cues are performed, after playing. GTP is generally not associated with psychopathology, substance use, distress or dysfunction but a small number of gamers reported severe GTP (i.e. different types and frequently).

Aim Understand the underlying factors (e.g. medical conditions, drugs, problematic/gaming addiction) associated with experiencing several episodes of particular GTP (e.g. hallucinations).

Methods A total of 1,782 participants who experienced GTP “many times” or “all the time” was extracted from a larger sample recruited via an online survey. The 20 GTP-related items were categorized into: (i) hallucinations, (ii) distorted perceptions, (iii) dissociations, and (iv) urges/impulses.

Results Pearson’s Chi² test showed that: (i) 18–22-year-olds were more prone to experience several episodes of GTP and females were more susceptible to hallucinations; (ii) all four categories were associated with mental disorders and distress/dysfunction; (iii) drugs were associated with almost all categories with the exception of distorted perceptions; (iv) visual disorders were associated with hallucinations and dissociations; and (v) problematic/gaming addiction was associated with all categories except urges/impulses.

Conclusions The findings suggest that individuals with mental disorders are more prone to experience several episodes of GTP, which can lead to distress/dysfunction. Substance use appears relevant but not for all manifestations of recurrent GTP. The relation between gaming disorder and GTP requires further investigation.

⁵ Nursing postgraduate Program in Primary Health Care, University of Applied Sciences of Thessaly, Larissa, Greece

* Corresponding author.

Introduction Chronic diseases such as childhood diabetes mellitus constitute a challenge for both the affected children and their families. Childhood diabetes mellitus is characterized by complex therapeutic management and has a profound physical and psychological impact on the whole family and a number of losses for the parents.

Aim and objectives To recognize and quantify the factors affecting shame feelings for parents of children with diabetes mellitus.

Method A cross-sectional design was performed. A sample of 316 parents (110 men–206 women, mean age 40.6 years, SD=6.0 ranged 17–57) participated to the present study. The questionnaire included: (a) social-demographic characteristics, (b) The Other As Shamer Scale (OAS), (c) The Experience of Shame Scale (ESS). SPSS for Windows 20.0 was used for the statistical analysis.

Results Age and the place of residence of the parents, the duration and the severity of disease were identified as significant multivariate factors on internal and external shame.

Conclusion Feeling of shame consist a significant psychological burden of the parents with children suffering from diabetes mellitus. Screening for psychological distress in parents of children is indicated, and preventive interventions are needed, targeted according to the increased needs as suggested in the research results.

³ Nursing Research Laboratory Psychology of Patients Families and Health Professionals, University of Applied Sciences of Epirus, Ioannina, Greece

⁴ Nursing Postgraduate Program in Primary Health Care, University of Applied Sciences of Thessaly, Larissa, Greece

* Corresponding author.

Introduction It is reported in global literature that Chronic Obstructive Pulmonary Disease (COPD) may cause a wide range of psychological effects, some of them not fully explored. The aim of this study is to investigate if patients with COPD experience intense feelings of shame.

Objectives To find differences in shame experience between males and females, and if there is a correlation of shame with other socio-economic factors.

Method Using the “Experience of Shame Scale” questionnaire (ESS) in 191 patients with COPD (104 men and 87 women) treated in Primary Health Care services in Greece.

Results Statistical analysis showed relatively low scores (M 39.5 sd 14.9) for the experience of shame in COPD patients. There is no statistically significant difference of shame for marital status, education level or disease stage. Statistically significant difference shown between males and females (bodily shame *P*: 0.001, total shame *P*: 0.031), and between smokers and those who quit smoking. (characterological shame: *P*: 0.007 behavioral shame *P*: 0.030, total shame *P*: 0.009). Also statistically significant difference appears for bodily shame among Body Mass Index (BMI) groups (*P*: 0.009) and economic status of the patients (*P*: 0.008).

Conclusions Patients with COPD seem to have not heavy burden with experience of shame. Any associations of shame with some patient groups are rather expected for cultural and social reasons.

Deficits in mentalization predict suicide risk among psychiatric inpatients

M. Pompili^{1,*}, M. Innamorati², D. Erbutto¹, M. Amore³, P. Girardi¹

¹ Department of Neurosciences Mental Health and Sensory Organs, Sapienza University of Rome, Rome, Italy

² Department of Human Sciences, European University of Rome, Roma, Italy

³ Section of Psychiatry Department of Neuroscience Ophthalmology Genetics and Infant Maternal Science, University of Genoa, Genova, Italy

* Corresponding author.

Introduction Suicide is a major public health issue.

Objectives Mentalization is a form of imaginative mental activity about others or oneself that may shed light on the phenomenology of suicide.

Aims To assess the role of a number of variables in suicide risk.

Methods Participants were 156 (73 men and 83 women) adult psychiatric inpatients (age range = 18/74 year). Most of the patients had a major mood disorder (26.3% BD-I, 3.2% BD-II, and 11.5% MDD), psychosis (16.7%), or a schizoaffective disorder (20.5%). All the patients were administered the Mini International Neuropsychiatric Interview (MINI) for assessing diagnosis and suicide risk, and the Impact of event scale, Mentalization Questionnaire, Childhood Trauma Questionnaire. Some patients (18.6%) were admitted for a recent suicide attempt and 34.6% had attempted suicide in the past.

Results At the MINI, 44.9% of the patients resulted at a moderate to high risk of suicide, and 55.1% at no or low risk of suicide with no difference for sociodemographic variables (sex and age) and diagnosis, but they differed for mentalization and symptoms of intrusions and avoidance caused by a traumatic event. Groups also did not differ for self-reported childhood trauma. Only mentalization was independently associated with higher suicide risk, and patients with moderate to severe risk of suicide were 1.7 times more likely to report more mentalization deficits than those with no or low risk of suicide.

Conclusions Our study supports the notion that the investigation of mentalization among patients may help in proper assessment of suicide risk.

Effectiveness of treatment of young psychotic patients on psychotherapeutic inpatient unit

B. Restek-Petrovic*, A. Bogovic, G. Majda, M. Nina, F. Igor
Psychiatric hospital, Sveti Ivan Psychotherapeutic unit, Zagreb, Croatia

* Corresponding author.

Introduction The psychotherapeutic unit for psychotic patients in Psychiatric hospital Sveti Ivan, Zagreb, Croatia provides psychotherapeutic and psychosocial treatment for mostly young psychotic patients. Psychotherapeutic program has basically psychodynamic frame and patients participate in small and medium groups. Also, they participate in workshops based on cognitive behavioral principles (anti-stigma, self-concept, emotion, relationships, goals, stress), psycho-education, therapeutic community, work and occupational therapy, recreational therapy.

Aim The aim of this study was to determine effectiveness of this comprehensive program during hospitalization of individuals with first psychotic episode on psychotherapeutic ward. We evaluated the possible changes during treatment in attitudes towards drugs, in quality of life, insight and self-esteem.

Methods Participants were 37 individuals with first psychotic episode, average age: 25.1. They fulfilled: Drug attitude inventory (DAI-10), The World Health Organization Quality of Life (WHOQOL), Insight scale and Rosenberg's Self-Esteem Scale at the beginning of treatment and at discharge from the hospital.

Results Results show tendency of more positive attitude towards drugs at discharge, as well as tendency of better self-esteem, statistically significant more satisfaction with physical health ($P=0.004$), psychological health ($P=0.004$) and with environment ($P=0.001$), and statistically significant better quality of life ($P=0.000$). There was no significant difference in insight.

Conclusion During psychotherapeutic treatment of individuals with first psychotic episode, positive changes were observed. So, our findings indicate importance of implementing such a comprehensive program in treatment.

Change in attitude towards psychotherapy in the course of clinical practice: Qualitative analysis of experience of students from various health care fields

L. Sapezinskiene^{1,*}, L. Jukstaite-Pacesiene¹, A. Vagonis¹, S. Liutkus², N. Mickuviene¹

¹ Psychosomatic Research Laboratory, Lithuanian University of Health Sciences Behavioral Medicine Institute, Palanga, Lithuania

² Clinics Stress Diseases inpatient and day patient department, Lithuanian University of Health Sciences Behavioral Medicine Institute, Palanga, Lithuania

* Corresponding author.

Introduction A stigmatizing attitude towards psychiatry and psychotherapy still prevails in Lithuania. It is evidenced by a variety of patterns, especially by a controversial social opinion about a person suffering from mental disorders.

Objectives To investigate the experiences of students in Psychiatry and General Practitioner Residency studies and those in Bachelor's and Master's degree programs of Psychology who during their clinical psychiatric practice joined a multi-professional team at the Stress Related Disorders Department as temporary members; and to analyse how their attitude towards psychotherapy changed in the process.

Aims To analyse students' feedback about their experiences and involvement into the activity of the multi-professional team at the Stress Related Disorders Department (day care) during their clinical psychiatric practice.

Methods Qualitative research methods based on phenomenological sociology were employed in the study. Students responded to five questions in writing during interview. Collected qualitative research material was analysed while applying content analysis.

Results Eighteen subthemes were obtained and they were matched with the following nine main thematic codes: (1) past, present, future; (2) difficult beginning: "birth"; (3) childbirth pain; (4) childhood challenges; (5) birthing team; (6) adulthood; (7) mourning; (8) joining the team; and (9) future prospect.

Conclusions Clinical psychiatric practice develops a multidisciplinary attitude towards psychiatry including both pharmaceutical and non-pharmaceutical treatment while using individual and group psychotherapy. Significant experience and attitude of health care students changed during clinical psychiatric practice as they acquired deeper understanding of the meaningfulness of psychotherapy.

EW0469

Relationship between self-reported and clinician-rated psychopathology in youth psychiatric outpatients

J. Silva Ribeiro*, S. Morais, P. Oliveira, E. Mendes, A. Botelho, H. Godinho, L. Vale, A. Bessa, P. Renca, V. Santos, N. Madeira
 Psychiatry Department, Coimbra Hospital and University Centre, Coimbra, Portugal

* Corresponding author.

Introduction Psychopathology rating scales have been widely used. Studies evaluating the congruence between self and observer-reported ratings show inconsistent results.

Objectives or aims Determine whether there was consistency between psychopathology as assessed by patients and clinicians' assessment in outpatients observed in the Young Adult Unit of our Psychiatry Department (Coimbra Hospital and University Centre-Portugal).

Methods Socio-demographic characterization was undertaken with young adult outpatients observed during nineteen months (1st January 2015–31st July 2016). Brief Symptom Inventory–53 items (BSI-53) and Brief Psychiatric Rating Scale (BPRS) were applied at the first clinical evaluation. Spearman correlation coefficient between General Severity Index (GSI) of BSI-53 and BPRS total score was calculated.

Results During the mentioned interval 255 outpatients were observed: 64.3% females and 35.7% males; aged between 17 and 39 years old (average: 20.56; median: 20). Fifty percent were diagnosed with neurotic, stress-related and somatoform disorders (ICD-10 F40-48) and 14.1% with mood disorders (ICD-10 F30-39). BPRS and BSI-53 rating scales were administered to 55 patients: 72.5% females and 27.5% males; average age 21.2. A statistical significant correlation was found between BPRS total and GSI score.

Conclusions Several factors can determine the accuracy of psychopathology self-assessment, including diagnosis and severity of illness. In fact, studies show strong correlation between self and observer assessment of depressive and anxious psychopathology, but no correlation in psychotic psychopathological dimensions. Therefore, the correlation found in this population can be explained by the fact that the majority of patients were diagnosed with neurotic, stress-related and somatoform and mood disorders.

Executive functions in delusion-prone individuals – Preliminary studies

A. Teresko^{1,*}, W. Janeczko¹, J. Słowik¹, K. Brzezicka¹, K. Prochwicz², M. Siwek³, D. Dudek³

¹ Students Scientific Association of Affective Disorders, Jagiellonian University Medical College, Kraków, Poland

² Institute of Psychology, Jagiellonian University, Kraków, Poland

³ Department of Affective Disorders, Jagiellonian University Medical College, Kraków, Poland

* Corresponding author.

Introduction Executive dysfunctions in psychotic disorders, mainly schizophrenia are well-known phenomenon, however the information about executive functioning in subclinical psychotic states are still scarce. The rationale for focusing on the delusion-proneness (delusion-like states) is suggested role of executive dysfunction in the process of developing delusions.

Aims Our aim is to assess the relationship between delusion-proneness and executive functions.

Objectives We would like to assess two cognitive functions: shifting and inhibition and updating, depending on the

severity of delusion-like symptoms. We expect that higher delusion-proneness is associated with more pronounced executive dysfunctions, as it is observed in clinical population with existing delusions.

Methods In order to assess delusion-proneness, we used Polish version of Peters et al. Delusions Inventory (PDI). To evaluate shifting and inhibition, two test were conducted–Berg's Card Sorting Task (BCST) and Stroop task respectively. Correlation analysis were performed.

Results Sixty-four participants (41 women and 23 men) were recruited in this study. Mean age was 28.8, SD=10.37. Statistical analysis revealed significant negative correlation of PDI distress subscale and BCST non-perseverative errors. The overall score, as well as all PDI subscales correlated negatively also with the Stroop task's total number of errors and positively with the accuracy in incongruent variant.

Conclusions Contrary to our expectation, results have shown that delusion-proneness is associated with better results in executive functions test, especially in terms of accuracy. These results suggest that executive functions may play a role in the development and maintenance of delusional ideation, however, its relationship may be a bit more complex.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Impact of an intervention of neuro-cognitive rehabilitation in treatment resistant schizophrenia (TRS) compared to schizophrenia responder patients

L. D'Ambrosio, E. Prinziavalli, N. Oliviero, R. Balletta, G. Callovi, A. Benedetta, M.V. Formato, S. Lattanzio, E. Razzino, C. Avagliano, F. Iasevoli*, A. de Bartolomeis

Department of Neuroscience Reproductive Sciences and Odontostomatology, University of Naples Federico II, Naples, Italy

* Corresponding author.

Introduction Schizophrenia is a condition with high impact in terms of disability, also because between 30% and 60% affected individuals do not respond to treatment. It has been proposed that cognitive functioning is strongly impaired in schizophrenia and even more in TRS patients. Cognitive dysfunctions are regarded to worsen psychopathology, psychosocial functioning, and overall course of the illness.

Objectives To investigate the impact of Cognitive Remediation (CR) on psychopathology and psychosocial functioning in TRS vs. schizophrenia responder patients.

Aims To determine whether a CR intervention could improve functional outcomes in TRS patients.

Methods We evaluated proximal and distal effects of CR on approximately 20 schizophrenia responders and 20 TRS patients. Patients in each group were randomized to receive CR or not. Patients were assessed in training task performance, neurocognition, functional capacity, symptoms and psychosocial functioning. Evaluations were conducted at baseline, at the end of the 4-month intervention, and at 6-month, 1 and 2 year-follow-ups. The study is still in active recruitment phase.

Results Both TRS and schizophrenia responder patients exposed to CR exhibited a significant improvement in specific neurocog-

nitive domains, and in psychosocial functioning as assessed by either rating scales (SLOF and PSP) and performance-based measures (UPSA) at the 4-month time-point.

Conclusions CR improved psychosocial functioning in both group of patients, however, they were more pronounced in TRS patients.

Estradiol production suppressed by prolactin in at-risk mental state and first episode psychosis female patients? Preliminary results

S. Ittig*, E. Studerus, U. Heitz, S. Menghini-Müller, L. Egloff, K. Beck, L. Leanza, C. Andreou, A. Riecher-Rössler

University of Basel Psychiatric Hospital, Center for Gender Research and Early Detection, Basel, Switzerland

* Corresponding author.

Introduction Clinical, epidemiological and basic research studies have confirmed that estradiol can have protective effects in schizophrenic psychoses. At the same time many patients with schizophrenic psychoses – even antipsychotic naïve at-risk mental state (ARMS) patients show hyperprolactinemia and gonadal dysfunction with estrogen deficiency in women and possibly testosterone deficiency in men.

Aim To investigate the relation between the stress hormone prolactin and the sex hormones estradiol in women and testosterone in men in emerging psychosis.

Methods Forty-seven antipsychotic-naïve ARMS (38 men and 9 women) and 17 antipsychotic-naïve first episode psychosis (FEP) (14 men and 3 women) patients were recruited via the Basel Früherkennung von Psychosen (FePsy) study. Blood was taken under standardized conditions between 8 and 10 am after an overnight fast and 30 minutes of rest. We performed a linear regression model to evaluate the association between prolactin and sex hormones including age and current antidepressant use as covariates.

Results In women, estradiol was negatively associated with prolactin ($\beta = -1.28$, $P = 0.01$) whereas in men there was a positive association of testosterone with prolactin ($\beta = 0.52$, $P = 0.031$).

Conclusion The often observed estrogen deficiency in women with psychosis could therefore be explained by the stress hormone prolactin suppressing the gonadal axis already in very early untreated stages of the emerging disease.

In ARMS or FEP men prolactin does not seem to influence the gonadal axis in the same way as in women.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Association between prolactin gene polymorphism (–1149 G/T) and hyperprolactinemia in anti-psychotic treated patients with schizophrenia

S. Ivanova^{1,*}, D. Osmanova¹, A. Boiko¹, I. Pozhidayev¹, O. Fedorenko¹, E. Kornetova², A. Semke², N. Bokhan², B. Willfert³, A. Loonen³

¹ Mental Health Research Institute, Tomsk National Research Medical Center of RAS, Molecular Genetics and Biochemistry Laboratory, Tomsk, Russia

² Mental Health Research Institute, Tomsk National Research Medical Center of RAS, Department of Clinical Psychiatry, Tomsk, Russia

³ University of Groningen, Department of Pharmacy, Groningen, The Netherlands

* Corresponding author.

Hyperprolactinemia (HPRL) is a classical side effect of anti-psychotic drugs. Extrapituitary prolactin (PRL) production is regulated by an alternative promoter, which contains the functional single nucleotide polymorphism – 1149 G/T (rs134,1239) in prolactin gene. We examined whether this polymorphism is associated with hyperprolactinemia in patients with schizophrenia. The experimental group comprised 443 patients with schizophrenia. The control group comprised 126 healthy persons. The PRL concentration was measured in serum using the AccuBind ELISA Microwells kit. The functional polymorphism – 1149 G/T (rs134,1239) of the PRL gene was genotyped using the The MassARRAY[®] system. Genotype and allele frequencies were compared using χ^2 test. A total of 227 patients suffered from HPRL (98 males/129 females) according to the criteria of hyperprolactinemia. The frequency of genotypes and alleles in patients with schizophrenia did not differ from those in control subjects. A comparison between patients with schizophrenia with and without hyperprolactinemia revealed that the frequency of G allele in patients with hyperprolactinemia is significantly higher than in patients without hyperprolactinemia ($\chi^2 = 7.25$; $P = 0.007$; OR = 1.44 [1.10–1.89]). Accordingly, the genotype GG was found to be more often in patients with hyperprolactinemia than without it ($\chi^2 = 9.49$; $P = 0.009$). A significant association of the polymorphic variant rs134,1239 with the development of hyperprolactinemia in patients with schizophrenia treated with anti-psychotic drugs was revealed. Therefore, the serum concentration of prolactin in anti-psychotic treatment patients with schizophrenia may also give an indication of the activity of gene regulating extrapituitary prolactin expression.

The study was supported by the Russian Science Foundation, Grant 14-35-00023.

* Corresponding author.

Introduction The life expectancy of severe mentally ill (SMI) patients is shortened up to 30 years, due to cardiometabolic diseases, partly caused by unhealthy lifestyles behaviors. In residential facilities, adopting a healthy lifestyle is hampered by the obesogenic environment; an obesity promoting environment.

Objective To determine, the effectiveness of a 12 month lifestyle intervention addressing the obesogenic environment to improve cardiometabolic health of SMI residential patients.

Methods The effectiveness of lifestyle interventions in psychiatry (ELIPS) trial is a multi-site, cluster randomized controlled pragmatic trial. Twenty-nine sheltered and long-term clinical care teams serving SMI patients in the Netherlands were randomized

into intervention ($n=15$) or control ($n=14$) arm, including 736 patients (73% psychotic disorder, 63% male, 48 ± 13 years). The intervention aimed to improve the obesogenic environment using a small change approach with a focus on nutrition and physical activity. Primary outcome was waist circumference (WC) after three and twelve month's intervention. Secondary outcomes were BMI and metabolic syndrome.

Results General linear mixed models adjusted for age, gender, housing facility and antipsychotic medication showed that WC significantly decreased with 1.51 cm (95%CI = $-2.99; -0.04$, Cohen's $d=0.07$) in the intervention group compared to control group after three months and tended to remain lower with 1.28 cm (95%CI = $-2.79; 0.23$, Cohen's $d=0.06$) after twelve months. Metabolic syndrome Z-score decreased after three months with 0.225 SD (95% CI = $-0.4038; -0.096$, Cohen's $d=0.20$), mainly due to lower fasting glucose and WC. No significant effects were found on BMI.

Conclusion A small change approach targeting the obesogenic environment of SMI residential patients reduces cardiometabolic risk.

Paliperidone palmitate and quality of life in schizophrenia

N.B. Juan Carlos*, B. Girela, A. Maria Angeles

Hospital de Motril, Department of Psychiatry, Granada, Spain

* Corresponding author.

There is growing interest in the study of the quality of life of mental disorders in general, and particularly in schizophrenia. The quality of life is defined by the world health organization as the perception that an individual has of his place in existence, in the context of culture and value system in which they live and in relation to its objectives, their expectations, their rules, their concerns. Paliperidone palmitate is a depot anti-psychotic treatment monthly application is indicated for maintenance treatment of schizophrenia in adult patients. In this work the quality of life in 5 subjects with a diagnosis of paranoid schizophrenia (less than 10 years of diagnosis) is evaluated, all males, aged between 42 and 45 years and with poor adherence to oral treatment. The patients received an average of paliperidone palmitate 100 mg/month. We evaluate the quality of life at baseline and after 3 months – BREF quality of life (WHOQOL – BREF) Scale Quality of Life (QOLS) and WHO was used. The results showed significant improvements in major QOLS scale in all subjects. There were no significant differences in total score WHOQL – BREF scale, but if there was improvement in the scores of some subscales. They no side effects evaluated in the UKU scale. The quality of life in schizophrenic patients can be affected by the presence of, particularly cognitive and negative clinical symptoms. New treatments as paliperidone palmitate improve adherence and have fewer side effects can improve the perceived quality of life. However, they need more extensive studies double-blind evaluation.

* Corresponding author.

Introduction Atypical anti-psychotics are associated with an impaired in glucose and lipids homeostasis.

Aims To evaluate, the effect in lipids and glucose levels after switching to long-acting injectable (LAI) aripiprazole.

Methods This was a prospective, observational, 1 year study carried out in 125 outpatients with schizophrenia who were clinically stabilized but a switching to another anti-psychotic was indicated. We measured basal levels of glucose and lipids at the time to start the study and 1 year after switching to LAI-aripiprazole.

Results In basal analytic we observed these abnormalities: hyperglycemia (16.7%), high-levels of LDL-cholesterol (33.3%), low-levels of HDL-cholesterol (39%) and hypertriglyceridemia (22.2%). One year after switching to LAI-aripiprazole we found: glucose levels were normalized in all patients; levels of LDL-cholesterol were lower in 66.7% (in 33.3% levels were normalized) and they were higher in 16.7% (in 11% marked a change from normal to abnormal parameters); levels of HDL-cholesterol were lower in 23.3% and higher in 32.2% (in 11% levels were normalized); and finally, levels of tryglicerides were higher in 66.7% (in 8% marked a change from normal to abnormal parameters) and in 16.7% they were lower (in 7.3% levels were normalized).

Conclusions LAI-aripiprazole has a beneficial effect in glucose and cholesterol levels. Although, it usually increases tryglicerides levels, only in seven cases there was a change from normal to abnormal parameters. Our study suggests that LAI-aripiprazol could be an alternative in patients with schizophrenia who have high levels of glucose and lipids related with atypical anti-psychotics treatment.

Risk factors related to homicide in Moroccan patients with schizophrenia

A. Kachouchi^{1,*}, D.S. Majda², D.S. Said¹, P.A. Imane¹, P.M. Fatiha¹, P.A. Mohamed², P.A. Fatima¹

¹ University Hospital Mohammed VI, Department Of Psychiatry, Marrakech, Morocco

² University hospital Mohammed VI, Clinical research unit, Mohammed VI university hospital/Community Medicine and Public Health department, Marrakech, Morocco

* Corresponding author.

Background The relationship between schizophrenia and homicide is complex and cannot be reduced to a simple causal link.

Objectives The objectives of this study were to describe the characteristics of homicide in Moroccan patients suffering from schizophrenia and to determine the correlated socio-demographic, clinical and toxic variables.

Methods The study included two groups of patients with a DSM-IV diagnosis of schizophrenia who attended the "Ibn Nafis" university psychiatric hospital of Marrakech in Morocco. The first group was composed of 30 patients hospitalized for homicide in the forensic unit between the first January 2005 and the 31st of August 2015. The second group included 90 patients without any criminal record. These two groups have been matched according to age and gender. Demographic, clinical and therapeutic variables were analyzed and compared between the two groups.

Results The mean of age in the first group was 37.03 and in the second group was 31.4. No significant difference was found

between the two groups regarding the different socio-demographic variables and the age of onset of disease. Significant difference was found between the two groups regarding: personal antecedents of attempt of homicide ($P < 0.003$), personal antecedents of attempt of suicide ($P < 0.001$), a history of previous violence ($P = 0.005$), untreated psychosis before the act ($P < 0.001$) poor medication compliance and a low familial support ($P < 0.001$), antisocial behavior ($P < 0.001$), addictive behavior ($P = 0.007$).

Conclusion Awareness of these factors will allow us to provide improved prevention of violence within schizophrenic subjects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Elevated C-reactive protein levels associated with aggressive behavior in Moroccan patients with schizophrenia

A. Kachouchi*, D.S. Said, P.A. Imane, P.M. Fatiha, P.A. Fatima
University hospital Mohammed VI, Department Of Psychiatry,
Marrakech, Morocco

* Corresponding author.

Background Recent studies reported an association between aggression and inflammation. In this study, we examined the association between aggressive behavior and inflammatory markers (serum levels of CRP) in schizophrenia inpatients.

Methods Adult schizophrenia inpatients ($n = 145$) were prospectively identified and categorized according to their C-reactive protein measurement at admission as either elevated (CRP > 1 mg/dL; $n = 45$) or normal (CRP < 1 mg/dL; $n = 100$). The following indicators of aggression were compared: PANSS excitement component (PANSS-EC), restraints and suicidal behavior during hospitalization.

Results The results show that patients with elevated CRP levels are more aggressive during hospitalization as detected by statistically significant higher scores of aggressive behavior (PANSS-EC score), and by increased rates of physical restraint during hospitalization. No statistically significant differences in the other clinical features, including suicidal behavior.

Conclusion Our results are consistent with previous findings linking schizophrenia to activation of the inflammatory response system.

