Background The most prevalent disorders between the chronic diseases are the mental health disorders. Almost 650 million of people in the world suffer of some mental health disorders, which cause serious impact on individual abilities, family relationship and social rehabilitation.

Aims We describe and study the sociodemographic characteristics and the diagnosis of a sample of male and female psychiatric inpatients undergoing treatment in a mental health care center in Brazil.

Methods It is a descriptive cross-sectional study, carried out with 517 psychiatric inpatients from a Brazilian health institution – IMAS Nise da Silveira. Data was collected from January to December 2014 and occurred through consultation of the patients' hospital notes. Univariate analysis was used for the data collection and analysis.

Results Our sample was composed by 52.6% ($n = 272$) of men and 47.4% of women ($n = 245$); 50.5% were over 40 years old and have a long time of hospitalization. Overall, 64.6% had schizophrenia; 27.2% mood [affect] disorders; 3.7% mental and behavioural disorders due to psychoactive substance use; 1.4% mental retardation; 0.4% personality disorders; 0.2% disorders of psychological development.

Conclusion The profile could advance the mental health care and rehabilitation of these people. Although could improve public policies.

Attitudes towards psychiatry among physiotherapy students in Poland – pilot study

A.R. Szczegielniak^{1,*}, J. Szczegielniak²

¹ Medical University of Silesia, Department of Psychiatry and Psychotherapy, Katowice, Poland

² Opole University of Technology, Faculty of Physical Education and Physiotherapy, Opole, Poland

* Corresponding author.

Poor knowledge regarding mental health in general population in Poland, along with media coverage limited to repetition of harmful stereotypes towards patients treated at psychiatric wards and reinforcement of discriminative attitudes, results in an unfair evaluation and stigmatization of mental healthcare services. As a consequence, psychiatry, in comparison to many other medical fields, is unpopular among physiotherapy students, even though there is a compulsory subject in the university curriculum that covers, in theory, all the important knowledge that healthcare worker should possess in this regards. Young physical therapists are not taught about specific needs of the psychiatric patients. After graduation, they are lacking all basic skills on how to communicate with the patient. Being devoid of a direct contact with people suffering from mental disorders, physical therapists do not feel comfortable

placed in the mental healthcare facilities. The aim of the study was to assess the extent of a basic psychiatric knowledge and general attitudes towards mentally ill of the physiotherapy students. The group consisted of 147 students. The pilot study has been limited to those studying physical therapy within borders of the Opole voivodship. Authors' questionnaire has been developed in order to reach the aim and answers were gathered between January and June 2016. The results will be used to develop questionnaire suitable to share with physiotherapy students within the whole country and, consequently, formulate recommendations on necessary changes that must be introduced to the physical therapy curriculum in Poland by Polish Society of Physiotherapy (Psychiatry Section).

Feelings of guilt and fantasies in life experiences of Brazilian parents due to death of their newborn: A clinical-qualitative study conducted at a university hospital

L. Rodrigues, J.V. Freitas-de-Jesus, G. Lavorato-Neto, D.D. Lima, E.R. Turato*, C.J.G. Campos

UNICAMP, State University of Campinas, LPCQ, Laboratory of Clinical-Qualitative Research, Campinas, Brazil

* Corresponding author.

Introduction The relationship between parents and children is a complex link. In the process of pregnancy-birth-puerperium, frequent feelings such as responsibility, love, fear, uncertainty, generate strong expectations at birth. The death of a newborn may not be perceived as natural by the parents, considering the local culture and the context of great technological development of neonatology.

Objective To explore possible guilt and fantasies in life experiences of parents during mourning process due to death of their newborn.

Method Clinical-qualitative design, a particularization of qualitative methods here applied in clinical assistance settings with highlight to psychological aspects. Data collection with the technique of semi-directed interview with open-ended questions, in-depth. Sample intentionally constructed, with closure by theoretical saturation of information. The participants were 7 parents, mourning by the death of their child at the neonatal intensive care unit, in a university hospital of Campinas, São Paulo State.

Results Feelings of guilt – conscious or not – lead to an internal and particular movement so that mourning can be lived. The participants showed certain embarrassment, accompanied by natural suffering facing to the cultural pattern that permeates the emotional experience. It predicts types of psychological meanings that the experience will give to the person.

Conclusion Health professionals working with bereaved parents should consider more deeply the moment these one experienced, with emphasis on the details of the death scenery, beside the problems of illness and death properly so called.

* Corresponding author.

Introduction Adherence to practice guidelines for diagnosing and treating attention-deficit/hyperactivity disorder (ADHD) by primary care providers (PCPs) is important for optimizing care for many children and youth. However, adherence is often low. To address this problem, we implemented an intensive intervention in 2009 aimed at improving diagnosis and management of ADHD among PCPs.

Objectives The study objective is to assess the sustainability of intervention-attributable outcomes.

Aims The study aims are to assess the sustained effect of the intervention on PCP intentions to implement, attitudes toward, and obstacles to implement ADHD practice guidelines.

Methods During November 2009, 48 PCPs from 31 clinical practices completed a 3-day training, 6 months of biweekly telephone peer group reinforcement, and baseline questionnaires; follow-up questionnaires were completed at 12 months. To assess sustainability, we tracked PCPs and administered the questionnaire in 2016.

Results Intentions to implement ADHD guidelines remained stable over seven years, with all mean values ranging from “probably will” to “definitely will” implement guidelines.

Conclusions Generally, favorable self-reported intentions (see Exhibits 1 & 2), attitudes and obstacles to implementing ADHD guidelines were sustained seven years after the intensive training and follow-up intervention.

Task-shifting in mental health services: Extent, impact and challenges in Ghana

V. Agyapong

University of Alberta, Department of Psychiatry, Edmonton, Canada

Aim To examine the role and scope of practice of community mental health workers (CMHWs) as well as the impact and challenges associated with work of CMHWs within Ghana's mental health delivery system.

Methods A cross sectional survey of 11 psychiatrists, 29 health policy directors and 164 CMHWs as well as key informant interviews with 3 CMHWs, 5 psychiatrists and 2 health policy directors and three focus group discussions with 21 CMHWs. Results of quantitative data were analysed with SPSS version 20 whilst the results from qualitative data were analysed manually through thematic analysis.

Results In addition to duties prescribed in their job descriptions, all the CMHWs identified several jobs that they routinely perform including jobs reserved for higher level cadres such as medication prescribing for which most of the CMHWs have no training. Some CMHWs reported they had considered leaving the mental health profession because of the stigma, risk, lack of opportunities for continuing professional development and career progression as well as poor remuneration. Almost all the stakeholders believed CMHWs in Ghana receive adequate training for the role they are expected to play although many identify some gaps in the training of these mental health workers for the expanded roles they actually play. All the stakeholders expressed concerns about the quality of the care provided by CMHWs.

Conclusion The study highlights several important issues, which facilitate or hinder effective task-shifting arrangements from psychiatrists to CMHWs and impact on the quality of care provided by the latter.

Fit note use in UK clinical practice 2010–2016: A systematic review of quantitative research

S. Dorrington^{1,*}, E. Roberts¹, S. Hatch¹, I. Madan², M. Hotopf¹¹ King's College London, Department of Psychological Medicine, London, United Kingdom² King's College London, Occupational Health, London, United Kingdom

* Corresponding author.

Background The fit note, introduced in England, Wales and Scotland in 2010, was designed to radically change the sickness certification process from advising on individuals' inability to work to what they could do if adjustments were made available. Our review aimed to evaluate: (1) the percentage of fit notes utilizing the new "may be fit for work" option or advising on work adjustments, (2) the impact of the fit note on sickness absence and return to work, (3) demographic variation in fit note use.

Methods We systematically searched in Embase, Cochrane CENTRAL, Pub Med, Worldcat, Ovid and PsychInfo from 1 Jan 2010–30 Nov 2016 for studies on working aged adults which included the search terms "fit note" or "fitnote". Relevant abstracts were extracted and we assessed the quality of the papers and assessed bias using the modified Newcastle Ottawa Scale.

Results Nine papers met the inclusion criteria, four of which were based on the same cohort. Maybe fit notes made up just 6.6% of all fit notes. Work adjustments were most often recommended for patients who were less deprived, female and patients with physical health problems. Fit note advice for patients with physical health problems increased over time, but the opposite was seen for patients with mental health problems.

Conclusions Further research needed to evaluate the use, impact and potential of the fit note, especially for patients with mental illness.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The impact of change in the 2007 English law on mental health act detentions

J. Beezhold¹, G. Mosa¹, A. Pandey¹, S. Pandey¹, M. Dyer², C. Kitromilidou^{2,*}¹ Norfolk and Suffolk NHS Foundation Trust, Department of Psychiatry, Norwich, United Kingdom² University of East Anglia, Norwich Medical School, Norwich, United Kingdom

* Corresponding author.

Background The Mental Health Act (MHA) 2007 made some significant changes from the Mental Health Act 1983, including the fact that detention is now only allowed if an appropriate medical treatment is available to the patient at the time [1]. There was considerable concern at the time that the 2007 Act would lead to an increase in detentions.

Objective The primary objective is to assess how the change in the English law with the MHA 2007 has affected the number of detentions under the MHA.

Methods A retrospective, observational and noninterventional study used anonymised and routinely collected data regarding 11,509 people who were formally assessed under the Mental Health Act during the period of 2001–2011 in the county of Norfolk. This included 7885 assessments before the 2007 MHA and 3620 done after implementation.

Results The proportion of people detained following assessment decreased from 53.2% before the 2007 MHA to 42.9% after imple-

mentation ($P=.000$). The total proportion of patients admitted (whether informally or detained) also decreased from 63.3% before the 2007 MHA to 52.8% thereafter ($P=.000$).

Conclusion These results show a significant decrease in the rate of detentions under the MHA since the 2007 Act became law.

Admission to in-patient psychiatric care in the Veneto region (Italy), specialisation vs. personal continuity of care approach. Preliminary findings from the COFI study-Italian sites

E. Miglietta^{1,*}, A. Lasalvia¹, P. Sara¹, G. Zanatta¹, S. Zoppei¹, G. Dimitri¹, C. Comacchio¹, D. Cristofalo¹, C. Bonetto¹, D. Giacco², S. Priebe², M. Ruggeri¹

¹ University of Verona, Department of Neurosciences, Biomedicine and Movement Sciences, Section of Psychiatry, Verona, Italy

² Queen Mary University of London, Unit for Social and Community Psychiatry, London, United Kingdom

* Corresponding author.

Introduction In Italy, considerable variations exist in the organisation of out- and in-patient mental health care. One main issue is whether to prioritise specialisation (distinct clinicians for inpatient and outpatient care) or personal continuity of care (same primary clinician for a given patient within the two settings).

Aims To study the use of psychiatric in-patient units in the Veneto region (Italy) and to evaluate differences between personal continuity of care and specialization systems.

Methods Study conducted in the context of the COFI, multisite naturalistic EU-funded research aiming to compare the two care approaches in 5 European countries. In Italy, baseline data collection was carried out in 14 in-patient units. Data on hospitalisation, diagnosis, severity of the illness (Clinical Global Impression Scale-CGI) and patients' appraisal of inpatient care (Client Assessment of Treatment Scale- CAT) were collected.

Results Overall, 1118 patients were assessed. Most frequent diagnostic categories were mood (41.6%) and psychotic (38.3%) disorders, while anxiety disorders were less represented (11.9%). The majority of patients were at least at their second admission (69.4%) and had been voluntary admitted (91.5%). Length of stay and CGI scores were significantly higher for patients with mood and psychotic disorders. No difference in CGI score between the two systems was found. Patients in the continuity of care systems reported higher level of satisfaction with initial treatment and longer hospital stay ($P<.001$).

Conclusions These preliminary findings suggest higher service satisfaction for personal continuity system, possibly reflecting a more individualised and comprehensive focus on the patient's needs, rather than on symptoms reduction only.

In 2008, the UNHCR issued a convention on the rights of persons with disability. Since then, many countries were visited by the High Commissioner for Human Rights. In a number of countries, for example Germany and the Netherlands, mental health legislation was considered unsatisfactory and either regional variations in procedures or new legislation was drafted. In Germany, the final decision after different admission procedures is always made by a judge. In the Netherlands, detention on mental health ground with involuntary admission is decided by a Governmental administrator working for the local Major. In England and Wales, it is decided by three medical/psychiatric professionals. Currently, the Netherlands is drafting a law following the main principles of the Anglo-Saxon law. In Germany, all federal states are currently adopting their mental health laws to fulfil requirements of the Constitutional Court, which decided that coercive treatment is only admissible under very strict conditions after a judge's decision. Studies show the Dutch legislation is associated with higher seclusion rates, in numbers, and duration. Moreover, recent German findings show in a recent period when involuntary medication was not admissible, inpatient violence and coercive measures increased significantly. In this symposium, we discuss the several laws and regulations of four countries (Wales, Ireland, Germany, Netherlands), now and in the near future. Each presentation of a certain countries' regulations is followed by a description of standard figures of the country, first by an expert in the respective country's law, and consequently by an expert in nationwide or regional figures.

Stigma as an obstacle to paradigm change in mental health care in Lithuania

E. Sumskiene (Social Work)

Vilnius University, Vilnius, Lithuania

The paper is based on the data gathered during implementation of the "Project paradigm change of mental health and Well-being in Lithuania: towards empirically valid model". This project is aimed to contribute to the paradigmatic change by scientific research and evaluation of efficacy of pharmaceutical and psychotherapeutic treatment to psychological and social functioning and to estimate economic burden of treatment and mental diseases. Aim of the research is to analyse stigma as an obstacle for transition from biomedical to bio-psycho-social paradigm. Objectives

are as follows: to evaluate manifestations of stigma in mental health care from the point of view of different experts; to discuss influence of stigma on different levels of mental health care; to identify consequences of stigma to mental health care reform. A qualitative experts' research was implemented in order to reveal professional discourse around stigmatization of mental health and consequences of this phenomenon to mental health care reform. Research data reveal the strong prevalence of stigma on all levels mental health care. Individuals with psychosocial disabilities tend to choose medication instead of psychotherapy. Under influence of stigma, they prefer rapid daily consumption of medication as a substitute to active participation in the process of treatment. Politicians are influenced by stigmatizing attitudes in the society towards individuals with psychosocial disabilities, the persisting pressure to isolate them in closed facilities. Under influence of stigma, the process of reform lingers or obtains a shape reverse to a modern transformation.

Dissociative amnesia with fugue vs. Shenjing Shuairuo: A clinical case report. Are DSM-5 distress cultural considerations truly transcultural relevant?

I. Alberdi-Paramo*, M. Tenorio, G. Montero, R. Baena, L. Niell, J. Ibañez, J. Peman, M. Villanueva, J. Gomez, J. Rodriguez
Hospital Clinico San Carlos, Psiquiatria, Madrid, Spain
* Corresponding author.

Introduction We present the case report of a 21-year-old Chinese female, who was brought to the emergency department. We open the debate between the operative criteria established by DSM-5 of the clinical entity dissociative amnesia and Shenjing Shuairuo - the Chinese "culture-bound syndrome".

Objectives To expose the relevance of the cultural formulation in the clinical evaluation of patients with a different non-Western culture in Psychiatry.

Aims The Shenjing Shuairuo syndrome ("nervous system weakness") was originally described in China, it has a gradual onset, usually after a stressful event. It involves a minimum 3 of 5 symptoms group: weakness, emotions, excitement, neurological pain and sleep. This complex group of symptoms overlap with dissociative syndrome such as dissociative amnesia.

Methods/results The cultural formulation interview (CFI) was used for the diagnostic and subsequent treatment of dissociative amnesia with fugue in a different culture patient who met the clinical criteria of this two divergent clinic entities.

Conclusions In our clinical practice, we will deal with different culture patients, who could present common clinical entities or with the so-called "culture-bound syndromes". The cultural formulation of the clinical cases will help the clinicians to diagnose and have better treatment's options in clinical manifestations do not correspond to the conventional entities included in mostly Western-based nomenclatures.

Syrian refugees in Canada: Clinical experience in mental health care

K. Bazaid

CHEO, Psychiatry, Ottawa, Canada

War is the most serious of all threats to health (World Health Organization, 1982) and can have severe and lasting impacts on mental health. Forced displacement and migration generate risks to mental well-being, which can result in psychiatric illness. Yet, the majority of refugees do not develop psychopathology. Rather, they demonstrate resilience in the face of tremendous adversity. The influx of Syrian refugees to Canada poses challenges to the health care system. We will present our experience to date in the Ottawa region, including a multisector collaborative effort to provide settlement and health services to newly arriving refugees from the Middle East and elsewhere. The workshop will be brought to life by engaging with clinical cases and public health scenarios that present real world clinical challenges to the provision of mental health care for refugees.

Objectives (1) Understand the predicament of refugees including risks to mental health, coping strategies and mental health consequences, (2) know the evidence for the emergence of mental illness in refugees and the effectiveness of multi-level interventions, (3) become familiar with published guidelines and gain a working knowledge of assessment and management of psychiatric conditions in refugee populations and cultural idioms of distress. How will the participants receive feedback about their learning? Participants will have direct feedback through answers to questions. The authors welcome subsequent communication by email. Presenters can give attendants handouts on pertinent and concise information linked to the workshop.

Psychoeducation trauma intervention for refugee women survivors of intimate partner violence

R.M. Bramble (P.C., Psychotherapy/Consultant)
Caballero Counseling Services, Woodside, USA

For intimate partner violence survivors, groups are helpful in that they reduce the sense of isolation, which accompanies trauma survivors as well as provides a sense of belongingness. Judith Herman states that survivors of gender-based violence in particular, suffer from the secrecy, shame and stigma that are predictable social consequences of this form of violation. Moreover, intimate partner violence increases when women are isolated from their families, communities and peers. For refugee women, the shame associated with migration trauma, along with having an undocumented status is prevalent and keeps them from seeking services. The psychoeducation 8 session intervention helps this vulnerable population understand the physiological response stress, trauma and post traumatic stress disorder. Once symptoms have been identified, sessions enable women to reduce the symptoms by utilizing methods of self-care. Cultural specific material for Latina undocumented IPV survivors in New York City with integration of breath work, sensorimotor, music and easy movements will be highlighted to demonstrate intervention.

Suicidal ideation among international medical students studying medicine in Romania

A.D. Buzoianu^{1,*}, C.A. Popescu²¹ UMF CLUJ NAPOCA IULIU HATIEGANU, Department of Pharmacology- Toxicology and Clinical Pharmacology, Cluj-Napoca, Romania² University of Medicine and Pharmacy "Iuliu Hatieganu", Department of Abilities-Human Sciences, Cluj-Napoca, Romania

* Corresponding author.

Background The burden of mental health impairment in medical students is an important research subjects. Evidence shows that medical students have a higher prevalence of symptoms of depression and anxiety than the general population. A number of studies regarding suicidal ideation among medical students have been carried out, but this topic has largely been ignored in regard to international medical students coming from Western European countries studying medicine in Eastern European countries. Suicidal ideation is the early symptom of suicidal actions. The students are the most vulnerable and easily influenced by cases of suicide, especially in a closed group with little connections with the general population like the international students.

Objectives Following 2 suicides in our university, we aim to measure the prevalence of suicidal ideations in international students.

Methods Overall, 150 medical students from the French section studying at the University of Medicine and Pharmacy "Iuliu Hatieganu", Romania, were evaluated for symptoms of depression using BDI and for suicide ideation using Beck HS.

Results Suicidal ideation was present in 28.57% of the French international medical students. Depression and the lack of social support had a significant relationship with suicidal ideation.

Conclusions Suicide is a serious issue that has to be dealt with immediately. It is important to assist medical students who are considering the possibility of committing suicide, so that they overcome their difficulties. There is a need to identify the prevalence of suicidal ideation among medical students and for student counselling.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Homelessness and immigrants: In front of the border between Spain and France

F. Calvo^{1,â^}, C. Giralt², C. Xavier³¹ FPCEE Blanquerna, Universitat Ramon Llull, Cas Girona, Barcelona, Spain² Institut DâL(tm)Assistencia Sanitaria, Cas Girona, Girona, Spain³ FPCEE Blanquerna, Universitat Ramon Llull, Psychology, Barcelona, Spain

â^ Corresponding author.

Introduction In 2006, prior to the worldwide economic crisis which especially affected Western countries, Southern Spain was one of the illegal immigrant gateways from Africa into Europe. The aim of this study is to establish the rate of homeless immigrants in a cohort of 2006 and carry out a follow up until 2015 in order to explore the chronicity associated to the territory.

Methods Sample: 949 persons experiencing homelessness in Girona, according to official records. Procedure: prospective longitudinal study of the total population of homeless people in Girona. In 2006, a list was made of all the homeless people detected by both specialised and nonspecialised teams, which have been followed until the present day. Instruments: data bases of different official teams. Statistical analysis: measures of central tendency and dis-

persion and contingency tables were used for the comparison of qualitative variables.

Results Overall, 64.8% of the population of Girona are immigrants ($n=614$), principally from the Maghreb, ($\chi^2=36.9$, $df=4$, $P<.001$) and 333 (36.3%) are autochthonous. The percentage of homeless immigrants in relation to the total immigrant population was 4.4%. Comparing the homeless autochthonous population with the total of the autochthonous population, homelessness among autochthonous population was 0.4%.

Conclusions The results suggest that homelessness was more incidental in the immigrant group than in the autochthonous group. The percentage of immigrants who still live in homeless conditions suggests that immigration is a risk factor in the chronicity of the problem.

Migrants and psychosomatic symptoms: An evaluation in an emergency centre

M. Perito^{1,*}, R.M. Calia², G. Carpentieri¹, S. De Guglielmo¹, G. Del Buono³, V. Fasano¹, N. Fiorentino⁴, R. Napolitano¹, M. Forgione², D. Scotti², B. Solomita², F. Franza⁴¹ Neamente Neuroscience Association, Neuroscience, Avellino, Italy² You Think Association, Psychology, Avellino, Italy³ University of Salerno, Psychiatry, Salerno, Italy⁴ Neuropsychiatric Centre "Villa dei Pini", Psychiatry, Avellino, Italy

* Corresponding author.

Introduction In recent years, there has been an increase in migration in Europe. Particularly, Italy has been one of the most important landing place. Currently, migrants in the province of Avellino, South Italy city, amount to about 1400, housed in 40 facilities in 23 municipalities. Psychological interest on migration and its impact on lifestyle patterns has increased in recent years.

Objectives There are few studies that evaluated the frequent psychosomatic symptoms in these populations. Despite the trauma experienced, they are not able to give a name to the suffered and somatized pain.

Aim Assessment of somatic symptoms reported by the immigrant cohort after a three-month observation period.

Methods We included 50 migrants (21.3 mean years) hosted in emergency centre in Avellino, Italy. All guests have conducted psychological clinical interviews. At baseline, were administered following scales: the patient health questionnaire (PHQ-9); Illness Behaviour Inventory (IBI); Symptoms checklist-90-Revised (SCL-90-R) scale. Same data was collected after three months.

Results The migrant group was a heterogeneous group. Overall data on IBI and PHQ-9 scale indicate a statistically significant variation baseline vs deadline Data of IBI scale is statistically significant [T-Score: 3,921; $P: 003$]; also with PHQ-9 [T0 vs. T1: T-Score: 3,986; $P: .003$]. Similar results have been found with SCL-90-R.

Conclusions In their vocabulary, terms such as anxiety, sadness, fear exist hardly. They tend to minimize the psychological pain, not because I do not feel, but because move it on the body. They have difficulty to talk about emotions, not just a matter of culture and language, but also because they are ashamed.

Identity and immigration. From Ulysses' syndrome to the identity construct and their cultural development

E. Garcia^{1,*}, R. Moreno², B. Tarjuelo³¹ *Psychiatry- General Hospital Toledo, Addictive Conducts Unit, Toledo, Spain*² *Sermas, CSM Vallecas, Madrid, Spain*³ *Infanta Sofia Hospital- San Sebastián de los Reyes, Brief Hospitalation Unit, Madrid, Spain** *Corresponding author.*

Immigration is one well known but complex stressor. When we analyze its consequences, we discover the loss of social or family support, the need to afford a new unknown and many times hostile perceived environment, or languages/communications problems. Greek myths have been used as a way to explain how men afford that kind of events/monsters. However as cultural productions, myths grow and change trying to reflex the culture, society and time when they are used. Identity has been a main question for many disciplines, psychiatry has wondered about its construction but society has too, and sometimes last explanations are even better than clinical ones. We would like to discuss the immigration phenomena using anthropology tools, which previously have nourish other psychiatric disciplines as systemic therapy. If we want to be able to treat immigrants, we have not only to fulfill their physical needs or treat their mental symptoms but to look every travel as a risk one, in which as Ulysses they are at risk of losing what they are, their identity. Identity is described in old Greece as the life lived with others, but not any other person, just those who know us and may accept our own images. In the past, the city, our born place, as a social support was what made us humans. Ulysses, out of Ithaca, found monsters, those who weren't humans, because they didn't live in his Greek society. As the new Ulysses, the immigrant maybe should be first helped to construct a new identity, which makes monsters disappear.

Mental health of child & adolescent refugees: The hidden momentum for a paneuropean call for action

A. Kanellopoulos

Evgenidion Therapeftirion National Kapodistrian University Athens, Mental Helath Care Unit, Athens, Greece

Introduction Over one percent of the world's population are currently uprooted. Over half of the world's displaced population are children.

Objective There is considerable evidence that refugee children are at significant risk of developing psychological disturbance as they are subject to a number of risk factors.

Aim Consistent research findings show that as the number of risk factors accumulates for children, the likelihood that they will develop psychological disturbance dramatically increases.

Methods Traumatic events can have an effect on a child's emotional, cognitive and moral development because they influence the child's self-perceptions and expectations of others. The multidimensional effects of trauma on children and their families are compounded by forced uprooting, multiple losses and the myriad changes brought about by migration. Mental health services can be key to restoring basic psychological functioning and to supporting resilience and positive coping strategies for children, adolescents and adults.

Results Refugee children are a silent group that are easily overlooked. Our attitude toward young refugees and their families will determine the burden of trauma, not only on their adult future but also on our community.

Conclusions An empathic and mentalizing attitude, secure sheltering, addressing health and educational needs will create a sense of stability and confidence. This is the very first step to favour, for these future adults.

Helping abused children from various minorities in the Greek context

A. Kanellopoulos*, K. Dionysopoulou, X. Antoniou, E. Marini, G. Nikolaidis

*Child & Adolescent Psychiatrist, Day Center "The House of the Child", Child of the Child, Athens, Greece** *Corresponding author.*

Introduction Children's abuse and neglect is widely studied as a major risk factor for emotional and behavioural disorders, various somatic and psychiatric problems during adulthood.

Objective Mental health is fundamental to health. Mental illnesses are real, disabling conditions affecting all populations regardless of race or ethnicity but disparities in mental health services exist for racial and ethnic minorities, and thus, mental illnesses exact a greater toll on their overall health and productivity.

Aim The most important aim when working with ethnic minorities is to better understand the roles of culture, race and ethnicity, and overcome obstacles that would keep anyone with mental health problems from seeking or receiving effective treatment.

Methods The Day Centre "The House of the Child" is a community unit which provides customized clinical mental health services for therapeutic treatment and psychosocial rehabilitation of children victims of abuse, neglect or domestic violence. The Day Centre was founded by the non-profit voluntary organization "THE SMILE OF THE CHILD". The services are based on the bio-psycho-social model approach and treatment, which aim at early detection, and treatment of possible mental disorders and the overall psychosocial rehabilitation of victims of abuse/neglect and the support of their carers.

Results By identifying the many barriers to quality care faced by racial and ethnic minorities, the Day Center provides mental health services also to children who come from minority populations.

Conclusions Different case studies highlight challenges and various levels of difficulties in this specific scheme of cooperation aiming to open an interesting dialogue on the topic.

Relationship and family therapy for newly-resettled refugees: A qualitative inquiry of an innovative, needs-adapted approach in Sydney, Australia

A. Karageorge^{1,*}, P. Rhodes¹, R. Gray², R. Papadopoulos³¹ *University of Sydney, Clinical Psychology Unit, Sydney, Australia*² *Relationships Australia NSW, Research & Evaluation, Sydney, Australia*³ *University of Essex, Centre for Trauma Asylum and Refugees, Essex, United Kingdom** *Corresponding author.*

Introduction The needs of refugees are of pivotal concern internationally. Relational trauma, in particular, is an area that is under-emphasised and under-researched. The strength to strength program (STS) was a rare, innovative relationship and family counselling service for recently-arrived refugees in Sydney, Australia during 2006–2014. The service model built on post-Milan systemic family therapy principles to include innovative cultural and trauma-informed aspects of care.

Objectives We were interested in the experiences of staff who delivered the program, and the ways in which more traditional, Western-informed modes of family therapy were transformed by the needs of refugee clients.

Aims To identify and describe transformations to the delivery of relationship and family counselling with refugees that enabled care, from the perspective of staff.

Methods A thematic analysis, guided by interpretive description, of individual interviews and focus groups with STS service staff ($n=20$), including family therapists, bicultural workers and managers.

Results Key themes pertaining to innovative aspects of the relationship and family counselling service provided by STS staff will be outlined and lessons for future service provision in this space considered.

Conclusions STS is an example of staff-driven innovation to the therapeutic care of refugee families resettling in Western countries, taking into account the unique and complex set of cultural, practical and psychological needs. Important and timely lessons for future service delivery can be drawn from qualitative inquiry into the experiences of staff who deliver such programs, with refugee numbers continuing to increase internationally.

Interdisciplinary treatment and complex rehabilitation of internally displaced persons in University Clinic

V. Korostiy*, O. Platynuk

Kharkiv National Medical University, Psychiatry- narcology and medical psychology, Kharkov, Ukraine

* Corresponding author.

Introduction Over 1,5 million of them are Ukrainians who were forced to leave their home after Crimea annexation and military conflict in the East of Ukraine.

Objectives By 2015, the University Clinic asked 156 people displaced from Lugansk and Donetsk regions. Reasons treatment: all patients were somatic complaints. In screening: using the scale hospital, all patients were found higher rates of anxiety and depression. Overall, 48% of patients abandoned psychiatric examination, even 24% of psychological counseling.

Aims Screening of IDPs' mental health who sought medical help in somatic clinic (University clinic KhNMU) and estimation of efficiency of interdisciplinary treatment and complex rehabilitation.

Methods Psychodiagnostical, clinical-psychological, clinical-psychopathological.

Results Clinical examination during the period of acute stress reactions was observed, dominated by anxiety disorders, prolonged depressive reaction. Anxiety disorders were found in 56.5%, prolonged depressive reaction in 32.0%, post-traumatic stress disorder in 10.5% of patients. The treatment of the underlying disease, complex psychological and physical rehabilitation. Psychological rehabilitation included CBT, relaxation, art therapy. Physical rehabilitation includes kinesiotherapy and TRE. A set of measures of physical rehabilitation led to reduction of anxiety to physiological levels in all mentally healthy patients, reduce the severity of psychosomatic symptoms in the structure of the underlying

disease, increased satisfaction with the results of treatment by 28.5%.

Conclusions Analysis of mental health study of IDPs and evaluation of comprehensive rehabilitation in terms of the University Clinic show the need for screening mental state when applying for medical assistance and the desirability of psychological and physical rehabilitation of patients during hospital stay somatic profile.

Epidemiological study between Greek people and immigrants with regard to diagnosis in a Greek hospital in Athens

G. Lyrakos^{1,*}, D. Menti², A. Dimitriou¹, I. Spyropoulos¹, V. Spinaris¹

¹ General Hospital Nikaia "Ag. Panteleimon", Psychiatric, Nikaia, Greece

² City Unity College- Cardiff MU, Master in Health Psychology, Athens, Greece

* Corresponding author.

Introduction Differences between the most frequently reported diagnoses of Greek people and immigrants in Greece are expected due to the different underlying factors which are associated with mental health issues.

Objectives Examine differences in diagnoses between Greek people and immigrants.

Aims To investigate whether Greek people and immigrants had significant differences with regard to reported diagnoses in a Greek hospital.

Methods The patients who participated in this study are 5551, among them 2760 (49.7%) were males and 2791 (50.3%) were females. The mean age of the sample was 45.54. The sample consisted of 455 (8.3%) immigrants and 5,042 (91.7%) Greek people. Convenience sampling method was used and the sample was collected at the General Hospital of Nikaia, "Ag. Panteleimon" in Athens, Greece, between 01/01/2012 and 31/12/2015.

Results There were significant differences between Greek people and immigrant with regard to diagnosis as $\chi^2(20): 136.875, P < 0.001$. More specifically, among Greek people, the most frequently reported diagnosis was psychotic disorder (26.2%), followed by depression (24.7%), general anxiety disorder (9.9%) and substance abuse (8.4%). Among immigrants, the most frequently reported diagnosis was psychotic disorder (22.9%), followed by substance abuse (21.3%), depression (17.4%) and general anxiety disorder (12.1%).

Conclusions The differences between Greek people and immigrants with regard to diagnoses showcase the different needs between the two populations with regard to mental health. Especially, the higher prevalence of anxiety disorders and substance abuse problems among immigrants highlight the need for protective measures to improve their well-being and reduce their risk of mental health issues.

EV0677

The perceptions of Greek immigrants in Germany about the health illness and pain in the context of mental health

S. Kotrotsiou^{1,*}, A. Tsoumani¹, E. Kotrotsiou¹, M. Gouva², E. Dragioti³, T. Paralikas¹

¹ University of Applied Sciences of Thessaly, Nursing-Postgraduate Program in Mental Health-Research Laboratory of Care, Larissa, Greece

² University of Applied Sciences of Epirus, Nursing-Research Laboratory Psychology of Patients Families and Health Professionals, Ioannina, Greece

³ Linköping University, Medical and Health Sciences, Linköping, Sweden

* Corresponding author.

Aim This study aims to investigate the perceptions of health, disease and pain issues among Greek immigrant, living in Germany, as they were formed through their previous experiences, their immigration routes and their experiences in a new sociocultural environment, while taking under consideration their varying cultural backgrounds.

Material-method This research was based on the personal interpretations of ten Greek immigrant (6 women and 4 men). As to methodology, qualitative research was employed. The methodological tools used for the collection of the material were semi-structured interviews (face to face), participant observation and a field diary. Finally, the method of analysis used for the empirical material was content thematic analysis.