* Corresponding author.

Introduction The association between childhood trauma and psychotic symptoms is still not clearly understood. Findings for positive and negative symptoms are confounding. This symptomatic response may differ according to the type of childhood trauma, for example childhood abuse was associated with positive symptoms while childhood neglect was associated with negative symptoms.

Objectives This study examined the relationship between childhood trauma and psychotic symptoms in schizophrenic patients after controlling for the possible confounding factors, such as clinical features, depression, and sleep quality.

Methods The childhood trauma questionnaire – short form, Positive and Negative Syndrome Scale (PANSS), Calgary Depression Scale for Schizophrenia, Pittsburgh sleep quality index, and the suicidality subscale of mini-international neuropsychiatric interview were administered to 199 patients with schizophrenia. We used sequential multiple stepwise regression analyses in which positive symptoms, negative symptoms, overall psychopathology and total symptoms of schizophrenia were dependent variables.

Results Depressive symptomatology and childhood physical abuse (CPA) significantly contributed to positive, negative, general psychopathology and global schizophrenia symptomatology. Stepwise regression analysis results are presented in Table 1.

Conclusions Our findings suggest that CPA during childhood could have an impact on psychopathology in schizophrenia.

Table 1 Stepwise regression analysis results.

	Depressive symptomatology	Childhood physical abuse
Positive symptoms	$\beta = 0.29, t = 4.051$ $P < 0.001$	$\beta = 0.20, t = 3.160$ $P < 0.01$
Negative symptoms	$\beta = 0.30, t = 4.575$ $P < 0.001$	$\beta = 0.14, t = 2.214$ $P < 0.05$
General psychopathology	$\beta = 0.53, t = 8.966$ $P < 0.001$	$\beta = 0.17, t = 2.939$ $P < 0.01$
PANSS Global	$\beta = 0.46, t = 7.643$ $P < 0.001$	$\beta = 0.20, t = 3.343$ $P < 0.01$

* Corresponding author.

Families of patients with first episode of psychotic illness are exposed to numerous distress factors related to the care of their relative. It has been shown that these families experience higher levels of anxiety, depression, economic strain, and helplessness. According to the prior studies, long-term psychotic illness can also have negative impact on quality of life (QoL) in healthy siblings [1]. The aim of our study was to assess QoL in siblings of patients with first episode of psychosis and to examine effects of sibling-related and illness-related variables on QoL. Study sample consisted of first-episode psychosis patients ($n = 20$) and their healthy siblings ($n = 20$). All subjects were administered World Health Organisation Quality of Life Questionnaire Scale Brief (WHOQOL-Brief). Duration of untreated psychosis, medication adherence (Hayward scale) and severity of positive psychotic symptomatology (evaluated by Positive and Negative Symptom Scale) were used as illness-related variables, birth order served as a sibling-related variable. QoL has

been accepted as a valuable outcome measure in many psychiatric conditions; thus, identification of contributing factors may help to improve overall outcome. Moreover, close monitoring of adverse effects of illness on QoL in healthy siblings may become a part of larger prevention strategies.

Diagnosis of predominant negative symptoms: Post-hoc analyses of a phase 3 clinical trial with cariprazine monotherapy and risperidone

I. Laszlovszky*, Á. Barabásky, E. Szalai, B. Szatmári, J. Harsányi, G. Németh

Gedeon Richter Plc, Medical Division, Budapest, Hungary

* Corresponding author.

Objective To present, post hoc analyses from a controlled, prospective study of predominant negative symptoms (PNS) of schizophrenia on baseline patient characteristics, severity of symptoms and their variability among participating countries.

Methods Data were analyzed from a phase 3, randomized, double-blind, active-controlled, parallel-group study in adult PNS patients with schizophrenia (EudraCT Number 2012-005485-36). Subjects with a PANSS factor score for negative symptoms (PANSS-FSNS) ≥ 24 and no pseudo-specific factors (e.g. high positive symptoms, extrapyramidal symptoms, depression) were randomized to cariprazine 4.5 mg/d (dose range: 3–6 mg/d) or risperidone 4 mg/d (dose range: 3–6 mg/d) for 26 weeks. Baseline values of PANSS-FSNS, individual PANSS items, personal and social performance (PSP), and clinical global impression of severity (CGI-S) were analyzed based on the data gained from 11 European participating countries.

Results Average PANSS-FSNS of patients was 27.6 ± 2.48 , reflecting severe negative symptoms. Patients were moderately ill (CGI-S 4.2 ± 0.75), with marked difficulties (PSP 48.4 ± 10.78) predominantly in social functioning. The investigated patient population was fairly homogeneous as shown by small variability in all three scores. Moreover, baseline values in the 11 countries presented low variability while number of enrolled patients per country showed high variance ($n = 7–118$). Narrative description of symptoms and individual PANSS items rated as most severe and prominent were in high correlation.

Conclusion Post hoc evaluation of this predominant negative symptom study showed that, this patient population can be identified reliably by psychiatrist. Additional training on the judgment of personal and social relationships can increase the diagnostic accuracy.

Day-to-day and social functioning of patients with negative symptoms of schizophrenia: Post-hoc analyses of a phase 3 clinical trial with cariprazine monotherapy and risperidone

Á. Barabásky*, I. Laszlovszky, B. Szatmári, E. Szalai, J. Harsányi, G. Németh

Gedeon Richter Plc, Medical Division, Budapest, Hungary

* Corresponding author.

Introduction Negative symptoms have substantial impact on day-to-day functioning of patients with schizophrenia affecting their ability to perform activities of daily living and to maintain personal relationships.

Objective To present post hoc data on day-to-day and social functioning of patients with predominant negative symptom (PNS) of schizophrenia, treated with cariprazine versus risperidone.

Methods Data from 26 weeks, phase 3, randomized, double-blind, active-controlled study in PNS patients were analyzed (EudraCT 2012-005485-36). Subjects with PNS (PANSS factor score for negative symptoms ≥ 24) were randomized to cariprazine 4.5 mg/d or risperidone 4 mg/d. Change from baseline to end of treatment on the personal and social performance scale (PSP) and PANSS prosocial subscale (P3, P6, N2, N4, N7, G16) was analyzed.

Results Significantly greater improvements were seen with cariprazine compared to risperidone in the change from baseline to end of treatment on the PSP (LSMD + 4.632 [2.71, 6.56]; $P < 0.001$) from week 10 onwards (effect size 0.48); in the PSP subdomains of self-care (LSMD -0.2 [-0.3 ; -0.1]; $P = 0.004$), personal and social relationships (LSMD -0.2 [-0.4 ; -0.1]; $P < 0.001$) and socially useful activities (LSMD -0.4 [-0.5 ; -0.2]; $P < 0.001$); in the number of patients who improved at least 10 points on the PSP (OR 2.1; $P = 0.001$) or shifted to a higher category (OR 2.2; $P = 0.001$); and on the PANSS prosocial subscale (LSMD -0.8 [-1.41 , -0.16]; $P = 0.014$).

Conclusion Post hoc evaluation of this study showed that cariprazine treatment is associated with a clinically relevant improvement in patient functioning and social competence compared to risperidone.

The relationship between negative symptoms and cognitive functioning in patients with an at risk mental state for psychosis

L. Leanza*, L. Egloff, E. Studerus, C. Andreou, U. Heitz, K. Beck, S. Menghini-Müller, S. Ittig, A. Riecher-Rössler

University of Basel Psychiatric Hospital, Center for Gender Research and Early Detection, Basel, Switzerland

* Corresponding author.

Introduction Negative symptoms and cognitive impairments are both present in patients with an at risk mental state (ARMS) for psychosis and negatively affect functioning and outcome. According to previous studies in patients with first-episode psychosis, negative symptoms are negatively associated with cognitive functioning while positive symptoms do not seem to be associated. Yet, little is known about the specific relationship of negative symptoms and cognitive functioning in ARMS patients.

Objective To evaluate, the relationship between negative symptoms and cognitive functioning in ARMS patients.

Methods Data of 154 ARMS patients were collected within the prospective Basel early detection of psychosis (FePsy) study. Negative symptoms were assessed with the SANS, positive psychotic symptoms with the BPRS, cognitive functioning with an extensive neuropsychological test battery. Multiple regressions were applied and results were controlled for age and gender.

Results Regression analyses showed a significant, negative association between negative but not positive psychotic symptoms and cognitive functioning, showing the strongest association with verbal fluency (see Fig. 1). However, results mainly did not withstand correction for multiple testing.

Conclusions The association found between verbal fluency and negative symptoms may be indicative of an overlap between those constructs. Finally, verbal fluency might have a strong influence on the clinical impression of negative symptoms, especially on alogia.

Schizophrenia and pregnancy: The tactics of management

S. Lukmonov*, G. Ruzieva, I. Nazarova

Tashkent Medical Academy, psychiatry and narcology, Tashkent, Uzbekistan

* Corresponding author.

Purpose The study of literature data of the treatment of pregnant women with schizophrenia and making recommendations on the management of this category of patients.

Methods Theoretical analysis of a number of scientific works of foreign researchers, which studied questions of application of psychotropic drugs in patients with schizophrenia during pregnancy.

Discussion The important source of problems for patients with schizophrenia is a protection against pregnancy. The number of children born in mentally ill mothers has increased at least three times. Hereditary factors in children born from two parents with schizophrenia plays, an important role: approximately 46–68% of these children may develop schizophrenia. In studies on psychotic means, there were no increase in number of anatomical anomalies or deviations in the development associated with this treatment. Low doses do not have a deleterious effect on fetal body weight, duration of pregnancy, fetal or neonatal mortality, as well as the frequency of malformations and deformities. Neither oral nor deposited anti-psychotic drugs are not associated with malformations and malformations of the fetus.

Conclusion (1) The drugs should be administered at the lowest effective dose for the shortest possible time and decrease in the dose during the last days before the birth. (2) Pregnant women with acute psychotic disorders are dangerous, both for herself and for the child. (3) After the birth due to high risk of recurrence or exacerbation of schizophrenia taking anti-psychotic drugs should be in full dose.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Single-photon emission computed tomography (SPECT) is a valid method for measuring regional cerebral blood flow (rCBF). Recent studies regarding rCBF in patients with first episode psychosis (FEP) reported heterogeneous results, but were limited with small sample size. Neuroimaging can help us in setting the diagnosis of illness, as well as in following the progress and finding more effective treatment for psychotic disorders.

Objectives To compare, baseline alterations of the rCBF using SPECT with psychopathological status in FEP during acute phase.

Aims To investigate the changes of rCBF in patients with FEP during acute phase.

Methods We conducted a study on 40 drug-naïve patients with FEP at acute phase of illness during their hospitalization at Zagreb University hospital centre. The diagnosis was confirmed using diagnostic and statistical manual of mental disorders, fifth edition. rCBF was measured with SPECT and psychopathological status rated with the Positive and Negative Syndrome Scale.

Results Our findings showed moderate to severe parieto-temporal perfusion deficits, mild to moderate parieto-fronto-temporal perfusion deficits or borderline perfusion deficits in all but one patient.

Conclusion Our results showed alteration in rCBF at the beginning of the illness that indicate a biological marker of psychotic disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Treatment adherence in psychosis: A 2 years follow-up of first-psychotic episode patients

S. Malta Vacas*, R. Carvalho, M.J. Heitor

Hospital Beatriz Ângelo, Psychiatry and Mental Health, Lisboa, Portugal

* Corresponding author.

Introduction Much research on psychosis has focused on early detection and the development of effective interventions. However, the effectiveness of any intervention depends on the willingness of the patient to engage with an intervention in a sustained manner. Disengagement from treatment by patients with serious mental illness is a major concern of mental health services.

Objectives This study aims to examine the prevalence of disengagement in a longitudinal cohort of first episode psychosis (FEP) patients.

Methods Retrospective naturalistic 2 years follow-up study of FEP patients aged 18 to 35 admitted into the department of psychiatry of the Beatriz Angelo's hospital from 2012 to 2014. Data on socio-demographics, clinical characteristics, appointments and medication adherence and readmissions were collected.

Results Between 2012 and 2014 were admitted 56 patients with a FEP into the department of psychiatry of the Beatriz Angelo's hospital. The great majority of the patients (67.9%) disengaged from the treatment, both appointments and medication. Of those, 13.2% did not attend any appointment, 26.3% attended between one and three appointments and 60.5% attended at least 3 appointments before disengaged. About 23% were readmitted between the 2 years follow up period, 15.4% were readmitted more than once.

Conclusions The evidence reviewed indicates that approximately 30% of individuals with FEP disengage from services. Continuity of care is of particular importance with FEP, given evidence suggesting that long-term care can improve symptoms and functioning and reduces relapse risk.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁹ Fondazione P. Alberto Mileno Onlus, Department of Psychiatric Rehabilitation, Vasto, Italy

* Corresponding author.

Purpose The aim of this analysis was to evaluate the economic consequences of a new treatment approach in the treatment of schizophrenia in the Italian setting. In terms of direct costs, in Italy was estimated that the main driver were represented by hospitalization and residential cost (71% of total direct cost per patient), followed by semi-residential services (13%), anti-psychotic and other drugs (8%) and ambulatory services (8%).

Methods A probabilistic cost consequence model was developed to estimate the potential cost reductions derived from an early treatment with atypical long-acting injectable anti-psychotics (aLAIs) drugs. A systematic literature review was carried out to identify direct and indirect costs associated to the management of schizophrenic patients in Italy. The model projects a scenario analysis in order to estimate potential cost reductions applying a new model management (MoMa) based on patient recovery and early aLAIs treatment.

Results Overall, the total economic burden associated with schizophrenia was estimated at €2.7 billion per year. A total of 50.5% of the economic burden was related to indirect costs and 49.5% to direct costs. Drug costs correspond to 10% of the total

expenditure in terms of direct costs, while hospitalization and residential costs accounts for 81%. Scenario analysis demonstrate a potential cost reduction between 200 million and 300 million based on the effects of MoMa over the reduction of hospitalization and residential costs.

Conclusions This analysis was the first attempt to translate clinical management aspects in economic consequences and will be a useful instruments for decision maker.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Insight and social cognition in first episode of psychosis

L. Martínez*, A. Mané, R. Cortizo, I. Cáceres, D. Treen, L. Galindo, P. Salgado, D. Berge

Hospital del Mar Medical Research Institute IMIM, Psychiatry, Barcelona, Spain

* Corresponding author.

Introduction Impairment of insight in psychotic disorder is associated with adverse impact in treatment compliance, outcome and social functioning although its underlying mechanisms are still unknown. Social cognition and more specifically Theory of mind have been proposed to be correlated to insight. However, the relationship between both factors is still not well defined.

Aims To study the association between social cognition and insight into mental illness in individuals with early psychosis included in the first episode of psychosis program of Hospital del Mar.

Methods From the 94 patients included in the first psychotic episode program between January 2011 and January 2016, thirty-eight patients were evaluated six months after the episode. The three initial items of SUMD (Scale Unawareness of Mental Disorder) were used to measure insight and MSCEIT (Mayer-Salovey-Caruso Emotional Intelligence Test) was used to assess social cognition. Linear correlation analysis by Pearson correlation was conducted.

Results Insight results of SUMD six months after the first episode of psychosis were significantly associated with several subsections of MSCEIT, such as experiential area total punctuation ($r = -0.574$; $P = 0.025$), emotional facilitation section ($r = -0.633$; $P = 0.011$) and the facial emotion perception task ($r = -0.572$; $P = 0.026$).

Conclusions Results suggest an association between insight and emotional perception and facilitation performance in first episode patients, which may suggest a role of social cognition in psychosis insight impairment. Further research to better define the participation of social cognition in insight into psychosis alteration is mandatory to understand the etiology of insight, define treatment targets and consequently improve the disorder prognosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Objective To evaluate the use of micronutrients (minerals and vitamins) as adjunctive therapies for psychosis when added to conventional medications.

Setting/locations Rural primary care and psychiatry clinic in Northern New England, USA.

Subjects People over age 18 diagnosed with a psychotic disorder on medications.

Intervention Fifty consecutive clients during one month's time were invited to participate; 19 completed a one-month open-label phase of the addition of a micronutrient to their medication regimen; all 19 then withdrew rather than risk randomization to a placebo. We then compared the response of those 19 over 24 months of micronutrients + medication to the 31 people who declined participation enriched by an additional 28 consecutive patients recruited over the second month of the study for a total of 59 who received medication without micronutrients.

Outcome measures All clients were evaluated with the Positive and Negative Symptom Scale and the Clinical Global Impression scale at study baseline and after 3, 6, 9, 12, 15, 18, and 24 months. Psychosis was confirmed with clinical interview using DSM IV-TR criteria. All participants had normal physical examinations and laboratory studies.

Results Outcomes were similar for both groups until 15 months, though the micronutrient group used significantly less antipsychotic medication throughout that time ($P < 0.001$). At 15 months, the micronutrients + medication group exhibited significantly fewer symptoms than the medication only group, a difference that was even stronger at 24 months.

Conclusions Micronutrients may be a beneficial long-term, adjunctive strategy for people with psychotic disorders, allowing for smaller doses of antipsychotic medications.

Strategies for managing psychosis with small amounts or no medication: A proof of concept paper

L. Mehl-Madrona^{1,*}, B. Mainguy²

¹ Eastern Maine Medical Center, Family Medicine Residency, Bangor, USA

² Coyote Institute, Education, Orono, USA

* Corresponding author.

Introduction Some patients with the diagnosis of a psychotic disorder wish to minimize or avoid medications.

Methods We report qualitative and quantitative data on a group of patients as a proof of concept study—that management with minimal or no medication is possible.

Patients A series of 60 adult patients presented with psychosis and engaged with us in dialogical psychotherapy, medication, and lifestyle management over at least six months in an effort to minimize or eliminate medication. An additional 209 patients presented for treatment but did not continue for six months. An anonymous, matched comparison group of 60 patients of the same age, socio-economic status, diagnosis, and severity of illness was generated from the electronic health records at another large clinic where one of us also worked (LMM). We quantified symptom level using the Brief Psychiatric Rating Scale, the Positive and Negative Syndrome Scale, two depression rating scales, the Clinical Global Inventory, and the Revised Behavior and Symptom Identification Scale. Narrative interviews of all 269 patients generated qualitative data.

Results Thirty-nine patients managed well without medication; 16 managed well on low-dose medication. Four individuals required progressively higher levels of medication and one decompensated. The overall cost-benefit was favorable in creating fewer hospitalizations, crises, and diminished suicidality.

Conclusions The results suggest the need for individualized approaches that are client-centered and build upon the previous successes of the person, enroll family and friends in a community effort, and collaborate with those communities to apply those approaches desired by the people themselves.

Relationships between smoking, psychopathology and medication outside effects in schizophrenia

L. Ghanmi^{1,*}, K. Zitoun¹, L. Zouari², M. Maalej²

¹ Regional hospital of Gabes, Psychiatry, Gabes, Tunisia

² University Hospital Hedi Chaker, Psychiatry "C", Sfax, Tunisia

* Corresponding author.

Aim To determine the relationship between smoking status and clinical characteristics of schizophrenic patients.

Methods It was a cross-sectional study. One hundred and seventy-five schizophrenic outpatients were assessed by the Positive And Negative Syndrome Scale (PANSS), the Global Assessment of Functioning Scale (GAF), the scale of measurement of abnormal involuntary movements (AIMS) and by the rating scale akathisia caused by a drug Thomas Barnes. Current smokers ($n = 85$) were compared to non-smokers ($n = 90$) on clinical variables.

Results The mean number of cigarettes was 15 cig/day. In our sample, current smokers account for half of the patients and were exclusively men. Smokers were significantly more single patients (76.5 vs. 58.9, $P = 0.01$). There were no significant differences between smokers and non-smokers regarding clinical variables, including age of onset of the disease, the duration of the disease, the severity of positive and negative symptoms, and GAF scores. Smoking was significantly associated with more frequent prescription of conventional neuroleptics (98.8 vs. 92%, $P = 0.03$) and poorer adherence to treatment (77 vs. 62.2%, $P = 0.02$). There were no significant differences between the 2 groups regarding the average doses of neuroleptics, the presence of extrapyramidal signs, scores on the AIMS score and akathisia.

Conclusion Smoking is common in patients suffering from schizophrenia. Smoking status should be considered in the assessment of neuroleptic treatment in schizophrenia.

Evaluation of sleeping profile in schizophrenia patients treated with paliperidone-extended release: Result from an open labeled perspective study in south East Asia (perfect study)

R. Kongsakon

Faculty of Medicine Ramathibodi hospital, Dep. of psychiatry, Bangkok, Thailand

Objective To evaluate the impact of treatment with paliperidone extended release for 6 months on sleeping profile in schizophrenia patients.

Methods A total of 984 patients meeting the DSM-IV criteria for schizophrenia who switched their antipsychotics to be paliperidone ER were recruited from 61 sites in five countries in Southeast Asia. We assessed patients in terms of demographic profile, sleep quality and daytime drowsiness as visual analog scale.

Results Patients in our studies received paliperidone ER treatment for 6 months. About 70% completed the treatment. Sleep quality and also daytime drowsiness were significantly increased in patients compared with their baseline. The predictive factors that have effect on sleep profile improvement were completion of the study and baseline PANSS score.

Conclusion Patients receiving paliperidone ER were found to have improvement in sleep quality and also improvement in daytime drowsiness, especially in patients within completion group and the higher baseline PANSS score.

Measuring motivation in patients with schizophrenia with apathy evaluation Scale (AES). Pilot study of the Russian version

M. Minyaycheva*, K. Kiselnikova, L. Movina, I. Gladyshev, O. Papsuev

Moscow Research Institute of Psychiatry, Outpatient psychiatry and organization of psychiatric care, Moscow, Russia

* Corresponding author.

Introduction Reduction of mental productivity and motivation in patients with schizophrenia is one of the core features of negative symptoms of schizophrenia spectrum disorders. Lack of motivation affects social functioning and outcomes, reduces effects of psychosocial treatment and rehabilitation.

Objectives To research AES abilities in measuring motivation in patients with schizophrenia spectrum disorders. The aim of the study was to investigate correlations of Russian translation of clinician-rated and self-rated versions with PANSS amotivation subscale and negative subscale items.

Methods Fifty patients with schizophrenia spectrum disorders were recruited to participate in the study and were assessed with PANSS, AES-C and AES-S by trained raters. Only patients in “stabilized” state that met inclusion criteria of PANSS total score \leq 80 points were eligible for consecutive AES assessment.

Results Overall, moderate positive correlations were established between AES-C and PANSS amotivation subscale N2 and N4 items, N6 item and total PANSS negative subscale. No significant correlations with G16 item were registered. AES-C and AES-S versions also showed positive Spearman correlations ($r=0.43$; $P<0.05$), while no correlations between AES-S and amotivation PANSS items were registered.

Discussion Moderately strong correlations between AES-C and PANSS N2, N4 and N6 items show feasibility of AES-C version in terms of measuring motivation in patients with schizophrenia spectrum disorders. Results of AES-S analysis demonstrate certain problems in patients' abilities in self-assessing motivation. Patients with prevailing paranoid syndrome showed poorer results in AES-S scores.

Conclusions AES-C is a sensitive psychometric tool with good properties in measuring amotivation in patients with schizophrenia.

Efficacy and quality of life in patients with schizophrenia and schizoaffective disorders treated with long-acting paliperidone palmitate: A naturalistic longitudinal study

A. Nivoli^{1,*}, L. Folini¹, L. Floris¹, M. Antonioli¹, F. Pinna², M. Paolo¹, C. Bernardo², L. Iliana¹

¹ University of Sassari, Department of Psychiatry, Sassari, Italy

² University of Cagliari, Department of Psychiatry, Cagliari, Italy

* Corresponding author.

Introduction Intramuscular paliperidone palmitate (PP) is a long-acting, atypical antipsychotic for intramuscular (IM) administration in the treatment of patients with schizophrenia.

Objective To study efficacy and quality of life in patients with schizophrenia and schizoaffective disorders treated with long-acting paliperidone palmitate.

Method A non-randomized, prospective naturalistic study was performed in out-patients with schizophrenia and schizoaffective disorder unsuccessfully treated with oral antipsychotics. Efficacy of PP over time was evaluated by using BPRS 24-items (Brief Psychiatric Rating Scale) Quality of life was evaluated by the QL-Index (Quality of life Index) at T0 and at most recent visit (T1).

Results Data were available for 16 outpatients consecutively prescribed PP and naturalistically treated attending at the Psychiatric Clinic, University of Sassari. Patients were predominantly male ($n=9$; 56.2%), with schizophrenia ($n=10$; 62.5%). Three patients dropped out (18.8%). Mean time on PP treatment was 870.0 days (sd 217.02) at a mean PP maintenance dose of 97.82 ± 37.17 mg eq. BPRS mean total score at T0 was 55 (sd 14.5) and at T1 was 44.8 (sd 11.8). QL-Index mean total score was 5 (sd 1.6) at T0 and 7.2 (sd 2.4) at T1. Paired sample test showed a statistically significant difference in decreasing symptoms at BPRS over time ($P=0.009$) and in improving Quality of life at QL-Index ($P=0.017$). The analyses showed a significant improving at the following BPRS sub-items: Depression ($P=0.021$), Hostility ($P=0.022$), Suspiciousness ($P=0.005$), Hallucinations ($P=0.050$), Unusual thought content ($P=0.029$), Self-neglect ($P=0.028$), Conceptual disorganization ($P=0.044$), Emotional withdrawal ($P=0.028$) and Distractibility ($P=0.014$).

Disclosure of interest The authors have not supplied their declaration of competing interest.

A randomized single-blind placebo controlled trial of memantine, as adjunctive therapy for treatment of negative symptoms of paranoid schizophrenia

Y. Osadshiy*, D. Archakov, E. Tarakanova
The Volgograd Scientific-Production Association “YugMed”, Psychiatry and Addiction, Volgograd, Russia

* Corresponding author.

This study analyses the efficiency of memantine—an antagonist of N-methyl-D-aspartate receptors—as adjunctive therapy for the treatment of negative symptoms of paranoid schizophrenia. Fifty-two patients (30 males; age 20–50 years) were included with the diagnosis of F20.014 and F20.024 according to the international classification of diseases (version 10). The patients had been receiving neuroleptic monotherapy with a fixed dose for a period of at least 4 weeks prior to randomization. Clinical data were collected 8 weeks after memantine had been introduced as part of the treatment regimen. A patient was considered as responding to treatment if they:

– scored 1–2 on the Clinical Global Impression Scale;
 – showed a greater than 25% reduction of the total score on the Positive and Negative Syndrome Scale (PANSS) or a greater than 20% reduction on the negative subscale of PANSS.

Forty-seven patients were randomized: treatment group (neuroleptic + memantine, $n = 24$), control group (neuroleptic + placebo, $n = 23$); 44 patients completed the study. Neither memantine nor placebo led to a reliable decrease of negative symptoms, and the groups did not differ from each other. Future studies should pay more attention not only to the treatment of already formed negative and cognitive symptoms, but the prevention of their occurrence. Including through antagonists of N-methyl-D-aspartate receptors.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cannabis use in a first onset psychosis sample: Prevalence and clinical differences in relation to age of onset

M. Pardo^{1,*}, J. Matalí¹, A. Butjosa², V. Regina², M. Dolz¹, J. Usall²

¹ Hospital Sant Joan de Déu, Child and Adolescent Psychiatry, Barcelona, Spain

² Parc Sanitari Sant Joan de Deu, Unitat de Recerca i Desenvolupament, Sant Boi de Llobregat, Spain

* Corresponding author.

Introduction There is a wide range of studies focusing on the use of cannabis in first episode psychosis (PEP). Literature using child and adolescent samples is scarce.

Objectives and aims To determine the prevalence and clinical differences between cannabis users and non-cannabis users of early onset first episode psychosis (EOP), and adult onset first episode psychosis (AOP).

Method One hundred and forty patients were recruited in adult (AOP subsample, $n = 69$) and child and adolescent (EOP subsample, $n = 71$) mental health services. The Positive and Negative Syndrome Scale was used for psychotic symptoms and the Calgary Scale for affective symptoms. The Chi² test analysed clinical differences between users and nonusers within subsamples, and in the total sample a Pearson correlation was used for the relationship between age at cannabis use and PEP.

Results The prevalence of lifetime use of cannabis and the average age at first use were 48% and 13.82 years (± 1.15) in the EOP subsample, and 58% and 17.78 years (± 3.93) in the AOP subsample. Within EOP, cannabis users were older ($P = .001$), had fewer negative symptoms ($P = .045$) and less depressive symptoms ($P = .005$). Within AOP, cannabis users were younger ($P = .018$) and had greater severity of positive symptoms ($P = .021$). Age at first cannabis use and age at PEP were positively correlated.

Conclusions Cannabis use is prevalent in adult and early onset psychosis. Cannabis users differ clinically from non-users, and the earlier the use of cannabis, the earlier the onset of psychosis.

The regional project for the treatment of early psychosis implemented in the Reggio Emilia Mental Health Department: Preliminary data from a 2-year follow-up

L. Pelizza*, A. Raballo, E. Semrov, S. Azzali, S. Garlassi, F. Paterlini, I. Scazza, F. Fontana, R. Favazzo, M. Fabiani, L. Pensieri, V. Barbanti Silva, L. Cioncolini
 Reggio Emilia Public Health Service, Reggio Emilia Department of Mental Health, Reggio Emilia, Italy

* Corresponding author.

Introduction Several studies had shown the effectiveness of combined interventions in the treatment of young patients with a first episode of psychosis (FEP). More controversial are the evidence about the stability of the therapeutic outcomes in individuals ultra-high risk (UHR).

Aims To describe the regional project for the treatment of early psychosis implemented in the Reggio Emilia Mental Health Department (ReMHD) and also to report preliminary data from a 2-year follow-up.

Methods In addition with the treatment as usual (TAU), treatment implemented within the regional project for early psychosis (PREP) in the ReMHD comprises the following:

- pharmacotherapy according to international guidelines;
- a phase-specific individualized Cognitive-Behavioural therapy;
- a psycho-educational intervention addressed to family members;
- a case management recovery-oriented.

Action strategies are preceded by the administration of Reggio Emilia at Risk mental States Battery Checklist as a comprehensive assessment useful to define the severity and the quality of symptoms, the degree of functioning, the subjectivity of suffering, and the perceived quality of life.

Results The assessment carried out after 24 months of continuous treatment showed significant improvements in both the psychotic symptoms (positive, negative and general psychopathology PANSS subscales) that the daily functioning (SOFAS).

Conclusions Although our sample is still relatively small ($n = 50$) to draw definitive conclusions, it is emerging the good prognosis for UHR individuals and patients with FEP submitted on PREP treatment implemented in the ReMHD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Neuropsychological profile of specific executive functions in patients with deficit and non-deficit schizophrenia

J. Pelka-Wysiecka^{1,*}, T. Ernest², M. Monika³, S. Jerzy¹

¹ Pomeranian Medical University, Psychiatry, Szczecin, Poland

² University of Szczecin, Department of Clinical Psychology- Institute of Psychology, Szczecin, Poland

³ Pomeranian Medical University, Independent Clinical Psychology Unit- Department of Psychiatry, Szczecin, Poland

* Corresponding author.

Although it has been shown that there are more profound deficits present in the deficit schizophrenia (DS) patients compared with their non-deficit (NDS) counterparts, there still remain a few matters that require further investigation.

Aims (1) Comparison of executive functions between the investigated groups; (2) determining the relationship between their particular aspects within the groups; and (3) drawing up their neuropsychological profile.

Methods One hundred and forty-eight schizophrenia patients, divided into two groups: patients with DS ($n = 70$) and NDS ($n = 78$). Patients were matched for sex, age, number of years of education and their overall cognitive functioning. For the assessment of executive function, we used the Wisconsin Card Sorting Test (WCST), the Trail Making Test (TMT), Verbal Fluency Test Phonemic (VFT P), Stroop Color Word Test (SCWT) and Go/No Go task (GNG).

Results The DS patients compared with the NDS ones obtained lower scores in WCST and TMT (relative flexibility). We did not

observe any inter-group differences in VFT P, SCWT (relative inhibition) or the GNG. In both patient groups, there appeared significant correlations between their WCST and TMT scores. The general neuropsychological profiles were similar in both groups. The DS patients exhibited slightly greater interference within concept formation and non-verbal cognitive flexibility. Such problems may therefore be specific to that particular subset of schizophrenia. Our results may be useful for the development of new rehabilitation activities, which may increase the chance of the patients' better social functioning.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW0499

Relapse after first-episode psychosis: A 3-year follow-up

E. Pereira*, M. Mota Oliveira, R. Guedes, M.J. Peixoto, I. Ferraz, C. Silveira

Centro Hospitalar de São João, Clinic of Psychiatry and Mental Health, Porto, Portugal

* Corresponding author.

Introduction Relapse after first-episode psychosis (FEP) is a frequent problem, which can lead to patients' poorer functioning and response to treatment. Its prevention is one of the most important and challenging targets in the treatment of psychotic disorders.

Objectives To characterize and evaluate relapse rates after FEP, during the course of 3 years, of a group of patients admitted at a psychiatry department.

Methods A retrospective observational study was conducted. Patients with a FEP between ages 18 to 40, admitted at the Clinic of Psychiatry and Mental Health at São João Hospital Centre between January 1, 2007 and September 30, 2013. Only patients with, at least, 3 years of follow-up at the clinic were included.

Results Final sample of 58 patients, 39 of which were male (mean age = 26.4 years). Forty patients were excluded by not completing the 3 years follow-up at our department. The cumulative relapse rates were 32.8% at 12 months, 53.4% at 24 months and 63.8% at 36 months. Patients with at least one relapse were younger (25.78 years vs. 27.52 years) and had shorter periods of first hospitalization (19.25 days vs. 23.52 days). These data did not reach statistical significance. Non-adherence to prescribed medication was described in 73.0% ($n=27$) of patients at the time of relapse. Eight of them (21.6%) presented with cannabis use.

Conclusions Although no statistical significance was reached, our findings are consistent with other studies. A future study with a bigger sample would be important in achieving statistical significant results.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Medical comorbidity in schizophrenia

A. Pestana Santos*, J. Amílcar Teixeira

Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

* Corresponding author.

People with schizophrenia have higher prevalence of physical disease and its lifespan is shortened when compared with general population. On average, they die 10 to 25 years earlier than general population.

Aim The authors aim to identify the main comorbidities in people with schizophrenia and define strategies to prevent it.

Methods Literature review on Medline database.

Results People with schizophrenia have higher risk to have hepatitis, cardiovascular diseases, diabetes, overweight, sexual dysfunction and obstetric complications. This high vulnerability is associated with higher rates of preventable risk factors, such as smoking, alcohol consumption, use of street drugs, poor dietary habits and lack of exercise. Moreover, some antipsychotic medications used to treat schizophrenia have been associated with higher incidence of physical disease. At last, there are risk factors attributable to patients and healthcare services. Psychiatrists are often not trained in detection and treatment of physical disease. Despite this, there are several attitudes that can reduce the associated morbidity and mortality in people with schizophrenia, such as improving access to healthcare services, integrated healthcare interventions to enable early diagnosis and promotion of healthy habits.

Conclusions Diagnosis and management of morbidity in people with schizophrenia are more difficult because obstacles related to the patient, the illness, the medical attitudes and the structure of the healthcare services. Regardless these difficulties, the increased frequency of physical disease in people with schizophrenia must be valued due to improved detection and treatment of medical disease will have significant benefits for their psychosocial function and overall quality of life.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Empowerment with Psychotic Symptoms Scale (EWPSS): Exploratory study of the scale's psychometric properties

M.J. Martins^{1,2}, C. Carvalho^{1,3}, P. Castilho¹, A.T. Pereira², J. Gonçalves⁴, R. Guiomar⁴, A.M. Pinto^{2,*}, C. Marques², D. Carreiras^{2,4}, M. Bajouco², A. Macedo²

¹ Faculty of Psychology and Educational Sciences of the University of Coimbra, Cognitive and Behavioural Center for Research and Intervention, Coimbra, Portugal

² Faculty of Medicine of the University of Coimbra, Psychological Medicine Department, Coimbra, Portugal

³ University of Azores, Department of Educational Sciences, Ilha São Miguel, Portugal

⁴ University of Coimbra, Faculty of Psychology and Educational Sciences, Coimbra, Portugal

* Corresponding author.

Background Empowerment has been defined as the ability to act autonomously, the willingness to take risks and being aware of responsibility. The importance of this construct in psychosis has been emphasized by recovery models. An integrant part of the Clinical Interview for Psychotic Disorders (CIPD), the EWPSS is a visual analog scale in which the participants assess their sense of empowerment regarding symptoms (delusions, hallucinations, negative symptoms and disorganization). EWPSS focuses on personal empowerment (self-worth and self-efficacy) as it could apply to symptoms.

Aims To preliminarily assess the psychometric properties of the EWPSS in a sample of participants with psychosis.

Methods The sample comprised 22 participants (68.2% male), 72.7% single, 50% employed, between 19 and 47 years old ($M=31.05$; $SD=7.088$), with 4–17 years of education ($M=11.77$; $SD=3.176$). The most prevalent diagnosis was schizophrenia (68.2%) and the participants had a mean of 1.90 hospitalizations ($SD=2.548$). The participants were assessed with the CIPD (EWPSS) and Depression, Anxiety and Stress Scales-21.

Results EWPSS has shown acceptable reliability for all dimensions (with alphas ranging between .54 and .78). Empowerment

with delusions was associated with the other dimensions, excepting for empowerment with negative symptoms (which in turn was not associated significantly with any dimension). Empowerment regarding hallucinations and with disorganization were only associated with empowerment with delusions, which was also associated with anxiety symptoms ($r = -.52, P = .016$).

Conclusions The EWPSS presented adequate reliability and validity. Further studies intended to explore the factorial structure of the EWPSS are under development.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Audit on prescribing practice of depot antipsychotic injections in the adult community mental health service

M. Ray^{1,*}, S. Rao²

¹ Leicestershire Partnership NHS Trust, General Adult Psychiatry, Nottingham, United Kingdom

² Leicestershire Partnership NHS Trust, General Adult Psychiatry, Leicester, United Kingdom

* Corresponding author.

Introduction There are a number of good standard practices available for prescribing long acting antipsychotics. Adherence to these guidelines will minimise any harm to the service users.

Aims To compare depot antipsychotic prescribing practice with good standard practice guidelines of BNF, Trust and Maudsley guidelines.

Objectives To compare practice with standards in the areas of:

- licensed indication;
- dose/frequency range;
- avoiding poly-pharmacy;
- regular review of clinical and side effects.

Methods Case notes of a randomly selected sample of 30 patients from the depot clinic at the City East Adult Community Mental Health Team Leicester, UK were retrospectively investigated. The data collected was analysed and the results were produced. Compliance with the best practice guidelines was calculated and recommendations made based on the findings.

Results One hundred percent compliance was noticed in licensed indications and dose/frequency within BNF range. However, 14% patients received poly-pharmacotherapy, 86% had regular outpatient review, but only 46% had review of side effects.

Conclusions Better quality of documentations by the clinicians, improvised technology to elicit automatic review reminders, introduction of checklist for clinics to include review of all clinically important information, wider dissemination of the findings of this investigation, and re-auditing practice to explore impact of this investigation was recommended.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The role of cannabinoids in schizophrenia: Where have we been and where are we going?

J. Reis^{1,*}, G. Pereira²

¹ Centro Hospitalar do Algarve, Departamento de Psiquiatria e Saúde Mental - Unidade de Faro, Faro, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Departamento de Psiquiatria e Saúde Mental, Lisboa, Portugal

* Corresponding author.

Introduction Several studies have shown that both endocannabinoid system (ECS) and synthetic cannabinoids (SC) might be involved in schizophrenia.

Objectives To review recent literature on the role of cannabinoids in schizophrenia. The review includes the evidence of cannabis use as a risk factor for the development of schizophrenia, but also the preliminary evidence for the use of cannabinoid-based compounds in the treatment of psychosis.

Methods The authors made an online search on PubMed for clinical trials and reviews published in the last 12 months, using the keywords: “cannabinoids”, “endocannabinoids”, “phytocannabinoids” and “schizophrenia”.

Results The use of *Cannabis sativa* is associated with increased risk of developing psychotic disorders, including schizophrenia, and earlier age at onset of psychosis. Δ 9-Tetrahydrocannabinol (THC) has multiple actions in the brain development, including impairment of neuroplasticity, dysregulation of dopamine and glutamate signaling, and, possibly, neurotoxicity. The ECS has been implicated in psychosis both related and unrelated to cannabis exposure. Cannabinoid receptors type 1 (CB1 R) and type 2 (CB2 R), as well as the endogenous ligand N-arachidonylethanolamine (AEA) and 2-arachidonylethanolamine (2-AG) levels, are most likely to be involved in the pathophysiology of this disorder. On the other hand, the antipsychotic effects of some cannabinoids have been investigated in recent studies. Cannabidiol (CBD) and Δ 9-tetrahydrocannabivarin (THCV) may have therapeutic potential for the treatment of psychosis.

Conclusions Emerging evidence suggests an important role of ECS system and SC on schizophrenia. On the other hand, recent studies have shown some phytocannabinoids might represent therapeutic promises in this disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ University Hospital Center Zagreb, Day Care Hospital for First Psychotic Episodes, Zagreb, Croatia

⁴ University Hospital Center Zagreb, University Psychiatric Clinic, Zagreb, Croatia

* Corresponding author.

Introduction Some findings in patients with first psychotic episode (FEP) could be related to alterations of stress responses. Alterations of stress response are reflected in the alterations of the HPA axis.

Objective To assess the difference in stress response in FEP patients and healthy controls as well as implications of environment to vulnerability to psychosis.

Aim To assess endocrine and autonomic responses to acute psychosocial stress, their associations with onset of the first psychotic episode as well as the influence of the environmental factors.

Methods We have assessed clinical status through clinical psychiatric interviews, standardized psychiatric scales and validated psychological scales, (LEQ, WHOQOL-BREF, PBI, Rosenberg) in 45 subjects with FEP and 50 age and gender matched controls. All participants were then exposed to the Trier Social Stress Test (TSST).

Results Our preliminary findings on a sample of 95 participants indicate a differences between patients and controls in salivatory

cortisol measured in 5 time points during the TSST. Patients with FEP experience more levels of baseline cortisol, and less changes during the stress test than controls. Baseline stress levels indicated in the salivatory cortisol levels correlate with perceived self-esteem, psychological and social quality of life.

Conclusion Our findings support the alterations of stress response, possibly indicating vulnerability to stress in persons with FEP.

Funding This work was funded by the grant of the Croatian Science Foundation No UIP-2014-09-1245 Biomarkers in schizophrenia – integration of complementary methods in longitudinal follow up of first episode psychosis patients.

Executive function assessment in young hospitalized schizophrenic patients with the “CANTAB Schizophrenia Battery” (Russian sample)

G. Rupchev^{1,*}, A. Alekseev¹, M. Morozova¹, V. Kaleda¹, A. Tkhostov², D. Tikhonov¹, A. Listova²

¹ Federal State Budgetary Scientific Institution “Mental Health Research Center”, Laboratory of Psychopharmacology, Moscow, Russia

² Moscow State University, Department of clinical psychology, Moscow, Russia

* Corresponding author.

Introduction Impairment of executive function is the fundamental feature of the cognitive dysfunction in schizophrenia has to be measured throughout the illness regularly. Computerized technologies for assessment of cognitive dysfunction are widely used. However, their applicability in hospitalized schizophrenic patients setting should be specially examined.

Objective Executive function in schizophrenia.

Aims To test the applicability of “CANTAB” neurocognitive battery for measurement of executive function in young hospitalized schizophrenic patients in Russian sample.

Methods Fifteen inpatients diagnosed with schizophrenia according to ICD-10 (F 20.xx), 13 males and 2 females, aged 23.5(SD 3.2), disease duration is 5(SD 1.6) years and 16 healthy individuals, 7 males and 9 females, aged 21.3(SD 0.7). Spatial Working Memory (SWM) (Mnemonic Executive function), Stockings of Cambridge (OTS) (Planning Executive function), Intra/Extra-Dimensional Shift (IED) (Cognitive flexibility) were administered.

Results The majority of patients and controls easily understood the test instructions. Both groups did not have any difficulties with the touchpad. The “CANTAB” demonstrated sensitivity to the impairments of executive function. As a group, patients with schizophrenia performed significantly worse than controls on almost all tests: SWM–Between errors ($P=0.028$), Total errors ($P=0.019$), Strategy ($P=0.03$), Mean time to last response ($P=0.001$); OTS–Mean choices to correct ($P=0.044$), Problems solved on first choice ($P=0.009$), Probability of error given correct ($P=0.021$); IED–Total errors ($P=0.015$), Total trials ($P=0.002$).

Conclusion The “CANTAB” is an applicable instrument for assessment of the executive function in young hospitalized schizophrenic patients. It can be used both for experimental and clinical needs.

⁴ Lovonosov Moscow State University, Department of clinical psychology, Moscow, Russia

* Corresponding author

Introduction Despite the intense discussion of psychiatric comorbidity in psychodermatology, research on psychological components of skin picking and psychogenic itch is limited, especially when it concerns patients’ representation of skin perception and their attitude towards disease.

Objectives To characterize psychological traits of skin picking and psychogenic itch disorder by comparing aspects of bodily experience.

Aims To reveal internal relations of different components of bodily experience in skin picking and psychogenic itch.

Methods Thirty patients with skin picking disorder (L98.1) and 18 patients with psychogenic itch (F45.8) participated in the study. The psychosemantic method “Classification of sensations” was used to assess bodily experience. It includes estimation of 80 descriptors from 6 classes of bodily sensations: skin (ex. “itch”), inner body (ex. “sickness”), receptor (ex. “sticky”), emotional (ex. “anxiety”), dynamics (ex. “exhaustion”) and attitudinal descriptors (ex. “bad”). Cluster and factor analysis were performed.

Results The most significant aspect of bodily experience in skin picking was its dynamics as a transition from irritation to calmness connected with the sensation of itch opposed to all other sensations (there were opposite signs of factor loadings of these variables and they were included in the factor explaining 45% of total variance). In contrast, in psychogenic itch these relations are diffuse and consist of connections between skin sensations and inner bodily sensations and descriptors of emotions reflecting functional origin of disorder.

Conclusion Traits of psychological components in skin picking disorder and psychogenic itch should be concerned in the complex (psychiatric, psychological and dermatological) treatment of these disorders.

Interaction of symptoms and cognitive dysfunction in remitted schizophrenic patients with and without residua – important sign of heterogeneity for design of cognitive enhancer studies

G. Rupchev^{*}, M. Morozova, D. Burminskiy
Federal State Budgetary Scientific Institution “Mental Health Research Center”, Laboratory of Psychopharmacology, Moscow, Russia

* Corresponding author.

Introduction It is well-known fact that cognitive dysfunction (CD) determines the quality of remission in patients with schizophrenia. However many attempts to demonstrate the link between symptoms and CD failed. The reason for this fact is unclear.

Objectives Heterogeneity on basis of the important sign jeopardizes the signal detection.

Aims Assessment of interaction between clinical symptoms and CD in schizophrenic patients in remission with and without residual psychotic symptoms (RPS).

Methods Adult schizophrenic patients in remission with and without RPS (DSM 295.30) on stable treatment not less than 6 months were assessed with PANSS, CGI, BACS. The indices of the testing were compared between groups. The correlation analysis was performed. The correlation was considered significant if $R > 0.60$.

Results Ten females and 34 males were divided into two groups according to presence (27 patients) or absence (17 patients) of RPS (PANSS items P1 and P3 > 2 but < 5). The severity of symptoms and CD were equal in both groups, excluding P6 ($P = 0.0005$), P20 ($P = 0.007$), P23 ($P = 0.0004$), and positive subscale PANSS ($P = 0.00001$). In the group without RPS, we found that CGI score, scores of 10 items of PANSS, scores of PANSS subscales, excluding negative subscale, and total PANSS score highly negatively correlated with total BACS score (average $R = -0.70 \pm 10$). In the group of patients with RPS, no correlations were found.

Conclusions Patients with RPS has clinical significant dissociation of psychic and cognitive functioning that should be considered in planning, and assessing of results of cognitive enhancers studies.

The peculiarity of experiencing body by patients in schizophrenia

G. Rupchev^{1,*}, A. Alekseev¹, A. Tkhostov², A. Spivakovskaya³, V. Guldan³

¹ Federal State Budgetary Scientific Institution “Mental Health Research Center”, Laboratory of Psychopharmacology, Moscow, Russia

² Lomonosov Moscow State University, Faculty of Psychology, Clinical Psychology Department, Moscow, Russia

³ Lovonosov Moscow State University, Department of clinical psychology, Moscow, Russia

* Corresponding author.

Introduction By the present, the study of corporeality as a psychological phenomenon in schizophrenia has had a lack of attention. At the focus of works, there have been mainly psychopathological phenomena: cenestopathies, visceral hallucinations and body scheme disturbances. There is an evidence of the necessity for psychological investigations: the execution of radical changes in appearance, a frequent turning to plastic surgery, dysfunctional wearing and transsexuality.

Objectives The experimental group consisted of 23 patients in schizophrenia of paranoid type (F 20.00). The control group consisted of 27 healthy subjects.

Aim It is to study the peculiarity of experiencing their own body by patients in schizophrenia.

Methods There are projective techniques, such as: “A Picture of Me”, “Verbal Self-Portrait”, “A Picture of Inner Body” and the psychosemantic test “Classification of Sensations”.

Results There are statistically significant differences ($P < 0.005$) found between the groups:

- patients with schizophrenia are characterized for their deficit of experiencing their body. It does not refer to “Myself” and is deindividualized. The body does not serve as a physical presentation of the subject in a social world;
- a wary attitude is observed in relation to body displays in the form of inner body sensations with a minor (than in norm) awareness relatively to the inner arrangement of their own body. This causes

the increase of the quantity of intrceptive sensations categorized by patients in schizophrenia as unhealthy or a threat.

Conclusion The above-mentioned peculiar features of corporeality in schizophrenia make it a source of negative experiences.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction An appropriate early intervention (EI) after the onset of a first episode of psychosis (FEP) is a key factor to prevent relapse, cognitive and functional impairment related to neurotoxicity as it is a critical period in order to get good adherence to treatment. This is the most reported factor linked to relapse. Therefore, interventions focused on getting good adherence to treatment may make the difference in terms of outcome.

Aims To compare relapse rates, symptom severity and level of functionality before and after treatment with Paliperidone Palmitate Long-Acting Injectable (PP-LAI). To analyze prior antipsychotic treatments and side effects registered before and after the introduction of (PP-LAI).

Material and method This is a cross-sectional descriptive study. We analyzed a sample of 15 patients, recruited from PAFIP (an specialized EI unit) and treated with variable doses of PP-LAI. They all met diagnostic criteria for schizophrenia according to DSM-IV. Clinical and functional data of the two years before and after treatment introduction were recorded.

Results Twenty-seven percent of the patients resumed their work activity or studies and 33% of the patients increased their social activity. Thirteen percent of the patients improved from negative symptoms. Prior to treatment introduction, more than a half of the sample, had suffered one or two relapses. After treatment introduction, 87% did not experience more relapses while 13% experienced another relapse.

Conclusions Treatment with PP-LAI is associated to a recovery of functional abilities, and a trend to clinical stability with high adherence to treatment related to few side effects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Academic Medical Centre, University of Amsterdam, Academic Psychiatric Center, Early Psychosis Department, Arkin, Amsterdam, Netherlands

* Corresponding author.

Introduction In a recent placebo-controlled, double blind crossover trial ($n=52$), we found significant beneficial effects on memory ($d=0.30$) and negative symptoms ($d=0.29$) after 12 weeks memantine augmentation in patients with clozapine-refractory schizophrenia.

Aims In this open-label 1 year extension study, we report the long-term effects and tolerability of memantine add-on therapy to clozapine.

Methods Completers of the first trial who experienced beneficial effects during 12 weeks of memantine treatment received memantine for one year. Primary endpoints were memory and executive function using the Cambridge neuropsychological test automated battery (CANTAB), the Positive and Negative Syndrome Scale (PANSS), and the Clinical Global Impression Severity Scale (CGI-S).

Results Of 31 RCT completers who experienced beneficial effects from memantine, 24 received memantine for one year. The small improvement in memory found in the memantine condition in the placebo-controlled trial remained stable in the extension study. Executive function did not improve. After 26 weeks of memantine add-on therapy to clozapine, PANSS negative symptoms ($r=0.53$), PANSS positive symptoms ($r=0.50$), and PANSS total symptoms ($r=0.54$) significantly improved. Even further significant improvement in all these measures was observed between 26 weeks and 52 weeks memantine, with effect sizes varying from 0.39 to 0.51. CGI-S showed a non-significant moderate improvement at 26 weeks ($r=0.36$) and 52 weeks ($r=0.34$). Memantine was well tolerated without serious adverse effects.

Conclusions In the one-year extension phase, the favorable effect of adjunctive memantine on memory was sustained and we observed further improvement of positive, negative and overall symptoms of schizophrenia.

Disclosure of interest P.F.J.S. reports personal fees from H. Lundbeck A/S, outside the submitted work and he is a board member of the Dutch Clozapine Collaboration Group. Efficacy and tolerability of aripiprazole intramuscular as maintenance treatment in patients with paranoid schizophrenia

B. Serván*, A. Montes, M. Machín, P. Gómez, J. García-Albea, S. González, J. Ibáñez, M.D. Morón

Hospital Clinico San Carlos, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Patients suffering from paranoid schizophrenia, require long-term anti-psychotic treatment, which provide, in addition to adequate efficacy both positive and negative symptoms, a good safety and tolerability profile that would ensure adequate adherence to prevent relapse.