Results All participants experienced immigration as an especially stressful period of their lives that changed their state of health (these changes extend from physical complaints to manifestation of depression). Most person describe life in Germany as difficult due to various problems (loss of relatives and friends' social networks, poor language knowledge, isolation, etc.). However, the public health system's organization (regardless any flaws), which ensures their access to health services, positively contributed in changing their attitudes regarding the issues under question. Lastly, the reference to psycho-traumatic situations, transitional life phases, as well as to stimuli in the difficult everyday life feed person's meaning-makings about pain.

Conclusions The research's results showed that health and disease are not only biologically determined phenomena. They also are socially determined situations, given that they are not only related to changes in the individual's psychology but are influenced by the broader sociocultural environment in which the individual lives and works.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Problems of investigation of immigrants' students and their relation to psychopathology

S. Kotrotsiou^{1,*}, E. Tsoumani², E. Kotrotsiou¹, M. Gouva³, E. Dragioti⁴, T. Paralikas¹

¹ University of Applied Sciences of Thessaly, Nursing-Postgraduate Program in Mental Health-Research Laboratory of Care, Larissa, Greece

² University of Applied Sciences of Thessaly, Nursing-Postgraduate Program in Mental Health, Larissa, Greece

³ University of Applied Sciences of Epirus, Nursing-Research Laboratory Psychology of Patients Families and Health Professionals, Ioannina, Greece

⁴ Linköping University, Medical and Health Sciences, Linköping, Sweden

* Corresponding author.

Introduction The purpose of this research was to investigate the problems of first-generation immigrant students and the linkage of these problems with the psychopathology of students.

Objectives The sample of this study included men and women students, that were second-generation immigrants aged from 18 to > 25 years.

Methods The research tools used were: (a) Psychopathology Scale (Symptom Checklist 90-R - SCL-90) and (b) State - Trait Anxiety Inventory (STAI), (c) the orientation test life (LOT-R) d) Other As Shamer Scale (OAS), (e) Experience of Shame Scale (ESS). The statistical processing of data showed Q (a) the students immigrants have higher levels of student migrants stairways: inferior (OAS), empty (OAS), (Mistakes (OAS), Total internal shame (ESS), characterological shame (ESS), behavioral shame (ESS), bodily shame (ESS), Trait Anxiety (STAI), Somatization (SCL-90), Inter. Sensitivity (SCL-90) and Depression (SCL-90).

Results The results of our study found high levels of psychopathology students immigrants and students migrant and interpretative this finding is explained by the lifestyle of their parents immigrants and different cultures which have to cope and adapt and their marginalization from society and official institutions, a situation that results in their exposure to a variety of risks to their mental health.

Conclusions In addition to increased levels of psychopathology, second generation immigrants such as students and the students in our sample suffer from violence the authorities and their fellow citizens.

⁹ European Federation of Psychiatry Trainees, Brain drain study, Brussels, Belgium

* Corresponding author.

Introduction It is a well known fact that qualified health professionals generally migrate to high-income, developed regions. Nevertheless, the perceptions of this immigrant skilled health workforce on access to opportunities or feeling discriminated in their host countries, have not yet been explored or adequately addressed.

Objectives This work has focused on the perceptions of immigrant psychiatry trainees in several European countries about their

views on having equal access to opportunities as natives or feeling discriminated.

Methods A semi-structured 61-item questionnaire was circulated by National Coordinators in each country and was completed by 2281 psychiatric trainees from 33 European countries between year 2013 and 2014. Data has been analysed using the Software Package for Social Sciences for Windows v. 22.0 (SPSS Inc. Chicago, IL).

Results In these findings, more than one in ten psychiatry trainees across Europe were immigrants, with top host countries being Switzerland, Sweden and UK. Satisfaction with migration and the perception of having equal opportunities as the native trainees varied depending on the host country they migrated to. More than one-third of the trainees felt discriminated, not having the same opportunities as the local colleagues, especially concerning the work opportunities and the academic conditions. Still, nearly two-thirds considered having the same opportunities than natives.

Conclusions A high number of immigrant psychiatry trainees subjectively feels they do not have the same opportunities as local trainees. Further research about factual and perceived discrimination by immigrant workforce should be done.

Suicide risk among immigrants and ethnic minorities

M. Pompili

Sapienza University of Rome, Department of Neurosciences- Mental Health and Sensory Organs, Rome, Italy

Introduction Recent historical perspective suggests that suicide is a neglected issue among immigrants and ethnic minorities.

Objective Given the need to delivering proper care to such populations, government is now requested to address suicide risk and involve proper interventions.

Aims To provide comprehensive overview of suicide risk among immigrants and ethnic minorities and possible targeted preventive measures.

Methods Given the relatively early and underdeveloped state of this area of inquiry, the author viewed his task as gathering and critically appraising the available research relevant to the topic, with the aim of formulating a hypothesis to be tested with further research.

Results Evidence support the notion that certain communalities across ethnic groups are influenced in a considerable way by the suicide risk in the country of origin. Furthermore, some well-known risk factors for suicide may not play a central role in the case immigrants and ethnic minorities; on the contrary, adjustment problems point to the explanation that emotional distress may be caused by social problems, racism and discrimination. Suicide risk among these individuals may also be referred to the risk in the country of origin pointing to greater complexity when individuals immigrate into a country with different suicide rates as well as different contributing factors. Help-seeking barriers are still a major obstacle for delivering proper preventive intervention. The author aims at providing a comprehensive picture of suicide risk among this population and highlight possible preventive strategies.

Conclusions Social interventions, culture-sensitive community projects or interventions targeting specific subgroups might be possible solutions.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Symptoms of anxiety and depression in Romanian and international medical students: Relationship with big-five personality dimensions and social support

C.A. Popescu^{1,*}, A.D. Buzoianu²

¹ University of Medicine and Pharmacy "Iuliu Hatieganu", Department of Abilities-Human Sciences, Cluj-Napoca, Romania

² University of Medicine and Pharmacy "Iuliu Hatieganu", Department of Pharmacology-Toxicology and Clinical Pharmacology, Cluj-Napoca, Romania

* Corresponding author.

Background A wide variety of countries are seeking to attract international medical students. International students are quite distinct from local students with respect to ethnicity, race, social and cultural norms, customs, nationality and physical appearance. Medical students are more predisposed to mental disorders, including depression due to several factors, such as: individual personality characteristics, chronic exposure to stressors from an occupation that deals with pain and death and trouble with the teaching-learning process. In the host country, international medical students meet a lot of stressful situations as: language barriers, academic demands, homesickness and lack of social support.

Aims To evaluate the prevalence of anxiety and depression in Romanian and international medical students studying medicine in Romania. To assess the relationship between symptoms of anxiety, symptoms of depression and big-five personality dimensions in medical students.

Methods Overall, 230 first year medical students (90 from English section, 70 from French section and 70 from Romanian sections studying at the University of Medicine and Pharmacy "Iuliu Hatieganu", Romania, were evaluated for symptoms of anxiety and depression using the STAI and BDI and for personality using the NEO FFI.

Results Symptoms of anxiety and symptoms of depression were prevalent in medical students (43% and 14%, respectively).

Conclusions Symptoms of anxiety and depression are prevalent in medical students. Severity of symptoms of anxiety and symptoms of depression in medical students are negatively related to emotional stability. Special attention should be paid to those students who have high levels of depression and low levels of emotional stability.

A pilot study on posttraumatic stress disorder prevalence in asylum seeker in primary reception setting

N. Vaccino^{1,*}, M.S. Signorelli¹, A. Rodolico¹, M.C. Riso^{1,2}, E. Aguglia¹

¹ University of Catania, Clinical and Experimental Medicine, Catania, Italy

² Italian Red Cross, Local Branch of Catania, Catania, Italy

* Corresponding author.

Introduction Social, political and health related effects of "European migrant crisis" are challenging our Old Continent, not always capable to address immigrants' needs.

Objectives Our main purpose is to estimate the prevalence of post-traumatic stress disorder among asylum seekers arriving in Italy.

Methods We designed a cross-sectional study for prevalence estimation in a reception centre where asylum seekers stay for their

first period in Italy. They are given hospitality until the possibility of their permanence is verified. We created a survey asking for general information. Participants also received PTSD Checklist (PCL-C). In our analysis, we adopted 45 as cut-off for diagnosis. Questionnaires have been delivered house-to-house and collected when completed.

Results In this pilot study, we collected 61 questionnaires. The majority of answers came from male subjects (46). The prevalence of PTSD was 44% (47% among men and 53% among women, not statistically different).

Conclusions So high rate of PTSD depicts a reality that cannot be left apart. Our attention toward immigrants must focus also on their mental health. European Union should consider new solutions to take care of these critical aspects of those.

EV0683

The impact of EU political ambiguity towards migrant crisis on the mental health of migrants

S. Veceric Kulovic

Private psychiatric practice, psychiatry, Zagreb, Croatia

For last couple of years, EU is facing migrant crisis that is challenging its capacity to help and its unity to decide the modes of assistance. Such political context brings additional uncertainty and insecurity into migrants' lives which causes extreme experiences that are often damaging migrants' mental health. In humanitarian plans regarding assistance for migrants, mental health is a cross cutting issue. Status of mental health is a result of complex intertwining of genetics, developmental and current life experiences. The experience of migration is a current life event which highly determines migrants' mental health. Hardships of travel along migration route are worsened by often hostile reception by authorities at borders of countries that are on the way to desired rich EU countries. On migrants' way to desired safety, there are countries like Slovenia and Hungary which protect their borders with wire. Therefore, migrants are stuck in countries, like Greece and Croatia, which are not their desirable destination. While waiting to get free passage, migrants are exposed to various political rhetoric of politicians of EU countries who hold their destiny in their hands. Migration experience does not make migrants mentally ill but it does make them vulnerable in that respect. Migrants' vulnerability is highly challenged by ambiguity of political decisions, media coverage influenced by the same policies and concomitant changes in immediate surrounding. It is crucial to make publicly clear that political decisions mean life or death, health or mental disorder to migrants and that therefore they at least carry ethical responsibility.

⁴ Duke University, School of Medicine, North Carolina, USA

⁵ Humanitarian Organization for Migration Economics, Humanitarian Organization for Migration Economics, Singapore, Singapore

* Corresponding author.

Introduction Approximately one in every five Singaporean households employs Foreign Domestic Workers (FDWs) (Humanitarian Organization for Migration Economics [Home], 2015). Mental health problems, especially depression, are prevalent among FDWs in Singapore (HOME, 2015). Yet, there is a lack of empirically-supported interventions to address their mental health needs.

Objective To train FDWs as mental health paraprofessionals with selected CBT skills for depression, which may enable them to provide basic assistance to their fellow domestic workers with depressive symptoms.

Aims To present and assess the effectiveness and acceptability of a 4 weekly 3-hour group CBT-based paraprofessional training program for FDWs.

Methods Participants were randomized into either an intervention or a wait-list control group. Participants in the wait-list group received the training after the intervention group completed the training. Both groups completed questionnaires assessing attitudes towards seeking psychological help; stigma towards people with depression; self-confidence in delivering CBT; general self-efficacy; knowledge of depression and CBT before, immediately after, and two months following the training.

Results Thirty-eight out of 40 participants completed the program. Both groups did not differ on changes in any of the outcome variables. However, within-group analyses showed improved attitudes towards seeking professional health for mental health issues; greater depression literacy; and CBT knowledge following the training. These changes were sustained at 2-month follow-up. All participants indicated high level of satisfaction with the program.

Conclusions These preliminary results highlight the potential effectiveness and feasibility of implementing the training as a stepped-care mental health service to address the high rate of depression among the FDW community.

Identity, culture and psychosis: A non-systematic review

S. Xavier*, A.F. Correia, S. Barbosa, V. Dindo, T. Maia
Hospital Prof. Doutor Fernando Fonseca, Psychiatry, Amadora, Portugal

* Corresponding author.

Introduction Given the results of multiple epidemiological studies showing a greater incidence of schizophrenia in migrants, especially in second-generation migrants, many researchers tried to investigate which factors could be associated to these findings, in order to have a better understanding of the migration process itself and simultaneously to contribute to improve knowledge about schizophrenia. In line with the research suggesting that social factors are important contributors to psychological suffering and vulnerability to psychosis, several authors pointed cultural identity as a possible mediator between migration and psychosis.

Objectives To review different perspectives on the current literature about the relationship between cultural identity and psychosis.

Methods Non-systematic review searching on the database MEDLINE and additional searches through secondary references.

Results Concepts like identity clarity and identity value attributions are closely related to psychological well-being and may influence vulnerability or resilience to severe mental illness. Simultaneously, these concepts are also regarded as closely linked to social and cultural identity. Feelings of uncertainty between multiple existential positions that may arise for migrants (especially if hierarchical and unequal relationships of power are established) could compromise the sense of meaning and coherence of the self and compromise identity structure, thereby predisposing to psychotic experiences.

Conclusions Even taking into account the heterogeneity of the reviewed articles, there seems to be some consensus regarding the importance of culture on how individuals experience themselves and others and that preservation of a solid and coherent cultural identity may be a crucial aspect to take into account when studying resilience against severe mental diseases.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Major depressive disorder comorbid severe hydrocephalus due to Arnold Chiari malformation in an apathetic patient

A. Kandeger¹, H.A. Guler^{2,*}, O. Guler³

¹ Selcuk University, Psychiatry, Konya, Turkey

² Selcuk University, Department of Child and Adolescent Psychiatry, Konya, Turkey

³ Selcuk University, Department of Psychiatry, Konya, Turkey

* Corresponding author.

Objective Arnold Chiari Malformation (ACM) is a disorder of embryologic development that is characterized of herniation of the cerebellar structures through the foramen magnum by four types. ACM type 1 (ACM 1) consists in cerebellar tonsil herniation, which is sometimes associated with other abnormalities, including syringohydromyelia, hydrocephalus and skull base alterations. To date, five cases of psychiatric disorders comorbid with ACM-I have been reported. We here present an apathetic patient have delayed diagnosis ACM-I and severe hydrocephalus and comorbid major depressive disorder.

Case A 36-year-old, male patient who is married and two children, was admitted to hospital with don't want to make anything, despondency, thoughts of have an incompetency, uselessness and want to death, tiredness, weakness complaints which are increased day by day last 2 months. He was diagnosed with major depression after the psychiatric evaluation and hospitalised. He has unwillingness, tiredness and headache complaints which are started when he was 20 years old and he used antidepressant, anxiolytic, and low dose antipsychotic drugs under psychiatrist control at this years. In radiologic evaluation, Arnold Chiari type 1 and severe hydrocephalus was detected in brain magnetic resonance imaging.

Discussion ACM 1 is related to hydrocephalus as a result of posterior fossa hypoplasia and causes spinal injury by obstruction to cerebrospinal fluid (CSF) flow at the foramen magnum. Apathy is a common yet often overlooked symptom in hydrocephalus. This symptom may be a significant obstacle for cognition and quality of life and is associated with increased level of depression.

Perfusion SPECT in the differential diagnosis of dementia

D. Brigadeiro*, J. Nunes, T. Ventura Gil, P. Costa

Hospital Sousa Martins-ULS Guarda EPE, Departamento de Psiquiatria e Saúde Mental, Guarda, Portugal

* Corresponding author.

Dementia is a syndrome—usually of a chronic or progressive nature—in which there is deterioration in cognitive function beyond what might be expected from normal ageing (WHO). As the world population ages, the number of people afflicted with dementing illnesses will increase. This neurodegenerative disease is one of the major causes of disability and dependency among older people worldwide. Brain single-photon emission computed tomography (SPECT) allows the study of regional cerebral blood flow, providing functional information. Each of the different types of dementia has a distinct blood flow pattern that is revealed with SPECT imaging and which can be used for differential diagnoses. This imaging technique can also be used to differentiate dementia from pseudodementia. The use of SPECT has been recommended in various guidelines to help in differential diagnosis of dementia. The National Institute for Health and Clinical Excellence in the UK recommend the use of SPECT or positron emission tomography (PET) to help differentiate Alzheimer's disease (AD) from frontotemporal dementia and vascular dementia when there is diagnostic doubt (NICE, 2006). The European Federation of the Neurological Societies guidelines for diagnosis also supports the use of FDG-PET (18F fluorodeoxyglucose positron emission tomography) or perfusion SPECT when clarifying a diagnosis of AD. This review describes the utility of perfusion SPECT in differential diagnosis of neurodegenerative dementias.

Examining the clinical utility of neuroimaging on an inpatient psychiatric unit

L. Gonzalez*, M. Mashayekh, W. Gu, P. Korenis, A. Khadivi

Bronx Lebanon Hospital Center, Psychiatry, Bronx, USA

* Corresponding author.

Introduction Recent developments in neuroimaging have revolutionized medicine and aided in our understanding of how biological abnormalities may contribute to clinical presentation. While such advances have begun to enhance our knowledge about the timing of abnormalities, it remains unclear at this time how neuroimaging impacts the clinical course of the patient. In addition, much debate exists regarding the clinical necessity of neuroimaging for psychiatric conditions, and there are contradictory reports and guidelines for the application of conventional brain imaging (MRI and CT) in the evaluation of patients with mental illness.

Objective We aim to review the clinical utility of neuroimaging in an acute psychiatric setting, and hypothesize that there will be no significant differences between the outcome of neuroimaging and clinical course for patients.

Method We conducted a retrospective chart review of adult patients who were diagnosed and treated for psychiatric conditions on an inpatient psychiatric service over a period of 36 months July 1, 2013–June 30, 2016.

Conclusions While imaging advances have added to our understanding of biological abnormalities and can aid in ruling out organic causes of psychiatric illness, at this time it is not guiding clinical management for patients.

Cerebellar activity in young people with familial risk for psychosis – The Oulu brain and mind study

T. Jukuri^{1,*}, V. Kiviniemi², J. Veijola¹

¹ Research Unit of Clinical Neuroscience, University of Oulu, Psychiatry, Oulu, Finland

² Oulu University Hospital, Diagnostic Radiology, MIPT, Oulu, Finland

* Corresponding author.

Objective The cerebellum plays a critical role in cognition and behavior. Altered function of the cerebellum has been related to schizophrenia and psychosis but it is not known how this applies to spontaneous resting state activity in young people with familial risk for psychosis.

Methods We conducted resting-state functional MRI (R-fMRI) in 72 (29 male) young adults with a history of psychosis in one or both parents (FR) but without their own psychosis, and 72 (29 male) similarly healthy control subjects without parental psychosis. Both groups in the Oulu Brain and Mind Study were drawn from the Northern Finland Birth Cohort 1986. Participants were 20–25 years old. Parental psychosis was established using the Care Register for Health Care. R-fMRI data pre-processing was conducted using independent component analysis with 30 and 70 components. A dual regression technique was used to detect between-group differences in the cerebellum with $p < 0.05$ threshold corrected for multiple comparisons.

Results FR participants demonstrated statistically significantly increased activity compared to control subjects in the anterior lobe of the right cerebellum in the analysis with 70 components. The volume of the increased activity was 73 mm³. There was no difference between the groups in the analysis with 30 components (Fig. 1).

Conclusion The finding suggests that increased activity of the anterior lobe of the right cerebellum may be associated with increased vulnerability to psychosis. The finding is novel, and needs replication to be confirmed.

Atypical callosal morphology in developmental language disorder

E. Luders^{1,*}, F. Kurth¹, L. Pigdon², G. Conti-Ramsden³, S. Reilly⁴, A. Morgan²

¹ UCLA School of Medicine, Psychiatry, Los Angeles, USA

³ University of Manchester, University of Manchester, Manchester, United Kingdom

⁴ Menzies Health Institute at Griffith University, Gold Coast, Australia

* Corresponding author.

Introduction Developmental language disorder (DLD) is common, yet the neurobiology of DLD is poorly understood. A key hypothesis suggests atypical functional lateralization of language, which might be accompanied structurally by a deficit in inter-hemispheric connectivity of language-related regions. Indeed, aberrations of the corpus callosum have been associated with language deficits in children with frank neurological lesions and/or born pre-term. In contrast, studies examining the corpus callosum in children with DLD remain elusive.

Objective We aimed to expand this largely understudied field by comparing callosal morphology between 17 children with DLD and 17 typically developing children carefully matched for sex and age.

Methods We analyzed high-resolution structural magnetic resonance imaging data applying a well-validated computational approach, which captures the thickness of the corpus callosum with a high regional specificity at 100 equidistant points.

Results As shown in Fig. 1, we observed a significantly thinner corpus callosum, particularly in the splenium, in children with DLD compared to typically developing controls (DLD < CTL).

Conclusions These findings indicating pronounced aberrations in the brain's largest whiter matter tract make an important contribution to an understudied field of research and support the theory that DLD is accompanied by atypical lateralization of language function.

Quantitative EEG may help differentiating bipolar disorder at old age from frontotemporal dementia

S.Z. Metin^{1,*}, B. Metin², B. Kocarlan², C. Salcini³, N. Tarhan¹

¹ Uskudar University, Psychiatry, Istanbul, Turkey

² Uskudar University, Psychology, Istanbul, Turkey

³ Uskudar University, Neurology, Istanbul, Turkey

* Corresponding author.

Introduction Especially the behavioral variant of Frontotemporal Dementia (FTD) may present with impulsivity, social disinhibition or depressive symptoms and these symptoms may create a clinical profile very similar to Bipolar Disorder (BD). In clinical practice, this similarity at symptom level creates substantial diagnostic confusion and often errors. As the treatment approach to the two disorders differ significantly, it is essential to make a reliable differential diagnosis.

Aim In this study we aimed to identify EEG differences between FTD and BD.

Methods For this aim we recruited 22 patients with FTD and 32 patients with BD. Patients in both groups were evaluated with a standardized neuropsychological battery and structural MRI. All patients were evaluated with resting EEG. There were no significant age and gender differences between groups.

Results EEG power analysis showed that FTD group had increased frontal and temporal theta as compared to the BD group. There were no consistent group differences for other bands.

Conclusion Based on this result we conclude that quantitative EEG may help differentiating BD from FTD and may eliminate diagnostic uncertainty.

The effects of medication on default mode network (DMN) connectivity in attention deficit/hyperactivity disorder (ADHD): Bibliographic review

V. Pereira*, P. de Castro-Manglano

Clinica Universidad de Navarra, Psychiatry and Medical Psychology, Pamplona, Spain

* Corresponding author.

Introduction ADHD is a neurodevelopmental disorder comprising brain structural and functional alterations, especially in default mode network (DMN), as MRI studies have recently shown. However, it is not clear in which extent medication for ADHD may influence the activity of these networks.

Objectives The main purpose is to look up published evidence about the effects of ADHD medication on the connectivity of DMN in patients as measured with functional-MRI.

Methods A review was conducted with Pubmed, using search terms 'default mode network'+ 'ADHD'+ 'medication'/'methylphenidate'/'atomoxetine'/'stimulant'/'lisdexanfetamine'. Original research studies in English using f-MRI to assess DMN connectivity in ADHD patients were included in a more comprehensive review.

Results The searches found 124 articles, 8 meeting the review criteria. A total size of 146 ADHD patients was comprised (mean size: 18.25 patients). Three studies used specific resting-state f-MRI. Seven were drug trials, 3 of them short-term, randomized and controlled ones. Six included methylphenidate, 2 atomoxetine, 1 lisdexanfetamine and 3 amphetamines. Two also assessed drugs clinical effects. Evidence seems heterogeneous, but mostly consistent with normalizing drug effects on DMN in patients (in some studies also compared with healthy controls), associated with a measured clinical improvement in one study with amphetamines and one with atomoxetine. One trial found little differences on DMN activity.

Conclusions Psychostimulant drugs and atomoxetine are clinically effective medications; DMN connectivity may partially explain their action mechanisms and constitute a potential response predictor. Further f-MRI studies might more deeply assess the imaging-clinical relationships for each drug.

EV0693

Dynamic of NAA and BOLD after single short stimulus in motor cortex of Schizophrenia patients

M. Ublinskiy^{1,*}, N. Semenova¹, I. Lebedeva², T. Akhadov¹

¹ Children's Clinical and Research Institute Emergency Surgery and Trauma, Radiology, Moscow, Russia

² Psychiatry, National Mental Health Research Centre of the Russian Academy of Medical Sciences, Psychiatry, Moscow, Russia

* Corresponding author.

Introduction The aim of this study was the analysis of dynamics of motor cortex metabolite in the norm and in early stage of schizophrenia in period of BOLD response to event related single stimulus.

Objectives The patients group consisted of 9 mails of 16–28 years old in initial stage of schizophrenia and in remission. The group of 9 age matched healthy mails was used as a control.

Methods Phillips Achieva 3.0T scanner was used for the study. Volume of interest in motor cortex was localized on the base of fMRI. 1H MR spectra were run using synchronization of FID signals acquisition (PRESS, TE = 30 ms TR = 3000 ms) with dynamics of BOLD response at the same paradigm.

Results The BOLD signal in both groups demonstrated maximum at the 6th s after target stimulus, however its value was reliably lower in schizophrenia in comparison with the control. The only [NAA] in normal motor cortex was changed after stimulation. The stable values of [NAA], [Cr] and [Cho] were observed in dynamic of resting state as well. [NAA] in normal cortex statistically significantly decreased at the 12th s after stimulus presentation and returned to initial value at the 15th s.

Conclusion Different behavior of [NAA] in the norm and schizophrenia might be related with a difference in location (or activity) of aspartoacylase (ASPA). Decreased expression of glutamate transporters in schizophrenia could also reduce consumption of NAA as a source of acetate in synthesis of AcCoA which is used for restoration of ATP.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Normal pressure hydrocephalus as a possible reversible cause of dementia, neuroimaging findings

A. Zacharzewska-Gondek^{1,*}, T. Gondek², M. Sasiadek¹, J. Bładowska¹

¹ Wrocław Medical University, Department of General and Interventional Radiology and Neuroradiology, Wrocław, Poland

² Wrocław Medical University, Department of Psychiatry, Wrocław, Poland

* Corresponding author.

Introduction Normal pressure hydrocephalus (NPH) occurs in 0.5% of persons over 65 years old. The etiology of NPH is still unknown. Clinically NPH is characterised by cognitive deterioration, gait impairment and urinary incontinence. NPH is a possible reversible cause of dementia. Neuroimaging techniques such as computed tomography (CT) and magnetic resonance imaging (MRI) allow to assess typical brain changes in this disorder.

The objectives are to present the typical findings of NPH on CT and MRI and to demonstrate differences between NPH and central brain atrophy in neuroimaging.

Results The imaging features of NPH include: supratentorial ventriculomegaly with callosal angle less than 90°, tight sulci at the vertex and considerable out of proportion enlargement of Sylvian fissures. In case of central brain atrophy there may be a predominance of ventriculomegaly and/or widened sulci without crowding of the gyri at the vertex and callosal angle greater than 90°. In both entities, the decrease of density in periventricular region may be seen: in NPH could be a sign of transependymal oedema or in brain atrophy as an accompanying leukoaraiosis. Additionally, it is possible to assess changes in flow of cerebrospinal fluid (CSF) on MRI: in NPH an increased pulsatile CSF circulation in aqueduct as flow void sign may be observed.

Conclusions Correct diagnosis of NPH on CT or MRI in relation to clinical data is very important. Treatment with ventriculoperitoneal shunt or third ventriculostomy may partially improve the

quality of life in some patients with cognitive impairment due to NPH.

Rural and urban childhood environment effects on episodic memory

X. Zhang^{1,*}, H. Yan¹, S. Shah², G. Yang², X. Zhao¹, J. Zhu², X. Zhang¹, J. Li¹, Y. Zhang¹, Q. Chen², A. Mattay², W. Yue¹, D.R. Weinberger², D. Zhang¹, H. Tan²

¹ Peking University, Institute of mental health, Beijing, China

² Lieber Institute for Brain Development, Neuroimaging Core, Baltimore, USA

* Corresponding author.

Introduction Childhoods in urban or rural environments may differentially affect risk for neuropsychiatric disorders. Here, we leveraged on dramatic urbanization and rural-urban migration since the 1980s in China to explore the hypothesis that rural or urban childhoods may differentially influence memory processing and neural responses to neutral and aversive stimuli.

Objectives Explore the underlying mechanisms of childhood environment effect on brain function and neuropsychiatric risk.

Methods We examined 420 adult subjects with similar current socioeconomic status and living in Beijing, China, but with differing rural ($n = 227$) or urban ($n = 193$) childhoods. In an episodic memory paradigm scanned in a 3 T GE MRI, subjects viewed blocks of neutral or aversive pictures in the encoding and retrieval sessions.

Results Episodic memory accuracy for neutral stimuli was less than for aversive stimuli ($P < 0.001$). However, subjects with rural childhoods apparently performed less accurately for memory of aversive but not neutral stimuli ($P < 0.01$). In subjects with rural childhoods, there was relatively increased engagement of bilateral striatum at encoding, increased engagement of bilateral hippocampus at retrieval of neutral and aversive stimuli, and increased engagement of amygdala at aversive retrieval ($P < 0.05$ FDR corrected, cluster size > 50).

Conclusions Rural or urban childhoods appear associated with physiological and behavioural differences, particularly in the neural processing of aversive episodic memory at medial temporal and striatal brain regions. It remains to be explored the extent to which these effects relate to individual risk for neuropsychiatric or stress-related disorders.

Possible Involvement of Endogenous Opioids and Nitric Oxide in the Anticonvulsant Effect of Acute Chloroquine Treatment in Mice

A. Abkhoo

Students' Scientific Research Center SSRC, Tehran University of Medical Sciences, Tehran, Iran, Medicine, Tehran, Iran

Introduction Chloroquine, a 4-aminoquinoline derivative, has long been used for the treatment of malaria and rheumatological

disorders, including rheumatoid arthritis and systemic lupus erythematosus. Accumulating evidence now suggests potential use of chloroquine as a neuroprotectant. Studies have shown that nitric oxide (NO) pathway is involved in the chloroquine actions. Considering the fact that nitricergic neurotransmission plays a crucial role in the central nervous system functioning, in the present study we evaluated whether nitric system is involved in the anticonvulsant effects of chloroquine in a model of clonic seizure in mice.

Methods Clonic seizure threshold was determined by infusion of pentylentetrazole (PTZ, 0.5%) at a constant rate of 1 mL/min into the tail vein of male Swiss mice (23–29 g). Minimal dose of PTZ (mg/kg of mice weight) needed to induce clonic seizure was considered as an index of seizure threshold.

Results Chloroquine (5 mg/kg, acutely 30 min before test, intraperitoneally), i.p significantly increased the seizure threshold. Acute co-administration of a non-effective dose of the non-selective NO synthase (NOS) inhibitor, L-NAME (L-NG-Nitro-L-arginine methyl ester hydrochloride, 5 mg/kg, i.p.) or the selective inhibitor of neuronal NOS, 7-NI (7-nitroindazole, 40 mg/kg, i.p.) with an effective dose of chloroquine (5 mg/kg) inhibited its anti-convulsant effects. Co-administration of a non-effective dose the selective inducible NOS inhibitor, aminoguanidine (100 mg/kg, i.p.) with chloroquine 5 mg/kg did not alter its anticonvulsant effects.

Conclusion Chloroquine increases the PTZ-induced clonic seizure threshold in mice. We demonstrated for the first time that nitric oxide signaling probably through neuronal NOS could be involved in the anticonvulsant effects of chloroquine in this model of seizure in mice.

Cannabis and confabulation: An intrusive relationship

A. Barcelos*, A. Lopes, M. Bernardo, C. Adriana

Hospital Garcia de Orta, EPE, Psiquiatria e Saúde Mental, Almada, Portugal

* Corresponding author.

Introduction The association between the neurocognitive impact of cannabis use and deficits in working and declarative memory is well documented. Studies with cannabis users suggest that recognition memory is particularly susceptible to cannabinoid acute intoxication. Studies carried out in the 1970s using free memory tests, showed that cannabis users not only named fewer words having also a tendency to evoke intrusive memories. Interestingly, a recent study has exposed an association between cannabis consumption and increased likelihood of creating fake memories.

Objectives The main objective of this work is to do literature revision, framing old data with recent works, exposing the relationship between cannabis consumption and memory confabulation/intrusion.

Methodology Literature review, comparison and description of empirical data [1].

Results Recent studies show that both cannabis users and abstinent are more susceptible to create false memories, not being able to identify trap stimuli as events that never occurred.

Discussion/conclusions Changes in perception and memory deficits are two common consequences of acute marijuana intoxication. The fact that these deficits remain during drug abstinence demonstrates the relevance of better understanding the mechanisms by which cannabinoids alter such cognitive functions. Reductions in the activation of brain areas comprised in the lateral and temporal lobe and in frontal cortex zones involved in the processes of attention and performance monitoring may be a possible explanation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Cannabidiol's role as a potential target in the treatment for schizophrenia

A. Carvalho*, J. Felgueiras, T. Abreu, C. Freitas, J. Silva
Centro Hospitalar Tâmega e Sousa, Psychiatry and Mental Health
Department, Porto, Portugal

* Corresponding author.

Objectives Schizophrenia is a debilitating psychiatric disorder which places a significant emotional and economic strain on the individual and society-at-large. Unfortunately, currently available therapeutic strategies do not provide adequate relief and some patients are treatment-resistant. Therefore there is urgent need for the development of mechanistically different and less side effect prone antipsychotic compounds. Recently, the endocannabinoid system has emerged as a potential therapeutic target for pharmacotherapy that is involved in a wide range of disorders, including schizophrenia. Modulation of this system by the main psychoactive component in cannabis, Δ^9 tetrahydrocannabinol (THC), induces acute psychotic effects and cognitive impairment. However, the non-psychotropic, plant-derived cannabinoid agent cannabidiol shows great promise for the treatment of psychosis, and is associated with fewer extrapyramidal side effects than conventional antipsychotic drugs.

Methods The aim of this review is to analyse the involvement of the endocannabinoid system in schizophrenia and the potential role of cannabidiol in its treatment.

Results and conclusions There is still considerable uncertainty about the mechanism of action of cannabidiol as well as the brain regions which are thought to mediate its putative antipsychotic effect. Further data is warrant before this novel therapy can be introduced into clinical practice.

Psychotic symptoms in patients with nmda antibodies

J. Cruz Fourcade^{1,*}, M. Garcia Poggio², R. Martín Aragón²,
A. Muñoz Domenjó², R. Molina Cambra²

¹ Associate Physician, Psychiatry, Madrid, Spain

² Resident, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction This paper is a review of literature about the relation in some cases between psychotic symptoms and NMDA antibodies. Most of these cases are early observed and treated by psychiatry, observing torpid evolution and symptoms that are rarely observed in Psychiatry patients, like visual hallucinations or rapid fluctuations of symptoms.