Objectives To analyze the efficacy, tolerability and therapeutic adherence over a year after the introduction of aripiprazole depot in patients diagnosed with paranoid schizophrenia previously treated with other oral or depot anti-psychotics [1,2,3].

Methods One-year prospective longitudinal study with a sample size of 23 patients diagnosed with schizophrenia in outpatient

treatment. Study variables (baseline, 6 and 12 months): Brief Psychiatric Rating Scale (BPRS), clinical global impression (CGI), mean dose of aripiprazole depot, previous treatments, adherence, relapse rate, prolactin levels, sexual dysfunction, BMIs.

Results Twenty-three patients (71% men, 29% women) diagnosed with paranoid schizophrenia were identified. Improvement was obtained in the different study variables with statistically significant difference ($P \leq 0.05$).

Conclusions Following the introduction of aripiprazole depot in patients diagnosed with schizophrenia previously treated with other oral or depot anti-psychotics in our study, we conclude that maintaining therapeutic efficacy a better tolerability and safety profile, better therapeutic adherence and consequently lower relapse rate were achieved.

Introduction Discrimination towards people with schizophrenia (PWS) by healthcare professionals is responsible of underdiagnosis and undertreatment of these patients. Negative attitudes toward PSW in health care professionals tend to be present since their university studies and are related to their knowledge and experience about the disease.

Objectives and aims To assess opinion towards PSW in medical, nursing and psychology students and to investigate the relation with their knowledge of schizophrenia and its causes.

Methods The study involved 133 medical, 200 nursing and 296 psychology undergraduate students. The opinion on mental illness questionnaire, the Devaluation Consumers Scale, and the Devaluation of Consumer Families Scale were administered to the sample. ANOVA and ANCOVA were used to test differences between groups and the relation between causal explanation of schizophrenia and discrimination towards PWS.

Results Psychology students were more aware than the other student of public stigma towards PWS and their families ($F 12.57, P < 0.001$; $F 32.69, P < 0.001$) and expressed a more positive view on treatments' effectiveness ($F 30.74, P < 0.001$). Psychology (OR 0.48, 95% CI 0.26–0.88) and nursing (OR 0.29, 95% CI 0.15–0.55) students were more likely to identify psychological and social risk factors as more frequent causes of schizophrenia (vs. biogenetics) and these, in turn, were related to a better opinion towards social equality of PWS.

Conclusions These preliminary findings underline the relevance of biopsychosocial model of schizophrenia within stigma-reduction programs for health science students.

Dyspareunia after childbirth: Does psychosocial context play a role?

A. Hajri¹, Y. Zgueb¹, M.W. Abdallah², U. Ouali^{1,*}, S. Ben Alaya¹, D. Chelli², F. Nacef¹

¹ Razi hospital, psychiatry A, Manouba, Tunisia

² Center of maternity and neonatology, gynecology and obstetrics A, Tunis, Tunisia

* Corresponding author.

Introduction Dyspareunia is defined as persistent or recurrent genital pain that occurs just before, during or after intercourse. Dyspareunia after childbirth is quite common and have a range of repercussions to women's lives, including their sexual functioning. It could be affected by different risk factors. While role of obstetric factors including mode of delivery has been largely investigated, the influence of psychosocial factors remains unclear.

Aims Our purpose was to determine frequency of postpartum dyspareunia and identify related psychosocial factors.

Methods Thirty women between 2 and 6 months postpartum were recruited in consultation of maternity and neonatology center of Tunis. Data were taken from medical file and questionnaire designed to record psychosocial data and postpartum sexual function.

Results The mean age of women was 28.74 ± 8.4 years. Dyspareunia was reported by 43.33% of women. Dyspareunia was not associated to professional status. On the other hand, dyspareunia was significantly associated to fatigue ($P=0.024$), lack of familial support ($P=0.03$), conjugal conflicts ($P=0.01$).

Conclusion We have found an association between dyspareunia after childbirth and several psychosocial factors, pointing out the influence of social and psychological aspects in the sexual function in women. Thus, management of sexual disorders should take in consideration psychological dimension and involve an appropriate psychological care.

Self-image and risk of suicide in eating disorders

A. Birgegård*, M. Andersen

Karolinska Institute, Department of Clinical Neuroscience, Stockholm, Sweden

* Corresponding author.

Introduction Suicide risk is increased in eating disorders (ED), and detection is key to prevention. Self-image as operationalized in the structural analysis of social behavior (SASB) model has been shown to be associated with symptoms, treatment dropout, and outcome. SASB is a circumplex organizing self-directed behaviors along affiliation (love vs. hate) and autonomy (set free vs. control) dimensions. In a recent study, SASB related to health care-detected suicide attempts in ED. Methodology in that study ensured high specificity but risked lower sensitivity in suicide variables, and with

such a high-threat outcome, research is needed on additional variables related to risk.

Objectives and aims We aimed to study associations between SASB self-image and clinician- and self-rated suicidality at presentation and predicted over 12 months in ED patients.

Methods Adult patients ($n=551$) from a Swedish clinical database included 19% anorexia, 32% bulimia, 7% binge ED, and 42% other ED. We ran separate regression models for these diagnostic groups using SASB questionnaire data, also controlling for general psychiatric and ED symptoms, and in longitudinal models including baseline of each outcome.

Results SASB alone was associated with suicidality at presentation (9–67% variance explained) and predictively over 12 months (7–29%), and in the majority of models explained additional variance beyond baseline and clinical variables. Both affiliation and autonomy related to dependent variables in diagnosis-specific patterns.

Conclusions The findings have implications for both theory and detection tools for suicide risk, as well as suggesting intervention targets to mitigate risk in treatment based on the well-validated SASB theory.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Patients with severe opioid dependency might be treated with methadone, a pure μ -opioid-receptor, with promising results. Though, as for opioids, side effects are high, and among those, sexual dysfunction is among the most disturbing side effects.

Aims Investigating the influence of Rosa Damascena oil to improve sexual dysfunction among male methadone users.

Methods A total of 60 male patients (mean age: 30 years) with diagnosed opioid dependence and currently under treatment of methadone were randomly assigned either to the verum (Rosa Damascena oil drops) or placebo condition. At baseline, and four and eight weeks later, patients completed self-rating questionnaires covering sexual dysfunction and happiness.

Results Over time sexual dysfunction decreased and happiness increased in the verum, but not in the placebo condition.

Conclusions Results from this double blind, randomized, and placebo-controlled clinical trial showed that Rosa Damascena oil improved sexual dysfunction and happiness among male opioid addicts while under substitution treatment with methadone.

Introduction Sexual dysfunction is a common consequence of cancer treatment that affects at least half of men and women treated for pelvic tumors and more than one quarter of individuals with other malignancies.

Objectives/aims Identification of the main sexual dysfunctions related to cancer treatments. Awareness to the importance of addressing sexuality to cancer patients, identifying the main reasons why healthcare providers usually do not.

Methods Literature review concerning researched articles published in Pubmed/Medline as well as related bibliography.

Results Most sexual problems are not caused by the cancer itself, but by toxicities of cancer treatment. Damage during cancer treatment to pelvic nerves, blood vessels and organ structures leads to the highest rates of sexual dysfunction. The most common sexual dysfunction in men under cancer treatment is the loss of desire for sex and erectile dysfunction. In women, the most common sexual dysfunctions are vaginal dryness, dyspareunia and loss of sexual desire, usually accompanied by difficulties in both the arousal and orgasm phases. According to literature, there are many cancer patients who would like to be informed and advised by their healthcare providers about the consequences of cancer treatment on their sexual health. Unfortunately, this rarely happens.

Conclusions This work intends to publicize current existing information on sexual dysfunction in oncology, focusing on the prevalence, etiology and clinical presentation. The authors also intend to promote communication about sexual function and possible sexual dysfunctions resulting from cancer treatments.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Structural covariance networks in anorexia nervosa (AN): A multimodal graph theoretical analysis

E. Collantoni^{1,*}, P. Meneguzzo², E. Tenconi², R. Manara²,
P. Santonastaso², A. Favaro²

¹ University of Padua, Department of Neurosciences, Santa Maria Si Sala, Italy

² University of Padua, Department of Neurosciences, Padua, Italy

* Corresponding author.

Introduction The possibility of evaluating cortical morphological and structural features on the basis of their covariance patterns is becoming increasingly important in clinical neuroscience, because their organizational principles reveal an inter-regional structural dependence which derive from a complex mixture of developmental, genetic and environmental factors.

Objectives In this study, we describe cortical network organization in anorexia nervosa using a MRI morpho-structural covariance analysis based on cortical thickness, gyrification and fractal dimension.

Aim Aim of the research is to evaluate any alterations in structural network properties measured with graph theory from multi-modal imaging data in AN.

Methods Thirty-eight patients with acute AN, 38 healthy controls and 20 patients in full remission from AN underwent MRI scanning.

Surface extraction was completed using FreeSurfer package. Graph analysis was performed using graph analysis toolbox.

Results In acute patients, the covariance analysis among cortical thickness values showed a more segregated pattern and a reduction of global integration indexes. In the recovered patients group, we noticed a similar global trend without statistically significant differences for any single parameter. According to gyrification indexes, the covariance network showed a trend towards high segregation both in acute and recovered patients. We did not observe any significant difference in the covariance networks in the analysis of fractal dimension.

Conclusions The presence of increased segregation properties in cortical covariance networks in AN may be determined by a retardation of neurodevelopmental trajectories or by an energy saving adaptive response. The differences between the analyzed parameters likely depend on their different morpho-functional meanings.

* Corresponding author.

The protein brain derived neurotrophic factor (BDNF) is a major contributor to neuronal plasticity. There is numerous evidence that BDNF expression is decreased by experiencing psychological stress and that accordingly a lack of neurotrophic support causes depression. The use of serum BDNF concentration as a potential indicator of brain alteration is justified through extensive evidence. Recently, we reported, for the first time, a relationship between BDNF and insomnia, since we could show that reduced levels of serum BDNF are correlated with sleep impairment in control subjects, while partial sleep deprivation was able to induce a fast increase in serum BDNF levels in depressed patients. Using a bi-directional stress model as an explanation approach, we propose the hypothesis that chronic stress might induce a deregulation of the HPA system leading in the long term to sleep disturbance and decreased BDNF levels, whereas acute sleep deprivation, can be used as therapeutic intervention in some insomniac or depressed patients as compensatory process to normalize BDNF levels. Indeed, partial sleep deprivation (PSD) induced a very fast increase in BDNF serum levels within hours after PSD which is similar to effects seen after ketamine infusion, another fast-acting antidepressant intervention, while traditional antidepressants are characterized by a major delay until treatment response as well as delayed BDNF level increase. Moreover, we revealed that stress experience and subjective sleep perception interact with each other and affect serum BDNF levels. We identified sleep as a mediator of the association between stress experience and serum BDNF levels.

* Corresponding author.

Introduction Anorexia nervosa (AN) is characterized by dysregulated eating that leads to chronic malnutrition, which may be responsible for several physical complications, including endocrine alterations, such as hyperactivity of the hypothalamus-pituitary-adrenal (HPA) axis.

Objectives Several studies have shown a dysregulation of the cortisol awakening response (CAR) in symptomatic AN patients. However, it has not been established if the deranged CAR of underweight AN patients is a primary phenomenon or an alteration secondary to malnutrition.

Aims The aim of this study was to explore the salivary CAR in both underweight and weight-restored patients with AN.

Methods We recruited 59 women: 18 undernourished AN patients, 15 weight-restored AN women and 26 normal-weight healthy controls. Saliva samples were collected in the morning, immediately after awakening and after 15, 30 and 60 minutes, in order to measure saliva levels of cortisol. Participants filled in the state-trait anxiety inventory (STAI) to test their anxiety levels in the morning of the test.

Results Compared to healthy controls, underweight AN patients showed an enhanced CAR whereas the weight recovered patients had a normal CAR. These results were not correlated with levels of anxiety.

Conclusions For the first time, our results demonstrate that the deranged CAR found in acute AN patients is not present in weight-restored ones, suggesting that altered activity of the HPA axis of symptomatic AN patients is a state-dependent phenomenon.

Tracking insomnia seasonal variations through consumption of hypnotics

I.P. Gradiški^{1,*}, P. Bilić², T. Sabo², M. Vilibić²

¹ University Psychiatric Hospital Vrapče, Zavod za dualne poremećaje, Zagreb, Croatia

² University Psychiatric Hospital Vrapče, Zavod za biologijsku psihijatriju i psihogerijatriju, Zagreb, Croatia

* Corresponding author.

Introduction Light-stimulated release of melatonin suppresses the nocturnal production of melatonin and is sending signals to multiple brain areas, including hypothalamic suprachiasmatic nuclei and thus controlling the release of the pineal hormone melatonin and therefore control the circadian rhythm. Consumption of sedatives and hypnotics was used as an indirect measure of seasonal variations in sleep disturbances among inpatients at University Psychiatric Hospital Vrapče.

Methods Retrograde record analysis was performed from 1st January to 31st December 2012 on commonly used hypnotics and sedatives: zolpidem, nitrazepam, flurazepam, and midazolam.

Results The lowest consumption of hypnotics was recorded in the months of November, August and September while the highest consumption was recorded in January, December and March which can be seen in Fig. 1. Although there were differences in the monthly

prescription of hypnotics, when it comes to seasonal patterns, there are no statistically significant differences.

Conclusions There is no significant difference between the consumption of hypnotics in the observed seasons although the consumption of hypnotics is higher in the months with shorter daylight. This study attempted to correlate exposure to light and insomnia through the prescription of hypnotics and it is possible there are other important variables not included in this study.

Antidepressants-induced sexual troubles

H. Ben Ammar, G. Hamdi*, H. Zalila, Z. El Hechmi
Razi Hospital, F, Mannouba, Tunisia

* Corresponding author.

Introduction For a long time, antidepressants sexual side effects have been neglected. Currently, no reliable scientific data is available regarding the nature and frequency of sexual dysfunction induced by antidepressants. The aim of our study was to evaluate the prevalence and type of sexual dysfunction induced by antidepressants, and to identify factors associated with the occurrence of these disorders.

Methodology A descriptive and analytical cross-sectional study extending over a period of two weeks. For the purpose of this research, a socio-demographic card, the Arizona Sexual Experiences Scale (ASEX) and the Psychotropic-Related Sexual Dysfunction Questionnaire (SALSEX) were used.

Results Fifty-five patients were recruited. The diagnosis of major depressive episodes was dominant (49.1%). Moreover, fluoxetine and tricyclic were in top of the list of antidepressants with respective proportions of 41.8% and 38.2% and respective dose 20.86 mg/24 h and 72.38 mg/24 h. The score using the ASEX scale was 14.63 ± 5.23 . Using the SALSEX scale, 47.3% of patients claimed to have had sexual disorders secondary to antidepressants with a moderate score of 9.19 ± 2.56 . Furthermore, sexual disorders were more common in the elderly aged of 45 (66.66%) as well as in patients started on paroxetine (66.66%) and on sertraline (66.66%) ($P \leq 0.05$).

Conclusion The sexual side effects of antidepressants have a major impact on the quality of life and adherence to treatment. They also represent an important risk factor for relapse and recurrence in major depression, in this context, the prescription of an antidepressant.

Burnout in medical residents: Prevalence and risk factors

I. Feki¹, S. Hentati¹, R. Sallemi¹, N. Bahloul², D. Zalila², S. Kammoun², J. Masmoudi^{1,*}

¹ University Hospital Hédi Chaker, psychiatry, Sfax, Tunisia

² University Hospital Hédi Chaker, pneumology, Sfax, Tunisia

* Corresponding author.

Background Burnout is a state of mental and physical exhaustion related to work. It is manifested in a variety of professions and is prevalent in contexts in which health professionals are required to interact directly with the public.

Objectives To estimate the burnout syndrome (BOS) prevalence and to identify its associated factors among medical residents.

Methods A descriptive and analytic study conducted during a period from 2012 until 2014, including 184 residents exerting at the two university hospitals of Sfax, Tunisia. Data collection was conducted using an anonymous self-questionnaire, including demographic items and working conditions items. Maslach Burnout Inventory (MBI) was used to assess BOS.

Results The average age was 25.14 ± 1.47 years. The sex-ratio was 0.65. The majority (154 residents) was single. Over than half (58.2%) of medical residents endure a high emotional exhaustion, 62.5% a high depersonalisation and 12.5% a low personal accomplishment. About eighty percent (79.3%) of them were in burn out with 37% at intermediate and 11.3% at a severe degree. No statistical association was found between the personal characteristics and BOS. Whereas, several factors related to employment status were correlated with the presence of BOS such us: number of working hours > 30 h/week, a number of free weekends < 2/month and a number of days off ≤ 30 days/year. In addition, we found that psychotropic and alcohol consumption were significantly associated to BOS with respectively $P=0.050$ and $P=0.002$.

Conclusion Burnout is a worrying reality among young doctors. Individual as well as organizational interventions should be targeted to prevention.

Eating disorders in schizophrenia

R. Sallemi, S. Hentati, I. Feki, J. Masmoudi*, M. Moala

University hospital Hédi Chaker, psychiatry, Sfax, Tunisia

* Corresponding author.

Background Due to their frequency and negative impact on quality of life, eating disorders in schizophrenia need to be considered and highlighting.

Objective To identify the risk of eating disorders (ED) and its correlates among mental patients.

Methods It was a descriptive and analytic study. It included 53 inpatients with DSM-5 diagnoses of schizophrenia or schizoaffective disorder, followed in the department of Psychiatry at the Hedi Chaker University Hospital of Sfax in Tunisia, during the three months of August, September and October 2016. Data collections were conducted using questionnaire exploring sociodemographic and medical data. The SCOFF (sick, control, one, fat, food) Questionnaire was used to screen ED. A total score of ≥ 2 was used as a cutoff point to select persons at risk of ED.

Results The average age of our patients was 30.47 ± 9.5 years old. The majority of our patients was male (71.7%) and single (71%). The

mean of extra Body mass was 27.9. The mean duration of disease was 9.9 ± 8.1 years and patients were mostly (54%) in atypical neuroleptics. According to the SCOFF Questionnaire, 35.8% had a risk of ED. Female gender and treatment with atypical neuroleptics were significantly associated to ED risk with respectively $P=0.02$ and $P=0.038$.

Conclusion Eating disorders remain underestimated among patients suffering from schizophrenia. Yet, its screening prevention and management are crucial and must be multidisciplinary for optimal care.

Palatable food access during adolescence increased BDNF expression in the nucleus accumbens and anxiety-/depression-like behaviors in males, but not in females

J.W. Jahng*, J.Y. Kim, J.H. Lee

School of Dentistry, Seoul National University, Dental Research Institute, Seoul, Republic of Korea

* Corresponding author.

Objectives This study was conducted to examine sexual dimorphic effects of highly palatable food access during adolescence and youth on psychoemotional behaviors of rats and its underlying neural mechanism.

Methods Male and female Sprague Dawley pups had free access to chocolate cookie rich in fat (highly palatable food) from post-natal day 28 in addition to ad libitum chow, and the control groups received chow only. The food conditions were continued though out the entire experimental period, and the neurochemical and behavioral measurements were performed during young adulthood. Corticosterone levels during 2 h of restraint stress were analyzed with radioimmunoassay, and Δ FosB and brain-derived neurotrophic factor (BDNF) expression in the nucleus accumbens (NAc) with western blot analysis.

Results Cookie access did not affect body weight gain and total caloric intake in both sexes; however, it increased retroperitoneal fat depot only in males. The time spent in open arms during elevated plus maze test was decreased and immobility during forced swim test was increased in cookie-fed males, but not in cookie-fed females. Main effect of food condition on the stress-induced corticosterone increase was observed in males, but not in females, and cookie access increased BDNF expression in the NAc only in males.

Conclusions Increased BDNF expression in the NAc and fat depot, in addition to the HPA axis dysfunction, may play roles in the pathophysiology of depression- and/or anxiety-like behaviors induced by cookie access.

Investigation of food addiction and impulsivity relations biological rhythms differences and insomnia in university students

A. Kandeger*, Y. Selvi

Selcuk University, Department of Psychiatry, Konya, Turkey

* Corresponding author.

Objective Increasing prevalence of obesity in the world and increasing role of processed foods in daily life has led to become the focal point of food addiction. This study aims to investigation of food

addiction and impulsivity relations biological rhythms differences and insomnia in university students.

Method One thousand and five hundred students planned to participate who studies in Konya Selcuk University central campus. Participants were to fill out the test during their classes under physician supervision. The volunteers completed a package of psychological instruments including the Morningness–Eveningness Questionnaire, Yale Food Addiction Scale, Insomnia Severity Index, and Barratt Impulsiveness Scale administered by two investigators in their classrooms.

Results In total, 1323 forms were suitable for statistical analysis. The mean age was 20.83, mean BMI was 22.02. Food addiction prevalence was 18.2%. Our study showed that association between the eveningness type and food addiction ($P < 0.045$). Also, the eveningness type and insomnia were in positive correlation in impulsivity ($P < 0.001$).

Conclusion This study has explored the association between eveningness type of biological rhythms, food addiction, insomnia and impulsivity.

* Corresponding author.

Introduction Despite an increasing focus on cognitive functions in eating disorders, only limited and contradictory knowledge regarding the relationship between cognitive functions and anorexia nervosa symptomatology currently exist.

Objectives The aim of this study was to investigate potential associations between cognitive functions and anorexia nervosa symptomatology in children and adolescents.

Method Eating disorder symptoms and cognitive functions were examined in this cross-sectional, multi-centre study. Diagnostic scores i.e. BMI, psychological symptoms, and global EDE-16 were stratified on cognitive function. Children and adolescents suffering from severe recent-onset anorexia nervosa ($n = 94$) and healthy controls ($n = 94$), between the age 10.6 and 17.9 years (mean age 14.9 years, SD 1.8), participated in the study. The patients were divided into two groups, respectively above and below the median of cognitive functions.

Results The study findings revealed that Global EDE score significantly increased with age ($P = 0.002$, CI 0.08–0.36). Besides this, no significant associations between low body weight or psychological symptoms and cognitive functions were found. However, a large variability in cognitive functions was found on all measure in patients with anorexia nervosa than healthy controls.

Conclusion While age seems to be significantly correlated to symptom burden the study results indicate that patients with anorexia nervosa is a much more heterogeneous group with regard to cognition than healthy controls. However, cognitive functions and anorexia nervosa symptomatology does not appear to be associated.

Comparative assessment of cognitive function and mood dynamics in patients with depression and eating disorders in the process of treatment

I. Makhortova^{1,*}, O. Shiryayev²

¹ LLC "LION-MED", psychiatry, Voronezh, Russia

² Voronezh State Medical University, Psychiatry, Voronezh, Russia

* Corresponding author.

Eating disorders of bulimic type are among the most common comorbidities with depression. The objective is to evaluate cognitive function and mood dynamics in patients with depression and eating disorders in pharmacotherapy. In total, 52 outpatients, who met criteria for "major depressive episode" (ICD-10), participated. The level of depression was estimated with Hamilton Depression rating scale (HAM-D) and cognitive function–Montreal Cognitive Assessment (MoCa). Sample was divided into two groups. Patients of group 1 also met criteria for eating disorder of bulimic type and patients of group 2 did not have any eating disorder. Treatment included standard doses of SSRI. Assessments were performed after 2, 4 and 8 weeks (D14, D30, D60). The level of HAM-D was significantly greater ($P < 0.05$) in eating disorders group (16.75 ± 2.83 in group 1; 13.04 ± 1.93 in group 2 at screening) and significance was preserved till D60 (9.39 ± 2.54 in group 1; 6.32 ± 1.27 in group 2 at D60). Clinically significant antidepressive effect was revealed faster in group 2 (at D7) compared to group 1 (at D14). Overall score of MoCA was significantly lower ($P < 0.05$) in eating disorders group (20.33 ± 0.54 in group 1; 23.43 ± 2.32 in group 2 at screening) at all stages of treatment (23.39 ± 0.78 in group 1; 26.96 ± 3.27 in group 2 at D60) and it reached normal range (25 and more) only in group 2 at D60. Significant change from screening was revealed at D30 at group 2 and at D60 at group 1.

Conclusion Eating disorder have an impact on SSRI treatment efficacy including antidepressive and procognitive effects. It is necessary to reveal eating disorders as a co-morbidity in patients with depression.

Is there an association between body uneasiness and aberrant salience in anorexic patients? A preliminary study

L. Mallardo*, B. Campone, T. Tofani, E. Ciampi, E. Corsi, C. Baschirotto, C. Appignanesi, L. Lelli, F. Pietrini, F. Rotella, V. Ricca, A. Ballerini

University of Florence, Department of Neurosciences, Psychology, Drug Research and Child Health, Neurofarba, Pharmacology and Toxicology Section, and Psychiatric Section, Florence, Italy

* Corresponding author.

The process whereby objects and representations come to be attention grabbing and capture thought and behaviour is called salience, and it is defined as aberrant when a significance is allocated to neutral stimuli. The Aberrant Salience Inventory (ASI) is a scale to measure aberrant salience, characterized by 29 dichotomic items. By now, a correlation between aberrant salience and eating disorders is unknown. Aim of this study is to evaluate an alteration of salience in patients with anorexia nervosa, to estimate the existence of a correlation between aberrant salience and the experience of body shape.

Methods Twenty-six female patients with AN (diagnosed using DSM-5) were enrolled at the Psychiatry Department of Florence. Psychopathological features were assessed at the time of enrollment using the following scales: SCL-90-R, BUT, EDE-Q. Salience alteration was assessed by the means of the ASI. Statistical analysis were realized using SPSS 20.0 with Spearman bivariate correlation. **Results** Mean age was (mean \pm SD) 26.2 ± 8.72 and mean Body Mass Index (BMI) 16.1 ± 2.46 . Global Severity Index (GSI), Positive Symptom Total (PST) and Positive Symptom Distress Symptom Index (PSDI) were estimated for BUT and SCL-90-R and compared to total value of ASI. Thus, we found a statistical significant ($P < 0.05$) direct correlation between ASI and BUTpsdi and ASI and SCL-90-Rgsi (correlation coefficient of 0.446 and 0.398, respectively).

Conclusion In this study, we found a significant direct correlation between Aberrant Salience Inventory (ASI) values and one dimension of body uneasiness in anorexic patients. These preliminary data need further studies with a wider sample to confirm the above-mentioned data.

Childhood emotional experiences and eating psychopathology: The mediational role of different emotion regulation processes

A.L. Mendes, C. Ferreira, J. Marta-Simões^{â^}

Faculty of Psychology and Education Sciences, University of Coimbra, CINEICC, Cognitive, Behavioral Center for Research and Intervention, Coimbra, Portugal

^{â^} Corresponding author.