Objectives Make a review of psychotic symptoms and NMDA antibodies, to think about other options when we are in front of some unusual cases in psychiatry, and it seems that “nothing is working”

Methods Systematic review of pub med literature, applying the keywords: “psychotic” and “NMDA antibodies” of last 5 years.

Results We found that in most of cases the patients presents Opisthotonus, catatonia, and rhythmic and non-rhythmic involuntary movements of the mouth and jaw, and most of them had a

psychiatric evaluation for those symptoms. There was no response to antipsychotic treatment. The treatment with corticoids and rituximab was effective.

Conclusions In psychiatry we have to think in some cases that maybe “the patient could have something else than a psychiatric disease”, most when we found that the symptoms has a rare presentation and the treatment is not effective.

We encourage our colleagues to “think outside the box” when something like this occurs, and hesitate about our own valuations of the patients, when the case is atypical strange.

Charles-bonnet syndrome: Hallucinations are in the eye of the beholder

N. De Uribe-viloria*, E. Mayor Toranzo, S. Cepedello Perez,
I. Sevillano Benito, M. De Lorenzo Calzon, M. Gomez Garcia,
G. Medina Ojeda, F. De Uribe Ladron De Cegama

Hospital Clinico Universitario De Valladolid, Psychiatry, Valladolid,
Spain

* Corresponding author.

Introduction Charles-Bonnet Syndrome (CBS) is a clinical entity characterized for visual hallucinations in patients with severe vision impairment and preserved cognitive state. Its pathogeny is still unknown, limiting management options. For diagnosis neurological and psychiatric disorders must be discarded. Treatment is based in three pillars: explaining to the patient the origin and nature of the symptoms, treating the visual deficit when possible, and pharmacotherapy with anti-psychotics.

Objectives and aims To outline the main characteristics and etiopathogenic theories of the CBS, so as to improve diagnosis and treatment.

Methods Basing on a case followed in mental health consults, we made a systematic review of the articles published in Medline (PubMed) in the last 5 years, with the following keywords, Charles-Bonnet Syndrome, hallucinations, deafferentation, visual impairment.

Results We found that all our case and the reported ones had in common the nature and characteristics of the hallucinations, the presence of a trigger, usually a new medicament, and the functional MRI patrons of activity; those patrons located the loss of input prior to the association cortex, which appeared hyper-excitability in functional MRI.

Conclusions Although the aetiology and pathogeny of CBS is still unclear, present data suggests that the key mechanism may be a dysregulation in the homeostatic adaptation of the neural pathway when it is left without external input, traducing a hyper-function of a physiological process, probably mediated by acetylcholine, as opposed with other neuropsychiatric pathologies, in which the cortex is the primary affected area.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Is borderline personality disorder a neuroendocrine disease?

C. Ferreira*, S. Alves, C. Oliveira, M.J. Avelino
Centro Hospitalar Psiquiátrico de Lisboa, SETA, Lisbon, Portugal

* Corresponding author.

Introduction Borderline personality disorder (BPD) is a disabling heterogeneous psychiatric disorder characterized by poor affect

regulation and impulse control, with a high reactivity and vulnerability to stress. It has been hypothesized that these patients may have a dysregulation of the neuroendocrine system.

Aims The goal of this work is to systematically review the scientific knowledge regarding the role of the neuroendocrine system in the pathophysiology of BPD.

Methods The literature was reviewed by online searching using PubMed®. The authors selected scientific papers with the words “borderline personality disorder” and “neuroendocrine”/“endocrine” in the title and/or abstract, published in English.

Results and discussion There is scientific evidence for an enhanced cortisol release and HPA axis hyperactivity in BPD. The dexamethasone suppression test has been used in BPD, finding high rates of non-suppressors in that sample. There also seems to be a reduced volume of the amygdala and anterior cingulate cortex, suggesting an involvement of those regions in the emotional disturbances in BPD. Symptoms of impulsivity, aggression and suicidal behavior seem to be strongly mediated by the serotonergic system. The available research suggests a serotonergic dysfunction in BPD, with lower levels of serotonin in those patients.

Conclusions There seems to be several neuroendocrine changes related to BPD, namely a hyperactivity of the HPA axis with stimulated cortisol release together with disturbances of the serotonergic system. Also some brain structural alterations in BPD are scientifically depicted. Further studies are needed to clarify the neurobiology of BPD improving both psychotherapeutic and psychopharmacological treatment in these patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Zoophilia in a patient with Parkinson's disease

A. Fornelos*, M. Roque

Centro Hospitalar Trás-os-Montes e Alto Douro, Psiquiatria e Saúde Mental, Vila Real, Portugal

* Corresponding author.

Introduction Parkinson's disease (PD) is a neurodegenerative brain disorder characterized by Bradykinesia, muscle rigidity and resting tremor. Non-motor symptoms like neuropsychiatric manifestations can also cause significant morbidity. Common medications used in anti-Parkinsonian treatment such as dopaminergic agonists, may help motor symptoms but can also cause or contribute to adverse behavioral manifestations. These include dementia, depression, anxiety, insomnia, psychosis and paraphilic disorders. There are sporadic reports of zoophilia in association with dopaminergic therapy.

Objectives Report of a clinical case of PD and zoophilia.

Aims clinicians must be aware of paraphilic disorders, namely zoophilia, in patients with dopaminergic medication.

Method Search of the Pubmed database was conducted for articles published that had “zoophilia [All Fields] and Parkinson [All Fields]”, resulting in 3 eligible articles through October 2016. The patient's clinical records were also reviewed.

Case Report A 77-year-old man, living in a rural area and with a low educational background, with akinetic-rigid PD in an advanced stage and followed by neurology since 2003. His family physician sent him to a psychiatric assessment for hyper-sexuality with zoophilia. The psychiatrist found that these behaviors had begun a week after levodopa was increased along with the introduction of selegiline. The psychiatrist has introduced quetiapine with significant decrease of the hyper-sexuality and the end of zoophilic episodes.

Conclusion Despite hyper-sexuality is found in just 2–6% of PD patients in connection with dopaminergic treatment. This case report emphasizes how crucial it is to evaluate PD patients' sex-

uality as well as to explain these adverse effects to the families involved.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Association between multiple sclerosis and depression

A. Fornelos^{1,*}, V. Espírito Santo², M. Silva¹, M. Roque¹

¹ Centro Hospitalar Trás-os-Montes e Alto Douro, Psiquiatria e Saúde Mental, Vila Real, Portugal

² Centro Hospitalar Trás-os-Montes e Alto Douro, Neurologia, Vila Real, Portugal

* Corresponding author.

Introduction Multiple Sclerosis (MS) is considered an autoimmune inflammatory disease and it is the most common demyelinating disease of the central nervous system. Although its aetiology remains unknown, it has been considered to be multifactorial. MS tends to be more commonly diagnosed in young Caucasian women. It has been described four clinical courses: relapsing-remitting MS, primary progressive MS, secondary progressive MS and progressive relapsing MS based on the temporal sequence in which the symptoms arise. Clinic is also very different because it depends on the sites where the lesions occur. The most frequent signs and symptoms are motor and visual deficits, paraesthesia, gait ataxia, diplopia, dizziness and bladder dysfunction. Depressive symptomatology is also among the most common symptoms of MS.

Objectives Show the importance of depressive symptomatology in patients with MS.

Aims Evaluation the connection between MS and depression.

Methods Search for articles concerning MS and depression on Pubmed and Scielo databases from July 2014 through October 2016.

Results Psychiatric manifestations, and especially depressive symptoms, affect almost 40% of MS patients in remission, and about 90% of those in a flare-up. This may be due to the diagnosis itself, with its large amount of symptoms and its variable progression, but also due to side effects of therapy. It gives a major contribute to suicidality (7.5%) when compared to the general population.

Conclusion A combined approach and treatment is in order to diminish the incapacity caused by both these illnesses in every single patient.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Case report of progressive supranuclear palsy (PSP)

B. Garcia

Benito Menni, Psychiatry, Barcelona, Spain

This is a case of an old man, affected by progressive supranuclear palsy (PSP), admitted due to behavioral alteration in long-term home. Medical background PSP's diagnosis in 2008. Debuts in the form of lower limb tremor, Bradykinesia and tendency to fall. Hypomimia, hypotonia, rigidity and slight postural tremor in upper limbs. Partial response to anti-Parkinson drugs. Psychiatric background, premorbid personality prone to cognitive rigidity, dichotomous thinking and impulsiveness. Join in acute unit from February to May 2012, where it is oriented as a depression of adaptive features. Several antidepressants were tested with partial response (venlafaxine, reboxetine, mirtazapina, bupropion, sertraline). Current episode patient, who comes presenting behavioral alteration with poor tolerance to the limitations imposed by the disease and passive aggressive behaviors. His wife reports dif-

faculties in ambulation, increment of falls, and lack of hygiene and dietary transgression. Complementary explorations blood test: hemogram and biochemical unaltered, hypertriglyceridemia, syphilis, HIV serology negative. Diagnosis stable PSP, behavioral disorders are objectified within his personality disorder. Pharmacological approach. In case levodopa causes clinical symptoms of postural hypotension, stavevo is decreased and sinemet is removed. Slight improvement is noticed. Case review PSP is an uncommon brain disorder that affects movement, control of walking and balance, vision, cognitive impairment and neuropsychiatric disorders. It is associated with the deposition of hyperphosphorylated, tau, in the pallidum, subthalamic nucleus, red nucleus, etc. Cognitive deficits and neuropsychiatric symptoms may precede the onset of Parkinsonism. Most changes are referred to personality, with presence of irritability, impulsivity. Psychotic symptoms may exist. There are no disease-modifying treatments. Management should focus on optimizing life quality.

Disclosure of interest The author has not supplied his declaration of competing interest.

Psychotic symptoms have been reported in association with a wide array of brain abnormalities. Few published reports have examined the association between schizencephaly and psychiatric illness. Originally defined by Wilmarth and later by Yakolev and Wadsworth – Schizencephaly is an uncommon congenital disorder of cerebral cortical development, defined as a grey matter-lined cleft extending from the pial surface to the ventricle. The nosology is based on neuroradiologic findings and confirmed by neuropathology when available. The Clinical presentation and neurodevelopmental outcomes of the disorder vary and are usually related to the extent/areas of the brain involved. In this article we review the medical literature around Schizencephaly paying particular attention to the pathophysiology, etiology and diagnosis of such patients. We then present a case of Schizencephaly and first episode psychosis in a 16-year-old adolescent who was admitted to our inpatient psychiatric service. Lastly, we present the findings of a systematic review from PubMed whereby we summarize 10 cases of Schizencephaly with associated psychiatric symptoms.

Glutamatergic synaptic plasticity in the periaqueductal gray governs fear-induced depression-like behavior in rats

Y.C. Ho*, M.C. Hsieh, C.Y. Lai, H.Y. Peng

Mackay Medical College, Department of Medicine, New Taipei City, Taiwan, ROC

* Corresponding author.

Introduction Major depressive disorder affecting more than 110 million people worldwide every year is a heterogeneous illness

influenced by a variety of factors, including repeated stressful factors. Despite widely research during the past several decades, the pathophysiology and neurobiological mechanisms of depressive disorders remain unclear. Ventrolateral periaqueductal gray (vlPAG), a midbrain nucleus, has been considered as an important part of the circuitry that involves in stress-induced depression-like behaviors. Dysregulation of glutamatergic neurotransmission in depressed patients suggests that glutamate-mediated excitatory system is critical involved in the depressive disorders.

Objectives It is still unclear that whether vlPAG involves in fear condition-elicited depression-like behavior.

Aims We investigated the synaptic transmission in the vlPAG to examine whether vlPAG participates in fear-induced depression-like behavior in rats.

Methods Depression-like behaviors, in the rats, were induced by learned helplessness procedure. The synaptic transmission was conducted by whole-cell patch-clamp recording in the rat brain slices containing periaqueductal gray.

Results Rats receiving learned helplessness procedure displayed high failure rate in the escapable foot-shock test compared to control group. Both amplitude and frequency of miniature excitatory postsynaptic currents were significant reduced compared to control group, suggesting reduced presynaptic glutamate release and postsynaptic responses were involved in the learned helplessness procedure-induced depression behavior in rats.

Conclusions Reduced glutamatergic transmission in the vlPAG contributes to learned helplessness procedure-induced depression-like behavior in rats through pre- and post-synaptic mechanisms.

Inter-analyzer interaction (IAI) at clinical psychology: Possibilities and challenges

M. Kovyazina^{1,*}, K. Fomina²

¹ Lomonosov Moscow State University, Department of Psychology – Chair of neuro – and abnormal psychology, Moscow original-Mytishchi, Russia

² Lomonosov Moscow State University, Department of Psychology – Chair of neuro – and abnormal psychology, Moscow, Russia

* Corresponding author.

Introduction White matter is an anatomical bases of brain integration realization, it provides the connection between different cortex zones inside one hemisphere as well as other hemisphere. Hemispheric interaction research is basic aspect of brain integration activity problem. Not less important is the aspect related with the processes of IAI.

Aims Evaluation of method by fixed set potential for neuropsychological research of inter-analyzer interaction.

Methods Russian neurophysiologists confirmed the presents of nervous processes irradiation and considered it as fundamental mechanisms of the higher functions realization. IAI is a particular case of the irradiation.

Uznadze's fixed set method allows one to model "section of behavior", which includes all general behavior mechanisms and provides a way to analyze complicated forms of activity. The central components of the set are related to different brain systems and analyzer's interactions. This is confirmed by the set irradiation experiments, performed by Uznadze's school and showed that the set forms in one sensory modality manifests in different.

Results Setting experiments by formation of fixed set are done at haptic sphere: two different in volume spheres are given into both respondents' palms. Critical experiments are done at visual

sphere: two equal in diameters circles are exhibited to respondent for comparison. The amount of illusion in visual modality is an index of IAI features.

Conclusions The fixed set method acquires a special relevant at the modern stage of clinical psychology development, since the IAI research seems to be important in psychiatric and neurological diseases, related with brain integration disorders.

³ Lomonosov Moscow State University, Department of Psychology – Chair of methodology of psychology, Moscow, Russia

⁴ Moscow Institute of mental health, Moscow Institute of mental health, Moscow, Russia

* Corresponding author.

Introduction Dependents of human behavior on the hemispheric interaction quality is extremely interesting question. The CC impairments are observed at schizophrenia, autism, Tourette syndrome, ADHD, etc. Difficulties in the sphere of emotional intelligence are typical at not only frontal zones disorders and right hemisphere of brain.

Aims Analyze the emotional intelligence of the patients with CC pathologies.

Methods Method for the recognition of facial expression (faces and gestures); Video test “estimation of another person emotional condition”; Survey for the estimation of emotional intelligence (EmIn); ten people with different CC pathologies participated.

Results Results of the person with the CC pathologies were different from normative indexes of the first two methods. They did not recognize the shown emotion: the sign of emotional expression was not identified, the gestures were not distinguished and three positive characteristics out of 24 suggested for the designation of emotion modality were used. The emotions of heroes from video test were recognized mistakenly. The indexes were normative for all scales of EmIn survey. However quite noticeable negative correlation of

“emotion control” and “interpersonal emotional intelligence” survey indexes with the index of emotional recognition video test was obtained.

Conclusions Weak emotional tone, leading to incorrect estimation of the emotional sign, is observed at CC pathology. This doesn't exclude the violation of face emotional expressions analyze criteria. The situational context does not help the another person condition recognition. The answers on the EmIn test questions are based on subjective visions of the patient about themselves, those witnesses about the criticism reduction.

EV0709

Illusion as a research tool for inter-analyzer interaction (Iai) characteristics in a psychiatric clinic

M. Kovyazina^{*}, K. Fomina, N. Varako

Lomonosov Moscow State University, Psychology, Moscow, Russia

* Corresponding author.

Introduction IAI does not only play a functional role but also has qualitative and quantitative characteristics. Biological significance of IAI consists in mobilization of some sensory functions and demobilization of others as a response to a stimulus signaling changes in the environment. This constitutes one of the manifestations of body's preparatory reactions for action in the forthcoming situation. It has been established that in patients with psychic pathology such preparation of the body systems is affected, which may manifest through changes in illusion frequency.

Objectives To apply Charpentier illusion to research IAI characteristics with the purpose of further detection of abnormalities in the sphere of intermodal interaction.

Methods One of the IAI research methods, is illusion research, e.g. Charpentier illusion, since it is based on interaction between visual and proprioceptive analyzers. Changes in preparatory reaction in subjects with psychic pathology is characterized by decline in illusion frequency, patients in these conditions should evaluate stimuli more correctly than healthy participants. Pre-experimental research design included two subjects: with white matter pathology (patient G., male, 27, full agenesis of CC, based on MRI results) and with IDD (subject A., male, 30).

Results Research subjects demonstrated absence of illusions, which is indicative of functional weakness of IAI, which results in inconsistency of sensory systems and meaningless perception. IAI plays an important role in formation of human psyche by enabling the development of significant patterns underlying human cognitive activity.

Conclusion Illusion research is relevant for clinical psychological diagnosis of diseases associated with integrative brain activity disorders.

Neuropsychiatric symptoms in Fahr's syndrome

A. Lopes^{*}, R. Trindade, A. Barcelos

Hospital Garcia de Orta, Psychiatry, Almada, Portugal

* Corresponding author.

Objectives and methodology To review the neuropsychiatric symptoms of Fahr's syndrome.

Results/discussion Fahr's Syndrome is a rare degenerative neuropsychiatric condition, characterized by bilateral and symmetrical calcifications of the basal ganglia. It can be associated with several metabolic, infectious or genetic conditions. It is clinically manifested by movement disorders, psychosis, cognitive impairment, mood disorders, personality dysfunction or obsessive-compulsive spectrum disturbances. First presentation can be psychiatric in approximately 40% of the cases. Cognitive dysfunction, mood disorders and psychosis are the most common presentations. In the present case, depression, dementia and movement disorders were the main clinical pictures. This report alerts for the significance of neuropsychiatric symptoms within this diagnosis, considering the multisystemic approach of the illness.

The relationship between responsiveness to social and monetary rewards and ADHD symptoms

B. Sutcubasi Kaya^{1,*}, B. Metin¹, F.Z. Krzan¹, N. Tarhan², C. Tas¹¹ Uskudar University, psychology, Istanbul, Turkey² Uskudar University, Psychiatry, Istanbul, Turkey

* Corresponding author.

Introduction Alterations in reward processing are frequently reported in ADHD. One important factor that affects reward processing is the quality of reward, as social and monetary rewards are processed by different neural networks. However, effect of reward type on reward processing in ADHD was not extensively studied.

Aims We aimed to explore the effect of reward type (i.e., social or monetary) on different phases of reward processing and also to test the hypothesis that ADHD symptoms may be associated with a problem in processing of social rewards.

Methods We recorded event-related potentials (ERPs) during a spatial attention paradigm in which cues heralded availability and type of the upcoming reward and feedbacks informed about the reward earned. Thirty-nine (19 males and 20 females) healthy individuals (age range: 19–27) participated in the study. ADHD symptoms were measured using ADHD self-report scale (ASRS).

Results The feedback related potentials, namely feedback related negativity (FRN), P200 and P300 amplitudes, were larger for social rewards compared to monetary rewards (Fig. 1). There was a consistent negative correlation between the hyperactivity subscale of ASRS and almost all feedback related ERPs. ERP amplitudes after social rewards were smaller for individuals with more hyperactivity.

Conclusions Our findings suggest that hypo responsiveness to social rewards may be associated with hyperactivity. However, the results have to be confirmed with clinical populations.

Fig. 1 FRN amplitudes.

The differential effect of event rate on pupil dilation patterns suggests effort dysregulation problems in ADHD

B. Metin^{1,*}, E. Sonuga-Barke², J.R. Wiersma², H. Roeyers², S. Vermeir²¹ Uskudar University, Psychology, Istanbul, Turkey² Ghent University, Psychology, Ghent, Belgium

* Corresponding author.

Introduction The state regulation model postulates that ADHD performance difficulties result from failures to regulate activation states in response to changing environmental conditions – producing poor performance under sub-optimal conditions. Behavioral and electrophysiological studies involving the manipulation of event rate (ER) lend support to this idea.

Aim In this preliminary study, we extended this investigation by comparing pupil dilation, an established marker of cognitive effort allocation, in individuals with ADHD, and controls, in response to varying ERs on a simple cognitive task.

Methods Nineteen children with ADHD (age range: 8–14 years) and 21 controls (age range: 10–16 years) completed a target detection task under three different ERs (1300, 4000, and 8000 msec). Pupil dilation was monitored using an eye-tracker.

Results Our results show that for controls, pupil dilation to targets varied as a function of ER according to a “U” function – with fast and slow ERs inducing greater phasic dilation than the moderate ER. However, for children with ADHD the relationship was linear with dilation increasing as ER decreased.

Conclusions The results provide the first pupillary evidence suggestive of effort allocation dysregulation in ADHD especially under fast event rate conditions. Future studies should explore interventions to overcome effort allocation problems.

Interrelationships between cortisol, cognition and dementia: A review of the literature and new own findings

S. Ouanes*, P. Julius

University Hospital of Lausanne, Department of Psychiatry, Lausanne, Switzerland

* Corresponding author.

Introduction Cortisol exerts effects on the brain via two different receptors, producing complex and sometimes opposite effects on the brain structures involved with the different cognitive functions.

Objective To scrutinize the interrelationships between cortisol, cognition and dementia.

Methods Review of the literature and new own findings.

Results Animal and clinical studies showed an association between increased cortisol and poorer overall cognitive performance, declarative memory, language, processing speed, executive functioning, spatial memory, as well as social memory. High cortisol may exhibit neurotoxic effects on the hippocampus, and exacerbate oxidative injury and amyloid β peptide toxicity. Increased CSF cortisol levels have been found in subjects with dementia and Mild Cognitive Impairment (MCI) due to Alzheimer's disease (AD) compared to control subjects with normal cognition. In MCI due to AD, high CSF cortisol may also predict a more rapid cognitive decline. Higher cortisol levels have been also observed in delirium. Increased cortisol levels interact with inflammatory mediators, neurotransmitters, and growth factors, and may mediate the effects of depression, stressful life events, and personality traits, sleep disturbances, and cardiovascular risk factor on cognitive performance and cognitive decline.

Conclusions High cortisol levels may exert deleterious effects on cognition and exacerbate AD pathology. Further studies are needed to explore glucocorticoid-based interventions in the management of cognitive disorders.

Plastic surgery treatment of post-bariatric patients cannot remain “brainless”

C. Pavan^{1,*}, V. Vindigni², A. Vallesi²

¹ University of Padova, Department of Medicine, Padova, Italy

² University of Padova, Department of Neurosciences, Padova, Italy

* Corresponding author.

Introduction The aim of this study was to investigate the presence of executive difficulties due to a lack of the management of cognitive conflict, inhibition, and cognitive flexibility in this group of patients. If executive difficulties are at the basis of uncontrolled alimentary behavior, these will be present also after a dramatic weight loss and could lead to a poor compliance of the patient after plastic surgery procedures.

Materials and methods We enrolled 21 consecutive post-bariatric patients. This clinical population was compared with a control group ($n=21$) from the general population sharing the same clinical and demographic features. Psychiatric evaluation was performed. Executive difficulties were investigated through electroencephalography using the stroop task, sustained attention to response task, and task switching tests.

Results The patient group reported more frequently psychiatric disorders than control group. Patients had higher prevalence of lifetime major depression (58.3% vs. 14.3%), of lifetime panic disorder (36.1% vs. 4.8%) and generalized anxiety disorder (16.75% vs. 0%). Finally, patients were more frequently affected by body dysmorphic disorder ($\chi^2 = 8.867$, $P = .003$). Electroencephalography confirmed the presence of executive difficulties sustained by a lack of the control of cognitive conflict and cognitive flexibility, and a difficulty of the inhibitory control in the patient group.

Conclusion Electroencephalography confirmed for the first time the high prevalence of psychological/psychiatric problems in post-bariatric patients. Patients showing high values of executive difficulties will need a psychological/psychiatric support to sustain a positive outcome after post-bariatric plastic surgery.

Cognitive functions recovery after traumatic brain injury of mild severity in adolescents

S. Pervichko

Lomonosov Moscow State University, psychology, Moscow, Russia

Introduction The effect of the traumatic brain injury of mild severity (mTBI) on the cognitive functions influences on the educational activities of adolescents in school and the quality of life in general.

Objectives To study the violations and to track the dynamics of recovery higher mental functions (HMF), after mTBI in adolescents with neuropsychological syndrome in the range of up to one year.

Materials and methods The study is based on the original set of techniques designed by A.R. Luria. We focused on assessing the

status of various components of the HMF. We also studied of the mental activity in its regulatory and dynamic aspects. Thirty-one patients with mTBI (mean age was 11.5 ± 1.3) and 20 healthy subjects (mean age was 12 ± 1.5) took part in the study.

Results Analysis of the results showed that violations of HMF in the acute period were represented by three types of syndromes. The leading place in each syndrome is occupied by deficiency symptoms of non-specific brain structures. Research of dynamics of recovery HMF demonstrated the symptoms related to deficiency of parietal-temporal-occipital area are reducing for the first month, as well as the symptoms of the anterior brain. After six months we observed the decrease all symptoms from cortical structures, but the symptoms persist in the form of fatigue, reduction the rate of mental activity, difficulty in concentration.

Conclusions Application of neuropsychological approach (Luria school) to the diagnosis and recovery of deficit cognitive function allows to describe the symptoms and to identify their hierarchy in the structure of violations.

Disclosure of interest The author has not supplied his declaration of competing interest.

Phenocopy frontotemporal dementia: A case series from a national memory clinic and a review of the literature

C. Power^{1,*}, O. Hannigan², M. Gibb², I. Bruce², M. McCarthy², R. Coen², D. Robinson², B.A. Lawlor²

¹ St James's Hospital, Memory Clinic – Mercer's Institute for Research in Ageing, Dublin, Ireland

² Memory Clinic, Mercer's Institute for Research in Ageing, Dublin, Ireland

* Corresponding author.

Introduction The existence of a frontotemporal dementia phenocopy (phFTD) syndrome remains controversial. Opinions differ on whether the phenocopy presentation represents the neuropsychological manifestation of a mid-life decompensation in vulnerable pre-morbid personalities or an indolent prodrome of behavioral-variant FTN (bvFTD). Literature on this topic is sparse and clinicians and patients have little guidance around prognosis and management.

Objectives To describe the demographic, neuropsychological and biomarker profiles of a case series of phFTD patients, attending the memory clinic and review relevant literature.

Methods Retrospective review of all cases diagnosed with phFTD. **Results** Eleven cases were identified (male = 9, female = 2). Mean age 55.8 years. Subjective complaints comprised memory and language difficulties. Collateral reports described apathy, aggression, impulsivity, disinhibition, hyperorality. Function was relatively preserved though motivation or supervision for higher-level tasks was sometimes required. All had non-neurodegenerative MRI and PET scans. Neuropsychological test (NPT) findings predominantly showed executive dysfunction and fluency impairment. A total of 3/11 had non-amnesic memory impairment. Follow-up imaging and NPT were invariably unchanged; 1/11 had a pre-morbid psychiatric diagnosis; 5/11 had unusual personality traits pre-morbidly. Major psychosocial stressors were documented in 7/11. Management consisted of psychosocial interventions to support function and interpersonal relationships.

Conclusions The literature describes the phFTD syndrome as predominantly affecting males though we include 2 females who meet the criteria. In keeping with our findings, personality traits and psychosocial stressors may be more common in phFTD than bvFTD. More severe symptoms, memory impairment at presentation and C9ORF72 gene mutation may predict eventual progression. Those who do not progress have minimal long-term functional impairment though behavioral symptoms persist.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0717

The biology of cognitive behavior therapy

H. Ramy

Egyptian Association of Cognitive Behavior Therapy, Psychotherapy, Cairo, Egypt

Cognitive behavior therapy outcomes and the mechanism of change that are related to its effects have traditionally been investigated on the psychological abilities, personalities or social functioning. Many psychiatrists have also held the unfortunate dichotomized position that psychotherapy is a treatment for “psychologically based” disorders, while medication is for “biologically based” disorders. During the past several decades, it has become clear that all mental processes drive from mechanisms of the brain. This means that any change in our psychologically processes is reflected by changes in the functions or structures of the brain. Straightforward reductionist stances, however, are unfounded because there is clear evidence that our subjective experiences affect the brain. Plastic changes in the brain have been difficult to study in humans, but there has been more than one successful trial. Changes in the brain in relation to experience have been detected at the cellular and molecular level using different experimental approaches. The advent of functional neuro-imaging, including photon emission CT (SPECT), positron emission topography, and functional MRI, has made it possible to study changes at the brain systems level (by measuring changes in the brain blood flow or metabolism) associated with cognitive behavior changes. The presentation will shed light on the biological basis of CBT reviewing the evidence from a historical perspective. In addition the imaging studies will be reviewed with emphasis on future perspectives in the use of CBT in the treatment of various psychiatric disorders and the importance of clarifying the biological changes associated with improvement.

² Universidad Complutense de Madrid, Clinical, Madrid, Spain

* Corresponding author.

Introduction Changes in the electrical cerebral activity, especially in frontotemporal regions, have been described after using the Superficial Neurostimulation Application (SNSA) in upper and lower limbs. The use of this technique is associated with emotional equilibrium and predisposition for a positive mood. Its application clinically improves hostility and anxiety symptoms.

Aims To compare the electrical changes observed after the use of SNSA with other techniques of mental concentration: Mindfulness (mental attention without judgment) and a technique based on the emission of a sound.

Materials and methods SNSA topology system: uses electricity through superficial electrodes placed on feet and hands and an

electrode over the 7th cervical vertebra; Digital encephalogram; Faraday cage.

Results Mindfulness and SNSA techniques show similarities regarding the alpha rhythm's frequency in frontal regions (Figs. 1 and 2) compared to a different mental concentration technique (Fig. 3).

Conclusion Further analysis would be required.

Case report Klinefelter syndrome and multiple sclerosis as the cause of psychosis

A. Rodriguez Rodriguez*, R. Blanco Fernández, M. Vizcaino da Silva, R. Fernández Fernández, O. Mendez Gonzalez

Universitary Hospital Puerta de Hierro, Brief Hospitalization Unit Psychiatry, Majadahonda, Spain

* Corresponding author.

Introduction and goals Forty-three-year-old male diagnosed with Klinefelter syndrome and showing radiological findings suggesting a demyelinating pathology who presents several psychiatric manifestations including megalomaniacal ideation, delusion, lack of impulse control and behavioral alterations.

Clinical case Forty-three-year-old male diagnosed with Klinefelter syndrome at the age of 31, presenting several psychiatric pathologies since adolescence: delusions, megalomania, mood fluctuation, and high impulsiveness. The patient had a poor therapeutic response to anti-psychotic drugs and ECT. He was hospitalized up to 9 times, but the full control of the symptomatology was not achieved. During his last hospitalization, a MRI revealed lesions compatible with a demyelinating pathology.

Discussion A higher prevalence of schizophrenia spectrum disorders has been described among patients suffering from Klinefelter syndrome, which might explain the role of the X chromosome in the susceptibility to psychiatric disorders, particularly to psychosis. Furthermore, the brain structure alterations presented by patients suffering from Klinefelter syndrome are similar to those described among schizophrenic patients: small brain volume, lateral cerebral ventricular enlargement and reduced temporal gyrus, amygdala, insula and cingulate cortex. Patients suffering from multiple sclerosis are more prone to psychiatric disorders, such as mood swing, aggressiveness or psychosis, which are not concurrent with the physical progression of the disease, sometimes being its first manifestation. Even when being patchy and multifocal, demyelination seems to be concentrated in the frontal lobes, related to the cognitive and affective functions and the personality.

Conclusions Both multiple sclerosis and Klinefelter syndrome may alter the brain structure, mainly in the frontal lobe, and predispose to psychiatric disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Neuroretinal dysfunctions in regular cannabis users: An impact of cannabis on retinal neurotransmission?

T. Schwitzer^{1,*}, R. Schwan¹, A. Giersch², E. Albuissou³, K. Angioi-Duprez⁴, V. Laprevote¹

¹ Centre psychothérapique de Nancy, Pôle hospitalo-universitaire de psychiatrie du Grand Nancy, Laxou, France

² Inserm U1114 Fédération de Médecine Translationnelle de Strasbourg CHRU de Strasbourg, Département de Psychiatrie, Strasbourg, France

³ CHRU de Nancy, Pôle S²R – Parc – Espri-biobase, Vandoeuvre-lès-Nancy, France

⁴ CHRU de Nancy, Département d'Ophthalmologie, Vandoeuvre-lès-Nancy, France

* Corresponding author.

Introduction Although cannabis is very widespread worldwide, its brain toxicity is poorly understood. The neuroretina is an accessible extension of the brain and could be a relevant site for investigating neurotransmission abnormalities in neuropsychiatric disorders. The retina has a functional endocannabinoid system involved in the regulation of retinal neurotransmission. In animals, the modulation of this system led to retinal dysfunctions measured with the electroretinogram (ERG).

Objectives To assess whether the regular cannabis use could affect the neuroretinal function.

Aims Assessments of the neuroretinal function in cannabis users compared with controls.

Methods Recordings of pattern, flash and on-off ERG were performed in 55 cannabis users and 29 controls. The amplitude and implicit time of the following waves were evaluated: N95 (pattern); a – and b – (flash); a –, b- and d1 – (on-off).

Results Cannabis users showed a significant increase in implicit time of the waves N95 ($P=0.0001$), a- ($P=0.029$) and b – ($P=0.002$) for the flash ERG and b – ($P=0.016$) and d1 – ($P=0.027$) for the on-off ERG, compared with controls. No significant difference was found between groups in terms of wave's amplitudes.

Conclusions These results show a delay in the response of cones, bipolar and ganglion cells of the on and off pathways to constitute a delay of ≈ 6 ms in the transmission of information from the retina to the brain in cannabis users. Cannabis could disrupt the regulatory role of the cannabinoid system and impair retinal glutamatergic neurotransmission. The consequences on visual perception should be explored in future studies.

In search of possible peripheral biomarkers for suicide: Similarities between platelet and cerebrospinal fluid proteome (preliminary results)

E. Semančíková^{1,*}, S. Tkáčiková¹, I. Talian¹, M. Bencková¹, E. Pálová², J. Sabo¹

¹ University of P. J. Šafárik, Department of Medical and Clinical Biophysics, Košice, Slovak Republic

² EPAMED s.r.o, Košice, Slovak Republic

* Corresponding author.

Despite the fact that proteomic analysis is becoming widely used in various medical branches its use in psychiatry is still very limited. Majority of psychiatric proteomic research is still oriented mostly on Alzheimer's disease, schizophrenia and depression but very few studies focus on suicidality. We decided, based on the current knowledge, to study suicidal behaviour with the use of proteomics to compare cerebrospinal fluid and platelets. We hypothesized that the same protein group can be detected in pathways that are part of platelet degranulation process in the platelet proteome and cerebrospinal fluid proteome. Based on these findings we suppose, that with use of proteomic analysis a specific protein (group of proteins) can be identified in both, cerebrospinal fluid and platelet proteome in patients with suicidal behavior.

Group of proteins identified in our sample in the reactome pathway database (release of platelet secretory granule components and exocytosis of platelet granule contents) supports the idea of link between central nervous system and platelets ("the periphery"). Further research is needed to clarify whether the identified group of proteins taking part in platelet pathways can be used as peripheral biomarkers for suicidal behavior.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Effects of hazardous alcohol use on neurocognition in hiv positive individualsG. Spies^{1,*}, G. Hoddinott², N. Beyers², S. Seedat¹¹ Stellenbosch University, Psychiatry South African Research Chairs Initiative: PTSD Program, Cape Town, South Africa² Stellenbosch University, Desmond Tutu TB Centre- Department of Paediatrics and Child Health, Cape Town, South Africa

* Corresponding author.

Introduction There is significant evidence that HIV is brain degenerative and long-term infection can impair cognitive functioning. In South Africa, alcohol remains the dominant substance of abuse and lifetime alcohol dependence has been found to impair memory, executive function and visuospatial capabilities. The individual liability of alcohol and HIV on neurocognitive function have been well demonstrated, however there is relatively little evidence of the potentially aggravating effects of this dual burden on neurocognitive outcomes.**Objectives** The present study is ongoing and sought to identify the effects of hazardous alcohol use on neurocognitive functioning in the context of HIV infection.**Aims** To describe the association between HIV and harmful alcohol use on neuropsychological test performance in a cohort of adults in the Western Cape of South Africa.**Methods** participants (n = 50) were tested using a battery of neuropsychological tests sensitive to the effects of HIV on the brain. Self-reported alcohol use was recorded using the alcohol use identification test (AUDIT). Results The sample consisted of 47 females and 3 males. All participants were HIV-positive and on antiretroviral therapy. A total of 23 (46%) participants reported no alcohol use and 27 (54%) reported drinking alcohol on the AUDIT.**Results** revealed a significant difference between groups on the Stroop colour word test, with poorer performance evident among the alcohol users (P = 0.008).**Conclusion** Alcohol use in the context of HIV infection contributes to poorer executive function. These preliminary data provide evidence for a synergistic relationship between HIV infection and alcohol use.**Disclosure of interest** The authors have not supplied their declaration of competing interest.<http://dx.doi.org/10.1016/j.eurpsy.2017.01.1053>

Do impulsive individuals respond better to cognitive bias modification treatment for alcohol dependence?P. Staiger^{1,*}, V. Manning², D. Leung¹, K. Hall¹, A. Verdejo-Garcia³, L. Hughes¹¹ Deakin University, School of Psychology, Melbourne, Australia² Turning:Point, Treatment Unit, Melbourne, Australia³ Monash University, Psychological Sciences, Melbourne, Australia

* Corresponding author.

Introduction Recent outcomes of novel cognitive bias modification (CBM) interventions targeting approach-bias have shown promising results in reducing drinking behavior in inpatient and community settings. These studies have primarily been conducted with patients who are receiving concurrent treatment. Alcohol inpatient detoxification provides an opportunity to intervene utilizing CBM to reduce the likelihood of early relapse. Furthermore, evidence suggests that those high on impulsivity may benefit most from this type of intervention and yet this remains untested.**Objective** The present study aimed to assess whether an approach-bias CBM intervention targeting alcohol reduces early relapse following medical detoxification and whether those individuals respond better to the treatment.**Aims** To conduct a randomized controlled trial to test the efficacy of CBM for alcohol dependent individuals in reducing early relapse following medical detoxification.**Method** Seventy-six alcohol-dependent inpatients were randomly allocated to four sessions of approach-bias CBM training or sham training. Assessments of alcohol use and impulsivity were obtained at baseline and two-week follow-up post-discharge.**Results** Findings revealed a significant intervention effect with those in the intervention group less likely to relapse. Furthermore, those high in impulsive responding were significantly more likely to report a treatment effect.**Discussion** Supporting previous research, findings suggest that approach-bias CBM continues to be a promising treatment for alcohol misuse. These findings are unique given this is the first examination of CBM during medical detoxification.**Disclosure of interest** The authors have not supplied their declaration of competing interest.<http://dx.doi.org/10.1016/j.eurpsy.2017.01.1054>

Patterns of eeg coherence associated with emotional burnoutS. Tukaiev^{1,*}, I. Zyma²¹ National Taras Shevchenko University of Kyiv, Department of Social Communication, Department of Physiology of Brain and Psychophysiology, Kiev, Ukraine² National Taras Shevchenko University of Kyiv, Laboratory of physicochemical biology- Department of Physiology of Brain and Psychophysiology, Kiev, Ukraine

* Corresponding author.

One of the main problems is evaluation of the influence of emotionogenic factors in everyday life and interpersonal communication on an individual. Burnout is a mechanism of psychological defense, which is responsible for partial or total loss of emotions in response to stressful situations during interpersonal communication. The changes of functional connectivity between different regions of brain in the rest state depends on the current level of brain activation, which, in turn, depends on the initial emotional state. The development of emotional burnout is characterized by decrease of information capacity of the brain: reduction of spatial synchronization provides delayed and less efficient spread of excitation in the cerebral cortex. The decrease of interhemispheric coherence of low and high-frequency components of EEG may indicate the increase of level of differentiation of neuronal groups. In women, decrease of coherence in theta-subband indicates the influence of burnout on attention concentration, working memory, and emotional processes. In men weakening of the relationship between left frontal and right occipital zones indicates the weakness of informational aggregation, reducing readiness of the neural centers for processing information in the "cognitive axis". Reduction of the level of coherence of alpha band may indicate problems of psychological adaptation within the experiment in examined groups of men with the Resistance stage of burnout. These EEG features allow us to conclude that participants with Resistance stage were concentrated on negative emotional reactions. Study indicates that men are more vulnerable to stress-induced conditions, which lead to burnout.

Unresolved grief and diogenes syndrome and misery senileS. Färber^{1,*}, M. Färber²¹ VIVER Psicologia e Tanatologia, Tanatologia, Cascavel, Brazil² VIVER Psicologia e Tanatologia, Psicologia, Cascavel, Brazil

* Corresponding author.

Introduction Mourning the death of a loved one, the loss of social aggregation or familiar, or any trauma may not follow the normal process when has any kind of complication In these cases of the complicated mourning, a person may develop or manifest dissociative behaviors, like diogenes syndrome or the misery senile syndrome.

Objective To investigate the presence of unauthorized mourning, complicated or not elaborate as triggers of diogenes syndrome and misery senile.

Methods To develop this research we use the systematic literature review, following the process of research, cataloging, careful

evaluation and synthesis of the documentation associated with the method of thanatological hermeneutics.

Conclusion Thanatology is useful tool in scientific and clinical research and care for patients with diogenes syndrome. The need for safety against the distress of fear of the future and loneliness is at the origin of compulsive hoarding. If the mythical diogenes lived in Athens a Spartan life, living in a barrel, as the character Chespirito of Roberto Bolaños (Fig. 1), the carriers of this syndrome follow the opposite path accumulating objects to achieve a sense of stability.

Results There is a significant presence of unresolved grief in the history of the psychiatric patient with diogenes syndrome.

* Corresponding author.

Introduction Hoarding often occurs without the presence of obsessive-compulsive disorder (OCD), showing distinguishable neuropsychological and neurobiological correlates and a distinct comorbidity spectrum. Furthermore, it presents itself secondarily to other psychiatric and neurobiological disorders. Therefore hoarding disorder has been included as independent diagnosis in DSM-5.

Objectives We aim to expose the possible organic etiology of a hoarding disorder case with atypical presentation.

Materials and methods We present a case of a 48 years old male patient who was brought to the hospital by the police after being reported for unhealthy conditions in his home. In the home visit paid by the Social Services an excessive hoarding of objects and trash was detected. A possible hoarding disorder was diagnosed in the psychiatric assessment. Among other diagnostic test, a brain CT was conducted, in which a frontal meningioma was identified. After surgical treatment, hoarding symptoms diminished significantly.

Discussion A significant part of the hoarding disorders are attributed to primary psychiatric disorders, resulting in potentially treatable organic pathology going unnoticed.

Conclusion It's important to rule out organic etiology before proceeding to make a definitive hoarding disorder diagnosis, optimizing that way the treatment options.

Keywords Hoarding; OCD; Meningioma

² Osakidetza, Psychiatry, Vitoria, Spain

³ Marqués de Valdecilla, Psychiatry, Santander, Spain

* Corresponding author.

Introduction Previous research suggests that hoarding aggregates in families and is associated with health, safety risks and family problems. Hoarding symptoms appear to be more common among first-degree relatives of people who hoard. A predominance of shared hoarding disorder has been observed among female relatives.

Objectives We present an atypical case report describing hoarding symptoms among first-degree male relatives who present two different subtypes of hoarding disorder.

Materials and methods We report the case of a 38 years old male patient, attended for the first time by the mental health services at the age of 22, and being diagnosed of severe OCD at that moment. In the home visit paid by the social services, an excessive object hoarding was observed, including the presence of over 40,000 books.

Moreover, they found a 38 years old man looking severely deteriorated; when they ask him about it, the patient's father admits to having been isolated in the house for almost 14 years. Hoarding history was gathered, through the acquisition of various objects by the patient's father, dating back to over 30 years ago.

Discussion The harmonic coexistence for over a decade between two patients affected with a hoarding disorder with two different clinical setting subtypes was only made possible by the complementary nature of their symptoms.

Conclusion The hoarding disorders amongst more than one person living under the same roof are uncommon, can present themselves in both genders and can exhibit different symptoms.

Keywords Hoarding; OCD; Genetics

About a case suicide attempt as a trigger of remission in obsessive and compulsive disorder

J.M. Gota Garcés*, R. García Lopez, A. Porras Segovia, J.E. Muñoz Negro, J. García Jiménez, L. Gutierrez Rojas
Hospital Campus de la Salud, Salud Mental, Granada, Spain
* Corresponding author.

Introduction This is the case of a 73 year old woman with a late onset, severe and refractory obsessive-compulsive disorder who experimented a sudden remission after a frustrated suicide attempt.

Objective Our target is to make a reflection about the relation between traumatic closeness to own death and neurosis spontaneous remission.

Method Patient has been interviewed and her medical record studied.

Results Patient's psychiatric history shows major depressive disorder, recurrent (ICD 10 CM-F33). Patient is a housewife with primary education. In her psychobiography distinguish a conflictive relationship which probably acted as a trigger for obsessive-compulsive symptoms. These symptoms include obsessive thoughts of contamination, ritual hand washing and avoid contact with others people. In the course of the last 10 years, since the OCD (ICD 10 CM-F42.2) diagnose, the patient has been through a wide therapeutic arsenal, from cognitive-behavioural psychotherapeutic interventions to psychopharmacological treatment, resulting with limited effectiveness. The last treatment was fluoxetine 200 mg (0–0–1) and pregabalin 300 mg (1–0–1). Subsequently, the patient underwent a failed suicide attempt by hanging. After physical recovery, all OCD symptoms had subsided.

Conclusions Traditionally, literature and philosophy considered catharsis as a purifying experience, and Breuer and Freud introduced this concept in modern psychology as a therapeutic method. More recent authors as Yalom have correlated the closeness to death as a stress factor with radical change in life's perspective and attitude. Although current research presents contradicting data about healing effectiveness through a catharsis processes, this case exposes a clear example of positive outcomes in this assumption.

Adenylate-cyclase activity in obsessive-compulsive patients

D. Marazziti*, S. Baroni, F. Mucci, L. Palego, A. Piccinni
University of Pisa, Dipartimento di Medicina Clinica e Sperimentale-Section of Psychiatry, Pisa, Italy
* Corresponding author.

Introduction A possible role of second messengers, such as cyclic adenosine monophosphate (cAMP) signalling, in the development of obsessive-compulsive disorder (OCD) has been recently postulated.

Aims The aim of the present study was to explore and to compare the adenylate cyclase (AC) activity in both basal conditions and after the stimulation by isoprenaline (ISO) in platelets of OCD patients and healthy control subjects. The AC activity was measured both in the absence and in the presence of α - and β -adrenoreceptor antagonists.

Materials and methods Forty patients were included in the study and compared with healthy volunteers. Biological assays were carried out with a method developed by us.

Results The basal AC activity was similar in both groups. The addition of 10 μ M ISO enhanced significantly ($P < .05$) platelet basal AC

in both groups. A stimulatory response following ISO in all subjects even without α -antagonists was also observed.

Discussion No difference in the basal AC activity in platelet membranes of healthy subjects and OCD patients was found. Our findings showed that there is an inhibitory component of ISO effect on platelet AC, due to the agonist interaction with α_2 receptors, at its higher concentrations ($>1 \mu\text{M}$), as well as a condition of supersensitive β -receptors. Our study suggests the presence of catecholamine system disturbances in OCD.

Antipsychotic adjuvant treatment in OCD

L. Montes Reula*, H. Saiz García, A. Portilla Fernández
Biomedical Research Center CIB, Psychiatric, Pamplona, Spain
* Corresponding author.

Antidepressant drugs selective inhibitors of serotonin reuptake (IRS) are the drugs effective in obsessive compulsive disorder. It has not been proven more effective none of them except clomipramine. Around 40–60% of the Patients with obsessive-compulsive disorder (OCD) remain unimproved by serotonin reuptake inhibitors (SRIs). Two cases are presented in relation to this disorder and its treatment.

Twenty-three year old woman begins to present anhedonia, apathy, isolation and low mood. Treatment was initiated with escitalopram with partial improvement.

Obsessive component traits Thirty year old man with obsessive clinic of years of evolution, with worsening in recent months treatment with 200 mg sertraline.

In both cases treatment with oral aripiprazole it was associated with a dose of 5 mg daily with improvement in obsessive symptoms.

Results The efficacy of aripiprazole as adjunctive drug treatment and obsessive anxiety is observed. However, we must take into account the potential risks posed as neuroleptic malignant syndrome and QTc prolongation.

Conclusion Aripiprazole is an antipsychotic which has a novel mechanism of action to be a partial agonist of dopamine D2 receptors. This fact has led to its inclusion in the group of antipsychotics called third generation, also called partial dopamine agonists, dopamine stabilizers or “dopamine-serotonin modulators system.” Its most common side effects such as nausea, headaches, agitation and akathisia were observed in studies on schizophrenia, schizoaffective disorder and bipolar disorder. Unlike other atypical antipsychotics, is considered a relatively neutral drug to weight gain, hyperprolactinemia, changes in metabolic parameters and sedation.

Ect combined with clomipramine and rTMS in an OCD patient with secondary severe depression

D. Mota*, F. Almeida, A. Oliveira, J. Silva, M. Gonçalves, J. Ribeiro, V. Martins, J. Andrade, A. Macedo
Centro Hospitalar e Universitário de Coimbra, CRI Psiquiatria e Saúde Mental, Coimbra, Portugal
* Corresponding author.

Introduction Obsessive-compulsive disorder (OCD) has high rates of comorbidity with mood disorders, mainly major depressive

disorder (MDD). Symptoms of depression are usually secondary to severe and disabling OCD. Electroconvulsive therapy (ECT) has been an effective and well tolerated therapeutic alternative in the management of refractory MDD. Other neuromodulation techniques, such as repetitive transcranial magnetic stimulation (rTMS), have well known efficacy in MDD and also have shown positive results, in clinical trials, treating other psychiatric disorders such as OCD.

Objectives/aims To determine the efficacy of combining rTMS, ECT and clomipramine in the treatment of severe OCD with comorbid severe MDD.

Methods The authors report a case of a 54-year-old male patient diagnosed with severe OCD for 23 years. He has been submitted to several drug treatments and intensive cognitive-behavioural therapy (CBT) always with poor response. The patient was admitted in the beginning of 2016 in our inpatient unit. Besides continuing drug treatment (clomipramine IV) and CBT, he was submitted to 12 ECT sessions during one month (3 sessions per week) and to daily sessions of rTMS during the following month.

Outcome measures were obtained using Y-BOCS for OCD and HAM-D for depression.

Results Our patient responded to ECT with mood improvement after session 4 to full euthymic state at the final session. He also responded well to rTMS with Y-BOCS score reduction.

Conclusion Combined ECT and rTMS treatment with clomipramine IV and CBT was effective in our patient with a severe form of both disorders (OCD and MDD).

Neuroleptic-induced parkinsonism in patient with obsessive compulsive disorder: A case report

J. Nunes^{1,*}, D. Brigadeiro¹, J. Andrade², A. Pissarra da Costa¹
¹ Hospital Sousa Martins, Department of Psychiatry and Mental Health of Sousa Martins Hospital- U.L.S. Guarda, Guarda, Portugal
² Centro Hospitalar de Universidade de Coimbra, Department of Psychiatry and Mental Health of CHUC, Coimbra, Portugal
* Corresponding author.

Obsessive-compulsive disorder (OCD) is a neuropsychiatric disorder characterized by either obsessions (recurrent unwanted thoughts, images or impulses) or compulsions (repetitive behaviors often performed to relieve anxiety or distress). In some cases, it is considered antipsychotic enhancement. However, in high doses, it can exacerbate OCD symptoms and cause extrapyramidal effects such as neuroleptic-induced Parkinsonism.

Here, the authors present a clinic case of a single male patient with 50 years old, in which with the age of 42, started with a obsessive-compulsive framework about the developed task at the work place (production of fabric) followed by several verifications of the assembled pieces, which interfered with his work performance. This patient was admitted to the psychiatric hospital due to the deterioration of the symptoms with obsessive ideas of HIV contamination resulting in rigid cleaning rituals. He was medicated with several OCD medications including Clozapine 50 mg.

In the following years and complaining of insomnia, the clozapine dose was increased by the patient reaching the dose of 200 mg. In 2016 he started secondary Parkinsonism framework to antipsychotics, characterized by akinesia, facial hypomimia, stiff, coarse tremor and stooped posture. Therapeutic setting was made with a reduction of clozapine at doses of 50 mg occurring fading of extrapyramidal symptoms and decrease the symptoms of OCD.

The authors intend with this presented case to highlight the importance of surveillance of patients receiving antipsychotics for OCD to avoid worsening of symptoms and the development of extrapyra-

midal effects, which deeply contribute to the decrease of quality life of these patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Efficacy of cbt plus acceptance & commitment therapy versus cbt alone for obsessive-compulsive disorder. Protocol for a randomised single-blinded superiority trial

A. Pozza^{1,*}, S. Domenichetti², N. Giaquinta³, D. Davide⁴

¹ University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy

² Azienda USL Toscana Centro, Mugello Functional Unit of Adult Mental Health UFSMA Mugello, Florence, Italy

³ Centre of Cognitive and Behavioural Therapy CTCC, Outpatient centre, Florence, Italy

⁴ University of Florence, Department of Health Sciences, Florence, Italy

* Corresponding author.

Introduction Cognitive behavioural therapy (CBT) is the first-line psychological treatment for Obsessive-Compulsive Disorder (OCD). However, 30% of individuals have a null or partial response. Preliminary evidence suggested that Acceptance & Commitment Therapy (ACT) may be effective. No study investigated whether the association of CBT with ACT may improve outcomes of CBT alone.

Objectives This paper presents the protocol of a trial where individuals with OCD will be randomly assigned to CBT alone or CBT plus ACT. Primary endpoints will be the number of individuals meeting OCD diagnostic criteria at post-treatment and follow-up. Secondary endpoints will be self-reported depression, anxiety, disgust and guilt, and obsessive beliefs. It is hypothesized that CBT plus ACT is associated to fewer individuals meeting OCD criteria and greater reductions in secondary endpoints.

Methods A single-blinded superiority randomised design will be used. Primary/secondary outcomes will be administered at baseline, post-treatment and 6-month follow-up. Treatment duration will be 25 weekly sessions in both conditions. Individuals (age \geq 18 years) with OCD diagnosis will be recruited at mental health services in a 60.000 inhabitants area in Italy. Chi squared will be computed to test group differences on OCD diagnosis. ANCOVAs will be calculated entering baseline scores as covariates, group allocation as random factor and primary/secondary outcomes as dependent variables.

Results To obtain a medium effect size, 80% power and 0.05 significance, a priori power analysis suggests inclusion for at least 34 individuals as total sample.

Conclusions A description of the protocol will be provided. Strengths and potential limitations will be addressed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0735

Intolerance for uncertainty is a prognostic factor of negative response after intensive inpatient CBT for medication-resistant obsessive-compulsive disorder

A. Pozza^{1,*}, G.P. Mazzoni², D. Dettore³

¹ University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy

² “Studi Cognitivi”, Postgraduate Program on Cognitive Psychotherapy, Florence, Italy

³ University of Florence, Department of Health Sciences, Florence, Italy

* Corresponding author.

Introduction Cognitive theories of Obsessive-Compulsive Disorder (OCD) have identified six types of beliefs, which have a role as vulnerability and maintaining factors: Inflated sense of responsibility, Threat overestimation, Importance of thoughts, Control of thoughts, Perfectionism and Intolerance for uncertainty. As previous research showed that strong obsessive beliefs are linked to severe OCD symptoms, it could be hypothesized that they act as prognostic factors of negative response after cognitive behavioural therapy (CBT). However, poor research investigated this aspect.

Objectives The aim of the current study was to examine which obsessive beliefs could predict a worse response after intensive CBT in a group of inpatients with medication-resistant OCD.

Methods Forty inpatients [mean baseline Y-BOCS = 26.70, SD = 7.01] with medication-resistant OCD underwent 5-week intensive CBT including daily and prolonged exposure and response prevention (2.5 hours in the morning, 2.5 hours in the afternoon). All individuals have had inadequate symptom response after prior serotonin-reuptake inhibitor trials. The Y-BOCS, BAI, OBQ-87, and BDI-II were administered at baseline and post-treatment.

Results Inpatients who endorsed stronger intolerance for uncertainty, measured by higher scores on the OBQ-87 Intolerance for uncertainty scale, showed worse response after CBT, measured by having still higher Y-BOCS scores at post-treatment ($\beta = 0.37$, $t = 2.48$, $r^2 = 0.14$, $P < 0.05$). No effect of the other beliefs emerged.

Conclusions Current data demonstrated the role of intolerance for uncertainty as predictor of negative response after intensive CBT for resistant OCD in inpatient setting. Augmentation strategies should be introduced to improve outcomes of inpatients with intolerance for uncertainty.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Background The objective of investigation was to determine whether patients with obsessive-compulsive disorder (OCD) resistant to drug therapy may improve their condition using intensive, systematic cognitive behavioural therapy (CBT) lasting six weeks and whether it is possible to predict treatment outcome using clinical and selected psychological characteristics.

Method From 66 OCD patients fifty-seven completed program. The diagnosis was confirmed using the structured mini international neuropsychiatric interview. Patients were rated using the objective and subjective forms of the Yale-Brown Obsessive Compulsive Scale (Y-BOCS), objective and subjective forms of the Clinical Global Impression (CGI), Beck Anxiety Inventory

(BAI), Beck Depression Inventory (BDI), dissociative experiences scale, 20-item Somatoform dissociation questionnaire and Sheehan disability scale before treatment, and with subjective Y-BOCS, objective and subjective CGI, BAI and BDI at the end of treatment. Patients were treated with antidepressants and daily intensive group CBT for six weeks.

Results During 6-week intensive CBT program in combination with pharmacotherapy, there was significant improvement in patients suffering from OCD resistant to drug treatment. There were statistically significantly decreased scores of scales assessing severity of OCD symptoms, anxiety, and depressive feelings. A lower treatment effect was achieved specifically in patients who (a) showed fewer OCD themes in symptomatology, (b) showed higher level of somatoform dissociation, (c) had poor insight and (d) had a higher initial level of overall severity of the disorder. Remission of the disorder was more likely in patients who (a) had good insight, (b) had a lower initial level of anxiety and (c) had no comorbid depressive disorder.

Hospital Clínico Universitario de Valladolid, Psychiatry Department, Valladolid, Spain

* Corresponding author.

We present the case report of a 46-year-old woman who experienced obsessive-compulsive symptoms for over twenty years, with multiple relapses, severe depressive symptoms and many hospitalizations in the psychiatric Inpatient Unit. Treatment with different SSRIs, tricyclic antidepressants, atypical antipsychotics and even electroconvulsive therapy were administered with poor results.

After her last hospitalization a Cognitive-Behavioral Therapy, including exposure and response prevention and cognitive therapy, is initiated combined with medication, improving depressive symptoms, the ritual behaviors and levels of anxiety.

Modern treatments for Obsessive-Compulsive Disorder (OCD) have radically changed how the disorder is viewed. While in the past OCD

was regarded as chronic and untreatable, a diagnosis of OCD may now be regarded with hope. Cognitive and behavior therapy and antidepressant medications are currently used to treat the disorder. They can be used to control the symptoms and enable people with OCD to restore normal function in their lives.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Misophonia: Case report

C. Vidal^{1,*}, L. Melo Vidal², M.J. Alvarenga Lage²

¹ Faculdade de medicina de barbacena, psiquiatria, Barbacena, Brazil

² Barbacena Medicine School, student, Barbacena, Brazil

* Corresponding author.

Introduction Misophonia refers to a condition in which there is a strong aversion to certain sounds, in response to it the person reports unpleasant emotional experiences and autonomic arousal. **Objectives** To present the case of misophonia carrier and discuss diagnostic features.

Methodology Case report and literature review.

Results Female, 32 years old, married, two children. In anamnesis reported obsessional symptoms (Check doors and windows, concerned with order and symmetry of objects; read all that lies ahead, pull the hand two or three times on mobile) since adolescence. Also reported triggering situations of anger: intolerance to some noises and sounds, like chewing third, mobile keyboard, click the "mouse" computer, printer and rub hands. In the presence of these noises, she tries to move away, and already tried to attack physically relatives and insulting co-workers. She was treated with escitalopram and re-evaluation after thirty days, reported partial relief misophonia and reduction of obsessional symptoms.

Conclusion The condition was first described in the early 2000s by two audiologists, and has become the focus of interest in the field of psychiatry. Some reports suggest that misophonic symptoms may be part of other conditions such as Tourette's syndrome, obsessive compulsive disorder and generalized anxiety disorder. Specifically, the characteristics shared between misophonia and OCD, as the relief of discomfort associated with avoidance behaviour suggest that the condition is part of the obsessive-compulsive spectrum, which seems to happen with the case described above.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Relationship of social skills with perceived social dignity and mental health of elderly people

H. Allahverdipour

Tabriz University of Medical Sciences, Health Education and Promotion, Tabriz, Iran

Introduction Social skills enables one to interact effectively and avoid the adverse responses. Factors such as non-use of the elderly's skills, impaired social skills, indifference and neglect of the elderly impair social dignity and conversely factors such as living independently and respectful relationship will improve social dignity. The aim of current study was to assess the association between social skills and perceived social dignity and mental health of elderly people as well.

Methods In this cross sectional design, of the 300 elderly participants were recruited based on the randomized sampling method and Reggio social skills questionnaire, Jacelon perceived social dignity and general health questionnaire (GHQ12) were applied to gauge data by using a written questionnaire in the self report manner. For all tests a significance level of 0.05 was considered and statistics software SPSS version 21 and AMOS version 13 were used.

Result The results showed a significant relationship between social skills and mental health base on gender and age and also; there was a significant relationship between social skills and social dignity ($P < 0.001$). Social skills predicted 26% of social dignity among older people and also social skills predicted 16% of mental health dignity. Therefore, social skills, was a proper predictor for mental health and perceived social dignity.

Conclusion Due to the positive impact of social skills on the perceived social dignity and mental health of older population, it is needed to improve social skills of middle aged population which consequently affect on psychological well-being of aged people.

Residential unit for the elderly: Cases study and reflections on the first 18 months of functioning

A. Amaral*, A.S. Machado, I. Costa

Centro Hospitalar de São João, Psychiatry and Mental Health Clinic, Porto, Portugal

* Corresponding author.

Introduction The Residential Unit for the Elderly (RUE) was established in August 2015 and has capacity for 8 inpatients. It is intended to behavioral reorganization and caregiver rest of elderly patients with behavioral changes, particularly in cases of cognitive impairment.

Aim We intend to describe the hospitalized population in the first 18 months and discuss the unit functioning and its impact on clinical stability of patients.

Methods Socio-demographic and clinical data were analyzed using the STATA v13.1 software, using multivariate regression model with a 0.05 significance level.

Results We present preliminary results from the first twelve months. Twenty-six patients admitted, 18 (69.2%) were female, with an average age of 76.7 years-old (IQR 71–86-years-old). The main reasons for referral were: caregiver rest (38.4%), psychopathological stabilization (30.7%) and autonomy training/cognitive stimulation (15.4%). Most patients had dementia (65.4%). Patients were hospitalized on average 78 days (IQR 30–98 days). Complications occurred in 18 patients (69.2%). There was an 85.7% reduction in the number of hospitalizations for any cause within 6 months after hospitalization in the RUE ($P < 0.001$) and a 75% reduction in hospitalizations from psychiatric cause ($P = 0.001$). Regarding visits to the emergency room (ER), we found a decrease of 87.1% in visits for psychiatric motive ($P < 0.001$) and 85.4% in visits for any cause ($P < 0.001$).

Conclusion Inpatient care in RUE has contributed to the clinical stability of patients with consequent reduced use of health services. Although the results still concern a short operating period, they appear to be promising.

* Corresponding author.

Introduction In dementia, delusions are common with prevalence up to 75%. However, erotomanic delusions, or De Clerambault's syndrome, are a rarity in dementia. To date, only six case-reports have been described in vascular dementia, frontotemporal dementia, and Alzheimer's dementia.

Objectives To present a case of De Clerambault's syndrome in an older adult diagnosed with vascular dementia.

Aims To review available literature on De Clerambault's syndrome in dementia.

Methods A case report is presented and discussed followed by a literature review.

Results We report a 72-year-old female with a history of right posterior cerebral artery infarction. The patient developed a sudden onset erotomanic delusion after she met a male patient of her age during her stay in a dementia day care center. She was agitated, disorientated, presented with confabulation, and showed a dysphoric mood. On MMSE she scored 14/30, the clock-drawing test revealed visuospatial deficits. On MRI, the right occipital lobe showed an encephalomalacia. The patient was treated with sertraline 50 mg/day and olanzapine 5 mg/day. Her erotomanic delusions improved after 3 months of treatment.

Conclusion De Clerambault's syndrome is a rare and poorly understood disorder with generally a poor response to treatment. Some cases were successfully treated with atypical anti-psychotics. However, further research is needed to explore the course and treatment of this delusion.

Late life depression, postural instability and dyspnea: The He.s.i.o.d. study (Hexameter study in older depressed)

¹² U.C. Davis, Department of Family and Community Medicine, Sacramento, CA, USA

* Corresponding author.

Introduction Late life major depression (LLMD) is usually treated within primary care, but still with unsatisfactory outcomes and significant residual symptoms. Moreover, LLMD increases symptoms of anxiety, dyspnea, fear of falling (FOF), and risk of falls. Evidence from non-depressed patients suggests the efficacy of breathing and postural exercises; in particular, rhythmic breathing during poetry recitation was shown to improve cardio-respiratory synchronization. Thus, the aim of the HESIOD study was to test the efficacy of antidepressants plus breathing and postural exercises to improve patients' anxiety mood, dyspnea, FOF, and postural stability.

Methods Two non-randomised groups were compared: (1) antidepressant drugs plus weekly sessions of breathing/postural exercises based on the rhythmic recitation of hexameter poetry (intervention); (2) antidepressant drugs plus weekly sessions of group reading (comparator). Patients aged 65+, with non-psychotic recurrent LLMD were recruited from a psychiatric consultation-liaison program for primary care. The main outcome measure was remission from depression (MADRS score ≤ 10) at 24 weeks. Secondary outcomes will include accelerometer-based measures of postural stability; patient-rated dyspnea, and FOF.

Results Preliminary data on 34 patients show that patients receiving breathing and postural exercises displayed greater remission rates than those in the reading group (47.1% vs. 11.8%, $P=0.02$). Further analyses will examine the effects on postural stability, dyspnea and FOF.

Conclusions Breathing and postural exercises may exert significant clinical advantage when added to the standard antidepressant drug therapy for LLMD. This study might prompt further research on innovative treatment strategies to improve the outcomes of late life depression in primary care.

The adherence to Mediterranean diet moderates the association between medical multi-morbidity and depressive symptoms in elderly outpatients

F.S. Bersani^{1,*}, R. Vicinanza², E. d'Ottavio², M. Biondi¹, M. Cacciafesta², G. Troisi²

¹ Sapienza University of Rome, Department of Neurology and Psychiatry, Roma, Italy

² Sapienza University of Rome, Department of Cardiovascular, Respiratory, Nephrologic, Anesthesiologic and Geriatric Sciences, Roma, Italy

* Corresponding author.

Background Depressive symptoms in the elderly are related to the advancing of age, loss of life purpose, medical multi-morbidity, cognitive decline and social-economic problems mounting evidence suggests that lifestyle behaviors and certain dietary patterns may improve mood and overall well-being in older adults. In the present study we investigated (i) the association of adherence to Med-Diet with depressive symptoms and multi-morbidity in a cohort of geriatric medical outpatients and (ii) the role of Med-Diet in mediating the association between depressive symptoms and multi-morbidity.

Methods Morbidity was assessed using the severity index of cumulative illness rating scale for geriatrics (CIRSG-SI). Montreal cognitive assessment (MoCA) and geriatric depression scale (GDS)

were administrated to evaluate cognitive and depressive symptoms. Adherence to Med-Diet was evaluated using the Med-Diet 14-Item questionnaire (MDQ). Pearson correlation was used to test association between variables. The Preacher and Hayes' strategy was used to test the mediational model.

Results One hundred and forty-three subjects were included in the study. Significant inverse correlations of MDQ with GDS ($r = -0.317$; $P < 0.001$) and CIRSG-SI ($r = -0.247$; $P = 0.003$) were found, with and without adjustment for potential confounders. A direct correlation between CIRSG-SI and GDS was also observed ($r = 0.304$; $P = 0.001$), with this association being moderated by MDQ ($b = 0.386$; $P = 0.047$).