Positive experiences from childhood have been consistently associated with well-being and with feelings of social safeness and connectedness. On the other hand, the lack of early experiences characterized by warmth, soothing and care may lead to the later experience of fearing to receive compassion from others, to the engagement in self-judgment, and may be associated with a large spectrum of psychopathology. The present study tested a model which hypothesized that the impact of early positive memories with family figures on the engagement in disordered eating is carried by the mechanisms of social safeness and connectedness with others, fears of receiving compassion from others, and self-judgment. The sample comprised 399 women, aged between 18 and 55 years old. The path model accounted for 33% of eating psychopathology's variance and showed excellent model fit indices. Results revealed that the impact of early affiliative memories with family figures on eating psychopathology was totally mediated by the mechanisms of social safeness, fears of compassion from others, and self-judgment. In fact, women who reported a lack of early memories of warmth and safeness with family figures seemed to present lower feelings of safeness and connectedness within

social relationships, higher tendency to fear receiving kindness and compassion from others, and more self-judgmental attitudes. These findings support the importance of developing intervention programs in the community, which target maladaptive emotion regulation processes (such as compassionate-based interventions) to promote mental health, especially in a context of early adverse experiences.

How dissociation, temperament and character influence at the eating disorders

V. Muñoz Martínez, T. Rodriguez Cano, L. Beato Fernández, G.A. Jimenez Londoño, B. Mata Saenz*, L. Asensio, L. Nuevo Fernandez, L. Mella

Ciudad Real University Hospital, Psychiatry, Ciudad Real, Spain

* Corresponding author.

Objectives Dissociation has been related to emotional dysregulation and eating psychopathology. Dissociation may interfere with the learning process, affecting at the therapy negatively. The aim of the study is to analyse if at the eating disorders (ED), dissociation is linked to temperamental traits or also to character traits, which are susceptible to be modulated during the therapeutic process.

Methods We studied 119 females that started an outpatient program for their ED. We used the Dissociative Experience Scale (DES), Temperament and Character Inventory (TCI), Eating Attitudes Test (EAT-40), and the State Trait Anxiety Inventory (STAI). We used multiple regression analysis.

Results Dissociation was associated with high scores on the EAT-40, even controlling the effect of anxiety traits, which also was related to dissociation. The temperament dimension "searching for novelty", has been related in an opposite way to the DES. Also, the "dimension of transcendence" "character and "self determination" influenced on the DES.

Conclusions This study confirms the importance of improving Self Determination levels at ED therapy, which influence on a lot of prognostic aspects, such as protecting from dissociation, which is related to anxiety and alimentary psychopathology and can interfere with the therapeutic progress.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Treatment in anorexia nervosa: The role of neuropsychological features in predicting response

P. Meneguzzo*, E. Collantoni, E. Tenconi, E. Bonello, G. Croatto, D. Degortes, P. Santonastaso, A. Favaro

University of Padua, Department of Neurosciences, Padova, Italy

* Corresponding author.

Introduction Neuropsychological impairments in anorexia nervosa (AN) have been considered both as putative risk factors and as a target for treatment. However, the role of neuropsychological variables as predictors of outcome is not clear.

Aims Our aim is to investigate the role of neuropsychological variables as predictors of response to treatment in a group of individuals affected by AN.

Methods The study sample consisted of 144 patients diagnosed with acute AN, according to the DSM-5 criteria, referred to the Eating Unit of the Hospital of Padova, Italy. All participants were assessed by means of a neuropsychological and clinical test battery

at intake and followed during outpatient treatment for an average of 531 days. Eighty-three percent of the patients underwent cognitive behavioral therapy, the families of 75% of the patients were included in the treatment and 48% of the patients took antidepressants (SSRI).

Results Both body mass index at assessment and illness duration appeared to be independent factors significantly affecting the outcome. The role of neuropsychological variables was explored including cognitive performance in a multivariate analysis including BMI at intake, duration of illness and diagnostic subtype. The inclusion in the model of the Wisconsin Sorting Card Task performance and the central coherence index (calculated by the Rey Figure Test) significantly increased the prediction ability of the model for full remission at the end of treatment.

Conclusions This is the first study to show that neuropsychological characteristics may predict treatment response in AN. These data support the implementation of cognitive remediation techniques in the treatment of AN.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ CMI dr Mihailescu S. Cristian, Family Medicine, Bucharest, Romania
* Corresponding author.

Introduction Emotional distress—specifically symptoms of anxiety and/or depression—in undergraduate medical student represent a major health issue for university life and for the entire society, as the onset of negative affectivity in young age is lowering quality of life of the affected individual and implicitly, the professional evolution.

Objective The purpose of this study is to investigate the prevalence of perceived stress in medical undergraduates and relationship between perceived stress and emotional distress.

Methods The study comprised a randomised population of 356 students from 1st and 2nd year in Faculty of Medicine who signed the informed consent for the research. Mean age in the group was 20.04 ± 0.9 years old. Instruments used in the study were self-rated Zung Anxiety Scale and Zung Depression Scale and Perceived Stress Scale. Data were analysed with SPSS 16. Statistical significance was at $P < 0.05$.

Results Perceived stress of medium and high intensity was found in 62.5% of the students in the study. There is a significant effect of perceived stress on presence of emotional distress ($F_{(3,352)} = 36,431$, $P < 0.001$). In the emotional distressed group, perceived stress in the period before the exams session is predicting emotional distress in the period of exams (academic stress) with OR = 1.145, $P = 0.04$, IC 95% = 1.006–1.303.

Conclusions There is a high prevalence of perceived stress and perceived stress in the period before session of exams is a predictive factor for having emotional distress in session of exams. Therefore, we are signaling the necessity of implementation of stress management programs in medical undergraduates from the pre-clinical years.

Microstructural changes in patients with Parkinson's diseases and REM sleep behavior disorder: Depressive symptoms versus non-depressed

S. Mohammadi Jooyandeh^{1,*}, M.H. Aarabi², F. Rahmani³

¹ University Hospital Regensburg, psychiatry and psychotherapy, Regensburg, Germany

² Basir Eye Health Research Center, neuroscience, Tehran, Iran

³ Tehran University of Medical Sciences, Student's Scientific Research Center, Tehran, Iran

* Corresponding author.

Introduction REM sleep behaviour disorder (RBD) is associated with psychiatric symptoms, such as anxiety and depression. RBD is characterized by loss of normal skeletal muscle atonia during rapid eye movement (REM) sleep with prominent motor activity and dreaming and is a usual symptom of the early stages of Parkinson's disease (PD). Diffusion MRI connectometry was used to carry out group analysis between age and gender matched PD patients with RBD in with and without depression to characterize possible depression-related white matter microstructural changes in the Parkinson patients with RBD.

Method DWI images were obtained for 15 PD-RBD with depression and 27 PD-RBD without depression. This dataset was acquired on a 3 Tesla Siemens scanner, producing 64 DWI at $b = 1000$ s/mm² and one b0 image. Diffusion MRI data were corrected for subject motion, eddy current distortions, and susceptibility artefacts due to the magnetic field inhomogeneity. Diffusion MRI connectometry was conducted in a total of 27 subjects using percentage measurement.

Results PD-RBD Patients with depressive symptoms showed decreased anisotropy ($FDR < 0.05$) in the fornix bilaterally, right cingulum, inferior longitudinal fasciculus bilaterally, right corticospinal tract and Genu of corpus callosum compared to PD-RBD patients without depression.

Conclusion Since RBD is considered to be an early symptom of PD and also a marker of progression to PD, these results might PD-RBD patients with depression may progress dementing processes and visuospatial dysfunction earlier since fornix, cingulum and ILF have proven to be associated with these cognitive dysfunctions respectively.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Electric indoor lighting can disturb sleep and increase depressive symptoms; both common complaints in psychiatric inpatients.

Aims To improve quality of sleep in patients using an indoor hospital lighting environment simulating nature in intensity, color, and circadian timing.

Methods Investigator-blinded parallel group randomized controlled effectiveness trial supplied with qualitative interviews in an inpatient psychiatric ward with fully automatic and adjustable lighting. Admitted patients received a room with a naturalistic lighting environment (intervention group) or lighting as usual (control group). The primary outcome was the Pittsburg Sleep Quality Index and secondary outcomes included the Major Depression Inventory and WHO-five Well-Being Index.

Results In this ongoing trial, we included 28 patients (16 treated and 12 controls). Patients in the intervention group reported higher subjective sleep quality and sleep efficiency, lower use of sleep medication (mean difference, 4.68 mg; 95% CI, 0.54; 53.5), fewer depressive symptoms (mean difference, 5; 95% CI, -2; 13), but lower well-being (difference, -4 percentage points; 95% CI, -20; 16), compared with the control group. At discharge, fewer patients in the intervention group had experienced use of involuntary treatment. Qualitative data indicated no side effects apart from issues in performing indoor leisure activities in dim light.

Conclusions A naturalistic lighting environment was safe and improved sleep and mood in our small patient sample. The trial integrated well with routine clinical care and our sample reflected the heterogeneity of the target population (Funded by Region Midtjylland and others; Clinicaltrials.gov number, NCT02653040)

Psychological and psychophysiological mechanisms of mental stress reaction in patients with 'hypertension at work', as compared with 'classical' version of essential hypertension

E. Pervichko^{1,*}, Y. Zinchenko¹, O. Ostroumova²

¹ Lomonosov Moscow State University, Faculty of Psychology, Moscow, Russia

² Moscow State University of Medicine and Dentistry, Faculty of General Medicine, Moscow, Russia

* Corresponding author.

Introduction 'Hypertension at work' today is found one of the most frequent forms of stress-induced hypertension.

Objectives To inquire into the specifics of psychological and psychophysiological mechanisms of stress reaction in patients with 'hypertension at work', as compared with 'classical' essential hypertension (EH).

Materials and methods The study developed simulation of emotional stress with the aspiration level (AL) modeling. The level of state anxiety (SA), BP values, urine catecholamine levels and levels of renin and angiotensin I in blood plasma were taken before and after the experiment. Eighty-five patients with 'hypertension at work' (mean age was 45.9 ± 2.8) and 85 patients with 'classical' EH (mean age was 47.4 ± 4.5 years) took part in the study.

Results Rates of 'hypertension at work' patients, when compared with second group patients, revealed a significant increase ($P < 0.001$) of systolic BP in response to stress loads (on average, for 16.1 ± 1.9 mmHg and 4.1 ± 0.7 mmHg, respectively). Initially 'hypertension at work' patients had significantly lower levels of catecholamines, than the second group, while the levels of renin and angiotensin I were comparable. During the experiment, the patients

in the first group showed a significant decrease in all parameters. After the experiment, the patients with 'HTN at work' did not show increase of SA, but revealed more frequent inadequacy (69.4%) and instability (56.5%) on the AL. Patients with 'classical' EH more often demonstrate adequate AL and lower growth of BP after the experiment.

Conclusions Patients with 'hypertension at work' are more prone to repress their emotions. They reveal physiological features of chronic stress and psychophysiological exhaustion, if compared with second group patients.

* Corresponding author.

Background Multiple sclerosis (MS) is a chronic progressive autoimmune disease. Fatigue, depression and cognitive impairments are the most common symptoms of patients with MS. Whereas there is extant research on fatigue, depression, and cognitive impairment of patients with MS during the clinical course, no research focused on the long term changes of psychological functioning, sleep problems, and physical activity on these patients. The aims of the present study were therefore to examine changes in physical activity, sleep disturbances, and mental toughness over a 1.5-year period of time in people with multiple sclerosis after the onset their MS.

Methods A total of 18 patients with diagnosed MS (mean age: $M = 33.61$ years) took part in this study. They completed a booklet of questionnaires covering socio-demographic data, mental toughness, sleep disturbances, and physical activity, at the onset of disease and 1.5 years later.

Results In total, 1.5 years after the onset of MS, patients had lower levels of vigorous physical activity, but not statistically significant change in moderate physical activity. Patients with sleep disturbances at the onset of disease had statistically significant sleep disturbances also 1.5 years later.

Conclusions Compared to the onset of disease, 1.5 years later, patients with MS reported similar mental toughness traits, sleep disturbances and levels of moderate physical activity. The pattern of results of the present pilot study suggests that the onset of MS is not an obstacle for doing moderate physical activity. Based on the result of this study, sleep disturbances remains stable by time.

Hypnotic drugs in hospital. Evaluation of their use: From prescription to administration

S. Wise^{1,*}, S. Lukat¹, M. Dalle Pécal¹, C. Diviné¹, C. Henry²¹ Hôpital Albert-Chenevier, hôpitaux universitaires Henri-Mondor, AP-HP, service pharmacie, Créteil, France² Hôpital Albert-Chenevier, hôpitaux universitaires Henri-Mondor, pôle de psychiatrie universitaire, centres experts, Créteil, France

* Corresponding author.

In 2015, a French agency, Haute Autorité de santé (HAS), published recommendations for the use of hypnotic drugs. We evaluated the compliance with good practice in prescription and administration studying 3 hypnotics (lormetazepam, zolpidem, zopiclone) referenced in our establishment (psychiatry, rehabilitation, recuperative and long-term care) and melatonin (immediate release hospital preparation). Prescriptions were analyzed on a given day (dosage, length of treatment, prescription modalities). Night nursing practices were collected. Amongst 423 hospitalized patients, 105 had a hypnotic monotherapy, 3 an association melatonin/zopiclone and 6 a melatonin monotherapy. The most prescribed molecule was zopiclone (79%). Prevalence of hypnotic prescription was 25.5%. 17.6% of these prescriptions were for less than 28 days, 82.5% were at maximum dosage, 46.3% were in systematic mode and 53.7% in conditional mode. Amongst the 22 patients over 65 years old, only 8 received half hypnotic dose. Concerning the 9 prescriptions of melatonin, dosage varied from 3 to 9 mg, 1 was in conditional and only 1 specified terms of use. All 15 nurses met, adapt administration to the patient's bedtime. Five nurses have already woken up patients to give them hypnotics. The prevalence of patients with hypnotics is higher than the general French population (6.4%). HAS recommendations are not all followed: duration of prescription greater than 28 days, few dosage adaptations. Nurses generally respect hypnotic administration rules. Melatonin is not often prescribed and has no prescription or administration recommendations. Our results confirm the need to spread hypnotic and melatonin recommendations in health facilities. Hospital pharmacists can relay such recommendations.

What do Tunisian general practitioners know about insomnia?

K. Yaich*, M. Maalej Bouali, N. Charfi, W. Sellami, N. Zouari,

L. Zouari, J. Ben Thebet, M. Maalej

Hedi Chaker University Hospital, Psychiatry C department, Sfax, Tunisia

* Corresponding author.

Introduction Insomnia is the most prevalent sleep disorders and affects 10% of adults worldwide. It has major social and economic consequences. The aim of our study was to evaluate the knowledge of Tunisian general practitioners (GPs) about insomnia.

Methods A cross-sectional survey was carried out during the month of May 2016. Among the 193 GPs randomly selected from different areas of Sfax, in Tunisia, 127 participated to the study. The latter filled a questionnaire including items related to socio-demographic data and clinical features of insomnia.

Results Among our participants, 58.3% ($n=74$) were men and 41.7% ($n=53$) women. The average age was 47.91 ± 10.1 years. They have been working for 17.36 ± 10.7 years on average. Seventy-six of GPs had an individual training and a training by attending conferences or by continuous medical education. Most participants (80.3%) thought that they had some lacuna in the management of insomnia. Specific recommendations for the management and

treatment of insomnia were known by 7.2% of the GPs. As for theoretical knowledge about insomnia, 74.8% of participants ($n=95$) had a high score of correct answers. The latter was correlated to age ($P=0.013$) and to the male gender ($P=0.008$). However, it was neither correlated to the seniority of the GPs ($P=0.051$) nor to the knowledge of specific recommendations for the management of insomnia ($P=0.11$).

Conclusion Our results showed that the GPs had a rather good theoretical knowledge about insomnia. Yet, an improvement of the continuous medical education and a better knowledge of specific recommendations for the management of insomnia are needed.

The management of insomnia by Tunisian general practitioners

K. Yaich*, M. Maalej Bouali, N. Charfi, W. Sellami, Z. Nasr,

L. Zouari, J. Ben Thebet, M. Maalej

Hedi Chaker University Hospital, Psychiatry C department, Sfax, Tunisia

* Corresponding author.

Introduction Sleep disorders are common in clinical practice. However, they are relatively poorly understood by doctors. The aim of our study was to describe the management of insomnia by general practitioners (GPs).

Methods A cross-sectional survey was carried out during the month of Mai 2016. Among the 193 GPs randomly selected from different areas of Sfax, in Tunisia, 127 completed a questionnaire about the management of insomnia.

Results Among our participants, 46.5% stated that they often discuss the quality of sleep with their patients even when it is not their chief complaint. Forty-three percent reported that they are often consulted by insomniac patients. Twelve percent of GPs declared they know the "sleep diary". Homeopathic treatment was the most prescribed first line medication (45.3%). Sleep hygiene measures were commonly recommended by 82.7% of the GPs. Relaxation therapy was known by 46.7% of the GPs and used by 26.7%. Sleep-restriction therapy was known and used by respectively 15.8% and 9.2% of participants. Discussing the quality of sleep with patients was correlated to: the frequency of solicitation for insomnia ($P=0.00$), the knowledge of sleep diary ($P=0.031$), and the recommendation of sleep hygiene measures ($P=0.032$).

Conclusion Continuous medical education, especially concerning non-pharmacological treatment measures, could drastically improve the management of insomnia by Tunisian GPs.

Emotion processing abnormalities in eating disorders: An fMRI pilot study

P. Zemánková^{1,2,*}, M. Gajdoš³, T. Kašpárek¹, M. Bareš⁴¹ Masaryk University, Faculty of Medicine, Department of Psychiatry, Brno, Czech Republic² Central European Institute of Technology, Behavioural and Social Neuroscience, Brno, Czech Republic³ Central European Institute of Technology, Multimodal and Functional Imaging Laboratory, Brno, Czech Republic⁴ Masaryk University, Faculty of Medicine, First Department of Neurology, Brno, Czech Republic

* Corresponding author.

Introduction Abnormalities in emotional functioning is one of the key features of eating disorders (ED), such as anorexia nervosa (AN)

and bulimia nervosa (BN). These patients show increased levels of alexithymia, problems understanding one's own emotion, which has been simultaneously, associated with difficulties in recognizing others emotions.

Objectives In this study, we were interested in the neuronal mechanism of emotion processing from both, self and others perspective, and we aimed to compare the underlying brain activations in eating disorder patients and healthy controls.

Methods A sample of 12 women with ED (10 AN, 2 BN) and 11 age and education matched healthy controls (HC) underwent fMRI examination while performing emotion recognition task, which requires either inferring mental states of depicted figures, or assessing participant's own feelings evoked by the pictures.

Results The task activated superior temporal sulcus bilaterally, left temporo-parietal junction, and medial prefrontal cortex. Those regions have been consistently identified in literature to be active while thinking about other people. Interestingly, group differences analysis revealed that ED patients group showed higher activations in right supramarginal gyrus, compared to HC group. This structure is critical to overcome egocentricity bias in social judgment. Contrary to ED patients, HC group showed greater activations in cingulate gyrus and insula, regions involved in emotion formation and processing.

Conclusion We hypothesize that ED patients tend to suppress their own perspective while thinking about emotional states of others more strongly than HC, probably due to alexithymia and the lack of awareness of their mental states.

e-Poster Walk: Suicidology and suicide prevention – part 1

EW0541

A systematic review of suicide prevention strategies

K. Aini

Widya Husada School of Health Sciences, Nursing, Semarang, Indonesia

Background Suicide is one of the serious problems, which become ten causes of death in the world. An increased risk of suicide groups stimulates researchers to undertake the development of suicide prevention efforts with various approaches.

Objectives To examine evidence of suicide preventive interventions and to make recommendation for the further programs and research.

Methods Fifteen identified systematic review articles were taken through an electronic search of the Cochrane library, McMaster health forum, Google Scholar, PubMed, and Suicidology online. They have been published between March 2008 until January 2015, using the keyword "suicide", "self-harm", "suicide prevention", and "systematic review". Criteria of this review include the type of intervention, intervention category, group intervention and intervention effectiveness.

Results The intervention was performed using a strategy of promotion, prevention, treatment, and rehabilitation of the target group of teenagers, sexual perversion, suicide risk groups, such as drug abuse, mental illness patients, a group of health workers and the general public. Effectiveness of therapy has different effects and requires a combination of an intervention strategy with other interventions to obtain optimal results.

Conclusion The strategies of suicide prevention which were identified by various intervention approaches given to the large population require more stringent controls and difficulty in performing evaluation. Furthermore, pharmacological and psychological therapies are recommended to reduce the suicide rate in more specific setting such as a hospital or mental health clinic.

Keywords Review; Suicide prevention; Intervention; And the results of intervention

Anxiety, depression and suicidal behavior among medical students from the university of Valladolid

A. Alvarez Astorga^{1,*}, M.H. De la Red Gallego¹, A. Alonso Sánchez¹, S. De la Fuente Ballesteros², T. Delgado Santillana², R. Hernandez Anton¹, M. Gómez García¹, M.M. De Lorenzo Calzón¹, E. Mayor Toranzo¹, J.A. Blanco Garrote¹

¹ HCU Valladolid, psychiatry, Valladolid, Spain

² University of Valladolid, Psychiatry, Valladolid, Spain

* Corresponding author.

Introduction Suicide is a major public health problem, especially in young people. It is one of the most significant causes of mortality and potential years of life lost. Medical students are a vulnerable group presenting mental health problems.

Objectives To study the prevalence of common mental illnesses among medical students from the university of Valladolid in order to assess the need for intervention programs.

Methods Cross-sectional study in which, 584 students participated during the academic year 2015–2016 by completing an online self-administered questionnaire. Mental health outcomes were measured by different batteries of depression, anxiety and suicide (BDI, GAD-7 and MINI). Information about possible related risk factors was also obtained. Statistical Chi² and Student *t*-tests were applied to estimate associations between socio-demographic, socioeconomic data and clinical results.

Results We found a prevalence of 15.8% for depression, 11.6% for ideation suicide and 38.5% for anxiety, with gender differences in the latter case. Prevalence rates were higher than those described in general population. Compared to other international studies, prevalence estimates were also higher among our sample.

Conclusions This study shows for the first time data of these three psychiatric disorders among medical students in Spain. It suggests the urge to implementing preventive activities to alleviate maladaptive behaviors, academic stress, improve the quality of life and adaptation of students to college life. Larger, prospective, multi-centre studies are needed to draw conclusions about the causes and consequences of students' stress, since evidence shows that mental health problems are perpetuated throughout professional performance.

Risk of suicide mortality among cancer patients: A meta-analysis of observational studies

R. Calati^{1,*}, V. Di Mattei², P. Courtet³

¹ Inserm U 1061, Neuropsychiatry: Epidemiological and Clinical Research, Montpellier, France

² Vita-Salute San Raffaele University, Clinical and Health Psychology Unit, IRCCS San Raffaele Hospital, Milan, Italy

³ *Inserm U1061, University of Montpellier UM1, Department of Emergency Psychiatry & Acute Care, Lapeyronie Hospital, CHU de Montpellier, Montpellier, France*

* *Corresponding author.*

Introduction Suicide rates among patients with cancer are higher than ones in the general population.

Objective This meta-analysis aims to estimate the suicide risk in patients with cancer.

Methods We searched Medline, PsycINFO, and the Cochrane library to identify articles published before July 1, 2016, examining the association between suicide [death (SD), attempt (SA), ideation (SI)] and any form of diagnosed cancer.

Results We initially identified 4880 records and after unsuitable studies were removed, our search yielded 102 publications of which 14 were used in the meta-analyses. Patients with cancer had higher risk of SD (seven studies, 247.869 participants; odds ratio [OR]=1.52, 95% CI=1.22–1.89, $P=0.0002$) compared with those without cancer (among case-control studies focused on SD versus living controls). Among studies focused on SD versus other deaths, patients with cancer had higher risk of SD (two studies, 23.839 participants; OR=1.53, 95% CI=1.03–2.27, $P=0.03$). No difference has been detected for risk of SA (four studies, 8.147.762 participants) and for SI (two studies, 37.879 participants).

Since publication bias was detected, the “trim and fill” method was applied. The majority of the included studies have a high quality at the STROBE statement.

Conclusion The assessment of suicide risk in this population is crucial.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW0544

Profile socio-demographic and clinical of suicide victims in Brusque County, Santa Catarina, Brazil, between 2012 and 2015

M. Cigognini

Setting Clinic, NUPE, Blumenau, Brazil

Introduction Among the main causes of mortality in the world stands out approximately 1 million deaths due to suicide. In Brazil, this is the third cause of death due to external factors, being 5.3 the average rate per 100,000 inhabitants. The state of Santa Catarina ranks second in the national ranking with an index of 8.6. According to WHO, it is necessary to detect probable suicide risk factors once information can prevent deaths.

Aim Identify socio-demographic and clinical profile of suicide victims in Brusque County, State of Santa Catarina, Brazil, between 2012 and 2015.

Methods Observational, descriptive and quantitative study, with analysis of 60 police investigations with suicide records, occurred from January 2012 to December 2015, in Brusque County.

Results The suicide was 15.29 per 100,000 inhabitants. The victims had an average age of 46.51, and ± 2.12 (SD). Among them, 67.5% suffered from depression and 88% received pharmacological treatment. Regarding marital status, 59% were married or living in a stable union. Men accounted for 78% of the sample. Death by hanging occurred in 65% of cases and 22% previous attempts were recorded, and in 15%, it was mentioned suicidal intent. Among the reasons for the act, it was highlighted family member's death. Given the underreporting, such data may be even more significant.

Conclusions The observed rates were significantly higher than the state and national rates. Prevention strategies can be focused on early diagnosis and treatment of depression in middle-aged men, and who had recent loss of a family member.

EW0545

Victimization in childhood as a suicide risk factor in adults

G. Dedic

Faculty of Medicine Military Medical Academy, Clinic for psychiatry, New Belgrade, Serbia

Objective Little is known about the predictive association between victimization among children and adolescents with depression and suicidal ideation in adults. The aim of our study was to examine whether victimization in childhood and early adolescence increases the likelihood of self-harming in adults.

Method The sample consisted of 82 patients, 65 females and 17 males, aged 38.02 ± 11.05 years on average, hospitalized in Daily hospital. The juvenile victimization questionnaire (JVQ), defense style questionnaire (DSQ) and Beck depression inventory were applied in 48 patients following suicide attempt and in 34 patients who were on psychotherapeutic treatment due to various life crises not resulting in suicide attempt. According to indication, we excluded patients with psychosis, substances abuse and dementia. The examinees of both groups were matched by age, education, professional and marital status. Comparison of the patient groups was done by *t*-test.

Results The suicide attempters were depressed (Beck depression inventory 19.13 ± 10.20), using immature defense mechanisms ($P < 0.005$). The JVQ established statistically differences in two general areas: Peer and Sibling Victimization ($P < 0.001$) and sexual victimization ($P < 0.05$).