Conclusion These findings (i) add to the accumulating evidence that Med-Diet is crucially involved in the regulation of physical and mental health of elderly people, and (ii) suggest that a Mediterranean-style diet may contribute to protect elderly subjects with higher levels of poly pathology/multi-morbidity from the development of depressive symptoms.

EV0744

Diagnostic accuracy of the overlapping infinity loops, wire cube, clock drawing tests and their combined score for cognitive impairment in mild cognitive impairment and dementia

T. Charernboon

Faculty of Medicine, Thammasat university, Department of Psychiatry, Pathumthani, Thailand

Objectives To investigate the diagnostic accuracy of the overlapping infinity loops, wire cube, clock drawing tests (CDT) and the combined score in the detection of mild cognitive impairment (MCI) and dementia.

Methods The participants were 60 normal controls (NC), 35 patients with MCI, and 47 patients with dementia. For the overlapping infinity loops and wire cube tests, the participants were told to copy the figures from the examples. For the CDT, the participants were asked to draw a clock face with numbers on it with the hands at ten past five.

Results The results illustrate that infinity loops, cube, or CDT alone, or combined score, were not able to discriminate between NC and MCI groups. In dementia detection, the CDT had the highest diagnostic accuracy (sensitivity 76.6% and specificity 87.4%) followed by infinity loops (sensitivity 83.7% and specificity 78.9%) and cube (sensitivity 93.6% and specificity 46.3%). Additionally, when the three tests were combined, better diagnostic accuracy was demonstrated with a sensitivity of 87.2% and specificity 86.3%.

Conclusion This study demonstrates that the three drawing tests are sensitive detectors of dementia but not MCI. The combination of these three drawing tests is a brief tool of good diagnostic accuracy for dementia screening.

EV0745

Anxiety for body symmetry and sexual performance in old and young patients, case series presentation

I. Christodoulou*, A. Kapsimalis, G. Dounias, N. Peitsidis, C. Lahana, D. Gonezou

G. Papanikolaou General Hospital, Thessaloniki, Greece, B'surgical Department, Thessaloniki, Greece

* Corresponding author.

Introduction It is not rare, old patients asking for better aesthetic results on multi-operated bodies causing anxiety and inconvenience. Objectives of our study is to present the emotional confrontation of patients towards surgery.

Methods We present 4 cases of interest.

Results A 75-year-old woman with abdominal asymmetry due to lose abdominal walls and prior operations underwent a failed operation because of her own persistence and finally was convinced to stop asking new surgery when she was told that her abdomen would never become symmetrical. A 79-year-old man, keen on parachuting, was interested to improve his sexual performance and tighten his loose skin with a re-operation on his well done hernia operation. A married man of 50-years-old with a temporary colostomy due to ruptured sigmoid colon suffering from acute diverticulitis, two months later was not at all interested in any kind of aesthetic improvement or his sexual life, and his only care was his nutrition and the avoidance of infections. A divorced man of 49-years-old, with a permanent colostomy, due to familial adenomatous polyposis and cancer occurrence on the site of his old operation (prior total colectomy in 1995), not even one time referred to sexual functioning or aesthetic problems, while his constant problem was to take care of his colostomy by himself.

Conclusions Old age does not mean loss of interest for body icon and sexuality. On the other hand middle-aged men seem to be more practical and less emotional than old patients.

EV0746

"The old lady and the dead bird" – A case of very-late-onset schizophrenia-like psychosis

V. Covelo*, M. Marinho, A.S. Machado, J. Rebelo, R. Moreira São João Hospital Centre, Clinic of Psychiatry and Mental Health, Porto, Portugal

* Corresponding author.

Introduction In 1943, Bleuler defined "late-onset schizophrenia" as a form of schizophrenia with onset after the age of 40. Half a century had passed with no consensus on the late psychosis' terminology, when in 1998 the international late-onset schizophrenia group Consensus proposed a nosology for these disorders: late-onset schizophrenia and very-late-onset schizophrenia-like psychosis.

Objectives Presentation of a case and diagnostic discussion.

Methods Interviews with the patient during his hospitalisation.

Results We present a case of a 73-year-old single woman, with no psychiatric history, who was driven to the emergency department by her relatives when they noticed her bizarre behaviour: she had drowned and strangled her pet bird. At examination she was agitated, had persecutory delusions, thought broadcasting, cenesthetic and auditory hallucinations in the form of a masculine voice, who sang and dialogued with her. Symptoms had evolved during the past six months with no apparent functional impairment. During hospitalisation she was treated with risperidone (up to 5 mg/day) with improvement in a few days. There were no significant abnormalities on cerebral tomography and analytical exams. Neuropsychological evaluation ruled out cognitive deficits. At the time of discharge although the patient kept referring auditory hallucinatory activity, she had an appropriate behaviour, and no evidence of negative symptoms.

Conclusions The small group of patients who meet schizophrenia's criteria for the first time at a later age present some particular

clinical characteristics to be taken into account. This case highlights some of them, drawing attention to this uncommon diagnosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Frontotemporal dementia: A diagnostic challenge

C.A. Crisan^{1,*}, I. Parau², L. Perju-Dumbrava¹

¹ University of Medicine and Pharmacy "Iuliu Hatieganu"

Cluj-Napoca, Department of Neurosciences, Cluj-Napoca, Romania

² Psychiatry Clinic I, Psychiatry, Cluj-Napoca, Romania

* Corresponding author.

Introduction Frontotemporal dementia (FTD), the second commonest cause of degenerative dementia after Alzheimer's disease in patients aged 65 years or less is characterized clinically by progressive changes in social, behavioural, and language function.

Objectives To do a complete psychiatric and neurological examination of a case with pick dementia.

Aims This case report wants to highlight the combination of psychiatric and neurological symptoms in FTD in order to improve the early diagnosis and therapeutical management.

Methods We report the case of a 62-years-old male who was admitted in psychiatric clinic, I Cluj-Napoca after he was transferred from neurology clinic I for distractibility, impersistence, apathy, loss of interest, emotional blunting, hyperorality, dietary changes, stereotyped behaviour, decline in personal hygiene. The delay in diagnosis was approximately 3 years, probably because his MMSE total score was 30 points and because he presented behavioural and verbal disinhibition, irritability, inappropriate emotional reacting and a CT with minimal changes.

Results Psychometric evaluations revealed: Frontal Assessment Battery (13/18), Frontotemporal Dementia Rating Scale (50% impairment, moderate severity level), ADL (activities of daily living) (Katz score = 4/7, moderate dependence, low self-care) and IADL (instrumental activities of daily living) (2/8 = high dependency level, low self-maintenance). MRI: fronto-temporal atrophy. The anamnesis, heteroanamnesis, para-clinical investigations led us to a diagnosis of FTD (Pick dementia).

Conclusions We should acknowledge that behavioural changes progress whatever the presentation, that cognitive decline occurs later and that FTD is a disease with a longer delay in onset of cognitive symptoms and diagnosis.

Self-compassion, well-being and health in elderly: Are there related?

M. Cunha*, L. Parente, A. Galhardo, M. Couto

Miguel Torga Institute, Clinical Psychology, Coimbra, Portugal

* Corresponding author.

Introduction The increase in aging population is a major advance in society, but also a great challenge, imposing the need for actions that promote successful aging, with higher subjective well-being and better health.

Objectives (1) analyse the possible influence of socio-demographic variables in self-compassion, satisfaction with life, affection, physical and mental health (study variables); (2) understand how is that the study variables are associated with each other in old age; and (3) explore which variables best predict satisfaction with life and health in the elderly.

Method The study sample consists of 155 individuals, aged between 65 and 94 years old, institutionalised and non-institutionalised.

Results (1) significant correlations were found between some demographic and the study variables. (2) Significant associations were also found between self-compassion, subjective well-being and health. (3) linear regression analysis revealed that physical health is best predicted by greater life satisfaction and lower age; mental health is best predicted by increased satisfaction with life, self-compassion and decreased negative affect; and, finally, life satisfaction is predicted by a higher physical health and self-compassion.

Conclusions These results suggest the importance of developing psychological skills such as warmth, tolerance and the acceptance of suffering bearing in mind that the elderly may experience difficulties resulting from the developmental characteristics of old age. Our findings suggest the possible beneficial effect of compassion, focused therapies designed for this specific population, particularly contributing to the promotion of life satisfaction and mental health of the Portuguese elderly.

The psycho-geriatric patient in the Emergency Room (ER) of the Maggiore della Carità Hospital in Novara

E. Di Tullio^{1,*}, C. Vecchi¹, A. Venesia¹, L. Girardi¹, C. Molino¹, P. Camera¹, M. Chiarelli serra¹, C. Gramaglia¹, A. Feggi², P. Zeppego²

¹ Università del piemonte orientale, translational medicine, Novara, Italy

² Azienda ospedaliero-universitaria maggiore della carità di novara, SC psichiatria, Novara, Italy

* Corresponding author.

Introduction Due to population aging, the health system will face increasing challenges in the next years. Concerning mental disorders, they are major public health issues in late life, with mood and anxiety disorders being some of the most common mental disorder among the elderly. For this reason, increasing attention has to be paid to the evaluation of the elderly in psychiatry emergency settings.

Objectives To evaluate the socio-demographic and clinical features of over 65 patients referred to psychiatric consultations in the ER of "Maggiore della Carità" Hospital in Novara, in a 7 years period.

Aims The analysis of the characteristics of the study sample could be potentially useful in resource planning in order to better serve this important segment of the general population.

Methods Determinants of ER visits for over 65 patients referred to psychiatric evaluation were studied retrospectively from 2008 to 2015.

Results Elderly patients made up 14,7% (n=458) of all psychiatric evaluation in the ER (n=3124). About two thirds (65,9%) were females and one third were males (34,1%). The mean age of patients recruited was 75.11 years. The majority of subjects (68.6%) presented without a diagnosis of Axis I according to DSM-IV. The other most frequent diagnosis was "cognitive disorders" (11.4%) and "mood disorders" (10.9%).

Conclusions The large proportion of patients without a diagnosis of Axis I, could be related to the misunderstanding of the psychosocial aspects of aging. Preliminary results highlight the importance of research on this topic, considering population aging and the impact of mental disorders in late-life.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A Delphi study to establish an expert consensus opinion on risk factors for type 2 diabetes, and potential complications of diabetes, including brain health associations

C. Dolan^{1,*}, R. Glynn², B.A. Lawlor³

¹ St. James's Hospital, General Adult Psychiatry, Dublin, Ireland

² University College Dublin, Public Health and Epidemiology, Dublin, Ireland

³ Trinity College Dublin, Psychiatry of Old Age, Dublin, Ireland

* Corresponding author.

Introduction Type 2 diabetes (T2DM) has a multifactorial aetiology, and wide-ranging potential health complications, including brain health associations.

Objectives A number of diabetes risk factors and complications have a strong evidence base. This study will address ambiguity in the literature regarding others.

Aims Results will inform development of a questionnaire for use among the public and individuals with diabetes, assessing knowledge of diabetes and brain health associations and the role of modifiable risk factors. Aiming to ultimately inform effective preventative strategies for both dementia and depression.

Methods A systematic literature review preceded this two-round modified Delphi study. Respondents rated their agreement with risk factors for T2DM, and potential complications of diabetes on an e-questionnaire.

Results Of 46 international experts invited to participate in round-one; 14 responded (30.4%). Thirteen respondents (92.9%) completed round-two questionnaire. Consensus was pre-defined as 70% or more agreement between respondents on questionnaire items. On completion, 11/18 risk factor items for T2DM met consensus criteria however 'depression' did not. Of diabetes complication items, 13/16 met consensus criteria (see Table 1).

Conclusions Study results indicate that international experts consider a number of brain health complications to be associated with diabetes. Results will be incorporated in a diabetes and brain health knowledge questionnaire for use among vulnerable populations.

Table 1 A sample of diabetes complications post round-two of Delphi.

	Median	Interquartile range	Percentage agreement
Kidney damage	5	0	100%
Eye damage	5	0	100%
Stroke	5	1	92.3%
Depression	4	2	92.3%
Dementia	5	1	92.3%
Memory problems	5	1	92.3%

Relevance of group devices in the psychological treatment of elderly patients

L. Emanuelli*, G. Garcia De Andreis

Casabierta, Buenos Aires, Mar Del Plata, Argentina

* Corresponding author.

The work aims to demonstrate the relevance of groupal psychotherapies and think tanks in elderly patients, suffering from various psychiatric disorders. The exhibition focuses on the consideration of a structural problem of aging seen from the point of view of defences and identifications, which some authors call "characteropatización of old age", resulting in stagnation in the development of treatments in therapeutic individual devices.

The paper postulates that groupal devices are more effective in treating patients older than treating individual cutting of different theoretical clinical guidelines, as are more suited to the production of mobilizing stiffened defences and crystallized identifications, won both by various effects of the death drive, which result in specific libidinal stasis, especially expressed in the substitutive formation called by some authors "letting die".

The statement places the group devices in the Freudian model of cell tissues, herringbone in various texts of his work, but expressed in more detail in "Beyond the Pleasure Principle", which postulates as the cause of the vital tension constellations composed of different but related cells. Communication is illustrated with clinical vignettes both therapeutic groups and think tanks, as with clinical material from patients who have received both individual treatment and group result of therapeutic work done in the Casabierta institution during the last ten years. As a conclusion and opening of new questions, the text pans across different forms of resistance indication of group psychotherapy, which rooted in many current social representations of the group and the therapeutic.

Keywords Caracteropatización; Defense; Identifications; Device group.

J. Masmoudi

CHU Hédi Chaker Sfax, Tunisia, Psychiatrie A, sfax, Tunisia

* Corresponding author.

Introduction The haemodialysis, one of the main treatment modalities of chronic renal failure, imposes a great psychosocial burden on elderly patients, which may cause many psychological impacts.

Objective The aim of this study was to screen anxiety and depression in elderly patients on haemodialysis, taking into account factors that may contribute to.

Methods Our study was transversal, descriptive carried out among 38 elderly patients aged more than 60 years with chronic kidney failure on haemodialysis. The structured questionnaire used in this study was gathered information on socio-demographic and disease characteristics. We used the hospital anxiety and depression scale (HADS) to access anxiety and depression.

Results The mean age of our sample was 71 years. The sex-ratio (σ/φ) was 1.92., patients were mainly married (73.7%), and have a low school level (76.3%). The mean haemodialysis duration was 5 years \pm 4.68. The most common cause of renal failure was polycystic kidney disease (18.4%), diabetes (15.8%), while in 28.9% the cause was unknown. Anxiety was found in 18.4% of patients and it was associated with both low school ($P=0.02$) and socio-economic

level ($P=0.04$). The prevalence of depressive symptoms was 42.1%. It was correlated to the unknown cause of kidney failure and the short duration haemodialysis ($P=0.03$).

Conclusion These data suggest that depression and anxiety are highly prevalent in elderly patients with renal failure on dialysis. This result shows the need for interdisciplinary teamwork in improving the quality of life of those patients.

New insights in the pharmacotherapy of psychosis: The example of Parkinson's disease psychosis

A. Fontaine^{1,*}, G. Radu²

¹ University Lille, CHU Lille, Department of Psychiatry, Lille, France

² Memorial University, Psychiatry, St John's, Canada

* Corresponding author.

Introduction With 10 million of patients across the world, Parkinson's disease is the second most common form of neurodegeneration, after Alzheimer's. Among half of patients develop psychotic symptoms, such as visual hallucinations and delusions, which are correlated with higher rate of placement in nursing home, are difficult to treat and severely affect quality of life, making Parkinson's disease psychosis (PDP) a major public health issue.

Objectives The aim of this study is to identify treatment options that could be used to treat PDP and clarify underlying pathophysiology.

Method We conducted a literature review on Pubmed, Google scholar and Cochrane library, using a combination of the following: "Parkinson's disease Psychosis" "visual hallucinations" "Pimavanserin" "Clozapine" "atypical anti-psychotics" 120 articles were screened.

Results Considering that hallucinations arise from overactivation of dopaminergic receptors, treatment options include reducing the dopaminergic drugs used to control motor symptoms; using atypical anti-psychotics such as Risperidone, Olanzapine, Quetiapine, which often results in the worsening of extra-pyramidal symptoms. Another option is the use of low doses of Clozapine, which has been proven efficient with no worsening of non-motor symptoms, suggesting the implication of other pathways, such as serotonin. Finally, Pimavanserin, a 5-HT_{2A} receptor inverse agonist, without any dopaminergic activity, has been demonstrated to be effective in the treatment of PDP, well tolerated and easy to use.

Conclusion Serotonin inverse agonists represent a major breakthrough in the pharmacotherapy of PDP, and may lead the way to changes in the treatment of schizophrenia and other psychotic disorders.

Visual hallucinations in elderly people: Early dementia, psychosis or Charles Bonnet syndrome? Review and case report

M. García Moreno^{1,*}, A. De Cos Milas², B. Poza Cano³, L. Beatobe Carreño²

¹ CSM Majadahonda, Hospital Universitario Puerta de Hierro Majadahonda, Psychiatry, Madrid, Spain

² CSM Móstoles, Hospital Universitario de Móstoles, Psychiatry, Madrid, Spain

³ CE San Carlos, Hospital Universitario El Escorial, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Charles Bonnet Syndrome (CBS) is an uncommon disease that involves visual hallucinations in visually impaired individuals, in absence of cognitive impairment or psychiatric illness, although some authors propose CBS as an early marker of dementia. **Objectives** Show the importance of differential diagnosis in individuals with presence of visual hallucinations, with distinction of CBS from others psychiatric or organic disorders such as hypnagogic and hypnopompic hallucinations, epileptic phenomenon, Parkinson disease, dementia, delirium tremens or late-onset psychosis.

Methods Literature review about visual hallucinations in people with psychiatric illness, dementia or in absence of these status, followed by a case report of a patient who met criteria for CBS.

Results Eighty one-years-old female with no previous psychiatric illness, experience suddenly visual hallucinations (animals, insects) with secondary anxiety, fear and insomnia as well as disruptive behaviour (throw lye to kill the animals) and delusional interpretations of the hallucinations considering them as a divine proof. Clinical exam, neuroimaging tests and SPECT confirmed just a minimal cognitive impairment nor suggestive of dementia. She had personal history of cataracts and macular degeneration, with no other medical condition. Olanzapine was prescribed but it was withdrawn because of adverse effects. Later, haloperidol was introduced with well tolerance and symptom's recovery ad intergrum.

Conclusions Charles Bonnet syndrome is a rare condition that may sometimes be the beginning of a dementia. Medical evaluation and complementary tests help differential diagnosis in order to reject others psychiatric/somatic disorders. Neuroleptic and anti-epileptic treatment should be useful to control symptoms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Violence against elderly persons is an intricate social, legal and ethic issue. Alzheimer's patients are the most vulnerable individuals to mistreatment and neglect. The aggressor can be even the main helper of the patient. We noticed a wide underestimation of this phenomenon, which remains taboo subject in our society.

Objectives and methods – The aim of our study is to identify predictive factors of mistreatment of Alzheimer's patients through a prospective and descriptive study, within patients following in the department of neurology in Razi's hospital.

– we evaluate cognitive function (MMSE) and the importance of behavioural disorders.

– we explored helper's socio-demographic characteristics and the quality of aid relationship.

– anger and hostility within relationship were estimated through family attitude scale.

Results Our sample accounts 60 informal caregivers predominantly female (91.7%) with an average age of 49.67 years, mostly are married (71.66%) and jobless (38.88%):

– in 78.3% of cases, caregivers spent about 12 to 24 hours per day with Alzheimer's patient.

- the average score of FAS was about 52.4% with an important emotional charge (score >60).
- twenty-five caregivers wished the death of the patient and 42 others admitted being sarcastic with him.
- We noticed a correlation between mistreatment and both cognitive function and behavioural disorders.

Conclusion Our results support the fact that mistreatment of people with dementia is closely related with the exhausting situation of the main caregiver.

Depression in the elderly with chronic medical illness

L. Ghanmi^{1,*}, S. Sghaier², R. Toumi², K. Zitoun¹, L. Zouari³, M. Maalej³

¹ Regional hospital of Gabes, Psychiatry, Gabes, Tunisia

² Oudhref's District hospital, Oudhref's District hospital, Gabes, Tunisia

³ University Hospital Hedi Chaker, Psychiatry "C", Sfax, Tunisia

* Corresponding author.

Background There is a bi-directional relationship between depression and chronic medical disorders.

Aims The objectives of our study were to measure the prevalence of depression in the elderly with chronic medical illness in primary care and to determine the socio-demographic and clinical factors related to depression.

Methods We conducted a descriptive and analytical cross-sectional study of patients aged over 65, followed at the outpatient chronic diseases in Oudhref's district hospital (south of Tunisia) during the month of September 2014. We used two instruments: the activity of daily living (ADL) to determine the degree of autonomy and the geriatric depression scale (GDS) validated in Tunisia.

Results At the end of our investigation, 100 chronic disease patients met inclusion criteria. The average age of our population was 75 years. Prevalence of depression was 48%. The most frequent chronic pathology was hypertension (79%), followed by diabetes (70%). In analytical study, we noted no correlation between depression and socio-demographic variables such as age, sex and marital status. Regarding clinical variables, depression was significantly more frequent in patients with sensory impairments (82% vs 18%, $P=0.017$), dependent (80% vs 20%, $P=0.002$). Regarding chronic disease, depression was significantly more frequent in patients with respiratory disease (80% vs 20%, $P=0.033$), a higher number of co-morbidities ($P=0.005$), who were hospitalised at least once ($P=0.015$).

Conclusion Depression is common in elderly with a chronic disease. Using screening instruments for major depression by primary care clinicians will help to detect depression.

Correlation between depression and cognitive decline in elderly outpatients: A preliminary study

A. Gogos*, G. Papageorgiou, E. Kavourgia, E. Papakyrgiaki, A. Mitsokali

Evangelismos Hospital, Psychiatry, Outpatient Department, Athens, Greece

* Corresponding author.

Introduction Depressive disorder is common psychiatric morbidity among the elderly outpatients. It is also evident that cognitive disorders, ranging from mild cognitive impairment to severe dementia, are widely prevalent in the elderly coexistence of the above is quite common. Treatment for both conditions is quite challenging, aiming at symptomatic relief and improvement in functional status.

Objectives To investigate the coexistence of depression and cognitive impairment in aged depressive outpatients, 65 years or older. Correlation of cognitive level and depressive symptomatology was measured.

Method We used hamilton depression scale (HAM-D) and MMSE in 35 (mean age 68.2 years) depressed outpatients over 65-year-old. We excluded depressed schizophrenics and bipolar patient.

Results. On a preliminary basis, a correlation between low MMSE and HAM-D ($P < 0.05$) was found. An interesting finding, though not measured primarily, was that low MMSE was accompanied with a low compliance with medication.

Conclusions The mental deterioration that accompanies cognitive impairment is being widely studied and it is real complex. In our ongoing study previous findings are confirmed and can be interpreted both ways, i.e. depression is a risk factor for dementia and also the fact that existing dementia is positively correlated with a low HAM-D.

Compliance to medication is affected, among other variables, by the patients' mental state.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Dementia or mania

C. Gomez*, V. Rodriguez

Hospital de Sant Joan de Alicante, Psiquiatry, Alicante, Spain

* Corresponding author.

Background In the clinical practice we encounter different clinical situations that require precise differential diagnosis and special treatment. This poster reviews the diagnosis and pharmacotherapy of two cases that points out how likely is to confuse the diagnosis of two apparently different pathologies, as are bipolar disorder and frontotemporal dementia. We study and compare two cases that were hospitalised in the psychiatric ward of Sant Joan's Hospital. Following their treatment and evolution. The first case is a 75-years-old man that presented behavioural changes, hypomania, and insomnia without previous known psychiatric history other than alcoholism. The family explained a history of episodes of mood changes going from depression to mania, compatible with a bipolar diagnosis never diagnosed, and the neuropsychological exam that was performed did not show any cognitive impairment finally receiving a diagnosis of bipolar disorder after the good response to the lithium treatment. In the second case we have a 58-years-old man with behavioural disturbances and mood fluctuation that changes from short periods of hypomania with disinhibition and insomnia to a predominance of hypothymia, apathy and self-care negligence, which received at the beginning a diagnosis of bipolar disorder and that after the proper complementary tests was shown to be a frontotemporal dementia.

Conclusions When facing behavioural and mood changes in advance age in the absence of psychiatric history we should take into account the considerable percentage of patients with a final diagnosis of frontotemporal dementia that received previously a mistaken diagnosis of bipolar disorder and vice versa.

Introduction In the context of untimely access to community formal services, unmet needs of persons with dementia (PwD) and their carers may compromise their quality of life.

Objectives/aims The Actifcare EU-JPND project (www.actifcare.eu) focuses on access to and (non) utilization of dementia formal care in eight countries (The Netherlands, Germany, United Kingdom, Sweden, Norway, Ireland, Italy, Portugal), as related to unmet needs and quality of life. Evaluations included systematic reviews, qualitative explorations, and a European cohort study (PwD in early/intermediate phases and their primary carers; $n=453$ days; 1 year follow-up). Preliminary Portuguese results are presented here (FCT-JPND-HC/0001/2012).

Methods (1) extensive systematic searches on access to/utilization of services; (2) focus groups of PwD, carers and health/social professionals; (3) prospective study ($n=66$ days from e.g., primary care, hospital outpatient services, Alzheimer Portugal).

Results In Portugal, nationally representative data is scarce regarding health/social services utilization in dementia. There are important barriers to access to community services, according to users, carers and professionals, whose views not always coincide. The Portuguese cohort participants were 66 PwD (62.1% female, 77.3 ± 6.2 years, 55.5% Alzheimer's/mixed subtypes, MMSE 17.8 ± 4.8 , CDR1 89.4%) and 66 carers (66.7% female, 64.9 ± 15.0 years, 56.1% spouses), with considerable unmet needs in some domains.

Conclusions All Actifcare milestones are being reached. The consortium is now analyzing international differences in (un) timely access to services and its impact on quality of life and needs for care (e.g., formal community support is weaker in Portugal than in many European countries). National best-practice recommendations in dementia are also in preparation.

Abstract submitted on behalf of the Actifcare Eu-JPND consortium.

Risk of suicidal behaviours in elderly

S. Goretti*, M.D.C. Sánchez Sánchez, B. Góngora Oliver, M.D. Sanz Fernández

U.G.C. Salud Mental Almeria, UHSM Torrecardenas, Almeria, Spain

* Corresponding author.

Introduction Older adults constitute the age group in which suicide more often reaches its most categorical expression: consummation.

Objective Identify risk factors for suicide in older people.

Method Systematic review of the literature on the subject. The databases consulted were Dialnet and Pubmed. The descriptors used have been: "suicide", "risk factors" and "elderly", accepting the works found in English and Spanish, with a total of 501 references found after the search, from which 75 have been selected.

Results As shown in the reviewed studies, there is a progressive increase in suicide rate with age in males. The purpose of dying in the old man is usually characterized by his firm conviction, not infrequently reflexive and premeditated. In the multifactorial etiology of suicidal behaviour in this age group, the main elements to be considered would be psychosocial factors, psychiatric diseases and chronic somatic diseases, resulting in a potentiation among them due to their frequent interaction. The feeling of abandonment, the feeling of emptiness, the despair of the organic collapse and the self-perception of being a useless person, without projects, generates deterioration in the quality of life.

Conclusions In the multifactorial etiology of the suicidal behaviour of the elderly, they usually play coprotagonistic roles, loneliness, isolation, somatic illness and depression. The most likely profile of the suicidal elder would be represented by a man with a history of depressive episode after age 40, who lives alone, with a family history of depression or alcoholism and a recent loss.

Decrease selected graphomotor skills in early stages of Alzheimer's dementia

E.J. Gorzelańczyk^{1,*}, K. Pasgreta¹, P. Walecki²

¹ Collegium Medicum, Nicolaus Copernicus University, Department of Theoretical Biomedical Sciences and Medical Informatics, Bydgoszcz, Poland

² Jagiellonian University Medical College, Faculty of Medicine, Kraków, Poland

* Corresponding author.

Introduction In the early stages of Alzheimer's disease (AD) motor and cognitive dysfunctions has been observed.

Objectives In previous studies we have shown that AD patients present abnormalities of selected graphomotor skills, but results were vary and not conclusive. In this study, we conducted more extensive tests on a larger study group.

Aims The aim of the study is to identify which graphomotor functions are impaired in the early stages of AD.

Methods Seventy-one patients with mild and moderate AD (F.00.0, F.00.1, F.00.2) (MMSE 20.3 ± 3.8 ; age 79.1 ± 5.21) were examined. Forty-four healthy ones (C) without symptoms of dementia, matched for demographic characteristics (MMSE 29 ± 1.1 ; age 78.3 ± 4.7) were examined. Graphomotor skills were assessed by the original drawing test (the eight figures and the signature) performed in a magnetic field (resolution 2540 dpi and

1024 pressure levels). These test were implemented on a graphic tablet (Wacom Intuos) with the specialized software. The length and time of drawing, the average and maximum speed of drawing, the average and maximum momentary speed, the amplitude and frequency (with FFT spectrum analysis) of hand tremors were measured.

Results Statistical analysis of the graphomotor signal revealed differences between the AD group and the C group with respect to various parameters. The largest differences have been observed in partially automated skills such as signature, and not drawing shapes (lines, spiral, etc.). The average speed of signature and maximum momentary speed of signature is lower in the AD group.

Conclusions This method allows for quantitative and objective measurement of the biophysical signal and assessment of the graphomotor skills.

The diagnostic value of saccadic profile in Alzheimer's disease

P. Walecki¹, K. Pasgreta², E.J. Gorzelańczyk^{2,*}

¹ Jagiellonian University Medical College, Faculty of Medicine, Krakow, Poland

² Collegium Medicum, Nicolaus Copernicus University, Department of Theoretical Biomedical Sciences and Medical Informatics, Bydgoszcz, Poland

* Corresponding author.

Introduction Appearing in the early stages of the disease pathological changes in different parts of the brain in Alzheimer's disease (AD) subjects cause disruption of neural circuits between the cortex and the basal ganglia. It may affect the ocular movement disturbances.

Objectives In previous studies we have shown that AD patients present abnormalities of saccadic eye movements. In this study, we conducted for the first time the advanced quantitative analysis profile of saccades on a large study group.

Aims The aim of this study is to find the features and the values of parameters in patients with AD differ from healthy individuals using quantitative measurement methods that could help in the future to differentiate people with an uncertain diagnosis.

Methods Seventy-one patients with mild and moderate AD (age 79.1 ± 5.21) were examined. Forty-four healthy ones (C) without symptoms of dementia, matched for sex, age and education level (age 78.3 ± 4.7) were examined. In this study we made use of the Saccadometer Advanced (ACI, Cambridge, UK), allowing the measurement of eye position with the time resolution of 1 ms (1000 Hz).

Results Statistically significant differences between AD and C groups were found ($P < 0.05$). The analysis of saccadic profile allows to differentiate Alzheimer's disease. The rising slope duration and the rising slope percent is lower in AD group, but the falling slope duration and the falling slope percent is larger in AD group.

Conclusions AD patients have much smaller slope in the rising phase of the saccade. The results show that the use of saccadometry may improve diagnosis of the AD.

Quality of life and depression in caregivers of patients with cancer

I. Feki, S. Hentati, R. Sallemi, M. Moala, J. Masmoudi*

University Hospital Hédi Chaker Sfax, Tunisia, psychiatry, sfax, Tunisia

* Corresponding author.

Background Most elderly patients, with cancer are cared for, by a family member who may be affected by various stressors that can influence their health and quality of life (QOL).

Objectives To explore depression, quality of life and its related factors among caregivers of elderly patients with cancer.

Methodology This is a descriptive and analytical cross-sectional study including 40 primary caregivers of old patients aged 65 or older, with cancer in oncologic radiotherapy service in university hospital Habib Bourguibain Sfax, Tunisia. The short form health survey (SF-36) and Beck inventory (13 items) were used to assess respectively QOL and depression.

Results The average age of caregivers was 44.62 years. The sex ratio (M/F) was 0.9. Most of caregivers (75%) had impaired QOL (score < 66.7). The two main components of SF-36 were altered with a standard score of 45 for the physical component and 41.1 for mental component. According to Beck inventory, Depression was present in 67.6% of cases. Impaired QOL of life was significantly correlated with somatic illnesses in the caregiver ($P = 0.016$), advanced stage of cancer ($P = 0.01$), financial difficulties ($P = 0.04$), the non-cohabitation with the patient before the disease ($P = 0.031$) and depression ($P = 0.00$).

Conclusion According to our study, caregiving can have a negative effect on the caregiver's mental and physical health. Assistance and information from healthcare professionals are the key to improving the ability of caregivers to cope with caring for older patients with cancer.

Pain assessment in people with dementia

I. Feki, S. Hentati, R. Sallemi, I. Baati, J. Masmoudi*

University Hospital Hédi Chaker Sfax, Tunisia, psychiatry, sfax, Tunisia

* Corresponding author.

Introduction Assessing and quantifying the experience of pain in elderly with cognitive impairment is particularly challenging and important.

Objectives To describe the overall profile and to identify the prevalence and characteristics of pain among demented elderly.

Methods A descriptive study including 60 institutionalized elderly aged 65 and older in the retirement home, Sfax, Tunisia. Data collection was conducted using questionnaire exploring socio-demographic and medical data. Mini-mental state examination (MMSE) and Katz index of independence in activities of daily living (ADL) were used to assess respectively mental status and dependence for ADL. Verbal Descriptor Scale (VDS) and elderly behavioural scale (ECPA) were used to evaluate pain. Thirty-two elderly were included and the inclusion criteria were: Age ≥ 65 and MMSE score ≤ 20 .

Results The average age of cognitively impaired residents was 74.2 years with a slight male predominance (57%). They were mostly illiterate (83%) and 56.3% of subjects were single. Almost two-thirds were admitted voluntarily and the average length of stay was 4.8 days. The ADL scale has shown that 65.6% were dependent. According to the VDS, the majority of demented subjects (93.8%) did not feel and express pain, 3% of residents with dementia had mild pain, 2.2% had moderate pain and 1.1% had severe pain. Whereas, the hetero evaluation (ECPA) concluded that 72% of demented elderly actually had pain with severe pain in 18.8% of cases.

Conclusion Pain in elderly persons with dementia is a significant problem. This underlines high needs of research as well as excellent implementation concepts for assessment and treatment of pain.

Depression in elderly patients with schizophrenia

I. Feki, K. Mdhaftar, S. Hentati, R. Sallemi, J. Masmoudi*
University Hospital Hédi Chaker Sfax, Tunisia, psychiatry, Sfax, Tunisia

* Corresponding author.

Background The presence of depressive symptoms impacts negatively the lives of patients suffering from schizophrenia-spectrum disorders. Likewise, the treatment poses many challenges for clinicians.

Objectives To specify the profile of elderly with schizophrenia and to evaluate the prevalence of depression and its related factors.

Methods A descriptive and analytic study involved 40 elderly patients aged 65 and over with DSM-5 diagnoses of schizophrenia or schizoaffective disorder, followed to the outpatient psychiatry department of Hedi Chaker University Hospital, in Sfax, Tunisia, during the two months of September and October 2015. Positive and negative syndrome scale (PANSS) and Calgary depression scales were used to assess respectively the symptoms of schizophrenia dimensionally and depression.

Results The majority of our patients was male (62.5%), single (55%), with low school and socioeconomic level. The mean duration of disease was 45 ± 6.02 years and patients were mostly (90%) in classical neuroleptics. The scale of PANSS showed the predominance of negative symptoms (67.5% of cases). In addition, according to Calgary scale, depression was found in 25% of patients. Factors positively correlated to depression were: the female sex among single ($P=0.043$), absence of family support ($P=0.001$), treatment with conventional neuroleptics ($P=0.039$) and negative symptoms ($P=0.001$).

Conclusion Depression in patients with schizophrenia is far from exceptional. It is often difficult to diagnose due to the recovery of other symptoms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Pupillometric assessment of cholinergic functioning in people with Alzheimer disease: A study from India

A.Q. Jilani^{1,*}, S. Srivastava², D. Shukla³, S.C. Tiwari²

¹ ERA'S Lucknow Medical College, Psychiatry, Lucknow, India

² King George's Medical University, Geriatric Mental Health, Lucknow, India

³ Ram Manohar Lohia Hospital, Psychiatry, Lucknow, India

* Corresponding author.

Background Diagnosis of Alzheimer disease is mainly clinical, based on longitudinal history and clinical criteria due to lack of specific biochemical tests and neuroimaging studies. Deficient central cholinergic activity of AD pathology is said to be reflected as decreased peripheral cholinergic activity. Assessing peripheral cholinergic function with pupillometer for diagnostic and prognostic purpose may be beneficial, as it may be a non-invasive, acceptable, and easily administered diagnostic tool if proven so.

Method This is a single point case control pilot study with sample size of 45 (25 AD patient and 20 controls). CAMDEX-R based

interview, HMSE, and DSM-IV criteria were used for detailed assessment and diagnosis. The pupillometric parameters (Horizontal and vertical diameters of pupil) were measured by Oasis Colvard pupillometer (SKU-0401A) under three conditions namely after 5 minute of dark adaptation in dark room (PD-5min-DA i.e. Baseline PD); after 5 minutes (PD-5min-T) and 15 minutes (PD-15min-T) of instillation of 2–3 drops of 1.0% Tropicamide.

Results There was no difference in baseline pupil diameter (horizontal + vertical) of AD patients and age matched healthy controls. 1% tropicamide induced significant increment in pupil diameters from baseline to after 5 ('PD-5min-T') and 15 minutes ('PD-15min-T') of its instillation in both AD patients and age matched healthy controls. But tropicamide induced increment in pupil diameters were approximately equal in cases and controls.

Conclusion The study did not find the role of 1% tropicamide induced pupillary hypersensitivity in AD patients for diagnostic purpose.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The burden of caregivers of patients with Alzheimer

G. Jmii^{1,*}, L. Robbana², F. Ghali², M. Zghal², M. Mezghani², J. Lamia², R. Rafrafi¹

¹ Mongi slim hospital, Department of Psychiatry, Tunis, Tunisia

² Razi Hospital, Department of Psychiatry, Tunis, Tunisia

* Corresponding author.

Introduction The Alzheimer's patient assistance relationship is a morally painful experience, most frequently discussed in terms of "burden" in the literature, especially as professionals and institutional intermediaries are underdeveloped in Tunisia.

Goal It is intended to assess the level of burden among caregivers of patients with Alzheimer's disease and to search factors associated with a high level of burden.

Methodology This is a retrospective descriptive study. Patients were recruited from neurology department of Razi hospital, which were hospitalised between the months of December 2012 and March 2013. The burden was measured using the Zarit inventory.

Results and discussion Thirty patients were included. The majority female, most caregivers are descendants (60%), then, daughters in law (33%), and finally the spouses (23%). 80% of caregivers lived in the same home as patients. Caregivers were asked about all the items of the grid Zarit. The average burden in our sample is 59.9 ± 16.3 . We observed that 33% have absent to light burden (score <21), 10% have a light to moderate burden (between 21 and 40), 36, 66% have moderate to severe burden (between 41 and 60) and 50% have a severe burden (>60), according to the classification proposed by Zarit. Sex, kinship and cohabitation with the patient were not associated with a higher burden.

Conclusion The study of factors correlated with high levels of burden aims at finding ways of intervention and support to fight against the isolation of caregivers and the occurrence of anxiodepressive complications.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Twenty percent of people aged over 80 have a serious dementia. Cognition disturbances are present both in depressive disorder and dementia. Vortioxetine is a new antidepressant with a multi-modal mechanism of action, being one of the antidepressants with more procholinergic action.

Aims to know the efficacy of vortioxetine in elder people with cognitive disturbances due to both pathologies: depression and dementia.

Methods It is described the result of using vortioxetine in one elder woman with dementia and affective symptoms with no clinical improvement after using two classical antidepressants.

Results Woman aged 82 without psychiatric history came to our consultation in April 2016. She had been diagnosed with dementia last year by a neurologist and she had started treatment with Donepezil 10 mg/d. Six months after this diagnosis she complained of depressive mood and faster deterioration of her previous cognition disturbances in terms of functionality level and autonomy, so her neurologist prescribed escitalopram until 10 mg/d and mirtazapine until 30 mg/d without clinical improvement. After first exploration, we decided starting treatment with vortioxetine 10 mg/d and withdraw previous antidepressants. Next week she complained of nausea and vomiting so we reduced the dose to 5 mg/d with good tolerance after that moment. Six months later her depressive mood had improved and her family remarked she had a little more autonomy and more desire to do things.

Conclusions Vortioxetine might be an effective and safe option in elder people who have cognitive disturbances due to mood disorder and/or dementia, probably because of its procholinergic action.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Background In this study we aimed to explore the role of inflammation in subjects with mild Alzheimer dementia (AD), mild cognitive impairment (MCI) and subjective cognitive decline (SCD) via new potential inflammation markers of Neutrophil-lymphocyte ratio (NLR) and Platelet-lymphocyte ratio (PLR). NLR and PLR are useful and cost-effective biomarkers, showing peripheral systemic inflammation, were previously shown in neuropsychiatric disorders [1].

Methods In screening phase the patients were assessed with mini-mental state examination, clinical dementia rating scale (CDR), geriatric depression scale (GDS) and Hachinski Ischemic Scale (HIS) after unstructured psychiatric interview according to

diagnostic and statistical manual of mental disorder, Text Revised (DSM-IV, TR). Spectrum of cognitive decline includes 31 patients with mild Alzheimer's disease, 30 subjects with mild cognitive impairment, 31 individuals with subjective cognitive decline. Thirty-one healthy controls enrolled to the study.

Results NLR value of patients with AD was 2.38 ± 0.81 , subjects with MCI was 2.48 ± 1.19 , SCD group was 2.24 ± 1.11 and control group was 1.85 ± 0.80 . NLR was significantly higher in AD and MCI groups when compared with control group ($P=0.006$, $P=0.03$, respectively). Platelet-lymphocyte ratio was not correlated with cognitive impairment. Neutrophil counts were indifferent when comparing either of groups. Lymphocyte levels were significantly lower in each of cognitive decline groups when compared to healthy controls.

Conclusion The present findings suggest that systemic inflammation may have a role in developing Alzheimer's Disease.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Acute angle-closure glaucoma (AACG) is an ophthalmic emergency, accompanied with severe eye pain, headache, and visual changes because of acute intraocular pressure elevation. Among psychotropic drugs, several antidepressants, typical antipsychotics with strong anticholinergic effects, and topiramate have been known to increase a possibility of AACG. Benzodiazepines have been used widely in the treatment of mental and physical illnesses regardless of age or indication. Since benzodiazepines have some anticholinergic properties and affect pupillae muscles, their use could be theoretically a risk factor for AACG. However, it is unclear whether benzodiazepines actually increase the risk of AACG. To our knowledge, there was no population-based study on the risk of benzodiazepines to the occurrence of AACG.

Objectives/aims To know whether benzodiazepines increase the risk of AACG in a geriatric population.

Methods We will perform a case-control study using a geriatric cohort from the National Health Insurance database. Case subjects will be defined as cases diagnosed with AACG confirmed by the claim data of laser iridotomy, which is the definitive treatment of AACG. The controls, which were not diagnosed with AACG, will be matched with case subjects according to similar age, sex, and the scores of the Charlson comorbidity index.

Results The data handling and statistical analyses will be executed in autumn and winter 2016.

Conclusions Any preliminary findings of this study will be presented at the EPA 2017. We will discuss the importance of a pharmaco-epidemiological study in the geriatric research.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The widowhood effect–mortality and adverse health effects when losing a spouse in old Age

C.B. Kristiansen*, A.B. Bojesen, P. Munk-Jørgensen, K. Andersen
University Hospital Odense, Psychiatric Research Department,
Odense, Denmark

* Corresponding author.

Introduction Losing one's spouse is a major life event which is associated to an increased risk of mental health problems as depression and sleep-disorders. There is also an increased risk of adverse effects on physical health, and even an increased risk of mortality. A phenomena called “the widowhood effect” Though this is well-known clinically, few studies have established the extent of the problem in old age.

Objectives This study aims to examine the risk of mortality associated to widowhood in old age, and adverse health effects both regarding physical and mental health.

Methods A nationwide register-based case control study. All Danish people aged 65 years and above who became widowed in the period of 2000–2010 are included. A background population sample of 4:1 is matched on age and gender. By using the personal identification number a linkage between registers containing information regarding health service use, pharmacologic use and demographic information is made. Mortality is analysed using Kaplan-Meier estimate and the statistical comparison between the groups is done by Cox-regression. Adverse health effects are assessed by the health care use and pharmacological use, and are compared between the two groups by t-test, linear and logistic regression depending on the variables.

Results The study is under conduction, results will be presented.

Conclusions Widowhood in old age has been associated to an increased risk of mortality and adverse health effects. This study assesses the outcome of this in a nationwide register-based sample.

Background Parkinsonism as a clinical syndrome needs to be diagnosed multidisciplinary. Cognition problems and behavioural symptoms together with the neurologic symptomatology make the treatment very complicated.

Aims To emphasize the importance of effective management strategies that may extend quality of life and independence.

Methods This is a case report of 59 year old male with complicated clinical presentation of dementia with parkinsonism last

two years treated with levodopa. Admitted with symptoms of fluctuating cognition, memory problems, visual hallucinations and depression and also generalized rigidity after introduction of atypical antipsychotic. Medical history: epilepsy in the last 15 years, trauma 7 years ago. After admission he was examined clinically and the brain computed tomography (CT) and electroencephalography (EEG) were done.

Results We analyzed possible etiologies and differential diagnosis of presented symptoms—extrapyramidal signs, mental confusion with hallucinations which are the three most common clinical features of Parkinson's disease dementia (PDD). CT reveals diffuse cortical atrophy with encephalopathy in the white matter combined with dilatation of lateral ventricles. EEG was with theta disrhythmic activity. After consultation with neurologist the patient was given Carbamazepine for epilepsy and Levodopa/Carbidopa to control parkinsonism. Donepezil was introduced. Two weeks after admission the patient was discharged with given advice to be treated in geriatric clinic.

Conclusion After thorough clinical examination with proper diagnostic procedures with imaging modalities we should try cholinesterase inhibitors because they might improve cognition and can be beneficial for reduction of the hallucinations and behaviour disturbances combined with proper management of the surroundings.

Introduction Bipolar disorder in elderly patients may present as an evolution of the disease initiated in younger stages or as an entity newly emerging. In addition, mania in the elderly, has characteristics that make it different from the adult. These disorders can be correlated with underlying vascular or degenerative disorders [1].

Methods Review of the relevant literature by searching PUBMED, limited to studies of greater scientific hierarchy.

Results The existence of changes in the manic phase motivated by the influence of vascular disease, as well as the importance of the changes experienced in therapy at the rate of underlying organic disease described. The useful pharmacotherapeutic approach in this case is discussed.

Conclusion The most recent research points in the direction of a more organic for mania late age-related substrate. The diverse etiology requires differential diagnosis for addressing the underlying causes [1]. The clinic does not dim with age, but increases the tendency to develop rapid cycling as age progresses. It is also more frequent occurrence of paranoid and aggressive traits, especially in situations of confrontation, along with increased dysphoria [2]. The therapeutic management by neuroleptics require very careful attention, because of the vulnerability of this group to develop adverse effects. Mood stabilizers use has been demonstrated as effective as in young [2].

Introduction In the older adult hypochondria is one of the most common somatoform disorders, and represents a particular challenge for approach, diagnosis and treatment, since in this age group, non-psychiatric medical comorbidity and concomitant presence of other psychiatric disorders very high. It is therefore very complex differentiate hypochondria disease with a real organic cause [1].

Methods Review of the relevant literature on the subject by searching PUBMED, limited to studies of greater scientific hierarchy.

Results Analysis of symptoms present in a hypochondriac patient with comorbid psychiatric disorders and organic pathology, valuing the importance it has in its clinical manifestations and the difficulty of differential diagnosis.

Conclusions In the elderly, the high frequency of somatic disease conditions the need for a deeper physical and mental examination to avoid subjecting patients to unnecessary scrutiny and risky complementary tests [1].

The evolution of hypochondriacs, dragging hypochondria from youth is not good, persisting in his complaint and his need to see a doctor for diagnostic examinations [2]. The therapeutic approach depends on the type of complaint, in which the treatment of the underlying disease as a psychotherapeutic and pharmacological mixed approach may be the right things [2].

Introduction Behavioural and psychological symptoms (BPSD) are frequent in dementia and their contribution to poor health outcomes is well recognized. Four major frameworks attempt an explanation their aetiology: biological, behavioural, environmental vulnerability and unmet needs models. The latter states that BPSD are symptoms of needs that are not being met due to patients' decreased ability to communicate/fulfil them. This model also implies that if needs were met, BPSD would improve.

Aims To explore the relation between needs and BPSD, and describe which unmet needs were contributing to BPSD in an elderly sample.

Methods A cross-sectional study was conducted in three Portuguese nursing homes. All residents were considered eligible. However, those unwilling or unable to participate were excluded. For each elderly patient, needs were assessed with camberwell assessment of need for the elderly/cane and BPSD with European Portuguese neuropsychiatric inventory/NPI.

Results The final sample included 166 elderly with an average of 80.9(sd = 10.2) years. Significant correlations between NPI and unmet and global needs were found ($r_s = 0.181, P = 0.020$; $r_s = 0.254, P = 0.001$, respectively). Additionally, the unmet needs of daytime activities ($P = 0.019$), company ($P = 0.028$) and behaviour ($P = 0.001$), presented significant correlations with NPI.

Conclusion In this sample, a high number of unmet needs were found. The absence of daytime activities, company and behaviour contributed to the identified BPSD, which is in line with other studies also highlighting the importance of these needs in nursing homes. This not only provides a framework for understanding BPSD, but also points to the identification of unmet needs as pivotal in prevention and treatment of these symptoms.

⁴ *Clinic of Psychiatry and Mental Health, CHSJ, Porto, Portugal*

* *Corresponding author.*

Introduction Demographic changes with the aging of the worldwide population imply an increase in prevalence of chronic diseases, such as diabetes mellitus. Many studies have suggested that depression is higher in diabetic patients, and that this association often contributes to under-recognition of the illness, limiting adequate metabolic control.

Aims To study the association between depression and adherence to treatment in elderly diabetic patients.

Methods A cross-sectional study was conducted with elderly outpatients (≥ 65 years) from the Internal Medicine Department in São João Hospital (CHSJ, Porto). Patients unable to communicate were

excluded. Anxiety and depression were assessed with the Hospital Anxiety and Depression Scale/HADS, and adherence to treatment with a clinical interview and from medical records.

Results The final sample included 78 patients, with an average of 75.3 (sd=6.75) years. They were mostly female (80%), married (66.7%) and with low education level (62.8%). The mean number of comorbidities was 5.76 (sd=1.6) and 98.7% took ≥ 5 drugs. In this sample, 23.1% had cognitive impairment, 16.7% depression and 24.4% anxiety. Patients not adhering to treatment presented a higher depression score, when compared with adherents (median 6vs3), even without statistical significance ($P=0.56$).

Conclusions Diabetic patients not adhering to treatment tend to present more depression, in spite of the lack of statistical significance. These results suggest that depression can limit the adherence to treatment, which is in line with previous studies. In this context, the early diagnosis and treatment of depression seems to be an important target in the management of diabetes, particularly in elderly patients.

⁴ Clinic of Psychiatry and Mental Health, CHSJ, Porto, Portugal

* Corresponding author.

Delirium is a neuropsychiatric syndrome, characterized by an acute change in mental status with a fluctuating course of symptoms, that affects almost 50% of people aged 65 years or older, admitted to hospital. Delirium is associated with negative outcomes, including increased risk of mortality, cognitive and functional decline. In 50% of the cases, the cause of delirium is multifactorial, resulting from a complex inter-relationship between several predisposing factors (e.g. advanced age, dementia) in highly vulnerable patients that are exposed to precipitating factors (e.g. infections). In this context, cognitive impairment and dementia are important risk factors for delirium, increasing its risk by two to five times, associated with worse outcomes. The underlying brain vulnerability of these patients with dementia may predispose to the development of delirium, as a consequence of insults related to the acute medical disease, medication or environmental factors. On the other hand, delirium may cause permanent neuronal damage, which may lead to the development or worsening of a pre-existing dementia. As a result, delirium and dementia frequently coexist and overlap, challenging differential diagnosis.

The identification of risk factors for delirium, specifically pre-existing cognitive impairment or dementia, in elderly people admitted to hospital is essential to the implementation of preventive strategies that may contribute to the decrease of delirium rates. The present literature review aims to highlight the association between delirium and dementia in elderly people, focusing on diagnosis, pathophysiology, prevention, and management.

³ UPCIG, Intensive Care Medicine Service, CHSJ, Porto, Portugal

⁴ UPCIU, Intensive Care Medicine Service, CHSJ, Porto, Portugal

⁵ Clinic of Psychiatry and Mental Health, CHSJ, Porto, Portugal

* Corresponding author.

Introduction Delirium is a frequent and serious acute neuropsychiatric syndrome, namely in elderly hospitalised patients, described as a psychologically traumatic experience by patients, family/caregivers and health professionals (HPs). In this context, the Delirium Experience Questionnaire (DEQ) was developed as a face-valid instrument assessing the delirium experience recall and the degree of distress related to delirium episodes in patients, family/caregivers, and HPs.

Aim To present the translation and cultural adaptation of the Portuguese version of DEQ (DEQ-PT).

Methods The translation process followed ISPOR guidelines. After preparation, forward translation, reconciliation, back translation, back translation review, harmonization and cognitive debriefing (involving experts' consensus), the DEQ-PT was tested (pre-test) in a group of elderly patients with delirium (≥ 65 years) in two Intermediate Care Units (Intensive Care Medicine Service-CHSJ, Porto). Exclusion criteria were: brain injury, blindness/deafness, unable to communicate, and Glasgow Coma Scale ≤ 11 . Their families were also assessed, as well as the HPs (physicians/nurse) in charge of patients during hospitalisation.

Results After obtaining permission to use the instrument, the DEQ was successfully translated into Portuguese, with harmonization of all new translations. Pre-test included a group of 5 patients, 5 families and 5 nurses. This version revealed good cognitive equivalence with the original English version and also a good level of comprehensibility.

Conclusion The DEQ-PT showed good feasibility, being suitable, quick and easy to use in the assessment of delirium experience in intermediate care units. These findings will be further developed by an ongoing validation study.

Attitudes and practices of general practitioners towards elderly patients with cognitive deficits

R. Masmoudi*, I. Feki, D. Trigui, I. Baati, R. Sellami, J. Masmoudi Hédi Chaker University Hospital, psychiatry "A", Sfax, Tunisia

* Corresponding author.

Background Tunisia has experienced a considerable increase in degenerative diseases associated with aging including in particular dementia and Alzheimer's disease.

Objectives To evaluate the diagnostic procedures of cognitive impairments in general medicine and to identify obstacles concerning the early diagnosis of dementia in these patients.

Methods An email questionnaire was sent to a sample of general practitioners (GPs) working in the Sfax region, Tunisia.

Results We received 55 answers. When facing a mnesic complaint, 20% of GPs perform a screening of cognitive disorders.

Among reasons leading to early identification, memory complaints (76.4%) was the most mentioned by GPs surveyed. The Mini Mental State was the most used (34.5%) by general practitioners. Twenty-nine point one percent (29.1%) of physicians conducted a comparative assessment 6 to 12 months later if the initial evaluation was normal and 83.6% send the patient to a specialist in case of a detected disorder. For GPs, in 58.2% of the cases, the major impediment is the lack of time, in 32.7% of the cases it is patient's and family's denial and in 23.6% of the cases it is the absence of effective medical treatment. A cross analysis shows that GPs who have had further training in geriatrics have a better approach.

Conclusion Our study shows a lack in the early identification of cognitive impairment in the elderly by GPs. Develop simple cognitive tests, reinforce training of doctors and promote research to develop new drugs would improve early diagnosis and management of dementia.

Cardiac issues raised by an examination of the antipsychotic prescribing practices in the elderly of St. James's hospital (SJH), Dublin

B. McCarthy^{1,*}, C. Power², B. Lawlor², E. Greene²

¹ St Vincent's University Hospital, Dept of Old Age Psychiatry, Dublin, Ireland

² St James Hospital, Mercers Institute of Successful Ageing, Dublin, Ireland

* Corresponding author.

Background Antipsychotic medication use may be associated with prolongation of the QTc interval, increasing the risk of potentially fatal arrhythmias [1]. This is particularly pertinent in the elderly due to comorbid cardiovascular disease and polypharmacy. Attention to the ECG and co-prescribed medications is essential to minimise cardiac risk when prescribing antipsychotics.

Methods On 23rd February 2016 all inpatients aged over 65 who were prescribed antipsychotic medications were identified as part of a hospital-wide survey. Data was collected from medical and electronic patient notes and medication kardexes.

Results Complete data was obtained for 36 patients aged over 65 who were newly-prescribed an antipsychotic or had their antipsychotic changed. Of these, 39%(n=13) had a cardiac history. One quarter did not have an ECG in the 12 months preceding antipsychotic initiation. Of the 28 patients with an ECG, 57% (n=16) had a QTc>450ms before starting antipsychotic treatment. Only 11% (n=4) had an ECG within 24 hours of starting the antipsychotic. The average change of the QTc interval in those with a repeat ECG was 30msecs. 42% (n=15) were co-prescribed another QTc-prolonging medication.

Conclusion Current monitoring of QTc interval in an elderly population newly prescribed antipsychotic medications is inadequate and a cause for significant safety concerns. Education and clear guidance is warranted to improve safety and minimise risk in this population.

Acute catatonic syndrome associated with hyponatraemia

E. McGuire*, D.M. Yohanathan, D.L. Lally, D.G. McCarthy
Sligo Leitrim Mental Health Service, Psychiatry of Old Age, Sligo, Ireland

* Corresponding author.

Introduction A 71 year old gentleman presented with two discrete episodes of delirium with prominent psychotic features and catatonia, over a 3-year period. Symptomatically, he was suffering from fluctuating consciousness, paranoid ideation and both auditory and visual hallucinations. He went on to develop catatonia, demonstrating negativism and mutism and he also exhibited pseudo-seizures. His symptoms resolved entirely after three weeks. He re-presented 3 years later with profound psychosis and hyponatraemia. On this occasion, he exhibited catalepsy, negativism, echolalia and mutism, which resolved when his sodium was corrected.

Objectives/aims To illustrate 2 episodes of acute catatonia temporally associated with hyponatraemia in an otherwise healthy elderly gentleman.

Methods This is a case study. Consent was sought from the patient to write up his case and distribute it for educational purposes. His medical inpatient notes, psychiatric inpatient notes, correspondence and bloods pertaining to both admissions were reviewed and analysed. A literature review was carried out using Pubmed.

Results Low sodium levels were a common factor in his presentations and normal sodium levels were associated with a return to normal consciousness.

Conclusions While medical issues confounded his first presentation of hyponatraemia associated catatonia, his second presentation was directly related to hyponatraemia. Given the coincidence of hyponatraemia during his first admission, it would strongly suggest that low sodium levels were an important factor in this gentleman's presentation. Importantly, this is the first case in the literature to demonstrate catatonia related to hyponatraemia on two separate occasions in the same individual.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Falls of the elderly to a degree been associated with poor mental health, poor social support and poor physical health.

Objectives To investigate the falls of elderly people in relation to their mental and physical healthy.

Aims To compare the effects of falls in the elderly in the areas of mental and physical health.

Methods The current study used purposive sampling comprised from 48 people that visited the emergency department at the Patras University Hospital in 2016. The inclusion criterion for participation was age (>65 years). Data was collected using WHO's questionnaire, the WHOQUOL-BREF. Finally, data was analyzed using the test t test for independent samples.

Results The sample constituted by 39.6% of male and 61.4% of female. The average age of the sample was $M = 75.89$ years. In relation to mental health, the average of the elderly with a history of falls found $M = 57.26$ ($SD = \pm 22.87$), while the other was found $M = 74.45$ ($SD = \pm 15.81$). The difference between the two groups was statistically significant ($P < 0.05$), while physical health although again the first group found to have a smaller average ($M = 56.65$, $SD = \pm 22.13$) relative to the second group ($M = 63.78$, $SD = \pm 12.59$) no statistical difference was observed.

Discussions These results demonstrates that falls beyond the physical damage that are immediately visible can as well create significant issues in the psychological state of the elderly exacerbating anxiety, fear and social isolation, which has been associated with depression event.

EV0783

Effects of the person-centered environment program (Belmont village's memory care) on behavioral and emotional problems in Mexican senior living residents, six week trial

F.J. Mesa Rios

Belmont Village Senior Living Mexico, Medical Direction, Ciudad de México, Mexico

Behavioural and psychological symptoms of dementia include agitation, depression, apathy, repetitive questioning, psychosis, aggression, sleep problems, wandering, and a variety of inappropriate behaviors. One or more of these symptoms will affect nearly all people with dementia over the course of their illness. These symptoms are among the most complex, stressful, and costly aspects of care, and they lead to a myriad of poor patient health outcomes, healthcare problems, and income loss for family caregivers. The complexity of these symptoms means that there is no "one size fits all solution, and approaches tailored to the patient and the caregiver are needed". Non-pharmacologic approaches should be used first line, although several exceptions are discussed.

The current pilot study examined the effects of the Person-Centered Environment Program (Memory Care[®], developed by Belmont Village Senior Living) on agitation, cognition, stress, pain, sleep, and activities of daily living for Mexican senior living residents with dementia. Thirty individuals participated in the study. Memory Care[®] included sensitive, cognitive and affective stimulation, based on participants' preferences and needs. memory care sessions were held daily (7 days per week, 8 hours) and a total of 6 weeks were performed at the first Belmont Village Community in Mexico City. Findings showed that agitation and pain improved with the Memory Care[®] Program ($t = 2.91$, $P < 0.02$; $t = 4.51$, $P < 0.002$, respectively). Findings suggested that a better study design, repeated with a bigger sample size, must be considered, but promissory results are shown.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Evaluation of dependence among benzodiazepines in population of elderly subjects followed in psychiatric service in Sfax

N. Messedi*, I. Feki, I. Baati, R. Sellami, D. Trigui, J. Masmoudi Hedi Chaker University Hospital, Psychiatry A, Sfax, Tunisia

* Corresponding author.

Introduction Benzodiazepines (BZD) are the most consumed psychotropic drugs by the elders. This prescription can lead to the dependence which is a major public health problem particularly in this population.

Objectives To study the prevalence of dependence of the (BZD) in elderly subjects followed as outpatients and to identify the factors associated with it.

Methods It was a cross-sectional study of 60 patients aged 65 years and older followed at the psychiatric consultation of the UH Hédi Chaker of Sfax; for 3 months. We used:

– Questionnaire containing demographic and clinical data.

– The cognitive scale of attachment to benzodiazepines (ECAB), a score ≥ 6 indicates dependence.

Results The average age of patients was 67.78 years, with a sex-ratio M/W = 0.46. They were smoking in 58.3% of cases. The most frequent psychiatric disorders were mood disorders (40%) followed by anxiety disorders (13.3%). The absence of diagnosis was observed in 23.3% of cases. A psychotropic drugs were associated with BZD in 86.7%. The most prescribed BZD was lorazépam (90%). Withdrawal signs were present in 90% of cases. The prevalence of BZD dependence has been estimated at 80%.

BZD dependence was significantly correlated with smoking ($P = 0.00$), with psychotropics association ($P = 0.04$) and with signs of withdrawal ($P = 0.001$).

Conclusion It appears from our study the importance of BZD dependence in the elderly what it is a source of withdrawal difficulty. So we need make more effort to comply with recommendations regarding the prescription of these molecules.

Voltage gated potassium channel antibody (VGKC)-associated encephalopathy and psychiatric symptoms (case report)

U. Narayana*, P. Nirodi

Tees Esk and Wear Valleys NHS Foundation Trust, Acute Hospital Liaison Service-Harrogate Hospital, Harrogate, United Kingdom

* Corresponding author.

Introduction and Objectives The limbic system is primarily responsible for modulating behaviour, emotions and neuro-endocrine functions. Limbic encephalopathy involves this part of the brain and is characterised by the acute or sub-acute onset of seizures, recent memory loss, confusion and psychiatric symptoms. Here we describe an unusual presentation of a well-functioning elderly man, who presented with sudden onset of confusion, cognitive impairment, treatment resistant hyponatremia, seizures and psychiatric symptoms.

Methods (Presentation) This 79 year old gentleman, previously well and independent was admitted to the acute hospital with a 3 week history of sudden onset of confusion, odd behaviour and weight loss. On admission he was hyponatremic ($Na = 118$), developed treatment resistant seizures and progressive cognitive impairment. He was referred to the Liaison Psychiatry team with increasing paranoia, agitation and persecutory delusions.

Results MRI and CT brain remained normal. Lumbar puncture revealed a positive VGKC antibody and his blood titres for VGKC was more than 3000. His hyponatremia and seizures remained chronic, but improved with plasmapheresis, oral corticosteroids and cyclophosphamide. He was commenced on aripiprazole for psychiatric symptoms, but was transferred to the acute psychiatric unit after being detained under section 2 of the MHA due to risks of aggression and absconson.

Conclusions Psychiatric symptoms related to this form of encephalitis have not been emphasised in literature. His aggression

improved over time on aripiprazole, but was transferred to a residential care home setting due to persisting cognitive deficits and social care needs. This case highlights the importance of recognising multimorbidity, joint working and more research required in the area.

Attitudes toward euthanasia: Contradictory views and ideas of Alzheimer patients' relatives

E. Nikolaev

Ulianov Chuvash State University, Department of Social and Clinical Psychology, Cheboksary, Russia

Introduction Alzheimer's disease (AD) is one of the pressing social problems as the negative effects of the disease often manifest on patients' relatives. Relatives of AD patients experience physical and psychological burden during the care.

Objectives To clarify what kind of views on euthanasia are more common among relatives of patients with AD.

Methods The study involved 23 AD patients' relatives (mean age 60, SD = 2). There were 5 men (22%) and 18 women (78%). All participants were directly involved in caring for their relatives with AD. A 19-item structured questionnaire (E. Nikolaev, 2016) was used for measuring medical, legal, ethical, socio-cultural, spiritual and personal aspects of attitudes to euthanasia.

Results The respondents were less likely to see euthanasia as medical issue. They also referred it to kind of ethical and legal problems. Legal aspects were determined by greater consent to its legalization and by awareness of imperfections of legal basis for its immediate implementation. Ethical issues according to which euthanasia practice was related to the development of humanity complemented this vision. These settings were in conflict with socio-cultural perceptions of euthanasia. Respondents were convinced in possibility of various forms of abuse during euthanasia. Supporting the ideas of euthanasia in general, many respondents on a personal level were not ready to apply them to their relatives with AD in practice.

Conclusions Attitudes to euthanasia in AD patients' relatives was contradictory. It was determined by divergent ideas about euthanasia in field of legal, social, cultural, spiritual and personal issues of this interdisciplinary phenomenon.

Prescribing tricyclic antidepressants in the elderly

B. Oueslati*, M. Oumaya, R. Bouzid

Hopital Universitaire Mohamed Tahar Maamouri, Mental health department, Nabeul, Tunisia

* Corresponding author.

Introduction Although not recommended as a first-line treatment for old patients with depressive, anxiety or somatic symptom disorders, we continue seeing tricyclic antidepressants being frequently prescribed.

Objectives To estimate the prevalence and to assess the implementation of safety measures related to the prescription of such molecules in the elderly. To explain their choice as a first-line treatment.

Methods We included all new patients aged 65 years or over between 1st January 2011 and 31st December 2015 whom, were

prescribed an antidepressant. Recommendations of the Canadian coalition for seniors' mental health, of the world federation of societies of biological psychiatry and of the national institute for health and care excellence were our evaluation tools. We compared tricyclic receivers to those having newer antidepressants to try to understand the choice of tricyclics as a first-line treatment.

Results Eighty patients were included. Mean age was of 75 years. 46% were prescribed a tricyclic as a first line treatment. Depressive disorders were the most diagnosed ones (79%) followed by anxiety disorders (14%) and somatic symptom disorders (7%). An electrocardiogram was not performed to all patients prior to the initiation of the tricyclic nor at anytime later. 11% continued being prescribed tricyclics in spite of contraindications. Only a low economic level was significantly related to their choice as a first-line treatment ($P=0.001$).