Conclusion Even after controlling for lifetime factors known to increase the risk of suicidal behavior, adults who reported peer and sibling and sexual victimization in childhood were still more likely than other adults to attempt suicide later in life. Psychotherapists must understand that history of childhood victimization is important to put suicide attempt in a psychodynamic context which can help them in their work with patients' psychotherapeutic crisis intervention following suicide attempt.

Decision making under ambiguity and under risk in depressed suicide attempters, depressed non-attempters and healthy controls

E.A. Deisenhammer^{1,*}, S.K. Schmid¹, G. Kemmler¹, B. Moser¹, M. Delazer²

¹ *Medical University of Innsbruck, Psychiatry, Innsbruck, Austria*

² *Medical University of Innsbruck, Neurology, Innsbruck, Austria*

* *Corresponding author.*

Introduction Study results on decision-making (DM) abilities in suicidal individuals are conflicting. Most studies have focused on DM under ambiguity and included patients with a lifetime history of suicide attempts.

Objective To assess DM abilities with two different instruments in recent suicide attempters.

Methods The study sample consisted of three groups. Group 1 (SA) were currently depressed inpatients having attempted suicide within the previous six months. Group 2 (NSA) consisted of depressed inpatients without a lifetime history of suicide attempts. Group 3 (CG) was a healthy control group. Besides depression severity, impulsiveness and suicidal intent (SA group only) DM was

assessed using the Iowa gambling task (IGT) for DM under ambiguity and the game of dice task (GDT) for DM under risk.

Results A total of 78 participants (SA group, $n = 21$; NSA group, $n = 31$; CG, $n = 26$) were included into the study. Significant between group differences were found regarding marital status, current partnership, smoking status, depression score, impulsiveness score and family history of psychiatric disorders (all discriminating controls from patients but not between SA and NSA groups). The three groups did not differ with regard to IGT scores. Concerning GDT, the SA group showed significantly lower scores compared to the two other groups, implying a readiness for more risky decisions in suicide attempters versus non-attempters and controls.

Conclusion Suicide attempters appear to make more risky decisions compared to depressed non-attempters as well as healthy controls even if the DM under ambiguity patterns do not differ.

Disclosure of interest The authors have not supplied their declaration of competing interest.

In-patient and post-discharge suicides in Tyrol 2004–2011

E.A. Deisenhammer^{1,*}, E.M. Behrndt¹, G. Kemmler¹, C. Haring², C. Miller³

¹ Medical University of Innsbruck, Psychiatry, Innsbruck, Austria

² State Hospital Hall, Austria, Psychiatry, Hall, Austria

³ Hospital Kufstein, Psychiatry, Kufstein, Austria

* Corresponding author.

Introduction Psychiatric patients constitute a high-risk population for suicide. In-patient status and the period after discharge are of particular interest concerning risk assessment.

Objective To assess risk factors for in-patient and post-discharge suicides.

Methods The Tyrol suicide register was linked with the registers of three psychiatric departments/hospitals of the region. Suicides were categorized according to whether the suicide was committed during a hospital stay or within 12 weeks after discharge or whether the suicide subject had not recently been hospitalized. Groups were compared with regard to demographic and clinical variables. Further, case-control comparisons were performed for the in-patient and post-discharge groups.

Results During the study period (2004–2011) 30 in-patients, 89 post-discharge and 592 not recently hospitalized suicides were identified. Groups differed in terms of gender distribution, history of suicide attempts, warning signals and suicide methods. Compared with controls matched for a number of variables, in-patient suicides were significantly more suicidal and depressed at admission, reported more often a recent life event and showed less often aggressive behavior and plans for the future. Post-discharge suicides had more often a history of attempted suicide, depressive and thought disorder symptomatology, a ward change and an unplanned discharge and less often a scheduled appointment with a non-psychiatric physician.

Conclusions Suicide victims differ with regard to whether they die during, shortly after or not associated with a hospitalization. Compared to controls there are specific risk factors for those who commit suicide during a hospital stay and within 12 weeks after discharge.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW0548

A descriptive analysis of psychological factors and childhood trauma in a sample of suicide attempters

C. Delicato^{1,*}, E. Gattoni¹, S. Di Marco¹, A. Venesia¹, C. Vecchi¹, F. Bert², P. Zeppegno¹, C. Gramaglia¹

¹ Università degli Studi del Piemonte Orientale “A. Avogadro”, Translational Medicine, Novara, Italy

² Università degli Studi di Torino, Public Health, Torino, Italy

* Corresponding author.

Introduction Childhood trauma, especially sexual abuse, is associated with an increased risk of suicidal behavior. However, studies also show that according to the stress-vulnerability model, not all individual exposed to this kind of trauma exhibit suicidal behaviors as some protective factors could diminish the aforementioned risk, such as personality factors. Resilience might be one such a protective factor. Furthermore, there has been growing evidence to support the role of impulsive and aggressive behavior in the risk of suicide.

Objectives To compare suicide attempters to non-suicide attempters (patients admitted for any other reason) for as far as psychological features and childhood trauma. To verify the role of resilience and coping strategies as protective factor for suicide attempt, mitigating the risk of an individual who has experienced childhood trauma.

Methods We recruited patients referred to the inpatient and outpatient facilities of psychiatry ward of “Maggiore della Carità” hospital in Novara during the period November 2015–December 2016. We included all patients from 18 to 65 years with a psychiatric disorder that met DSM–5 diagnostic criteria. For the analysis, we divided patients into two subgroups according to the presence/absence of suicidal behaviors. The assessment included: Resilience Scale for Adult (RSA), Brief cope, Rosenberg Self-esteem Scale (RSES), childhood trauma questionnaire (CTQ), temperament and character inventory (TCI).

Results and discussion Although, the recruitment is still ongoing preliminary results seem to confirm the role of resilience and coping strategies as protective factor mitigating the risk of an individual who has experienced childhood trauma from making a suicide attempt.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Risk evaluation in the emergency department: An algorithm for suicide prevention

T. Duarte*, C. Ferreira, N. Santos, D. Sampaio
Centro Hospitalar Lisboa Norte, Hospital de Santa Maria, Núcleo de Estudos de Suicídio N.E.S. do Serviço de Psiquiatria e Saúde Mental, Lisboa, Portugal

* Corresponding author.

Introduction Suicide is one of the biggest challenges that psychiatrists face, especially in the emergency room. According to the World Health Organization, there are approximately 3000 suicides every day: one every 40 seconds. About half of all violent deaths in the world are suicides with economic costs of billions of euros. The risk assessment is still based on a subjective approach, with no screening or evaluation tools that support the decision about in-hospital or ambulatory treatment for these patients.

Objectives Creation of a decision tree algorithm that can be used in the emergency room to guide the clinical decision.

Aims Increase the number of avoided suicides.

Methods PubMed database was searched and articles with the words “emergency”, “suicide”, “attempt” “screening” and “preven-

tion” were included. Articles that used the most reliable and valid measurement tools (i.e., Beck Scale for Suicide Ideation and Suicide Probability Scale) for patient evaluation were selected. World Health Organization guidelines and the Portuguese Suicide Prevention Plan were analyzed and an algorithm was designed based on the major risk factors identified.

Results No isolated risk factor was successful for preventing suicide: most are chronic and non-individualized. Having family history of suicide, a mental health disease, a suicide plan and previous suicide attempts are considered major risk factors. The algorithm is based on these factors and takes into account inter-personal variability.

Conclusions The best way to prevent a suicide is to ask patients for major risk factors, and then, by using this algorithm, treat them accordingly.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Acute psychiatric involuntary admissions in a general hospital after suicidal behavior. A 2-year follow-up

J.J. Fernandez Miranda*, D.F. Frias Ortiz, S. Fernandez Diaz
AGC SM-V-SESPA, Asturian Mental Health Service, Psychiatry and Mental Health, Gijón, Spain

* Corresponding author.

Introduction Patients with a plan, access to lethal means, recent social stressors and symptoms suggestive of a psychiatric disorder should be hospitalized immediately. Sometimes involuntary hospital admission is used to avoid a suicidal behavior, taking into account that after a suicide attempt 25% of people repeat attempt and 10% die by suicide.

Objectives/aims To know hospital admission due to suicide attempts, and how many of them were involuntary.

Method A 2-year retrospective study (2014–2015) of all cases admitted after suicidal behavior in an acute psychiatric ward in a general hospital in Gijón (Spain). Reasons for hospital admission were registered, including suicide attempts. And also if admissions were involuntary.

Results The total number of admissions to the psychiatric unit in 2014–2015 was 2376. Admissions due to suicide attempts were 427; 300 of them were involuntary admissions. There were a total of 347 involuntary admissions these two years; among them, due to suicide attempt: 300.

Conclusions Most of involuntary admissions in the psychiatric unit of the hospital studied followed a suicide attempt, as a prevention of repeated suicidal behavior. Obvious high risk of repeat suicide attempt generates an urgency to make an accurate assessment and create a safe treatment plan and determine to retain suicidal patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Mental illness and mental health care as experienced by persons who die by suicide; a qualitative analysis of suicide notes

Z. Furqan^{1,*}, J. Zaheer², M. Sinyor³, A. Schaffer³

¹ University of Toronto, Department of Psychiatry, Toronto, Canada

² Centre for Addiction and Mental Health, Health Outcomes and Performance Evaluation HOPE Research Unit, Institute for Mental Health Policy Research, Toronto, Canada

³ Sunnybrook Health Sciences Centre, Psychiatry, Toronto, Canada

* Corresponding author.

While mental illness is a risk factor for suicidal behaviour and many suicide victims receive mental health care prior to death, there is a comparative lack of research that explores their narratives of care. Suicide notes offer unique insight into these subjective experiences. Our study explores the following questions: “How is mental health care experienced by those who die by suicide?” and “What role does this experience play in an individual’s journey to suicide?” Our sample is a set of 21 purposefully selected notes that explicitly make mention of mental illness and/or mental health care, from a larger sample of 255 notes obtained through the Toronto Coroner’s Office. We utilized a constructivist grounded theory framework to engage in line-by-line open coding, axial coding, memo-ing and theorizing of the data. Preliminary themes include (1) perception of recurrent utilization of mental health care as personal failure, (2) recurrent utilization of mental health care as a manifestation of accumulating hopelessness, (3) the construction of suicide as being beyond the scope of mental health care, (4) tensions between the conceptualization of mental illness as an inherent part of the self and mental illness as a disease to be fought or overcome, and (5) suicide as an exertion of self-autonomy, distinct from the influence of mental illness. An exploration of the complexity of an individual’s relationship with mental illness and mental health care can foster better identification, understanding and support for those at risk for suicide.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Understanding the role of bereavement in the pathway to suicide

K. Galway^{1,*}, S. Mallon², G. Leavey³, J. Rondon-Sulbaran⁴

¹ Queen’s University Belfast, Centre for Evidence and Social Innovation, Belfast, United Kingdom

² Open University, Health Sciences, Milton Keynes, United Kingdom

³ Ulster University, Bamford Centre for Mental Health and Wellbeing, Londonderry, United Kingdom

⁴ Ulster University, Health Sciences, Belfast, United Kingdom

* Corresponding author.

Introduction Bereavement is considered to be a common precursor of death by suicide. Studies suggest those bereaved by suicide may be particularly vulnerable to suicide themselves. Recently, there has been a concern over the number of deaths by suicide across UK and Europe. As a result, an increasing number have been exposed to bereavement by suicide. It remains unclear how these deaths might impact on future suicide rates.

Objectives To examine a two-year cohort of all suicides in Northern Ireland, in order to report on bereavements recorded in the records of those who died by suicide. To assess the bearing of these deaths on those left behind.

Aims To provide an estimate of the prevalence and types of bereavements that may have contributed towards the suicide.

Methods Following the sociological autopsy approach to studying death by suicide, data was collected from a range of sources, including GP records and Coroner records and interviews with bereaved relatives. The analyses draw on relatives’ accounts in order to increase our understanding of the impact of suicide bereavement. Interviews took place between 18 months and 5 years after the death by suicide.

Results Of the 403 deaths by suicide, 15% of the individuals experienced bereavement and 9% bereavement by suicide. The results support the assertion in the literature that bereavement by suicide increases the risk of suicide through a process of suicide contagion.

Conclusions The conclusion explains how the findings will be fed into knowledge translation processes, to provide future programs of suicide prevention research and changes to practice.

Socio-demographic and clinical features of patients referred to emergency room psychiatric consultation between 2006 and 2015. A comparison between migrants and natives

E. Gambaro^{1,*}, C. Vecchi¹, C. Gramaglia¹, F. Bert², C. Delicato¹, G. Avanzi³, L.M. Castello³, P. Zeppego⁴

¹ University of Piemonte Orientale, Department of Translational Medicine, Novara, Italy

⁴ University of Piemonte Orientale, SC Psichiatria, Department of Translational Medicine-AOU Maggiore della Carità di Novara Novara, Italy

* Corresponding author.

In recent decades, Italy has become a desirable destination for immigrants. It should be noted that the organization of mental health services in Italy strongly relies on outpatient services, while the psychiatric wards usually accommodate patients in acute phases of their disorder. Nonetheless, migrants' first contact often happen in a psychiatry ward when they are in a severe and acute psychopathological condition. The research was performed in the Emergency Department (ED) of the Maggiore della Carità Hospital, Novara, Italy. We collected data about 3781 consecutive patients, 3247 Italian natives and 421 migrants, assessed in the ER of the Maggiore della Carità Hospital, and referred to psychiatric assessment after ER triage. From 1st January 2006 to 31st December 2007, only data for migrant patients were available. From 1st January 2008 to 31st December 2015, data were available for all consecutive patients assessed in the ER. An experienced psychiatrist assessed patients with a clinical interview, including the assessment of suicidal intent, suicidal behaviors and attempts. The psychiatrist filled in for each patient a data sheet, reporting demographic data and clinical features. The high frequency of substance use disorders was higher in the migrant population than in the native one. The request for psychiatric consultation for self-injury behaviors was more frequent in migrants and also suicide attempts were more common. Nonetheless, being a migrant was not a predictor of suicide attempt in our sample.

Several differences were found between migrants and natives in socio-demographic, clinical and treatment variables. Clinical implications will be discussed.

Clinical features of ADHD: An assessment of suicide risk and substance abuse

G. Giordano*, G. Falcone, A. Nardella, D. Erbuto, M. Migliorati, M. Innamorati, P. Girardi, M. Pompili

S. Andrea Hospital, NESMOS Department Neurosciences, Mental Health, and Sensory Organs, Sapienza University of Rome, School of Medicine and Psychology, Rome, Italy

* Corresponding author.

Introduction Several studies show that attention-deficit/hyperactivity disorder (ADHD) may persist into adulthood, increasing the risk of antisocial behaviour, drug abuse, psychiatric comorbidities, aggressive behaviour, social impairment and suicide risk.

Objectives Analyze correlations among ADHD, substances abuse, alcoholism and suicide risk.

Aim The aim of our study is to better understand the clinical features of ADHD during adulthood.

Methods We analyzed the presence of ADHD symptoms, suicide risk and levels of hopelessness, alcoholism and substance abuse in a sample of 50 (40% males) in/outpatients of S. Andrea Hospital in Rome, between February and May 2016. We administered the following scales: Adult-Self Report Scale (ASRS), Columbia Suicide Severity Rating Scale (C-SSRS), Beck Hopelessness Scale (BHS), Michigan Alcoholism Screening Test (MAST), Drug Abuse Screening Test (DAST).

Results In our sample of 50 adult patients, 20% had ADHD symptoms (10 subjects). We found that those with ADHD showed more frequently death desires (85.7%; $\chi^2 = 1.31$; $P = 0.25$) and higher levels of hopelessness (66.7%; $\chi^2 = 0.83$; $P = 0.36$) if compared to subjects without ADHD symptoms (respectively 63% and 45.8%). In the overall group of ADHD patients, 10% showed severe alcoholism, 20% ($\chi^2 = 1.39$; $P = 0.49$) had a borderline behavior, whereas 40% presented a substance abuse ($\chi^2 = 1.75$; $P = 0.18$).

Conclusions ADHD may represent a psychiatric disorder with an increased suicide risk. It would be important to screen for suicidality and comorbid symptoms routinely in ADHD in order to improve the treatment of the patients.

Impulsivity as a risk factor for suicidality in depressed patients

M. Hambrich*, B. Nemes, R. Soare, D. Cozman
Iuliu Hatieganu University of Medicine and Pharmacy, Medical Psychology, Cluj-Napoca, Romania

* Corresponding author.

Introduction Suicide behavior is an important and preventable cause of injury, disability and death in the world, and, at the same time, a major economic and social burden for modern societies. The majority of suicide attempts and completions are associated with psychiatric disorders, especially major depressive episode. Impulsivity has been associated with suicidality in major depressive disorder patients.

Aim The current study aims to evaluate impulsivity in major depressive disorder patients with a history of suicide attempts as compared to major depressive disorder patients without a history of suicide attempts.

Methods One hundred and twelve patients with major depressive disorder, aged 51.91 ± 10.72 (70% females) were included through convenient sampling procedure from the patient population of the 3rd Psychiatry Clinic of the Cluj County Emergency Hospital. Impulsivity was assessed through Barratt Impulsiveness Scale (BIS-11).

Results In total, 27.8% of the patients had a history of suicide attempts. Significant differences between the two groups were obtained only for the Perseverance subscale of the BIS-11. (12.7 ± 1.8 vs. 7.13 ± 2.1 , $P = 0.005$ –Mann Whitney U-test).

Conclusions Perseverance might be a discriminating element between patients that eventually commit a suicide attempt and those that do not.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Is there a case for using social outcomes in self-harm research?

P. Huxley^{1,*}, N. Ahmed²

¹ Bangor University, Centre for Mental Health & Society, Bangor, United Kingdom

² Swansea university, Health Science, Swansea, United Kingdom

* Corresponding author.

Introduction Self-harm is costly to individuals and health services and has high associated risks of further self-harm and completed suicide. Self-harm presentations to hospitals offer an opportunity to engage patients in interventions to help reduce future episodes and associated costs. This presentation reviews clinical trials for self-harm interventions conducted over the past twenty years in hospital emergency departments (1996–2016) comparing successful vs. unsuccessful trials (defined by the whole or partial achievement of trial defined outcomes) in terms of methodology, type of intervention and type of outcome measure.

Method Databases were searched using defined keywords. Randomized trials of adult subjects presenting to emergency departments were selected.

Results Twenty-four studies are included in the review. There was no significant difference between the type of intervention and “success”, nor were there index/control differences by sample size and follow-up length. Most trials (79%) used re-admission to hospital after a further episode as the primary outcome; only 4 (16%) of the studies reported social outcomes. As an example of social interventions and outcomes, we discuss trial results of a new social intervention for adults (many of whom do not receive a (UK-mandated) psychosocial assessment), and who are usually provided with little/no support after leaving the emergency room.

Discussion The findings suggest that the use of repetition and representation as outcome indicators may be missing the importance of social precipitants of self-harm and the need to assess social circumstances, interventions and outcomes. We discuss findings from a new social intervention trial, which addresses these limitations.

The spatial pattern of suicides in Europe

S. Kandrychyn^{1,*}, R. Yury²

¹ Republican Clinical Medical Centre, Cardiology, Minsk, Belarus

² Grodno State Medical University, Pathological Physiology, Grodno, Belarus

* Corresponding author.

Introduction The regularity in suicide rates in Europe was one of the essential challenges facing social scholars at the end of XIX century.

Aims The present study aims to assess the continuation of this phenomenon in XXI century.

Methods To explore this phenomenon, suicide rates were obtained from WHO official publications for 1990, 2000, 2010 and 2012 across 41 European nations. In order to examine the regularity of spatial suicide pattern, the data sets were subjected to Spearman's rank order correlation analysis.

Results The suicide rates rank order distribution between European nations in 1990 was associated with suicide rates in 2000, 2010 and 2012 ($r_s = .91, .81, \text{ and } .80$, respectively, $P < .001$). The national suicide death indices show the significant positive correlation over the studied period, what means the definite regularity of suicide mortality pattern and absence of essential changes or fluctuations between the regions. The highest indices have the countries situated on the Northern and Eastern part of the European continent (Lithuania, Russia, Belarus and Hungary). On the opposite pole are the nations settled the Mediterranean and British islands. Thus, the fixed gradient in suicide distribution with the growing to the north and northeast of European continent is visible. The same stable vector in suicide spatial distribution is duplicated on the vast territories on the east part of Europe.

Conclusions The data presented support the idea that spatial regularity in suicide distribution in Europe is not generally connected with social and cultural changes occurred during the centuries.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EW0558

Educational programme in primary care is the basic way of decreasing suicides

N. Kornetov

Siberian State Medical University, Psychiatry, Addiction and Psychotherapy, Tomsk, Russia

Introduction The depressive disorder (DD) is a widespread disease described to be a severe burden and to have high suicide risk. Depression is not yet listed in the primary care (PC), Russian specific educational program.

Objectives To create educational Recognition of Depressive disorders Program (REDEP) in order to decrease suicides in Tomsk City and Tomsk Area (TA).

Methods Educational Program WPA/PTD on DD (Russian version) was used as a basis of REDEP, comparative analysis of mortality ratio of suicides (MRS) throughout the period of 2004–2015 among the population of the Russian Federation (RF), Siberian Federal Region (SFR) and TA, analysis of suicide decrease in Tomsk City. The Program is based on ideas of collaboration between the Primary Medical Care institutions and the Service of Mental Health Care. Depression and its consequences on people and the economy should be listed as a non-infectious illness.

Results We conducted a comparative analysis of suicides in RF, SFR and TA; we also assessed the dynamics of suicides reduction in TA under the influence of educational program on DD. The most prominent MRS decline was in TA: from 38.3 to 12.8 ($P < 0.03$). During 2008–2015, MRS was being held below 10/100,000 in Tomsk City.

Conclusions Suicide prevention is possible if persistent and continual education of doctors in PC is in place. Such specialists are needed to recognize and manage depression and co-morbid conditions. The Program can be extrapolated to other regions of the country with high MRS.

Psychiatric ward consumption before suicide: A case-control study

T. Sellin^{1,*}, F. Hölländare¹, M. Tillfors²

¹ University Health Care Research Center, Faculty of Medicine and Health, Örebro, Sweden

² Center for Health and Medical Psychology, JPS, Psychology, Örebro University, Örebro, Sweden

* Corresponding author.

Introduction There is a need of identifying predictors of suicide. With effective treatment interventions for those at highest risk, suicide can be prevented.

Aim To investigate variables possibly associated with suicide, by comparing patients in psychiatry deceased by suicide to matched controls. We compared the psychiatric ward consumption two years prior to suicide, previous medical and psychological treatments, somatic co-morbidity and the professions of health care staff in previous visits.

Method The 153 suicide cases, 101 (66%) men and 52 (34%) women, aged between 13 and 96 years, were identified from the National Cause of death registry. All cases had previous contact in psychiatry in Örebro County and died between January 1st 2007 through December 31st 2013. Each case had one gender-, age- and diagnosis matched patient control from psychiatry. Data on care usage were collected from medical records. Correlations were calculated between ward variables and the outcome variable suicide yes/no. Variables significantly correlated to suicide were used in an adjusted logistic regression model to analyse possible associations with suicide.

Results Among the cases deceased by suicide, we found significantly fewer psychiatric outpatient visits ($P < .01$), a smaller amount receiving systematic psychological treatment ($P < .01$), less pharmacological interventions ($P < .01$) and a smaller amount of treatment provided by a multi-professional team ($P < .01$). Less occurrence of psychological treatment (OR(adj): 0.459; 95% CI 0.224–0.874, $P < .05$) was significantly associated to suicide.

Conclusions Results indicate that not only repeated visits in psychiatric care, but the content of visits (i.e. psychological interventions) seems to make an important difference between life and death.

Quality improvement project: Mentoring, career advice and placement introduction session for year 5 imperial college medical students. Should induction go beyond facts and numbers?

O. Agalioti*, S. Nayrouz

West London Mental Health NHS Trust, Psychiatry, London, United Kingdom

* Corresponding author.

Introduction Feedback received from previous rotations of year 5 Imperial College medical students in West London Mental Health NHS Trust has consistently shown that medical students feel uncertain about what to expect in their psychiatric placements and are sceptical about psychiatry as a future career option. This prevents them from maximizing the educational benefit and potential in their training.

Aims and objectives Tutorial aims to prepare medical students for their psychiatric placements and create the opportunity for informal discussion about psychiatry as future career option. The session aspires to motivate students to be more involved and active partic-

ipants and invite them to think about their future career option at an early stage.

Methodology A 1-hour tutorial has been added to medical students' induction in two successive rotations (July–October 2016). Thirty-seven (37) medical students have attended the tutorial so far. Tutorial provides information about psychiatric placements, learning opportunities as well as structural and operational issues. Besides, it encourages discussions about psychiatry as a future career option, informing students about psychiatric sub-specialties, career pathways and NHS operational structure. Feedback questionnaire is handed over at the end.

Results Data were collected and analysed and findings are outlined in the diagram below (Fig. 1).

Conclusions and recommendation The majority of medical students have feedback they found tutorial relevant and useful. Current tutorial formula will be revised based on feedback collated so far.

Findings are going to be shared with local Undergraduate Educational Committee and Imperial College medical school board.

Fig. 1 Imperial College medical students' feedback.

Workplace assessment in crisis? – The way forward

H. Al-Taiar

MRCPsych–SFHEA, Forensic Psychiatry, Oxford, United Kingdom

Introduction A recent Royal College of Physicians' (RCP) study on assessment raises serious questions for workplace assessment. To address these, a system that bridges the gap from competence to performance and integrates supervised learning events (SLEs) that are formative in purpose with summative assessment of performance by entrustable professional activities (EPAs) is recommended.

Aims and objectives As a working group on assessment in psychiatry, we were interested in the RCP findings which represent a significant milestone in studies of workplace assessment. The RCP aims were to evaluate the feasibility, validity and educational value of using existing WPBA tools but for different assessment purposes and processes.

Results These were based on the General Medical Council (GMC) working party on assessment. The RCP revised its assessment processes to differentiate between assessments of development and performance. The former are formative and aim to identify a trainee's areas of strength and development; the latter are summative and aim to determine fitness to progress. Of note is that the same workplace based assessment (WPBA) tool can be used for each type of assessment; the assessment's purpose is the discriminating factor.

Conclusions Initial design of the requisite EPAs requires value judgments by trainers and trainees alike on what represent core units of work. EPAs can contribute directly and more meaningfully to ARCP progression decisions.

Recommendations Inclusion of the required level of supervision as part of SLE feedback enables future decisions on meeting performance standards.

Trainee/trainer Interaction in this educational process.

Developing a specialised debrief model for simulation training in psychiatry

C. Attoe*, L. Valdearenas, S. Cross

South London & Maudsley NHS Foundation Trust, Maudsley

Simulation, London, United Kingdom

* Corresponding author.