Conclusions Tricyclics' prescribing rate was high. Safety measures were not applied for all patients. Regular availability of newer antidepressants in public health structures and a better awareness of antidepressants prescribing guidelines in the elderly are mandatory.

Study of the sensitivity of the organic psychosyndrome after one year of the disease

K. Paschalidis^{1,*}, P. Argitis², K. Gatsiou², C. Chatzidai³, P.P. Dalli³, E. Pantoulas³, I. Chaviaras³

¹ Psychiatric Hospital of Thessaloniki, Greece, 2nd Department of Mental Health, Serres, Greece

² University of Ioannina, Psychiatric Department, Ioannina, Greece

³ General Hospital of Corfu, Psychiatric Department, Corfu, Ionian Islands, Greece

* Corresponding author.

Introduction The delirium of the elderly is defined as an acute confusional state, with variation during the day, characterized by impaired consciousness, orientation, memory, thinking, attention and behavior.

Purpose The purpose of this research is to investigate whether the organic psychosyndrome of the elderly is a valid indicator of mortality after one year.

Material It was used material from patients with organic psychosyndrome older than 60 years, who were hospitalized in pathological clinics of the Hospital of Corfu and was diagnosed by the linker portion of the psychiatric clinic.

Methodology The patients diagnosed with organic psychosyndrome neither suffered from a psychiatric disorder psychotic type in the past, nor previously preceded anaesthesia in the context of physical disease. For the recognition and the criteria of ICD-10 to the exclusion of another psychiatric condition, it was used the delirium rating scale method.

Results According to the analysis of the data, 8% of patients died during hospitalisation, in the first 3 months after diagnosis, the 28% of the initially hospitalised patients, in 6 months the 42%, while during the year the 48% of the initial total patients died and in the next 12 months only one death was reported.

Conclusions The analysis of the survey results shows that while the instrument psychosyndrome could be considered as a poor diagnostic marker for the first 12 months, 48% mortality, in the long run it seems to lose its prognostic value with the mortality approaching the mortality index of the hellenic statistical authority for 2015 at ages 60+ (1.2%).

Parkinson psychosis: A complex interaction of disease and medication related factors

S. Petrykiv^{1,*}, L. de Jonge², M. Arts³

¹ University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands

² Leonardo Scientific Research Institute, Department of Geriatric Psychiatry, Department of Geriatric Psychiatry, Groningen, The Netherlands

³ University Medical Center Groningen, Department of Old Age Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction Psychotic symptoms are the most important non-motoric symptoms of the Parkinson disease (PD). The quality of life of those patients can be significantly improved with an appropriate therapy. In this article we provide evidence about the etiology, differential diagnosis and therapeutic possibilities with a work-up for the clinics.

Objectives & aims To provide a case report of patient with PD who developed a paranoid psychosis after administration of levodopa/carbidopa, followed by a literature review on psychotic symptoms evoked by psychotropic medication by patients with PD. **Methods** An English-language literature search was conducted using Pubmed, EMBASE searching for case reports and observational studies reporting iatrogenic psychotic symptoms by patients with PD.

Results Ms. C. was a 65-year old woman with PD who was observed in a polyclinic setting and who used a levodopa/carbidopa combination. She developed paranoid psychosis with a following admission to the psychiatric ward. We have gradually lowered the dose of anti-Parkinson medication. Subsequently, treatment with clozapine was initiated and the psychotic symptoms resolved within five months.

Conclusion Parkinson psychosis is due to a complex interaction of neurodegenerative changes and pharmacological therapy. Therefore, the role of iatrogenic factors must be always carefully assessed. Psychosis inducing agents should be lowered or stopped before the treatment with antipsychotic medication.

EV0790

The strategy to combat dementia in Russia

L. Pishchikova

Federal State Budgetary Institution "V. Serbsky" Federal Medical Research Center for Psychiatry and Narcology, Ministry of Health, Moscow, Russia

The 139th Executive Committee WHO was held in May 2016. The Russian delegation took part in its work. The main issue on the agenda was the report on "Dementia". It was noted that each year dementia develops in 8 million people in the world. It is expected that this figure will increase to 145 million by 2050. In Russia the national plan to combat dementia is missing. In the resulting meeting, all the WHO country-members voted for immediate action on the adoption of the strategy for the fight against dementia by 2017. We developed a strategy for dementia, which includes the following tasks;

- The need of epidemiological research in the field of dementia;
- Research on etiology, prevention, early diagnosis and treatment of dementia;
- The expansion of the network of specialized stationary and non-stationary facilities for patients with dementia;

- Development of programs of psychological care to patients with dementia and to caregivers;
- Development of palliative care for patients with dementia;
- Cross-sectoral cooperation and multidisciplinary approach in assistance to patients with dementia;
- Training in the field of geriatric psychiatry, denomination of the specialty of geriatric psychiatrist;
- Fighting stigma of patients with dementia, protection of their rights, including in psychiatry and forensic psychiatry.

The solution of these objectives requires foundation of the Russian observatory on dementia, the WHO cooperating center. The tasks of such an Observatory will be: centralization and coordination of actions concerning strategic planning, implementation of mechanisms of a multispectral cooperation, assessment of services, monitoring and providing reports on dementia issues in Russia.

EV0791

Evolutionism and involutionism in the ontogenesis of a late age

L. Pishchikova

Federal State Budgetary Institution "V. Serbsky Federal Medical Research Center for Psychiatry and Narcology", Ministry of Health-Russia, Moscow, Russia

Individual human development from birth to death is defined as the ontogenesis. The ability of the human psyche to development and to system acquisition of mental and social functions is called evolutionism. The psyche property, causing a gradual loss in the process of ontogenesis of biological, psychological and social functions is defined as involutionism.

Involutivitionism of higher mental functions manifests in their folding in the sequence reverse to the formation. Process of involution is uneven and abrupt. This is caused by their constant interaction with the evolution processes, that are struggling with age-related destruction and disruption and are responsible for the ongoing adaptation, although at a lower ontogenetical level.

In the event of critical psycho traumatic situations, which are related to the impact of jet-psychological, somatoneurological factors, there is a failure of adaptation mechanisms, decompensation develops, the action of the involutive mechanisms increases, which leads to a lower level of social functioning. In this interaction biological and social factors act in their unity and predetermine disadaptation options, while the latter, in their turn, determine intensification of involutive processes.

Because of the interaction of these processes mental aging unevenly affects higher mental functions with the advent of favorable (adamantix) and unfavorable forms, determined by the development of mental disorders and dementia. Favorable aging can manifest itself by specific quantitative somatoneurological and mental changes that do not lead to the loss of adaptation. Under favorable aging life experience, professional skills, biological, social, adaptive resources are preserved, evolutionary development of the older person continues.

Antipsychotics in dementia

A. Poças*, S. Almeida

Centro hospitalar Leiria, Psiquiatria e Saúde Mental, Leiria, Portugal

* Corresponding author.

Behaviour disorders and psychosis may represent a greater challenge in patients with dementia. There are evidence-based

recommendations to assess psychological and behavioral symptoms of dementia and the practice guidelines of American psychiatric association (APA) reinforce general principles of good clinical care. However, when these patients initiate a psychotropic, the agents often continue to be prescribed for a long time, even after the symptoms disappeared. The recommendation of reduce/stop an antipsychotic medication within 4 months of initiation may seem counterintuitive when the patient is better, with remission of the original symptoms. However, the studies showed that a large amount of patients with dementia can discontinue antipsychotic medication without a return of agitation or psychosis. Older patients are a particularly susceptible population and the risk/benefit of any medication should be carefully considered. For most patients the risk of harm outweighs the profits of continuing treatment and we need a routine evaluation of this factor to identify these cases.

It's important to reduce unnecessary medications but agitation and psychosis associated with severe distress also carry serious risks; discontinuing these medications can be dangerous so we need to manage it with caution evaluating each case as an individual one.

Antipsychotic prescribing practices amongst the elderly of St. James's hospital (SJH), Dublin

C. Power^{1,*}, B. McCarthy², B.A. Lawlor³, E. Greene⁴

¹ St James's Hospital, Memory Clinic- Mercer's Institute for Research in Ageing, Dublin, Ireland

² St. James's Hospital Dublin, Psychiatry of the Elderly, Dublin, Ireland

³ St. James's Hospital, Mercer's Institute for Research in Ageing, Dublin, Ireland

⁴ St. James's Hospital, Psychiatry of the Elderly, Dublin, Ireland

* Corresponding author.

Introduction Psychotic symptoms arise commonly in the context of behavioural and psychological symptoms of dementia (BPSD) in the elderly. While non-pharmacological interventions are preferable to manage such symptoms, antipsychotic medications are frequently used. This is largely unlicensed and associated with significant risks, particularly in dementia (1).

Objectives To examine antipsychotic prescribing practices in SJH. *Methods* On 23rd February 2016 all inpatients aged over 65 who were prescribed antipsychotic medications were identified. Demographic and medical data were collected from medical and electronic notes and medication kardexes.

Results Complete data were available for 53 of 59 identified cases. The cohort had a mean age of 80 (range 65–99) and 62% were male. Seventy-four percent ($n=39$) had documented cognitive impairment or dementia. Fifty-eight percent ($n=31$) were newly prescribed an antipsychotic following admission. The commonest indications for antipsychotics were: delirium (53%) and BPSD (25%). Haloperidol (56%), quetiapine (19%) and risperidone (8%) were prescribed most frequently. Non-pharmacological interventions were documented in 50% however in many cases it is not clear what these interventions were. Antipsychotic use was discussed with patients and/or next of kin in less than 25% of cases. Adverse effects were noted in 6/36 (17%) with equal incidence of falls, EPSEs and ECG changes.

Conclusion Positive and negative aspects of current antipsychotic prescribing practices are highlighted. Antipsychotics were prescribed for a small number of patients for appropriate indications. However, there was poor consideration of non-pharmacological interventions and a lack of consultation with the patient/NOK. This may reflect, in part, inadequate medical documentation. A

guideline needs to specifically address these areas of concern to improve safety and promote best practice.

⁴ University of Physical Education, Department of Physical Rehabilitation in Rheumatology and Geriatrics, Krakow, Poland

* Corresponding author.

Introduction Major depressive disorder (MDD) in the older adults is correlated with a significant decline in daily physical activity, consequently resulting in chronically impaired quality of life and an increased exposure to falls-risk.

Objectives Establishing whether geriatric depression Scale (GDS) scores, found correlated with dual motor tasks (TUG_{MAN}), are also correlated under the cognitive test constraints (TUG_{COG}).

Aims The study aimed to analyse the relationship of MDD symptoms, the number of depressive episodes and hospitalisations, with the efficiency of gait in single and dual task conditions, motor and cognitive, functional capabilities.

Methods The study was conducted in the outpatient clinic, university hospital, department of psychiatry, Krakow, on 30 patients over 60 years of age presenting recurrent MDD. The assessment consisted of GDS, MMSE, TUGT, TUG_{MAN}, TUG_{COG}, 30sChS, SLS. Spearman rho rank correlation was applied to determine the relationship between the variables.

Results Statistical analysis showed a significant association between the intensity of depressive symptoms expressed in the GDS and the number of completed episodes and depression and TUGT. The number of hospitalisations was associated with gait under motor (TUG_{MAN}) and cognitive (TUG_{COG}) constraints.

Conclusion Duration of the disorder and the number of hospital admissions are related to the functional efficiency of the single and dual-task performance in the persons suffering from this disorder for at least 10 years. Aged persons should effectively be encouraged to undertake physical activities.

Fronto-temporal Dementia with Early Onset

T. Sabo^{1,*}, D. Bošnjak¹, V. Jukić², P. Bilić³

¹ University Psychiatric Hospital Vrapče, Department for Psychogeriatrics, Zagreb, Croatia

² University Psychiatric Hospital Vrapče, Department for Forensic Psychiatry, Zagreb, Croatia

³ University Psychiatric Hospital Vrapče, Department for Neurocognitive Disorders, Zagreb, Croatia

* Corresponding author.

Introduction Even though it is not the most common type of dementia, frontotemporal dementia (FTD) is a major health problem. It affects people younger than 65 with similar frequency as

Alzheimer's dementia (AD) and has a progressive course that leads to inevitable deterioration in functioning. Still, FTD is not a unique entity in ICD- 10 classification.

Objectives To investigate the diagnostic and treatment difficulties in FTD.

Aims To show very rapid and progressive deterioration in people with early onset FTD.

Methods We will present a series of cases showing progressive cognitive deterioration and prominent personality changes in patients with FTD hospitalised at University Psychiatric Hospital Vrapce since 2013 to 2015. Collected data included anamnestic and heteroanamnestic information, blood tests and neuroimaging.

Results Our findings showed a significance of early onset FTD, with subtle, atypical symptoms at the beginning, and galloping deterioration during the course of illness.

Conclusions Presented patients with FTD showed rapid and progressive nature of disease with infaust prognosis. Even though early onset patients make 20% of overall number of patients with FTD, we consider that it is necessary to separate them from late onset patients in future classification systems.

Characteristics of elder mistreatment's perpetrators in Tunisian community-dwelling elders

B. Saguem*, S. Bouhlel, B. Ben Hadj Ali
CHU Farhat Hached, Psychiatry, Sousse, Tunisia

* Corresponding author.

Introduction While research is illuminating characteristics of elderly that are associated with mistreatment, far less research has investigated characteristics of the perpetrator that are involved in elder mistreatment cases.

Aim To address the characteristics of elder mistreatment's perpetrators in a population of community-dwelling elders.

Methods A cross-sectional study was conducted, including 80 subjects aged 65 years and older, with sufficient cognitive ability to complete the interview. Elderly were asked about several characteristics of mistreatment's perpetrators. Indicators of Abuse Screen (IOA) was used to evaluate abuse.

Results Findings show that 13.8% of the participants suffered from elder mistreatment, with a mean IOA's score of 8.35. According to subtypes, 10% reported psychological, 2.5% physical and 1.3% financial abuse. Abuse was recurrent and the victim's reactions were passive in all cases.

Perpetrators were family members in all cases, with being a partner in 63.6%, a child in 18.2%, a sibling in 9.1% and a stepdaughter in 9.1% of cases. They were men in 72.7% of cases and their mean-age was 64.09 years. Financial difficulties and psychological problems were reported in 54.5% and 36.4% of perpetrators, respectively. Perpetrators were most likely living with the victims ($P=0.009$). Partners were the perpetrators of half of the psychological abuse, and the totality of the physical and financial abuse. Abusive marital relationships were significantly associated with the perpetrator ($P=0.04$).

Conclusion Our findings suggest that the cause of elder abuse is rarely unique, and that this phenomenon is consequent to many pre-existing underlying problems affecting both elderly and perpetrators.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A comparative study of elder mistreatment between community-dwelling elders and those residing in long-term care facilities

B. Saguem*, B. Saoussen, B.H.A. Béchir
CHU Farhat Hached, Psychiatry, Sousse, Tunisia

* Corresponding author.

Introduction Elderly who live in settings other than their own homes or those of relatives have received little attention from researchers in Tunisia.

Aims To compare sociodemographic and clinical factors associated with elder abuse between community-dwelling elders and those residing in nursing home.

Methods A comparative study was conducted, including 50 subjects aged 65 years and older living in the community and 20 age- and sex-matched subjects living in a nursing home. Cognitive status, depressive symptoms and autonomy were assessed using mini-mental state examination (MMSE), geriatric depression scale (GDS) and activities of daily living scale (ADL). Elder abuse was evaluated with Indicators of Abuse Screen (IOA).

Results Elder abuse was more prevalent in elderly residing in nursing home ($P=0.009$) with a prevalence of 35% and 8% and a mean IOA score of 12.75 and 7.74. Psychological, physical, financial abuse and neglect were reported by elderly residing in nursing home. Those living in community reported exclusively psychological abuse. The victim's reactions were passive in all cases.

Elders living in nursing home were more single or divorced (0.000) and financially independent (0.003). They had lower scores of MMSE (0.002) and ADL (0.014), and higher scores of GDS (0.022). A binary logistic regression confirmed that elder abuse was significantly more prevalent in nursing home after eliminating these confounding variables: age, gender, MMSE, GDS and ADL scores ($P=0.018$).

Conclusion Our results confirm that elderly who live in long-term care facilities are at particular risk for abuse and neglect.

³ University of Lorraine, Nancy 2, Meurthe et Moselle, Nancy, France

* Corresponding author.

Today, the questioning about the life project of elderly with mental disorders seems not to be a priority of research and politics. Many studies shows that social representation of this specific population are mostly negative. They impact the place of these subjects on their social and community integration into the society. The purpose of our research work is to identify the nature of health professional's social representation involved in the accompaniment of these subjects. In that case, the authors aim to identify it impact on their life project. Consequently, the authors interviewed 715 professionals (doctors, psychologists and nurses) with the free association method of Abric. A prototypical and categorical analysis was conducted with the help of IRAMUTEQ software. Then a factorial analysis was performed in order to identify which factors could be possibly linked with some dimensions of the social representation we isolated (age, sex, profession and study level). Results shows that social representation of health professionals

is really close to the social representation of the rest of population. To conclude, the authors will discuss about the influence and impact of this social representation on the decision process concerning the life project developed by the medical staff in psychiatry

First neuropsychiatric symptoms and neurocognitive correlates of behavioral variant frontotemporal dementia

H. Santamaría García^{1,*}, P. Reyes², J.M. Santacruz-Escudero², D. Matallana², A. Ibañez³

¹ Pontificia Universidad Javeriana, Psychiatry, Physiology, Bogotá, Colombia

² Pontificia Universidad Javeriana, Psychiatry, Bogotá, Colombia

³ INCyT Laboratorio de Neurociencia Cognitiva y Traslacional, INECO-U Favaloro, Buenos Aires, Argentina

* Corresponding author.

Previous works highlight the neurocognitive differences between apathetic and disinhibited clinical presentations of the behavioral variant frontotemporal dementia (bvFTD). However, little is known regarding how the early presentation (i.e., first symptom) is associated to the neurocognitive correlates of the disease's clinical presentation at future stages of disease. We analyzed the neurocognitive correlates of patients with bvFTD who debuted with apathy or disinhibition as first symptom of disease. We evaluated the neuropsychological, clinical and neuroanatomical (3 T structural images) correlates in a group of healthy controls ($n = 30$) and two groups of bvFTD patients (presented with apathy [AbvFTD, $n = 18$] or disinhibition [DbvFTD, $n = 16$]). To differentiate groups according to first symptoms, we used multivariate analyses. The first symptom in patients described the evolution of the disease. AbvFTD and DbvFTD patients showed increased brain atrophy and increased levels of disinhibition and apathy, respectively. Whole brain analyzes in AbvFTD revealed atrophy in the frontal, insular and temporal areas. DbvFTD, in turn, presented atrophy in the prefrontal regions, temporoparietal junction, insula and temporoparietal region. Increased atrophy in DbvFTD patients (compared to AbvFTD) was observed in frontotemporal regions. Multivariate analyses confirmed that a set of brain areas including right orbitofrontal, right dorsolateral prefrontal and left caudate were enough to distinguish the patients' subgroups. First symptom in bvFTD patients described the neurocognitive impairments after around three years of disease, playing an important role in the early detection, disease tracking, and neuroanatomical specification of bvFTD, as well as in future research on potential disease-modifying treatments.

² Universidad Javeriana, Psychiatry, Bogotá, Colombia

³ Javeriana, Instituto envejecimiento, Bogota, Colombia

⁴ Instituto neurociencia Cognitiva y Traslacional INCyT, Neurociencia Cognitiva, Buenos Aires, Argentina

* Corresponding author.

Background Previous works highlight the importance of neurocognitive symptoms over cognitive and functional dependency in neurocognitive disorders. However, little is known regarding to what extent presence of neuropsychiatric symptoms predicts disease progression, cognitive and functional impairments in behavioral variant frontotemporal dementia (bvFTD) and in Alzheimer dementia.

Methods We performed two different evaluations (T1 and T2) with 3 years of difference in a group of bvFTD ($n = 18$), AD ($n = 20$) and controls ($n = 22$). Neuropsychological, clinical and cognitive correlates were measured in each time T1 and T2. By using different multiple regression models, we explored if behavioral symptoms (measured by Columbia, Yesavage at T1) predict disease progression as measured by changes over T1 and T2 in cognitive (MoCA, IFS, and clock figure) and functional dependency (Lawton).

Results Behavioral symptoms, in particular depression, psychosis, apathy and disinhibition were factors able to predict cognitive and functional progression in bvFTD. By contrast, regression model revealed that depression and insomnia were behavioral factors able to predict progression in AD.

Conclusion Neuropsychiatric symptoms are crucial to predict disease progression in bvFTD and AD patients in differentiated ways. Our results suggest the tracking early behavioral symptoms in neurocognitive disorders playing an important role in the early detection, disease tracking, and neuroanatomical specification of bvFTD, as well as in future research on potential disease-modifying treatments.

Mild cognitive impairments and whole-body cryotherapy – Placebo control study

K. Urbańska^{1,*}, B. Stańczykiewicz¹, D. Szcześniak¹, E. Trypka¹, A. Zabłocka², J. Rymaszewska¹

¹ Wrocław Medical University, Department of Psychiatry, Wrocław, Poland

² Ludwik Hirsfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Department of Immunochemistry, Wrocław, Poland

* Corresponding author.

Introduction Cognitive impairment is considered to be a result of oxidative stress and disturbances in inflammatory status. Whole-body cryotherapy (WBC), which is a short exposure to extremely low temperatures, probably regulates the release of cytokines and nitric oxide. The hypothesis is that WBC may be useful in the therapy of mild cognitive impairments (MCI).

Aims The effect of the whole-body cryotherapy (WBC) on cognitive impairments was investigated.

Objectives In this study the observation of several biological factors and cognitive functions were conducted to analyse the WBC influence on cognitive deficits.

Methods People with MCI participated in 10 WBC sessions divided for experimental group (-110°C till -160°C) or control group (-10°C till -20°C). The MoCa test (scores 26 and lower) was used for inclusion criteria. Cognitive functions were measured with: TYM, DemTect and SLUMS at baseline and in follow-up. Biological factors (cytokines, BDNF, NO) were also assessed.

Results It was shown that memory domains in experimental group improved after WBC sessions. Also modulatory effect on inflammatory mediators in plasma was shown. The results of this

study consist of the comparison of experimental and control groups regarding to cognitive functions as well as biological factors.

Conclusions Whole-body cryotherapy may be supposed to improve cognitive functions in MCI patients. The modulatory effect of WBC on immunological response may be considered as one of possible mechanisms of its action. However, there is no confirmation how long the effects resist so further investigations are needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Health-related quality of life in old age institutionalized patients with neurocognitive disorders

O. Vasiliu^{1,*}, D. Vasile¹, D.G. Vasiliu², F. Vasile³

¹ Dr. Carol Davila" Central Military Hospital, Psychiatry, Bucharest, Romania

² Coltea Clinical Hospital, Internal Medicine, Bucharest, Romania

³ University of Medicine and Pharmacy Titu Maiorescu, General Medicine, Bucharest, Romania

* Corresponding author.

Health-related quality of life (HRQOL) is an important indicator of how a patient perceives hi/her own physical and mental status. Evaluating this dimension in old age patients which are institutionalized for neurocognitive disorders is useful from several perspectives: (1) determination of an initial value for HRQOL parameters could help the case manager in structuring an individualized therapeutic intervention, adapted for psychological, somatic or psychosocial needs of each patient; (2) monitoring the evolution of HRQOL dimensions could help in improving through feedback the quality of therapeutic intervention(s), especially if the case manager is permanently in contact with the patient, as is usually the case of institutionalized subjects; (3) correlation between HRQOL and other important variables, like therapeutic adherence, regression of comorbidities, daily functioning etc. could modulate the therapeutic intervention. We suggest a plan for HRQOL evaluation in institutionalized patients diagnosed with neurocognitive disorder, consisting in monthly scoring of SF-36 or EuroQoL questionnaire, corroborated with MMSE and ADAS-Cog scoring. Psychotherapeutic interventions tailored to the needs identified through HRQOL periodic evaluations could be useful in this population, for example a perceived isolation could be compensated by increasing the rhythm of social interaction by group therapy under the direction of a counsellor, a reduced self-efficacy could be compensated by activation techniques, music or art-therapy, while dissatisfaction with own memory capacities could be mitigated using reminiscence therapy. Switching from a paternalistic way of perceiving the patient as the object of an intervention, to a more interactive style of communication, involves obtaining feed-back through HRQOL instruments.

Validation of a measure of positive and negative affect for use with cross-national older adults

S. Von Humboldt*, I. Leal

ISPA-Instituto Universitário, William James Center for Research, Lisbon, Portugal

* Corresponding author.

Introduction Positive Affect (PA) and Negative Affect (NA) have been used as general dimensions to describe affective experience, and they are the affective, emotional components of SWB.

Objectives Positive and negative affect is a relevant facet of well-being for community-dwelling older adults. This study aims to conduct a validation of the Positive and Negative Affect Scale (PANAS), by assessing the psychometric properties (distributional properties, construct, criterion and external-related validities, and reliability) of the PANAS in a cross-national sample of older adults.

Methods A cross-sectional survey design was used. A convenience sample of 1291 community-dwelling older adults aged 75 years old and older was recruited from community centers. Construct validity was estimated through confirmatory factor analysis and convergent validity. Criterion and external-related validities, reliability and distributional properties were also assessed.

Results The PANAS demonstrated satisfactory reliability, distributional properties, and construct, criterion and external-related validities in this sample of older adults.

Conclusions These results suggest that the PANAS can be used as a reliable and valid measure for examining positive and negative affect among cross-national community-dwelling older adults.

Keywords Older adults; Psychometric properties; Positive and negative affect; Positive and negative affect scale; Validation.

Older adults' adjustment to aging: The impact of sense of coherence, subjective well-being and socio-demographic, lifestyle and health-related factors

S. Von Humboldt*, I. Leal

ISPA-Instituto Universitário, William James Center for Research, Lisbon, Portugal

* Corresponding author.

Introduction Literature lacks of studies assessing correlates of adjustment to aging (AtA) among older populations.

Objective The aim of this study was to build a structural model to explore the predictors of adjustment to aging (AtA) in a community-dwelling older population.

Methods A community-dwelling sample of 1270 older adults aged between 75 and 102 years answered a questionnaire to determine socio-demographic (sex, age, professional and marital status, education, household, adult children, family's annual income, living setting and self-reported spirituality), lifestyle and health-related characteristics (perceived health, recent disease, medication and leisure). Several instruments were used to assert psychological variables, namely AtA, sense of coherence and subjective well-being. Structural equation modeling was used to explore a structural model of the self-reported AtA, encompassing all variables.

Results Significant predictors are self-reported spirituality ($\beta = .816$; $P < .001$), perceived health ($\beta = .455$; $P < .001$), leisure ($\beta = .322$; $P < .001$), professional status ($\beta = .283$; $P < .001$), income ($\beta = .230$; $P = .035$), household ($\beta = -.208$; $P = .007$), sense of coherence ($\beta = -.202$; $P = .004$) and adult children ($\beta = .164$; $P = .011$). The variables explain 60.6% of the variability of AtA.

Conclusions Self-reported spirituality is the strongest predictor of AtA. This study emphasizes the need for deepening the variables that influence older adults' AtA, in particular perceived health and further lifestyle-related characteristics, as being relevant for promoting aging well in later life, within a salutogenic context for health care.

A study on the factors that contribute to older adults' sexual unwellness

S. Von Humboldt*, I. Leal

ISPA-Instituto Universitário, William James Research Center, Lisbon, Portugal

* Corresponding author.

Introduction Older adults may remain sexually interested and capable into their 90s.

Objectives To analyze the contributors to sexual unwellness (SU) and to explore the latent constructs that can work as major determinants in SU for a cross-national older community-dwelling population, and to analyze the explanatory mechanisms of a SU model, in an older cross-national sample.

Methods A socio-demographic and health questionnaires were completed, assessing participants' background information. Interviews were completed, focused on the contributors to SU. Complete data were available for 109 English and Portuguese older adults, aged between 65–87 years ($M = 71.6$, $SD = 6.95$). Data was subjected to content analysis. Representation of the associations and latent constructs were analyzed by a Multiple Correspondence Analysis.

Results The most frequent response of these participants was 'lack of intimacy and affection' (25.1%) whereas 'poor sexual health' was the least referred indicator of SU (11.2%) A two-dimension model formed by 'poor affection, intimacy and sexual health', and 'poor general health and financial instability' was presented as a best-fit solution for English older adults. SU for Portuguese older adults were explained by a two-factor model: 'daily hassles and health issues', 'poor intimacy and financial instability'.

Conclusions These outcomes uncovered the perspective of older adults concerning SU and the need of including these factors when considering the sexual well-being of older samples.

Keywords Community-dwelling older adults; Content analysis; Multiple correspondence analysis; Sexual unwellness.

A checklist for assessing dementia-friendly design: Architecture as non-pharmacological mean in assistance of patients with dementia

M.V. Zamfir^{1,*}, M. Zamfir Grigorescu²

¹ Carol Davila University of Medicine and Pharmacy, Physiology II, Neurosciences Division, Faculty of Medicine, Bucharest, Romania

² "Ion Mincu" University of Architecture and Urbanism, Faculty of Architecture, Bucharest, Romania

* Corresponding author.

Introduction Although there are recommendations regarding dementia-friendly architecture, studies on design features and their impact on quality of life of patients with dementia are quasi-nonexistent. The design of the environment is one of the non-pharmacological methods in the assistance of patients with dementia.

Objectives Setting a checklist of design principles in order to assess centers for elderly with dementia; identifying the types of centers where will be applied the checklist; implementation of the checklist and determining results of assessment.

Aims Our aim is to challenge the contemporary architecture of centers for elderly to be friendly with dementia patients.

Methods After studying literature we built a check-list of 8 principles: providing a comfortable space and also a therapeutically environment; functionality and efficiency; flexibility and accessibility; optimal design of circulation routes in order to avoid disorientation and to reduce agitation; security and safe; aesthetics; sanitation; sustainability. We then performed a case-study on two types of settings, day care centers and respite centers, and we applied the check list on three examples: two urban Day Care Centers for patients with Alzheimer Dementia (2006, Pontevedra, Spain and 2011, Alicante, Spain) and a Respite Center (2009, Dublin, Ireland).

Results In general, the centers are verifying the proposed check-list. Four architectural tools were identified: light, form, colour and texture. Form is more recognizable than colour and colour more recognizable than function.

Conclusions Architecture contributes to increase quality of life in people with dementia. The proposed checklist is a promising tool for assessing dementia-friendly design.

Suicide risk in cancer patients – Are we prepared?

M. Alves^{1,*}, A. Tavares²

¹ Hospital Magalhães Lemos, Serviço C, Porto, Portugal

² Instituto Português de Oncologia, Serviço de Psico-Oncologia, Porto, Portugal

* Corresponding author.

Introduction Individuals with cancer are at increased risk for suicidal ideation and behaviour when compared to the general population. Suicidal thoughts are sometimes minimized and considered by clinicians as a normal reaction to diagnosis of oncological disease. Less severe forms of suicidal ideation, such a fleeting wish to die may happen in all stages of the disease.

Objectives We aim to highlight the cases of cancer patients that present an imminent suicide risk and its related psychopathological aspects, psychosocial and physical risk factors that may increase the probability of suicidal attempt.

Methods Non systematic literature review through the Medline and Clinical Key databases, with time constraints.

Results Individuals with cancer have twice the risk of suicide compared to the general population. It was found that suicidal thoughts are more common in patients with advanced disease, in hospital or in palliative care settings or in those who are experiencing severe pain, depression, cognitive impairment or delirium. The first months following the diagnosis are the period of greatest risk and the highest suicide risk occurs in men with respiratory cancers. Death by suicide occurs more often in cancer patients in the advanced stages of disease.

Conclusions An appropriate therapeutic response should include empathy, active listening, management of realistic expectations and permission to discuss psychological distress. The first intervention should focus on determining imminent risk of suicidal behaviour and act for patient safety.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Invisible effects of chemotherapyD. Brandão^{1,4}, T. Assunção^{2,4}, H. Almeida^{3,4,*}¹ *Interna Psiquiatria ULSAM, Departamento de Psiquiatria e Saúde Mental da ULSAM, Braga, Portugal*² *IPO-Porto, Porto, Portugal*³ *Hospital Magalhães Lemos, B, Porto, Portugal*⁴ *University of Porto, Department of Clinical Neurosciences and Mental Health Faculty of Medicine, Porto, Portugal** *Corresponding author.*

Introduction Chemotherapy is an essential component in the treatment and alleviation of oncological diseases. To your application are associated, as well as systemic effects, cognitive impairment in patients. These changes have received increasing attention due to the impact on quality of life of cancer survivors.

Objectives This study aims to evaluate the current evidence on the association between chemotherapy and cognitive impairment in cancer patients, especially in the areas affected cognitive function, possible mechanisms of action and consequences on the quality of life of these patients and the importance of identifying strategies intervention in order to minimize these effects.

Methods We conducted a literature review from literature articles addressing this topic with use of databases: Medline and Pubmed. The following keywords were used: “chemobrain”, “cognitive dysfunction”, “chemotherapy”.

Results Although some states have not found differences, several studies have shown that chemotherapy has implications cognitively. Underlying etiology remains unknown, and proposed several mechanisms to explain these changes: neurotoxicity, microvascular damage and inflammatory response. Cognitive impairment has significant implications in the daily life of patients both personally, socially and labour. The therapeutic approach focuses on the patient and family education, coping strategies, cognitive rehabilitation and cognitive behavioural therapy.

Conclusions It is vital to educate patients about the possibility of cognitive change as effect of chemotherapy as well as health professionals in the early identification of these changes. It is essential developing specific intervention strategies to improve the quality of life of the oncologic patient during and after treatment.

The study and comparison of the severity of coping strategies and defense mechanisms in prostate cancer patients, healthy individuals and patients with similar localization oncologyJ. Gardanova*, I. Abdullin, A. Chernov, D. Khritinin
*Pirogov Russian National Research Medical University, Psychotherapy, Moscow, Russia** *Corresponding author.*

This project deals with the problem of emotional response to their disease in prostate cancer patients compared with healthy people and patients with similar localization of oncology diseases. As a result, it was found that in patients with prostate cancer pronounced such defense mechanisms as repression, denial and reaction formation, which may lead to psychosomatic disease. The coping strategies of the system in patients with prostate cancer is most pronounced, such a mechanism as a “distancing”. The results may contribute to the creation of a

specific psychological rehabilitation for this group of patients the program.