Introduction High fidelity simulation training has a rich history in medical education. However, simulation as an education tool in psychiatry has been underused and neglected. More recently, clinical educators have begun to harness the potential of simulation in psychiatry, with increased usage at under- and postgraduate levels. An essential element of simulation training is the debrief that takes place with participants and observers following simulated scenarios. Current practices in simulation for psychiatry often rely on debrief models primarily designed for non-psychiatry training.

Aims and objectives This project aimed to develop a specialised debrief model for simulation training in psychiatry.

Methods The research team undertook a thorough literature search to identify existing approaches to simulation debriefing, and key theoretical constructs. Clinical educators from psychiatry and non-psychiatry disciplines were invited to attend focus groups to explore the use and key elements of structured and reflective debriefs in simulation. Focus groups were transcribed and analysed using thematic analyses.

Results Literature searching identified various debrief models that have been used in psychiatry and non-psychiatry disciplines. Pertinent educational theory was highlighted, such as experiential learning and adult learning. Focus groups highlighted adaptations required to tailor a debrief model to simulation in psychiatry, such as the containing of emotions and use of didactic sessions.

Conclusions Findings identified key differences between debriefing simulated scenarios in psychiatry compared to non-psychiatry. These findings have been used to develop a preliminary debrief model for simulation in psychiatry.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁵ Queen Mary University of London, Unit for Social and Community Psychiatry, London, United Kingdom

* Corresponding author.

Introduction Burnout syndrome is defined by three domains: emotional exhaustion, cynicism and reduced professional efficacy. Junior doctors have a high susceptibility to burnout reflected in the high prevalence identified in previous work. This is a significant issue as burnout has measurable effects on work performance. There has been limited research conducted on burnout in psychiatry trainees in the United Kingdom.

Aim This paper takes a step towards addressing this gap by extracting the data concerning UK psychiatric trainees collected in the international burnout syndrome study (BoSS), which aimed to assess the prevalence and contributing factors of burnout among psychiatric trainees from over 20 countries, and presenting the findings concerning UK trainees.

Method Data collected included demographic data and information related to working hours, bullying, harassment and stalking, supervision, suicidal ideation, depression (PHQ-9), and a personality trait assessment. Burnout syndrome was measured using the Maslach burnout inventory (MBI-GS). A total of 3964 psychiatry trainees in the UK were invited, of which 1187 (30%) responded including 811 (20%) providing complete responses for MBI-GS.

Results The mean age was 33 years, and 49.1% of respondents were male. Gender distribution of participants was the same as non-participants. Mean scores were 2.6 for exhaustion, 2.1 for cynicism and 4.5 for professional efficacy; and severe burnout was found in 309 (38%).

Conclusion Three factors were positively associated with severe burnout: long working hours, lack of clinical supervision and not having regular time to rest.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Working hours of United Kingdom psychiatric trainees: Findings from the BoSS study

J.N. Beezhold^{1,*}, K. Beezhold², G. Lydall², A. Malik³, A. Podlesek⁴, N. Jovanovic⁵

¹ Norfolk and Suffolk NHS Foundation Trust, Mental Health Liaison, Norwich, United Kingdom

² HSSD, General Psychiatry, Guernsey, United Kingdom

³ Innerhour, Innerhour, Mumbai, India

⁴ University of Ljubljana, Department of Psychology, Ljubljana, Slovenia

⁵ Queen Mary University of London, London, United Kingdom

* Corresponding author.

Introduction The international burnout syndrome study (BoSS) examined burnout in psychiatry trainees and associated factors. Long working hours were significantly associated with burnout.

Aims A high rate of severe burnout in UK psychiatric trainees (38%) was found in the BoSS study. This paper looks at the working hours of UK trainees.

Methods Data collected during the BoSS study included information related to working hours, looking in particular at the working time directive rules. A total of 3964 UK psychiatric trainees were invited to take part, of which 1187 (30%) responded, and 811 (20%) provided complete responses for working hours questions.

Results The mean age was 33 years, with 49.1% males and equal gender distribution of participants and non-participants. The mean hours of contracted work per week were 42.7 (42.2–43.2) for men, versus 41.1 (40.4–42.0) for women. Actual hours worked were significantly higher at 46.2 (45.0–47.4) for men and 46.0 (44.9–47.1) for women. Forty-six percent of trainees breached one or more working time directive (WTD) safety limits.

Conclusion Actual hours worked among psychiatric trainees in the United Kingdom are about 10% higher than contracted hours. Female trainees also work more uncontracted hours than male

trainees. This is significant when considering the association between hours of work and burnout, and also adds to the perception that women have to work harder for the same recognition as men. Forty-six percent of trainees breached WTD limits.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ University of Health Sciences, Erenkoy Mental Health Training and Research Hospital, Istanbul, Turkey

⁴ Bahcelievler State Hospital, Psychiatry Unit, Istanbul, Turkey

⁵ Dokuz Eylul University, Department of Psychiatry, Izmir, Turkey

* Corresponding author.

Introduction Previous studies reported high burnout rates and indicated significant factors associated with burnout syndrome among psychiatric trainees, such as hard working conditions, lack of supervision and not opting for psychiatry as a first career choice.

Objectives A substantial amount of variance was reported in psychiatry training across countries. However, there is not sufficient national data regarding the rates and risk factors of burnout syndrome among psychiatric trainees in Turkey.

Aims To determine the burnout syndrome rates and the risk factors associated with burnout syndrome among psychiatric trainees. **Methods** A questionnaire of occupational, educational and personal factors and Maslach burnout inventory (MBI) were answered by 180 of 450 psychiatric trainees in Turkey. The data was collected from 167 (56% females) trainees who completed the survey material. Converting the scores of three subscales by using MBI manual, a dichotomous variable (severe/non-severe burnout) was obtained for each participant and the data was analyzed using descriptive statistics and regression models.

Results Mean age was 28.85 ± 2.99 -year-old and mean duration of residency was 2.61 ± 1.31 years. Severe burnout was found in 38.3% of the trainees. Logistic regression confirmed that older age ($P=0.02$) and pressure from superiors ($P=0.04$) are predictive factors associated with severe burnout. The high number of patient visits ($P=0.001$), violation of employee personal rights ($P=0.04$) and pressure from superiors ($P=0.01$) were significantly associated with the "wish working in another institution".

Conclusions Pressure from superiors and older age can be described as risk factors associated with burnout syndrome among psychiatric trainees in Turkey.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The psychiatric morbidity and mortality teaching conference to improve patient safety: Lessons learned at the Massachusetts general hospital

O. Freudenreich*, F. Smith, J. Wozniak, M. Fava, J. Rosenbaum
Massachusetts General Hospital, Department of Psychiatry, Boston, Massachusetts, USA

* Corresponding author.

Introduction A morbidity and mortality (M&M) conference is a time-honored educational format in surgery and medicine to review bad patient outcomes and learn from mistakes made. However, despite the value of learning together as peers from difficult cases with unexpected outcomes, most psychiatric departments in the United States do not have an M&M conference. Several years ago, the department of psychiatry at Massachusetts's general hospital in Boston began a monthly M&M conference.

Objectives Describe our department's experience with the M&M format as an educational vehicle to teach patient safety and improve care in an increasingly complex care environment.

Aims Introduce the M&M format that we have developed at our department and obstacles encountered.

Methods We reviewed the content of our four years of M&M conferences; the feedback received from participants after each conference; and changes introduced to improve the conference.

Results Our department has successfully implemented and sustained a monthly psychiatric M&M conference that is well attended and valued. A critical decision was mandatory involvement of residents to prepare cases in conjunction with a dedicated faculty member. A structured presentation using a root cause analysis framework to guide the discussion in order to harness the wisdom of the group allows for a more comprehensive understanding of factors leading to bad outcomes, including systems-based problems.

Conclusions A psychiatric M&M conference can teach individual clinicians about patient safety. Developing a departmental mechanism to apply lessons learned in the conference to improve hospital systems is the next task.

Disclosure of interest The authors have not supplied their declaration of competing interest.

How satisfied are patients with interprofessional teams?

Meta-analysis of a pilot study

C. Lazzari^{1,*}, I. Masiello²

¹ North Essex NHS University Foundation Trust, General Adult Psychiatry, Pescara, Italy

² Department of Clinical Science and Education, Karolinska Institutet, Södersjukhuset, Clinical Education Centre, Stockholm, Sweden

* Corresponding author.

Introduction A doctor–patient encounter is a dyadic interaction between two people, one needing help and the other providing it. However, the encounter between an interprofessional team and a patient is changing this picture.

Objectives To measure how patient satisfaction changes when patients are treated by an interprofessional team.

Aims Ecological momentary assessment (EMA) directly evaluates patient satisfaction when patients interact with interprofessional teams. This research is a before-and-after study of undergraduate health care students undergoing interprofessional education. Answers to questions on a 5-point Likert scale (from "Totally satisfied" to "Totally unsatisfied") were uploaded online on a survey platform linked to a dedicated app.

Methods Twenty-nine undergraduate students before, and eight after, interprofessional training reported their evaluation of patient satisfaction with interprofessional teams. Meta-analysis used Tau², Cochrane's Q and I².

Results Meta-analysis showed a homogeneity in the answers before and after IPE training ($P=0.4$) and variability of only $I^2=39\%$, with $t^2=.006$, and $Q(4\text{ df})=4.0$. To a certain degree, the study showed a drop before and after in students who report their patients being "moderately satisfied" (from 20.7% to 0%), with C.I. $95\%=4.702(0.238-92.713)$ (Fig. 1).

Conclusions This study requires further inquiry on why a moderate level of patient satisfaction declines when patients are treated by an interprofessional team.

How satisfied are undergraduate students with interprofessional training? Meta-analysis of a pilot study

C. Lazzari^{1,*}, I. Masiello²

¹ North Essex NHS University Foundation Trust, United Kingdom

² Department of Clinical Science and Education, Karolinska Institutet, Södersjukhuset, Stockholm, Sweden

* Corresponding author.

Introduction Learning to work in an interprofessional team entails satisfaction in working with others.

Objective Contextual assessment of the degree of satisfaction of undergraduate healthcare students (doctors, nurses, occupational therapists and physiotherapists) during interprofessional education (IPE).

Aims Meta-analysis of degree of satisfaction contextually assessed during major interprofessional learning moments.

Methods Thirty-six undergraduate health care students (medical students, nursing students, occupational therapy students) answered questions on a 5-point Likert scale (from “Very satisfied” to “Very dissatisfied”). A meta-analysis with Tau² (t²), Cochrane’s Q, and I² analyzed IPE activities: self-reflection after daily training, interactions with teachers, discussion of clinical cases during ward rounds and patient care as a team.

Results Meta-analysis reported significant heterogeneity in the degrees of satisfaction (Fig. 1): 47.2% being “satisfied” with reflection after IPE, {t² = .011; Q (5df) = 30.03; I² = 83%, P < .0001}; 45% being “satisfied” during interactions with their teachers {t² = .01; Q (5df) = 25.74; I² = 80%, P < .001}; 31.4% being “satisfied” about the discussion of a clinical case during ward rounds {t² = .009; Q (5df) = 22.61; I² = 77.89%, P < .001}; and 44.4% being “satisfied” about patient care with the interprofessional team {t² = .009; Q (5df) = 22.99; I² = 78.25%, P < .001}.

Conclusions Undergraduate students show satisfaction with IPE activities. This helps improve the quality of care and teamwork in the busiest wards.

Can patients differentiate when they receive integrated care by interprofessional teams? Meta-analysis of a pilot study

C. Lazzari^{1,*}, M. Italo²

¹ North Essex NHS University Foundation Trust, General Adult Psychiatry, Pescara, Italy

² Department of Clinical Science and Education, Karolinska Institutet, Södersjukhuset, Stockholm, Sweden, Clinical Education Centre, Stockholm, Sweden

Introduction A patient’s quality of care and satisfaction depends greatly on the perception of being treated and attended to by an integrated team of professionals.

Objectives To make students mindful of a patient’s perception of being treated by a blended interprofessional team when undergraduate students in training perform as a team in the patient’s care.

Aims To assess if patients under the care of interprofessional teams perceive, they are being treated by an integrated team.

Methods Twenty-three undergraduate students undergoing a seven-day period of interprofessional training interviewed their common patients after each day of practice. Responses were given on a “yes-no-do not know” scale to the following question: “a team of students from different professions has just treated and cared for you. Do you think they have acted like a well-coordinated team?” Results were obtained by meta-analysis.

Results In 60.9% of cases (Tau² = 0.042; Q (2df) = 12.663; Het. P-value = 0.002; I² = 84.206%) (Fig. 1), patients perceived they were treated by a well-coordinated interprofessional team; however, this perception was not affected by the days of training by the same IPE team.

Conclusions Results suggest that other interpersonal factors might be involved in team-to-patient interactions that are barely affected by interprofessional training.

Figure 1 – Meta-analysis of patient's perception of being treated by a coordinated team.

Fig. 1 Meta-analysis of patient's perception of being treated by a coordinated team.

The EPA gaining experience programme: A great experience for young professionals

M.G. Oriani^{1,*}, J. Beezhold²

¹ Centro Salute Mentale Ancona AV2 ASUR MARCHE, Department of Mental Health, Ancona, Italy

² Central Acute Service, Norfolk and Suffolk NHS Foundation Trust, Norwich, United Kingdom

* Corresponding author.

Introduction Mental health services in many European countries are undergoing to changes: it is important that early career psychiatrists (ECPs) have opportunities to broaden their professional horizons and better understand the international context of the upcoming changes: then, they can become aware protagonists of these changes and the future of the mental health system in their countries and in Europe. The gaining experience programme (GEP), offering ECPs observership placements in various psychiatric institutions across the Europe, can boost it.

Aims We aim to consider how the EPA GEP can provide a unique professional and cultural understanding of the mental health services across the Europe and positively affect the ECPs' career.

Methods and results Starting from an experience of the GEP in 2016, we will discuss how it represents a great chance to observe the clinical work of multidisciplinary teams and an opportunity to visit different countries. Many aspects were significant, starting from the different organization of the mental health services, as well as the influence of different cultures on the mental health care system and the patient's expectations.

Conclusions Attending EPA GEP is an important chance for ECPs to improve their professional and organizational skills as well as a great skill-building opportunity and personal growth experience. The GEP is at his third edition this year and it has having a growing success among young psychiatrists. It gives them a chance to improve mentoring and professional networks among experts and ECPs and to get more involved in the EPA activities.

Transparency and due process: A systematic approach to educational decision-making and appeals

A. Peters

The Royal Australian and New Zealand College of Psychiatrists, OPCEO, Melbourne, Australia

Introduction Transparency and due process are inseparable principles that should underpin any educational and administrative decision made within an organization.

Objectives It is considered best practice for organizations to place the processes and structures surrounding reviews of decisions made by their organization at arm's length to the committee or group that made the original decision. This ensures there is and that due process is followed.

Aims An independent appeal process is an integral part of any fair system of assessment and decision making.

Methods The Royal Australian and New Zealand College of psychiatrists has undertaken several reviews of its current processes to examine its practices as both substantive and procedural issues arise in decisions with regard to the provision of psychiatric training. The reconsideration and appeal policy was developed to set out a clear and fair process for applicants to request decisions of the RANZCP to be reconsidered and appealed. This ensures that an applicant has a fair and reasonable opportunity to challenge the original decision whilst receiving support from the RANZCP to minimize any stress that may be experienced during this process.

Results The RANZCP has observed that the three phase process has enabled matters to be resolved at an earlier stage of the appeal cycle and do not require progression to a formal appeal.

Conclusion This presentation will identify best practice methods in educational decision-making and conducting appeals.

* Corresponding author.

Objective Assessment of suicide risk is of paramount importance for proper prevention.

Aims To examine the association between gatekeeper training and suicide-related knowledge among a diverse set of health care workers (psychiatrists, nurses, psychologists, and educators) and students enrolled in medical and psychological schools who took part in the world suicide prevention day 2015 conference.

Method Among 223 participants who completed the assessment, 204 provided complete data for analyses. Participants were administered the applied suicide intervention skills training (ASIST), a 13-item survey questionnaire to assess participants' knowledge about suicidal behavior and comfort dealing with suicidal clients. There were 62 psychiatrists; 23 nurses, 51 psychologists, 11 educators, and 57 university students.

Results Among participants, 57.1% of the sample had experiences of suicide a patient (students were excluded from these analyses). Those who reported a suicide among patients (compared with oth-

ers) less frequently answered that suicide risk is more alarming in older adults than youths. They also less frequently disagreed with questions asking if they had the training to deal with suicidal patients. Students more frequently answered correctly on the association between depression and suicide risk, and less frequently chose the correct answer on the seriousness of suicide intent in borderline personality disorder. Students also more frequently disagreed with questions asking on their suicide assessment skill.

Conclusions Our study highlights that differences exist when it comes to knowledge and skills related to suicide risk assessment both among health professionals and students. Our results also indicate that suicide awareness among these groups should be promoted.

* Corresponding author.

Introduction Global trends in the nature of working conditions pose significant threats to the training of medical professionals, as a result of cuts in educational grants and the salaries of professionals in training. Psychiatric trainees are not exempt from these changes.

Objectives To determine the current working conditions of psychiatric trainees and how they impact on their experience of training.

Methods A semi-structured survey was distributed to all members of the European forum of psychiatric trainees. Responses were collected online from 34 participating countries. The respondents were representatives of national trainee associations. Data collection was completed between May and July 2016.

Results Respondents reported that the most important issues affecting postgraduate training were firstly working conditions, then salary, psychotherapy training and supervision, respectively. The average official mandatory working hours for a trainee, including on call duty was reported to be on average 40.16 (\pm 10.14 hours per week). In reality, the time that trainees report working is more than 20% higher than official working hours (on average 49.08 \pm 15 per week). There is an officially recognized minimum vacation period of 20 days in almost all countries, ranging up to a maximum of 40 days (mean: 26.93 \pm 4.97, per year). Salaries demonstrate an even greater variation, ranging from 100 Euros (as in the case of Moldova), up to over 5000 Euros (as in the case of Germany or Switzerland) per month.

Conclusion Psychiatric trainees often work longer than the officially recognized hours and their income varies considerably between countries, which have been identified as the two biggest challenges trainees face.

Comparing learning outcomes for mental health simulation training delivered to entire clinical teams versus professionals not working together clinically

L. Valdearenas*, C. Attoe, S. Cross

Maudsley Simulation, South London and Maudsley Hospital NHS Foundation Trust, London, United Kingdom

* Corresponding author.

Introduction Working effectively with colleagues using a multi-disciplinary and interprofessional approach is vital in healthcare, particularly mental health, where the interface between physical and mental health is often missed due to involvement with different specialties. Collaborative clinical practice is essential to provide the best clinical care to people experiencing mental and physical health co-morbidities. Simulation training encourages experiential learning for human factors (or non-technical) skills, such as teamwork and interprofessional collaboration. This study explored the differences in learning outcomes between team and non-team training for physical and mental health co-morbidities.

Aims and objectives This project aimed to establish differences in human factors learning, confidence and knowledge, following training for teams that work together versus interprofessional groups from various teams. The project hoped to continue improving mental health simulation training and promote and enhance human factor skills that are basic pillars of multi-disciplinary and interprofessional care.

Methods The human factors skills for healthcare instrument (HFSHI), alongside confidence and knowledge measures were administered to all participants pre and post simulation training on interacting mental and physical health. A post-course evaluation survey with open questions was used to collect qualitative feedback on the impact of the training course.

Results With data collection ongoing, preliminary results indicate differences between team and non-team simulation training, with particularly interesting qualitative findings.

Conclusions Learning outcomes may differ for team versus non-team simulation training, evidencing the different value of these two training set-ups.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Who learns more in interprofessional mental health simulation training? A study comparing learning outcomes of different professionals who work in mental and physical health care settings

L. Valdearenas*, C. Attoe, S. Cross

Maudsley Simulation, South London and Maudsley Hospital NHS Foundation Trust, London, United Kingdom

* Corresponding author.

Introduction Simulation training has the potential to develop communication and teamwork skills, as well as technical knowledge and competency. Mental health simulation training aims to promote awareness of mental health conditions and to enhance human factors (or non-technical) skills that will enable professionals that work in mental and physical healthcare settings to improve their collaborative and patient-centered clinical practice. This study explored the differences in learning outcomes after a mental health simulation course between different professionals—nursing staff, medical staff, and allied health professionals.

Aims and objectives This project examined the different learning outcomes of human factors, confidence and knowledge, for nursing, medical and allied health professionals following mental health simulation training.

Methods Course-specific measures of confidence and knowledge were administered pre- and post-training to all participants, in addition to The Human Factors Skills for Healthcare Instrument (HFSHI). A post-course evaluation for with free-text responses to open questions regarding the impact of the training was utilised to collect qualitative data.

Results With data collection ongoing, preliminary results indicate differences in learning outcome depending on professional

background, both in terms of quantitative measures and qualitative findings.

Conclusions Learning outcomes may differ for different professionals despite receiving the same simulation training focusing on mental and physical health, evidencing the importance of sharing individual learning experiences in simulation using a debrief model.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Parenting a child with attention deficit hyperactivity disorder: Qualitative study from a developing nation, India

R. Shah*, A. Sharma, S. Grover, N. Chauhan, S. Jhanda
 Postgraduate institute of medical education and research,
 department of psychiatry, Chandigarh, India
 * Corresponding author.

Introduction Like elsewhere, studies from developing countries suggest that parents of children with attention deficit hyperactivity disorder (ADHD) report significant stress. Besides symptoms, parental stress stems from experiences in interpersonal, schooling and societal domains, which may in turn be influenced by socio-cultural factors. This is a highly under-studied area.

Objectives and aims Exploring experiences in familial, schooling and societal areas amongst Indian parents and understanding these in a cultural context using experiential qualitative research methodology.

Methods In-depth semi-structured interviews were conducted with consenting parents of 27 children diagnosed with ADHD (17 mothers; 10 fathers).

Results All parents reported experiencing moderate to high degree of stress, feeling worried and frustrated due to child's problems. 19 parents reported being "short-tempered", while 1 mother expressed feeling "lost". Majority reported strained relations with spouse and extended family. Mothers reported higher stress, more difficulties in family life, faced criticism from immediate family and community regarding handling of child, felt more embarrassment, guilt and sense of failure as a mother. Half of the parents avoided attending social gatherings. Other than 2 parents, all had negative experiences with schooling. Experiential descriptions included those of teachers being highly critical of child and parents, punitive, dismissive and discriminatory. Teacher had advised seeking treatment in only 6 children. Themes of blame, discrimination and rejection were identified.

Conclusions We conclude that cultural factors such as stigma, blaming of parent (especially mother) and lack of knowledge regarding ADHD amongst teachers and society may be responsible for these experiences and needs further investigation.

Parental causal explanations and treatment seeking in attention deficit hyperactivity disorder: Perspectives from a developing nation based on process theory

R. Shah*, A. Sharma, S. Grover, N. Chauhan, S. Jhanda
 Postgraduate institute of medical education and research,
 department of psychiatry, Chandigarh, India
 * Corresponding author.

Introduction Cultural factors have an important role in causal model of symptoms, threshold for treatment seeking and acceptability of professional help in ADHD.

Objectives and aims To explore causal explanations and treatment seeking amongst parents of children with ADHD and understand these in context of a largely collectivistic culture as in India.

Methods In-depth semi-structured interviews were conducted with 27 consenting parents; data interpreted using process theory.
Results Initial reaction to psychiatric referral revealed themes of disbelief/surprise, feeling confused/offended and lag of 6–36 months to consultation. Parents most commonly attributed causality to psychosocial reasons (lack of motivation/volitional, inadequate disciplining), while few gave one or more biomedical explanations (epilepsy, brain damage, low birth weight, nutritional deficiency, maternal ill health, low intelligence) alone or with a psychosocial reason. Despite the initial reaction, all but 1 parent was relieved with medical explanation, accepted diagnosis, and perceived need for treatment. Most parents were willing to start/continue medication if doctor suggested so as "he/she would know the best". All parents expressed that counseling was needed.

Conclusions Initial reactions and delay in treatment seeking is understood in light of cultural attitudes towards mental illnesses and psychiatric consultation in developing nations. More importantly, despite initial reluctance, most parents accepted biomedical explanation and treatment. The doctor patient relationship modeled on a guru-chela relation of complete trust in authority can explain this process change. We conclude that cultural attitudes not only influence causal models and initial treatment seeking, but also modify process of help seeking.

Outcomes in a group of 7–8-year-old children in a developmental-based intervention in autism spectrum disorder

M.T. Sindelar^{1,*}, N. Furland²

¹ Universidad Sudoeste, CS Humanas, Bahia Blanca, Argentina

² National center of research, Conicet, Biology, Bahia Blanca, Argentina

* Corresponding author.

Healthy parent-child interaction is essential for child development. Parents play a central role in the acquisition of social and communicative skills, both in typical and atypical children. Increased support for parent-mediated intervention in autism has been demonstrated. Developmental approaches for ASD are based in establishing strong interpersonal relationships through natural play to foster developmental capacities. This work reports outcomes from an intensive approach based on a developmental, individual difference, home-based intervention program with children with severe ASD. Parents were trained with DIR approach by a specialist. An individual intensive rehabilitation program was set up for each child and implemented at school, home and rehabilitation center. The intervention program also focused on semi-structured activities to promote problem solving, and meliorate sensory dysfunction. Standardized scales were administered pre- and post-intervention, with ABC). The Childhood Autism Rating Scale (CARS), the Social Communication Questionnaire (SCQ) and Vineland Adaptive Behaviours Scales.

Results Before initiating the intervention all children presented severe difficulties in communication, social interaction, lack of language, and gestures of communication, auto- and hetero-aggressive behaviors. After 6 months, children showed significant changes in mean scores for emotional functioning, communication, and daily living skills and diminution of aggressive behaviors. The present results provide strong support for the effectiveness of a developmental-based intervention, specifically in the domains of social skills behavior, social responsiveness, in a group of children with severe autism. These results highlight the positive effects of a rehabilitative approach that works in harmony with the family, school and professional team.

Music as a helpful instrument in the treatment of children with Asd in their school inclusion program

M.T. Sindelar^{1,*}, C. Meini²

¹ Universidad Sudoeste, CS Humanas, Bahia Blanca, Argentina

² Universita Vercelli, Lingua, Vercelli, Italy

* Corresponding author.

Since birth infants are active and communicative partners engaged in protoconversations with caretakers. Motherese, the simplified language adults spontaneously use with infants, has a musical structure. We believe that for developmental and evolutionistic reasons music is a preferential tool to favor communication and to promote group identity. We carried on a musical experience with a group of autistic (ASD) children aged 5 to 7 years. Each child participated at their school with 10 typically developed classmates and their teachers. Our ASD children love music and enjoy playing

and singing. With music, they overcome some communicative and social difficulties. Their bodily posture changed with music, facilitating joint attention and improvement of verbal language. When singing children learned linguistic skills, they ameliorated vowels' pronunciation and understood how a question and an answer differ in melodic contour. Taking into account the unique sensory motor profile of each ASD child, we proposed rhythmic music with high proprioceptive input (for under-reactive children) and smooth and calming music for avoidant and easily overwhelming children in order to ameliorate intentionality and enlarge circles of communication. A combination of semistructured and spontaneous activity is the main components of our approach, which has both therapeutic and educational impacts. In the musical group, all the ASDs appeared to be more attentive, motivated, better performing and able to teach their acquired skills to their peers. Typical peers interact more with children with ASD with music. We consider this very helpful in the inclusion of ASD children in a school setting.

Impulsivity and current alcohol use in adolescents

N. Smaoui, N. Charfi*, M. Turki, M. Maâlej-Bouali, J. Ben Thabet, N. Zouari, L. Zouari, M. Maâlej

Hedi Chaker university hospital, department of psychiatry C, Hedi Chaker university hospital, Sfax, Tunisia

* Corresponding author.

Introduction Many studies have focused on the strong link between impulsivity and addictive behaviors, such as alcohol use disorders.

Objective Our study aimed to investigate the links between alcohol use and impulsivity in a sample of Tunisian pupils.

Methods This was a cross-sectional study conducted in May and June 2016. It enrolled 317 pupils from four colleges and schools in Sfax (Tunisia). The participants were asked to answer a self-administered questionnaire, after their consent. Alcohol use disorders identification test (AUDIT) was used to evaluate alcohol dependence. The Barratt Impulsiveness Scale (BIS), in its 11th version, was used to assess impulsivity trait. Its three second-order factors were attentional impulsiveness, motor impulsiveness, and non-planning impulsiveness.

Results The mean age was 16 years with a sex-ratio of 1.07. The school children reported having drunk alcohol at least once in 18.9% of cases and 41.66% of them still consume. According to AUDIT, 1.6% of alcohol users presented an alcohol misuse and 21.6% presented dependence. According to BIS, impulsivity prevalence (IP) in the whole sample was 27.8% while it was 40% among the alcoholic participants versus 24.9% in non-alcoholic participants. The average BIS score was more important in the alcoholic participants (69.25 versus 65.53; $P=0.011$). Alcohol consumption was correlated to attentional impulsiveness ($P=0.01$) and motor impulsiveness ($P=0.008$). Alcohol dependence was correlated to motor impulsiveness ($P=0.018$).

Conclusion These results show the importance of clinically evaluating and intervening on impulsive personality traits to better prevent addictive behavior such as alcoholism among adolescents.

Influence of peers drinking and parental drinking and attitudes on adolescent drinking

N. Smaoui, N. Charfi*, M. Turki, M. Maâlej-Bouali, L. Zouari, N. Zouari, J. Ben Thabet, M. Maâlej
Hedi Chaker university hospital, department of psychiatry C, Hedi Chaker university hospital, Sfax, Tunisia
 * Corresponding author.

Introduction It is widely recognized that parents and peers play a critical role in the adolescent's introduction to alcohol.

Objectives The aim of the study was to examine the relationship of parental and peers drinking to adolescent drinking behavior.

Methods A cross-sectional study was carried out in four colleges and schools in Sfax in Tunisia, in May and June 2016. The sample consisted of 317 pupils, and was determined through a simple randomized sampling. These adolescents were asked to answer a self-administered questionnaire, after their consent. Alcohol use disorders identification test (AUDIT) was used to evaluate alcohol dependence.

Results The mean age was 16 years, with a sex-ratio of 1.07. The participants reported having drunk alcohol at least once in 18.9% of cases and 41.66% of them still consume. According to AUDIT, 1.6% of alcohol users presented an alcohol misuse and 21.6% presented dependence. They reported that parents' attitude toward their alcohol use was favorable in 27.11% of cases. Among dependent adolescents, the prevalence of fathers' alcohol consumption was 20% while that of friends was 70%. Adolescent drinking was significantly correlated to fathers, mothers and peers drinking ($P < 0.001$, $P = 0.004$, $P < 0.001$ respectively), mothers and peers smoking ($P = 0.05$, $P < 0.001$ respectively), fathers and peer's cannabis use ($P < 0.001$, $P < 0.001$ respectively).

Conclusion Findings suggest that negative family and peers influence increased risk of alcohol consumption in adolescents. Understanding the influences on parents' beliefs about their children's drinking and the functions of social networks in preventing alcohol consumption may be necessary to address adolescent risky drinking.

Drug metabolizing enzyme and transporter genes associated with plasma risperidone level in Thai autism spectrum disorder

C. Sukasem

Faculty of medicine Ramathibodi hospital, Pathology, Bangkok, Thailand

Background The associations between genetic variants of drug metabolizing enzyme and transporter (DMET) genes and steady-state plasma concentrations of risperidone, 9-hydroxyrisperidone, total active-moiety, and metabolic ratio remain unclear.

Objective The objective of the present study was to present the results of the association between genetic variants of DMET gene and steady-state plasma concentration risperidone and its metabolite using Affymetrix DMET Plus genotyping microarray.

Methods Subjects eligible for this study included male and female adolescents with ASD diagnosed according to the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV) criteria and being treated with risperidone for at least 4 weeks prior to the blood sample collection. Blood samples were drawn prior to the next dose of risperidone intake to determine the steady-state plasma trough concentrations of risperidone and 9-hydroxyrisperidone. Genotyping profile was obtained using the microarray. Steady-state plasma risperidone and 9-hydroxyrisperidone were measured using liquid chromatography/tandem mass spectrometry (LC-MS/MS) assay.

Results The polymorphisms of UGT2B4, CYP2D6 were highly associated with metabolic ratio. Of all the DMET analysis, ABCB11 (3084A > G, 420A > G, 368G > A, and 236G > A) and ADH7 (690G > A and -5360G > A) were found to be associated with plasma concentrations of risperidone ($P < 0.01$). In addition, 6 genetic variations among the SLC transporter family were associated with the plasma concentration of 9-hydroxyrisperidone.

Discussions This study provides a pharmacogenomic approach to investigate further among the DMET genetic variants which influence plasma concentration of risperidone. The treatment of ASD should be based on genetic factors making the challenge of psychopharmacological treatment more efficacious with lesser adverse events.

EW0583

Exome sequencing detection of genetic markers for Thai autism spectrum disorder

C. Sukasem

Faculty of medicine Ramathibodi hospital, Pathology, Bangkok, Thailand

Background Autism spectrum disorders (ASD) are neurodevelopmental disorders characterized by abnormalities in 3 domains; social interaction, communication/language, and restricted and repetitive behavior. The study of ASD prevalence in Thailand showed that it is approximately 9.9 children per 10,000 population for children 1–5 years old. ASD has a strong genetic basis, although the genetics of autism are complex and it is unclear. The objective of this study was to identify the genetic markers of Thai ASD.

Methods Exome sequencing was performed with twelve unrelated ASD affected individuals from twelve families. Each sample was sequenced on SOLiD 5500xl genetic analyzer, and the resulting data was processed and analyzed on LifeScope Genomic Analysis software. Exome sequencing with two additional samples was performed Ion Proton System and the data was processed on Ion Reporter server. Tertiary data analysis with all fourteen exome sequencing data were performed by using Golden Helix software. In filtering process, data were annotated to various databases including UCSC KnownGenes for non-coding and synonymous variants filter, 1000 Genomes Project for high frequency variants filter, and dbNSFP for functional prediction.

Results The genetic markers were identified for Thai ASD associated variants (c.2014G > A in EIF2AK3, c.2951G > A in FGD6, and c.6119A > G in CHD8).

Conclusions these genetic markers were the most possible of causing variants Thai. We also demonstrated a potential of exome sequencing and bioinformatics pipeline to identify the possible causative variants of ASD, which could be applied in the case that unable to identified variants by other technique.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Hyperuricemia and metabolic adverse effect in children and adolescents with autism spectrum disorder treated with risperidone

C. Sukasem

Faculty of medicine Ramathibodi hospital, Pathology, Bangkok, Thailand

Background Atypical anti-psychotics have been found to be associated with hyperuricemia. The aims of this study were to determine the prevalence of hyperuricemia and metabolic adverse events in children and adolescents with ASD treated with risperidone.

Methods In this cross-sectional study, we recruited 127 Thai ASD children and adolescents aged 3–20 years receiving risperidone for more than 4 weeks. The clinical data and laboratory data were obtained and analyzed. Hyperuricemia was defined as serum uric acid > 5.5 mg/dL.

Results Hyperuricemia was present in 57.48% of total ASD patients treated with risperidone. Uric acid levels were significantly higher in adolescents as compared to children. Uric acid levels correlated with risperidone dose ($P=0.01$), duration of treatment ($P<0.0001$), BMI ($P<0.0001$), waist circumference ($P=0.003$), triglyceride (TG; $P<0.0001$), triglycerides/high-density lipoprotein cholesterol ratio (TG/HDL-C; $P<0.0001$), insulin ($P=0.04$), homeostatic model assessment index (HOMA-IR; $P=0.03$), high-sensitivity CRP (hs-CRP; $P<0.0001$), and leptin levels ($P<0.0001$). HDL-C and adiponectin levels were negatively correlated with uric acid levels ($P<0.0001$). In multiple regressions analysis, age, BMI, TG/HDL-C, and adiponectin level remained significantly associated with uric acid levels ($P<0.0001$).

Conclusion Hyperuricemia may play a role in metabolic adverse effects in children and adolescents with ASD receiving high dose and/or long-term treatment with risperidone.

Effects of executive function stimulation in the language improvement of children with ASD

I. Sun*, F. Fernandes

University of São Paulo, FMUSP, São Paulo, Brazil

* Corresponding author.

The Autism Spectrum Disorder (ASD) is a neurobiological disorder that involves deficits currently classified into two areas:

- social communication and interaction across multiple contexts;
- restricted, repetitive patterns of behavior, interests or activities.

Although, these disorders do not have any causal relationship, both are always present. It has increasingly been sought methods aiming at the effectiveness of intervention for this population seeking to include all aspects. A promising research field is the one that considers the interdependence of the language and cognition areas, specifically regarding executive functions. This study was designed to verify the effectiveness of an executive functions stimulation program (EFS) during the regular speech-language therapy sessions and its impact in language development, specifically in the pragmatic aspects, through the evaluation of the functional profile of communication (FPC) in 14 children with ASD. During a 12-week period of regular speech-language therapy, the following areas were focused: working memory, cognitive flexibility, central coherence, inhibitory control and specific language aspects. Data were registered and analyzed statistically. The average performance of children in the stimulation was 85%, ensuring the effectiveness of EFS. The association analysis between pre- and post-EFS performance with FCP a significant improvement was observed in the occupation of the communicative space and the percentage of interactivity. These results are consistent with the hypothesis of the study, which believes in strong association between communication aspects and executive functions skills.

* Corresponding author.

Background and aims Anxiety-phobic disorders are caused both by environmental and hereditary factors. The study was designed to determine the level of chromosomal aberrations in the peripheral blood lymphocytes (PBL) of children and adolescents of both sexes with phobic-anxiety disorders (PAD).

Patients and methods Cytogenetic analysis was performed in 27 children and adolescents of both sexes with PAD, aged 9–15 years; the control group consisted of 50 healthy peers of both genders. Statistical analysis-Excel and SPSS statistics 17.0.

Results Cytogenetic analysis of patients with PAD and in healthy age-matched individuals has established normal female (46,XX) and male (46,XY) karyotypes. The frequency of the chromosomal aberrations (CA) spontaneous level in the PBL is 4.6 times higher than the CA frequency in healthy persons. In children and adolescents with the disease, the spontaneous frequency of aberrations of chromatid and chromosome types is also significantly higher than the same in healthy children and adolescents. Single acentric fragments and exchanges prevail among the chromatid-type aberrations; pair acentric fragments prevail among the chromosome-type aberrations. An increase in the frequency of the chromosome-type aberrations has been revealed in boys with PAD (1.72 vs.0.55 per100 cells in healthy boys, $P<0.001$ by pair acentric fragments), in comparison with healthy boys; and the chromatid-type aberrations have been observed in girls with PAD (3.22 vs.0.94 per 100 cells in healthy girls, $P<0.001$ by single acentric fragments), in comparison with healthy girls. A pronounced individual variability of CA frequency, which ranges in our patients from 2.0 to 18.0 per 100 metaphase plates, has been found along with an increase in the CA level in patients with PAD.

Conclusion Children and adolescents with PAD require a careful cytogenetic analysis and the consequent therapeutic measures for genome stabilization.

Effect of adenotonsillectomy on attention-deficit/hyperactivity disorder symptoms, sleep disturbance symptoms, and quality of life of children with adenotonsillar hypertrophy and sleep-disordered breathing

S. Türkoglu^{1,*}, B.T. Somuk², E. Sapmaz², G. Goktas², A. Bilgic³

¹ Selcuk university medical faculty, department of child and adolescent psychiatry, Konya, Turkey

² Gaziosmanpaşa university hospital, department of otolaryngology-head and neck surgery, Tokat, Turkey

* Corresponding author.

Objectives To date, limited data has been available regarding the impact of adenotonsillectomy (AT) on the psychosocial well-being of chronic adenotonsillar hypertrophy (CAH) subjects.

Aims In the present study, we examined the impacts of AT on attention-deficit/hyperactivity disorder symptoms (ADHD) and sleep disturbance symptoms and quality of life of children with chronic adenotonsillar hypertrophy.

Methods Parents of children with CAH filled in Conners Parent Rating Scale-Revised Short (CPRS-RS), children's sleep habits questionnaire (CSHQ), and the pediatric quality of life inventory, parent versions (PedsQL-P) before and six months after AT.

Results A total of 64 children were included the study (mean age: 6.8 ± 2.4 years; 50% boys). Mean ADHD Index (11.98 ± 6.94 versus 10.35 ± 6.44) (before AT versus after AT) and oppositional scores (6.73 ± 3.72 versus 5.87 ± 3.52) improved statistically significantly after AT ($P < 0.05$). All of the CSHQ subdomain scores, except sleep duration, significantly reduced after AT ($P < 0.05$). Regarding to quality of life, both PedsQL-P physical health (64.20 ± 19.81 versus 69.84 ± 18.63) and psychosocial health subdomain scores (67.83 ± 12.89 versus 75.57 ± 13.16), and PedsQL-P total score (66.57 ± 12.94 versus 73.58 ± 12.46) of the patients were significantly higher six months after AT ($P < 0.001$).

Conclusions It is necessary for child and adolescent psychiatrists to query the symptoms of CAH to identify children with chronic adenotonsillar hypertrophy who suffer from ADHD symptoms, oppositionality, and sleep disturbance. To carry out AT seems to be beneficial for coexisting ADHD and sleep disorder symptoms and quality of life in these children.

Intelligence functioning and associated factors in children with cerebral palsy

S. Türkoğlu^{1,*}, G. Türkoğlu², C. Celik³, H. Ucan⁴

¹ Selcuk university, faculty of medicine, department of child and adolescent psychiatry, Konya, Turkey

² Konya training and research hospital, physical medicine and rehabilitation, Konya, Turkey

³ Giresun university, faculty of medicine, department of physical medicine and rehabilitation, Giresun, Turkey

⁴ Ankara physical medicine and rehabilitation training and research hospital, department of physical medicine and rehabilitation, Ankara, Turkey

* Corresponding author.

Objectives Cerebral palsy (CP) is described as a primary disorder of posture and movement; however, intellectual impairment is prevalent in children with CP.

Aim The aim of the present study was to examine the association with intellectual level and gross motor function, hand function, type of CP, and the presence of co-morbid disorders in these children.

Methods A total of 107 children with CP were included in the study. Intellectual functions of the children were determined by clinical assessment, adaptive function of daily life, and individualized standardized intelligence testing. Gross motor function and hand function of the patients were classified using the gross motor function classification system and the bimanual fine motor function measurements.

Results The mean age of the patients were 8.10 ± 3.43 years (age: 2–16 years). During clinical typing, we observed that 80.4% of the patients were spastic, 11.2% were mixed, 4.7% were dyskinetic, and 3.7% were ataxic. No significant relationship was determined between the type of CP and intellectual functioning ($P > 0.05$). Intellectual functioning was found to be significantly correlated

negatively with both gross motor function and hand functions level ($P < 0.001$). The factors related to intellectual functioning were neonatal convulsion ($\chi^2 = 12.97$, $P = 0.002$), epilepsy ($\chi^2 = 29.221$, $P < 0.001$), and speech disorders ($\chi^2 = 23.29$, $P < 0.001$).

Conclusions There is an association between intellectual functioning in children with CP and the degree of motor impairment, neonatal convulsion, epilepsy, and speech disorders. Intelligence assessment should be an essential part of CP evaluation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Adolescents' well being is affected by their parenting situation and can influence their well being over time. We present an exploratory study with an Illumina 450 k array, comparing methylation in adolescents, based on perceived parenting at T_0 , and how methylation can interact with parenting in explaining depressive symptoms two years later (T_2).

Objectives Identify differentially methylated regions (DMRs) associated with perceived parenting at T_0 and investigate their association with depressive symptoms two years later.

Aims An exploratory analysis evaluating the association between methylation and depressive symptoms longitudinally.

Methods From two extreme parenting clusters: perceived supportive, and punishing neglecting, we randomly selected 44 adolescents ($M_{Age} = 14$ at T_0 ; 48% boys). The CES-D scale (Center for Epidemiologic Studies Depression Scale) assessed depressive symptoms. DMRs were identified based on the parenting clusters (DMRcate and comb-p) using Illumina Infinium HumanMethylation 450 BeadChip data. Associations between the most significant CpG for each DMR and the depression score at T_2 , were calculated using linear regression analysis.

Results We identified 17 DMRs, but only cg13306335 in PEX10 was associated with depressive symptoms at T_2 ($P = 0.0014$, Bonferroni (17 tests); $P < 0.0029$). Additionally, an interaction between parenting at T_0 and PEX10 methylation (T_0) in explaining depressive symptoms (T_2) can be suggested ($P = 0.014$).

Conclusions We show that methylation at PEX10's most significant CpG is correlated with depressive symptoms at T_2 , these exploratory results also suggest a possible interaction between parenting and PEX10 methylation at T_0 in association with depressive symptoms at T_2 . Validation in a larger sample is needed to support the role of methylation and its interactions in depression over time.

Integrated regional autism program: The IRAP multidisciplinary model

N. Varruciu^{1,*}, M. Manfredini², A. Di Santantonio¹, P. Roversi¹, R. Di Sarro¹

¹ Local health authority, health and disability integrated program, Bologna, Italy

² Local health authority, department of mental health and addictions, Bologna, Italy

* Corresponding author.

Introduction Receiving an autism spectrum disorder (ASD) diagnosis often is daunting for individuals and families because of the life-long difficulties with functioning, health and quality of life [1]. “Casa del Giardiniere” is the reference facility for ASD at the Local health authority. The multidisciplinary team is composed by child psychiatrist, psychiatrist, psychologist, behavior analyst, educator, speech therapists, neuropsychomotor therapist, and social worker. Following the international guidelines for the neurodevelopmental disorders, patients’ age changed from 0–18-year-old to lifespan.

Objectives This work aims to illustrate our model, resulting from the integration of family, social and health services, and school.

Methods Data on demographic, family, and clinical factors were gathered among subjects admitted to our ASD unit along 2015. All participants underwent to the following process: diagnostic assessment, Functional assessment of speech, communication, cognitive and adjustment skills, treatment, and parent training.

Results Data showed a general improvement of skills. The best results were achieved when a full sharing of methods and strategies in all areas of life were possible. Results will be discussed in details.

Conclusions This model allows to realize efficient individualized treatment programs and to benefit of specific training both on intervention programs and approach with families. Furthermore, parents learn to “see” their child not only within its limits.

Development and evaluation of a psychosocial model for children who experience trauma from low and middle-income countries

P. Vostanis

College of medicine, biological sciences & psychology, psychology, Leicester, United Kingdom

Introduction Despite fragmented evidence on individual interventions, good practice and child welfare programmes in low and middle-income countries (LMIC), there is no comprehensive model for early interventions, particularly for children who experience complex trauma.

Objective The objective of the World Awareness for Children in Trauma (WACIT: www.wacit.org) is to develop an evidence-based psychosocial model for vulnerable children in low and middle-income countries with limited or no access to specialist resources.

Methods The aim of the preliminary evaluation was to establish stakeholders’ views on the extent of need, socio-cultural context, service gaps, and recommendations for improvement and creation of working partnerships. This consisted of four studies:

- 1. Participatory workshops in six countries (Turkey, Pakistan, Indonesia, Kenya, Rwanda, Brazil) with a total 250 strategic and operational stakeholders;
- 2. Quantitative evaluation in two of these countries (Turkey, 32 participants; and Brazil, 80 participants);
- 3. Interviews with 17 stakeholders from the six countries;
- 4. Focus groups with 7 children, 7 parents, 9 teachers and 11 other professionals in one country (Kenya).

Results Findings indicated that lack of resources (funding, facilities, training and personnel), poor collaboration (between church, families, government, schools and community), impaired parenting, socio-economic challenges and limited knowledge on child mental health as key factors that impede interventions.

Conclusions The findings have informed the next phase of the WACIT programme in developing sustainable networks, training, and culturally appropriate interventions in the participating LMIC.

Startle habituation depends on selective attention in schizophrenia patients and cannabis users

E. Wehmann^{1,*}, K.K. Kedzior², M. Martin-Iverson³

* Corresponding author.

Introduction Schizophrenia is associated with cannabis use and deficits in selective attention.

Objectives/aims This study investigated these relationships using habituation of the startle reflex in schizophrenia patients relative to cannabis users during selective attentional tasks.

Methods Participants included 12 healthy controls (CON), 16 healthy cannabis users in the last 12 months (THC), and eight schizophrenia patients (SCZ). Auditory startle reflex was recorded from orbicularis oculi muscle while participants were attending to (Attend Task) or ignoring (Ignore Task) 100 dB startling pulses. Startle habituation was measured as the absolute reduction in startle magnitude on block 2 (last nine trials) vs. block 1 (first nine trials) on each attentional task and in each group.

Results All three groups were matched on demographics, alcohol, and caffeine consumption. ANCOVA with two within-subject factors (attention and habituation with 2 levels each), one between-subject factor (group with 3 levels), and one covariate (nicotine use which was higher in SCZ vs. CON or THC) showed a significant startle habituation with moderate to large effect sizes in all three groups on the Ignore Task (Cohen’s $d=0.67$ in CON, $d=0.59$ in THC, $d=0.90$ in SCZ) but not on the Attend Task. Attentional modulation of the startle reflex occurred only in CON ($d=1.33$) and THC ($d=1.17$), but not in SCZ.

Conclusion Auditory startle habituation depends on selective attention but is not affected by schizophrenia or cannabis use. Deficient attentional modulation of the startle reflex suggests that a more severe deficit in selective attention occurs in schizophrenia relative to cannabis use.

A neuro-developmentally sensitive and trauma informed service delivery approach for child and youth mental health and psychiatry

T. Wilkes^{1,*}, E. Wang², B. Perry³¹ Foothills medical centre, psychiatry, Calgary, Canada² Hull services, NMT service director, Calgary, Canada³ Child trauma academy, psychiatry and behavioral services, Houston, USA

* Corresponding author.

This presentation will introduce the innovative approach to child and youth mental health and psychiatry using the neurosequential model of therapeutics (NMT). This is a neuro-developmentally sensitive and trauma informed approach and acknowledges the importance of early experiences shaping the organization of the brain. An outline of the stress response and its relevance to hyperarousal and dissociative responses will be discussed as this impacts attachment and the reward neuro-biology. The hierarchy of brain development will be emphasized in the clinical approaches to child psychiatry especially in reference to child maltreatment and neglect. The critical role of sensory integration, self regulation, relational health and cognitive development in treatment planning will be discussed versus the categorical diagnosis of ADHD, autism, bipolar disorder and depression. This has profound economic and psychopharm practice implications in child and youth mental health treatments. Consequently the importance of these concepts in informing public policy for early child development and school mental health literacy will be emphasized. Additionally the outcome of these approaches on the reduction of staff turnover, critical incidents in schools and residential placements will be shared.

* Corresponding author.

Objectives The objective of this family-based whole exome sequencing (WES) is to examine genetic variants of autism spectrum disorder (ASD) in Korean population.

Methods The probands with ASD and their biological parents were recruited in this study. We ascertained diagnosis based on DSM-5TM criteria, using Autism Diagnostic Observation Sche-

dule and Autism Diagnostic Interview–Revised. We selected probands with typical phenotypes of ASD both in social interaction/communication and repetitive behaviour/limited interest domains, with intellectual disability (IQ < 70), for attaining homogeneity of the phenotypes. First, we performed WES minimum 50× for 13 probands and high-coverage pooled sequencing for their parents. We performed additional WES for 38 trio families, at least 100× depth. De novo mutations were confirmed by Sanger sequencing. All the sequence reads were mapped onto the human reference genome (hg19 without Y chromosome). Bioinformatics analyses were performed by BWA-MEM, Picard, GATK, and snpEff for variant annotation. We selected de novo mutation candidates from probands, which are neither detected in two pooled samples nor both parents.

Results Fifty-one subjects with ASD (5 females, 40~175 months, mean IQ 42) and their families were included in this study. We discovered 109 de novo variants from 46 families. Twenty-nine variants are expected to be amino acid changing, potentially causing deleterious effects. We assume CELSR3, MYH1, ATXN1, IDUA, NFKB1, and C4A/C4B may have adverse effect on central nerve system.

Conclusions We observed novel de novo variants which are assumed to contribute to development of ASD with typical phenotypes and low intelligence in WES study.

* Corresponding author.

Introduction The work was developed with the people hospitalized in the period of 1 year in a psychiatric clinic in Rio de Janeiro city, Brazil. 175 patients who presented dual diagnosis were evaluated.

Objectives The research aims to know the distribution of the most frequent psychiatric diagnosis associated with the disorders for the use of psychoactive substances. The work also has as objective to assess the treatment of patients carrying these disorders so that there is a better efficiency of the individual treatment plan.

Methods The work consisted of the evaluation of all patients who were admitted to the clinic in the period of 1 year, using the ICD-10 for the diagnosis of dual pathologies. All the patients were assessed by the multiprofessional team, composed by general practitioner, psychiatrist, psychologist, pharmacist, therapist in chemical dependence, family therapist and physiotherapist. The patients were treated with the use of psychopharms, cognitive behavioral psychotherapy, 12-step program, art therapy and moderate physical activity. Family members of all patients were also interviewed.

Results In the evaluation conducted by the team, it was found the following distribution of the most frequent diagnosis associated to disorder for the use of psychoactive substances: depression (26.3%), personality disorder (22.9%), bipolar disorder (22.3%), non-

schizophrenic psychosis (12.6%), schizophrenia (9.1%), and other diagnosis (6.8%).

Conclusions The formulation of the dual diagnosis provided a better approach of the patients on the part of the team, promoting the strengthening of the therapeutic bond and causing positive impact on the evolution of these disorders.