Bruxism as a consequence of chemotherapy?G. Da Ponte^{1,*}, J. Rato², C. Pinto², M. Lobo¹, S. Ouakinin³¹ *Centro Hospitalar Barreiro-Montijo, Psychiatry and Mental Health, Barreiro, Portugal*² *Centro Hospitalar Barreiro-Montijo, Oncology, Barreiro, Portugal*³ *Medical School of Lisbon University, University Clinic of Psychiatry and Medical Psychology, Lisbon, Portugal** *Corresponding author.*

Introduction Bruxism is a syndrome with uncertain etiology but with proposed factors: psychosocial, peripheral and central. Treatment is also controversial and one of the options focuses in GABA theory and regularization of ion channels. Xelox (capecitabine + oxaliplatin) and bevacizumab is indicated for metastatic colorectal cancer, being oxaliplatin the most neurotoxic agent (acute syndrome and/or a chronic sensory neuropathy). Acute neurotoxicity is very frequent and it is a sensory and/or a motor toxicity (as tongue tingling or jaw spasms). The proposed pathogenesis – neuronal hyperexcitability due to alterations of voltage-gated ion channels – is supported by mechanism of action of some treatments.

Objectives and Aims Review different causes of bruxism.

Methods Description of a clinical case.

Results This is a story of 76-years-old man in treatment for metastatic colon cancer that developed toxicity: nausea (treated with haloperidol), bruxism and gingival atrophy. He was referred to psycho-oncology by involuntary movements of mouth and trunk. The patient complained of sadness, anhedonia and insomnia since recurrence of cancer and related the movements with CT. At observation he was anxious, tearfulness and agitated. He was treated for a depressive episode, but the doubt remained about involuntary movements: haloperidol was a confounding factor for oxaliplatin acute neurotoxicity, also aggravated by psychic and peripheral factors.

Conclusions The authors believe that bruxism is linked to CT in a very complex relation that includes psychic, peripheral and central factors. Psychiatrists need to keep attention to the patient as a whole, not being seduced by easy answers like psychosocial factors.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction The frontal lobes are the brain structures of latest development and evolution in the human brain. It is considered that the frontal lobes represent the “executive center of the brain”. The frontal tumors represent 16% of all supratentorial tumors. Symptoms are easily confused as psychiatric rather than neurological.

Objectives Can see the alterations of the executive functions in a case of frontal affectation, for future cases know where to focus our attention and develop concepts associated with frontal lobe.

Method Thirty-year-old patient without relevant medical history. Go to the emergency department with major episode of agitation. After performing cranial CT abnormality, it is detected in the front area. Sign up study. It presents amnesia episode before admission, whereupon shown stunned and worried. The patient describes a change in your life 12 months ago, when it begins to be more nervous, increasing their impulsiveness, she has episodes of binge eating, purging behavior with subsequent occasional alcohol abuse. Jealousy. The patient is informed as much as your family of the possible impact of the injury on the behavioral sphere and impulse control when it is still unknown origin.

Conclusions From a neuropsychological point of view the frontal lobes represent a system of planning, regulation and control of psychological processes; coordination and allow selection of multiple processes and various behavioral options and strategies available to the human being. Tumour research is important as it provides enough information we cognitive impairment. These patients exhibit symptoms that are easily confused as psychiatric rather than neurological.

² Yonsei University College of Medicine, Department of Psychiatry and Institute of Behavioral Science, Seoul, Republic of Korea

³ NHIS Ilsan Hospital, Department of Internal Medicine, Goyang, Republic of Korea

* Corresponding author.

Introduction Cancer patients may encounter psychological distress, change of emotional status, and lowered quality of life. It is predicted that similar changes will be shown during the Endoscopic Submucosal Dissection (ESD) of early stomach cancer. The objective of this study is to evaluate changes of emotional status and quality of life over time depending on baseline level of psychological distress.

Method Ninety-seven patients indicated with ESD who visited National Health Insurance Service Ilsan Hospital in Korea between May 2015 and June 2016 were evaluated. Psychological distress, emotional status, and quality of life were evaluated at the day before ESD. Follow-up evaluations of them were done at the day after ESD, 2 and 10 weeks later.

Result The group with high psychological distress showed higher female ratio, more depressive and anxiety symptoms than those of the group with low psychological distress. Psychological distress was related to stress level and lowered quality of life. Repeated measures ANOVA analysis showed that significant differences of depression (MADRS), anxiety (HAM-A), level of stress (GARS), and quality of life (EORTC QLQ-C30) were sustained over time, but the decreasing tendency of the differences between the groups was also noticed.

Conclusion The study revealed that patients who feel more psychological distress may experience more depressive and anxiety symptoms, increased level of stress, and lowered quality of life. We recommend screening of patients with early stomach cancer for psychological distress before ESD, which may improve subjective life satisfaction of patients during ESD.

Psychological effect of semi-permanent tattooing rehabilitation in patients with mastectomy in 12 months period

P. Argitis¹, P. Platari¹, K. Gatsiou¹, C. Chatzidai², K. Paschalidis^{3,*}

¹ University Hospital of Ioannina, Psychiatric Clinic, Serres, Greece

² General Hospital of Corfu, Psychiatric Clinic, Corfu, Greece

³ Psychiatric Hospital of Thessaloniki, 2nd Psychiatric Clinic, Thessaloniki, Greece

* Corresponding author.

Introduction Breast cancer is the most common cancer type in Greek women as more than 4000 new cases are diagnosed every year. Seventy percent of those patents performs a type mastectomy. The breast has a societal and social connotation of femininity, motherhood, and sexuality.

Background Several studies support the existence of the relationship between psychological problems and mastectomy surgery. Body image and feminine self-concept also seems to influence quality of life of those women, considering the breast association of femininity, motherhood, and sexuality. During this study, we try to investigate how a non-psychiatric intervention might influence the mental state and the quality of life of those women.

Material A clinical interview was performed in 53 women with partial or total mastectomy before 3 and 52 weeks after the rehabilitation with the method of semi-permanent tattooing.

Methods Data were collected during the personal interviews, using Hamilton anxiety rating scale (Ham-A), body image scale and sexual activity questionnaire.

Results Moderate levels of anxiety were identified before the rehabilitation, associated with poor body image scale scores and sexual difficulties. Both Ham-A and body image score ameliorated after 3 weeks with unchanged sexual behaviour. One year after rehabilitation, anxiety scale score raises close to initial values, body image remains unchanged, comparing with the 3rd week interview and significant improvement noticed in sexual activity.

Pregabalin pain and anxiety treatment in oncological patient–Case report

D. Popovic^{1,*}, D. Pavicevic²

¹ Psychiatric Practice and Consultative Service, General Hospital

Petrovac na Mlavi, Petrovac na Mlavi, Serbia

² Clinic for mental disorders “Dr Laza Lazarevic”, Intensive Care Unit, Belgrade, Serbia

* Corresponding author.

Severe side effects of chemotherapy during treatment of malignant disease significantly disrupt patient's mental and physical state. Seventy five-years-old female patient was treated for breast cancer by protocol (operation, radiotherapy, chemotherapy-paclitaxel (CHT-PX) every tree weeks) and for dysthymia and generalized anxiety disorder with escitalopram (ESC). Tramadol (TRA) and clonazepam (KLO) given by oncologist due to severe side effects of CHT-PX: muscle cramps, lower back pain, walking difficulties, had partial results, increased anxiety and drug abuse (TRA doses increase from 100 to 300 mg/day and KLO from 4 to 6 mg/day). Efficiency of pregabalin (PG) in pain and anxiety control during

CHT-PX application. The assessment was made by 100 mm visual analogue scale (VAS), which assessed physical symptom severity and Hamilton Anxiety Rating Scale (HAMA) on the first day after CHT-PX application, on the 7th, 14th and 21th day. Effective PG dose was 300 mg/day with EST, KLO and TRA previously taken. On the first day after CHT-PX, patient rated pain level as 9 according to VAS. During TRA and KLO treatment, pain level on VAS was 6 from the 7th till 14th day after CHT-PX, on 21th day deceased to 2. HAMA score was 49. After PG augmentation, according to VAS, pain level was 3 on the 7th day and 0 on 14th day. HAMA score was 20. Tapering off the dose of TRA and KLO started till discontinuation of both medications. Pregabalin efficiency in pain and anxiety control increase compliance of oncological patient and reduce harm of drug abuse.

Severe mental illness and cancer – A program for psychiatric patients in a cancer center

J. Graça*, F. Silva Carvalho, R. Ramos Coutinho, A. Ribeiro, L. Monteiro

Instituto Português de Oncologia de Lisboa de Francisco Gentil EPE, Unidade de Psiquiatria, Lisboa, Portugal

* Corresponding author.

Introduction The prevalence of severe mental illness (SMI) is estimated to be 4%. There are increased risk factors for cancer in SMI patients. People with SMI have deficient access and referral to routine cancer screening and psychiatric illness is often associated to late oncological diagnosis.

Objectives Characterize the population of SMI patients that undergoes oncological treatment; establish a comparison with the general population in terms of stage at the time of diagnosis and the type of follow-up that ensued; characterize the psychiatric care available to these patients; propose the necessary changes to ensure adequate healthcare for SMI patients.

Aims To assess and improve the quality of oncological care for SMI patients in our hospital.

Methods We analyzed the data from SMI patients suffering from SMI observed by our group during a 12 month period.

Results Low percentage of SMI patients being treated in our center regarding general rates; surprisingly high referral time to psychiatry unity; good compliance with treatments and appointments; have mostly been submitted to the standard oncological protocols of treatment.

Conclusion In spite of serious psychiatric co-morbidity and psychosocial deficits, our SMI patients are able for standard cancer treatment and present sufficient compliance. We value the help of family members and social workers. We have to insist in educational sessions and psychiatric screening procedures for oncological teams. It is also fundamental to implement educational programs for mental health centers in Lisbon in order to sensitize for cancer risks among SMI and alert for the pivotal role of mental health staff, namely the psychiatrists.

⁴ National Research Center for Hematology, Research clinical department of leukemia chemotherapy, hematopoiesis depression and bone marrow transplantation, Moscow, Russia

⁵ Moscow State University, Clinical psychology, Moscow, Russia

* Corresponding author.

Introduction Personality disorders are rather widespread in oncology settings demanding special attention of clinician. Serious illness threatening person's life as well as severe treatment and side effects lead to specific self-regulatory emotional and cognitive efforts. Personality could both play an important role in this process predicting adjustment and survival and change in line with illness pathogenesis.

Objectives The personality patterns could be important predictors of operation success and further adjustment for patients with acute lymphoblastic leukemia (ALL) waiting for bone marrow transplantation.

Aim To reveal personality patterns specific for patients with ALL. **Methods** Twenty-five patients with ALL (11 males, 37.4 ± 9.5 years old) filled Millon Clinical Multiaxial Inventory–III and Big Five Questionnaire–2. Comparison group included 180 people of the same age and gender without history of mental or severe somatic disorders.

Results Male patients comparing to healthy males were lower on emotional control and higher in negativistic personality pattern ($P < .05$). Female patients were higher on dynamism but lower in openness to culture and antisocial pattern ($P < .05$). They rarely expressed patterns of borderline disorder and drug dependence but reported more compulsive traits ($P < .05$).

Conclusions Severe illness could increase likelihood of emotion regulation difficulties and passive-aggressive coping in male patients while stimulate activity and compulsive behaviour in females. These patterns should be taken into account in psychological support of patents to bone marrow transplantation.

Low income deteriorates quality of life in early breast cancer survivors

G. Ristevska^{1,*}, D. Rajchanovska¹, T. Jovanovska¹, B. Dejanova²

¹ University St. Kliment Ohridski, Higher Medical School, Bitola, Former Yugoslav Republic of Macedonia

² University Sts. Cyril and Methodius, Medical Faculty, Skopje, Former Yugoslav Republic of Macedonia

* Corresponding author.

Background Patients who have survived cancer and have lower socio-economic status, are more likely to leave the workforce. Financial problems are widespread among many of the breast cancer survivors, but their effect on the quality of life are not sufficiently explored. The aim of this study is to assess the effect of low income onto quality of life in early breast cancer survivors.

Methods In this study, 214 consecutive early female breast cancer patients, with mean age of 60 years (range 30–90), were interviewed for psycho-social aspects, depression (MINI) and quality of life (EORTC QLQ-Core 30 and BR-23). All patients were cancer free at the moment of interview and all initial oncological treatments were

completed. Monthly net family income distribution was: ≤ 150 euro 58 patients (27.1%); income between 150–500 euro 116 patients (54.2%); ≥ 500 euro 40 patients (18.7%).

Results Patients with income ≤ 150 euro, compared to patients with income ≥ 500 euro, had statistically significant worse global health status (60.2 ± 27.9 vs. 80.2 ± 19.2 ; $P=0.0007$); worse physical functioning (80.3 vs. 69.1 ; $P<0.001$); worse role functioning (92.9 vs. 78.7 ; $P=0.009$); worse sexual functioning ($P=0.019$); more severe fatigue (38 vs. 23 ; $P=0.01$), nausea/vomitus ($P=0.041$), appetite loss (18.4 ± 7.5). Major depression was diagnosed in 35 patients. Depressed patients have less income than not depressed patients (23.3% vs. 14.41%), but the difference did not reach statistical significance.

Conclusions Lower income negatively affects many aspects of quality of life. Specific interventions are needed for cancer survivors with lower socio-economic status to preserve and improve the quality of life.

Mental disorders in patients breast cancer: Differentiated approach to the study Nozogeny

O. Shushpanova

Scientific Center of Mental Health, Department for the Study of Children and Adolescent Psychiatry problems, Moscow, Russia

Objective The problem of mental disorders in patients with breast cancer is relevant due to the high prevalence of pathological changes in the mental health patients, insufficient development of clinical typology of psychosomatic correlations of the contribution of constitutional features.

Methods Nozogeny disorders are clinically heterogeneous and are represented by two nosologic categories: reaction and nosogenic patho-characterological personal development. The basic method of work was a clinical follow-up and statistical research methods (method using contingency tables and Fechner coefficient method using the χ^2 – test).

Results The manifestation of a nozogeny reaction is closely correlated with his premorbid personality characteristics. Anxious-depressive nozogeny reaction was recorded in 17 patients of the first sample with high direct correlation (coefficient Fechner $F=0.76$, $P<0.01$) with respect to accentuation of personality in the alarm type, and the weak direct link to the personal characteristics of the affective (bipolar) range ($F=0.22$, $P<0.01$). Anxious-nozogeny dissociative response was detected in 9 patients with hysterical (55.5%) and expansive schizotypal (vershrobene) (44.4%) lung cancer with a significant ($F=0.65$, $P<0.01$) a direct correlation with constitutional hyperthymia, anxiety-hypomaniac nozogeny response was observed in patients c schizotypal RL ($n=4$) paired with symptoms of persistent hyperthymia ($F=0.39$, $P=0.012$).

Conclusion Patho-characterological development of personality are formed on the remote catamnestic stage breast cancer and show the clinical heterogeneity of differentiation into 4 types: (1) the type of hypochondriacal dysthymia, (2) the type of “paranoia struggle”, (3) in an “aberrant hypochondria” and (4) the type of “new life”.

Chemobrain and anxiety in a patient with Hodgkin's Lymphoma: Case report and literature discussion

M. Silva^{1,*}, M. Roque², P. Macedo², A. Fornelos²

¹ CHTMAD-E.P.E, Psychiatry department, Felgueiras, Portugal

² CHTMAD-E.P.E, Psychiatry department, Vila Real, Portugal

* Corresponding author.

Impaired cognitive function is a common complaint among oncologic patients. Chemotherapy-induced cognitive impairment (CICI), also called “chemobrain” or “chemofog” is currently recognized as a relatively common adverse effect of chemotherapeutic agents and is defined as the impairment of patients' memory, learning, concentration, reasoning, executive function, attention, and visuospatial skills during and after discontinuation of chemotherapy. In particular, it is apparent that a subset of chemotherapy-treated haematological malignancy survivors experience cognitive impairment. On the other hand, the emotional distress associated with the disclosure of cancer diagnosis and/or the administration of chemotherapy represents a strong reason for psychosomatic manifestations in patients with cancer. The authors report a case of a patient with Hodgkin's lymphoma, cognitive impairment and symptoms of anxiety and they propose to discuss the controversies around the factors implicated on cognitive impairment in oncological patients.

* Corresponding author.

The number of new cases of cancer in Azores and the transfer of oncological patients to mainland Portugal for specialized treatment raise concerns about psychological adaptation and suitable support care. Further studies regarding the lack of support interventions available to meet the needs of Azorean oncological patients and survivors are required. The main objectives of this study are: (1) to evaluate psychosocial needs and other psychological adaptation variables among adult oncological survivors from the Azores; and (2), ensuing from objective (1), to develop a pilot study to test a model of support with a group of oncological patients from the Azores. Two studies will be performed. The first deals with objective (1) as described. Based on results obtained, a randomized control trial assessment will be run to test a support model based on the patient advocacy movement with oncological patients. The assessment protocol will be administrated three times: before and after the model's implementation and, again, as a follow-up. Results should enhance knowledge of assessing psychological adaptation variables involved in disease trajectory while testing a support model addressing this study major concerns. These, as suggested, relate to lack of support interventions to meet the psychosocial needs of oncological patients and survivors from the Azores. Given the peculiar experience of Azorean oncological patients', while away from their homes, there is a need to ensure adequate health care services on their behalf. Hence, the importance of devising

ways to monitor their psychosocial needs in order to overcome some of these constraints.

Clinical-qualitative study on emotional aspects of practices and learning, interviewing Brazilian nurses from a hemato-oncological unit who work with patients in risk or death process

R.A. Bastos¹, E.R. Turato^{1,*}, A.M. Quintana²

¹ UNICAMP, State University of Campinas, LPCQ Laboratory of Clinical Qualitative Research, Campinas, Brazil

² Federal University of Santa Maria, Psychology, Santa Maria RS, Brazil

* Corresponding author.

Introduction There is no clear limit between the personal and professional dimension, when the health worker cares for patients who have no prospect of cure. This shadowing of the personal dimension causes high emotional demands of the professional in the face of the experiences with the death.

Objectives In face of troubles which surround the nurse in the context of death, this article aimed to identify the learning and self-care practices experienced by nurses who work with patients in risk or in death process, in a haematology-oncology unit.

Method This is a clinical-qualitative study, conducted through individual interviews. The participants were 6 nurses from haematology-oncology unit of a university hospital, covering the sectors of chemotherapy clinic and children's unit.

Results The results highlight two phenomena built by the experiences of nurses: long learning experiences with the team work through the maturity arising over time or even with constant monitoring of the death situations; and self-care practices as self-preservation phenomenon through the development of pain by speaking and listening in groups, the motivation through professional achievement and the well-being caused by the charity care each other.

Conclusions Work towards the personal development of nurses as professional who deals with ethical conflicts should be focused on promoting opening spaces for speaking and listening of these nurses. This allows them to create ways of dealing with situations of death, which are professionally responsible.

Relations of post-traumatic growth and resilience in cancer experience

Y.S. Uzar Ozcetin*, D. Hicdurmaz

Hacettepe University, Faculty of Nursing, Psychiatric Nursing Department, Ankara, Turkey

* Corresponding author.

Introduction Each individual experience cancer in a different way. While some perceive cancer as a complex and traumatic experience by developing some psychosocial and additional physical problems, others overcome cancer-related difficulties by gaining benefits such as post-traumatic growth (PTG) owing to their resilience. Resilience and PTG that are very valuable concepts in human life to adapt positively to cancer process have relations which need to be better understood.

Objectives We aimed to provide a better understanding of relations between resilience and PTG and relations of these two concepts with cancer experience.

Methods Literature review.

Results Successful adjustment to life-threatening illnesses such as cancer, require resilience. On the other hand, resilience provides a barrier toward stressors by helping improvement of PTG and so, is an antecedent factor of PTG. PTG ensures a deeper perspective and strength to people after traumatic events. Hence, individuals having higher levels of PTG feel powerful enough to handle the problems in their life and can easily adapt to cancer process by focusing on the positive outcomes of trauma, having improved coping mechanisms and an improved psychological well-being.

Conclusions Resilience and PTG have strong mutual relations and this phenomenon should be considered for a qualified cancer care.

EV0823

Sources of meaning in family caregivers of terminally ill patients supported by a palliative nursing care team – A naturalistic three-month cohort study

J. Valdes-Stauber^{1,*}, R. Lemanczyk (General Practitioner)², R. Kilian³

¹ Zentrum für Psychiatrie Südwürttemberg, Department for Psychiatry and Psychotherapy I-University of Ulm, Ravensburg, Germany

² Private practice, Bad Wurzach, Germany

³ Bezirkskrankenhaus Günzburg, Department for Psychiatry and Psychotherapy II-University of Ulm, Günzburg, Germany

* Corresponding author.

Objectives To identify possible change patterns or robustness in sources of meaning in family caregivers of pre-terminal patients after onset of support at home by an outreach palliative nursing team during a survey period of three months.

Methods One hundred caregivers of terminally ill patients were included in a prospective observational trial. The Sources of Meaning and Meaning in Life Questionnaire (SoMe) was administered at four points of measurement: T₀ (immediately before onset of palliative care); T₁ (one week after T₀); T₂ (one month after T₀); T₃ (three months after T₀). Descriptive statistics, random effects regression analyses; multivariate linear and quadratic regression models were performed for the full ($n = 100$) as well as for the reduced sample ($n = 24$).

Results Growth curve analyses reveal significant parabolic changes for the dimension "order" and for the subscales "social commitment", "tradition", "morality", and "fun". All other dimensions or subscales remained stable during the time of the study. Cross-sectional multivariate regression models (T₀) showed negative associations of some dimensions with patients' age and psychological burden of the family caregiver while psychological burden of patients was found to be positively associated with some dimensions. No significant effects of interaction variables with time (linear and quadratic).

Conclusions With few exceptions, family carers seem to keep a stable sense of meaning in life during the final stage of their relatives' terminal illness. Particular associations between sources of meaning and age of patients as well as psychological burden both of patients and carers have to be taken into consideration in support planning.

The effect of a sleep-hygiene education and sleeping pill reduction program for hospitalized cancer patients at a general hospital

S. Youn*, B. Park, S. Lee, C. Kim, S. Chung
Asan medical center, Psychiatry, Seoul, Republic of Korea
* Corresponding author.

Objectives Sleep disturbances are common among cancer patients. Especially during hospitalization, not only adverse medical conditions but also ward environments can affect sleep. We have developed a program of sleep-hygiene education and sleeping pill reduction for inpatients (the i-sleep program) and applied it to cancer patients. This study aimed to explore the effect of the program.

Methods In a general hospital with 2,715 beds, we estimated the proportion of inpatients prescribed hypnotics at admission to and discharge from the department of oncology before (2014) and after (2015) the program. In addition, we estimated the proportion of inpatients prescribed hypnotics among all inpatients in the department of oncology on the first day of each month of 2014 and 2015.

Results A total of 12,382 patients (2014, before) and 12,313 patients (2015, after) were admitted to oncology department of Asan Medical Center. The proportion of inpatients prescribed hypnotics as discharge medication among inpatients who had been prescribed them at the time of admission decreased significantly, from 76.0% (2014) to 69.8% (2015), after the program (RR=0.92, 95% CI: 0.87–0.98). The proportion of inpatients newly prescribed sleeping pills after admission to the hospital did not significantly decrease (4.03% to 3.98%; RR=0.99, 95% CI: 0.87–1.12). The mean prescription rate of sleeping pills per day was 10.02% in 2014 and 7.99% in 2015 ($P=0.03$).

Conclusions Although the i-sleep program did not reduce the prescription rate of sleeping pills per day, it effectively reduced the proportion of cancer patients who continued to take sleeping pills from admission until discharge.

Screening for cognitive disorders in elderly diabetics

I. Baati^{1,*}, I. Abida¹, S. Omri¹, S. Ellouze¹, F. Hadj Kacem², L. Affes², M. Abid², J. Masmoudi¹

¹ Psychiatry "A" Department, Hedi Chaker University Hospital, Sfax, Tunisia

² Endocrinology Department, Hedi Chaker University Hospital, Sfax, Tunisia

* Corresponding author.

Introduction Old people with diabetes are more likely to develop cognitive impairment, Alzheimer's disease and vascular dementia. However, the determinants of the association between diabetes and cognitive impairments are only partially known.

Objectives To evaluate cognitive disorders in elderly diabetic patients and to identify risk factors of cognitive impairment in this population.

Methods It was a cross-sectional study. It involved outpatients aged 65 and older, who were followed for diabetes in the endocrinology department at the Hedi Chaker University Hospital in Sfax (Tunisia), from October 1 to December 31, 2015. For

each patient, we collected sociodemographic, clinical and therapeutic data. We used the Montreal Cognitive Assessment (MoCA) to identify mild cognitive decline (score < 26/30).

Results We identified 70 patients, all with type 2 diabetes. The average age was 66.8 years. The sex ratio (M: F) was 0.7. The mean duration of diabetes was 14.76 years. The average MoCA score was 20.68 ± 6. Forty patients (57%) had cognitive decline. The cognitive impairment was statistically correlated with female sex ($P=0.02$), low level of education ($P=0.00$), high levels of glycated hemoglobin (Hb A1c ≥ 7%) ($P=0.00$), presence of hypoglycemic episodes ($P=0.05$) and presence of dyslipidemia ($P=0.00$).

Conclusion Our study confirmed the high rate of cognitive decline in older type 2 diabetes patients. The profile of subjects at risk was consistent with the literature: poorly controlled diabetes, severe recurrent hypoglycaemia and associated dyslipidemia. Acting on these risk factors would prevent cognitive decline and therefore progression to dementia.

Introduction Fairness is a fundamental factor for prosocial behaviors and have a crucial role in social interaction. Examining fairness during maturation can shed light on different questions and hypothesis about the development of prosociality across life span.

Objectives The purpose of this study was to investigate the development of strategic planning in children and adolescents.

Methods A total of 288 healthy students between ages 7 and 18 from four community schools participated in a one-shut run game which the participants were proposed and should set a package of offers concluded six suggestions.

Results Among 288 students, 128 (44.44%) participants were male and 160 (55.56%) participants were female. In first offer, 29.7% of boys suggested an unfair offer but girls with 23% were more generous. However, in last suggestion in comparison with girls (73% unfair), boys showed more generosity (64% unfair). Notably, girls in average, spent 135.78 seconds (SD=86) to set their offers while boys needed less time to prepare their suggestions (117.16s, SD=119.7)

Conclusion According to the findings it seems that both genders start more generous offers and end up with less generous offers. In comparison with boys, girls need more time in economic decision-making and interestingly more fair options at the start of game.

Neurocognitive profile among Omani who have sustained traumatic brain injury with post-concussion syndrome

M. Albalushi

Oman medical speciality board, psychiatry, Muscat, Oman

Background Neurocognitive disorders, previously not featured in the psychiatric nomenclature such as the Diagnostic and Statistical Manual of Mental Disorders (DSM), have now been included in the latest, fifth edition of the DSM. There is a dearth of studies on neurocognitive disorders among non-western population.

Aims The aim of this study is to compare neuropsychological functioning measured by tests of executive function and cognition among patients marked by apathy and impulsivity following a traumatic brain injury in a non-Western population, Oman.

Methods Comparing the performance of various neurocognitive indices including negativistic features and disinhibition, which were identified using the symptom checklists Apathy Evaluation Scale and Disinhibited Evaluation Scale. Comparative neurocognitive measures included tapping verbal reasoning ability (Raven's Standard Progressive Matrices), working memory (Digit Span–Digit Forward–Digit Backward); Buschke Reminding Test, planning/goal-directed (Controlled Oral Word Association Test–verbal fluency, Tower of London(–planning time–number solved), (Wisconsin Card Sorting Test–perseverative errors, and–number of categories solved), and affective ranges (Hospital Anxiety and Depression Scale).

Result Analysis showed that those participants who scored highly at Apathy Evaluation Scale and Disinhibited Evaluation Scale did not differ on indices measuring working memory/attention and affective ranges except for one measure: Digit span–Digit Forward. In the measures operationalized here to tap planning/goal-directed behaviour, the two cohorts differ on all indices except for Tower of London–Number Solved.

Conclusion This study lays ground for further scrutiny in delineating the different characteristics of what previously labelled as frontal dysexecutive phenotype. It indicates that apathetic and disinhibited temperaments marked with specific neuropsychological performance.

Introduction Flupirtine is used in many European countries for the treatment of different pain states because of its analgesic attributes. It is a centrally acting, non-opioid analgesic.

Objective The aim of the study was to investigate an entire study the possibility of applying flupirtine (ktadolona) – selective neuronal potassium channel activators in the treatment of pharmacoresistant epilepsy and related non-psychotic depressive disorder in adults.

Material and methods A total of 20 patients with the diagnosis of primary – generalized idiopathic epilepsy (IGE) and “non-psychotic depressive disorder due to epilepsy (F06.362)”. Before applying katadolon forte, patients received standard antiepileptic and antidepressant drugs (Depakine-Chrono 1000 mg/day, 150 mg lamotrigine/day, levitiratsetam 3000 mg/day of citalopram 20 mg/day). Assigning a first katadolon fote 14 days 200 mg 2 times a day, followed by 200 mg three in day inside.

Results Of the 20 patients, 10 had no seizures, 8 marked decrease in the frequency of seizures in 2 patients therapy was not effective.

Conclusion Our data should be considered preliminary, because small sample of patients and duration of follow-up (18 months). The next phase of work will be carried out on a large sample of patients and a longer observation, placebo – controlled, double blind study.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The theme of violence and the teaching strategies used by teachers of nursing undergraduate courses

Z. Scherer^{1,*}, E. Scherer², D. Baragatti¹

¹ University of São Paulo at Ribeirão Preto College of Nursing, Psychiatric Nursing and Human Sciences, Ribeirão Preto–São Paulo, Brazil

² Ribeirão Preto Medical School Hospital of the University of São Paulo, Neurosciences and Behavioral Sciences, Ribeirão Preto–São Paulo, Brazil

* Corresponding author.

Introduction Understanding violence as a public health problem brings as required its inclusion in the curricula of undergraduate courses in health.

Objective To describe the approach to the topic of violence and the teaching strategies used by teachers of undergraduate courses in nursing of two public higher education institutions of the State of São Paulo, Brazil.

Aims Knowing the approach to the topic of violence in two nursing under graduation courses.

Method Descriptive, exploratory qualitative study. For data collection, semi-structured interview was used; were subject of the study, 15 teachers of the institutions studied that ministered courses whose programs contained the word “violence” or related. The data were subjected to analysis of the “collective subject discourse”.

Results The results referred to speeches about the importance of addressing violence in theory and practical course, the experience of violence in the everyday practice and pedagogical strategies in the theoretical and practical learning. Teachers recognize the importance of violence be crafted at graduation, describing that, although not always appear in the formal curriculum, the subject appears in an informal way in academic training. Recognize, however, that there is a fragmentation in the approach of the theme, because teachers are divided between theoretical and practical classes and not all of them study the subject.

Conclusion It is essential that there should be more discussions on violence among teachers as well as be designed strategies to better approach the theme at graduation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Risperidone induce recurrence of severe acute respiratory distress in a patient with psychotic disorders

N. Amel^{1,*}, M. Hadjadj¹, W. Maoudh²

¹ USLD La Rosaie, Eps Maison-Blanche, Seine Saint-Denis, Neuilly Sur Marne, France

² Pharmacie Eps Maison-Blanche, Seine Saint-Denis, Neuilly Sur Marne, France

* Corresponding author.

Mrs. R, 61-years-old was admitted into the department on July 2015 with a history of major paranoid psychosis. Notion of asthma

was indicated in the medical file without any specific treatment. At the admission she received risperidone 4 mg/day and duloxetine since one year. Between October 2015 and June 2016, the patient presented 19 episodes of respiratory decompensation, six of them required transfer in the emergency unit, and 3 in the intensive care unit (ICU) with the assistance of mechanical ventilation. During the last episode, transfer in the intensive care unit was refused by the ICU physician because of the high frequency of recurrence and the difficulty to extube the patient. “End of life” was therefore considered. Nevertheless, medical physician in charge of the patient decided to continue symptomatic treatment and to stop all anti-psychotic drugs susceptible to deteriorate respiratory disease. On the first day we observed a dramatic improvement and no recurrence occurred since now 3 months without any treatment. Between the admission and the occurrence of respiratory decompensation, hypereosinophilia (1610/mL) was observed with recovery in normal value after interruption of risperidone. We also noted an improvement of functional respiratory test. In conclusion, risperidone is an anti-psychotic drug largely used. Severe side effect may endanger life-threatening as described in this case. The recurrence of severe acute respiratory distress without induced factors founded needs to discuss the potential role of this drug.

Social phobia and co-morbid states-diagnosics and importance

S. Anakiev^{1,*}, G. Tasic²

¹ Special Hospital for Psychiatric Disease, Male admission department, Gornja Toponica, Serbia

² Special Hospital for Psychiatric Disease, Department for Psycho-social rehabilitation treatment, Gornja Toponica, Serbia

* Corresponding author.

Introduction The roots of social phobia, lay in the social nature of human beings who fulfil their basic needs in social relations. By the definition, it is the fear of witnessing the negative judgement and the criticism of other people, which is so intense that, is followed by reactions of avoidance of phobic situations and doings, followed by intense vegetative symptoms.

Aim Introduce social phobia as an important social and medical problem with common co-morbidity and exceptional risk of suicide. At the same time it gives special accent to the diagnostic procedures and differential diagnosis.

Method Analysis of the information from literature and practice and coming to conclusions with the inductive method.

Results Social phobia is a chronicle illness, equally present in both sexes. The central position is taken by all-the-time present intense irrational fear. Alcoholism, misuse of sedatives, depression, and panic with agoraphobia, OCD are common followers of social phobia. Differential diagnosis witch eliminates panic with agoraphobia, or just the lack of social skills allows the right therapeutic approach.

Conclusion Social phobia, alone or combined with other disorders, has a huge medical and social value. Coming back to regular life tracks depends on the right diagnosis and the right time to go into the healing process.

Postnatal depression: Can visual media and dramatisation of a young woman's experiences, enable student health care professionals develop knowledge to enhance clinical practice skills?

A. Lyons*, S. Church

London South Bank University, School of Health and Social Care, London, United Kingdom

* Corresponding author.

Introduction Since the presentation of the symptoms of postnatal depression (PND) can vary; healthcare professionals must receive the appropriate level of training to develop the knowledge required for the effective assessment and referral of women. Yet, healthcare professionals may have limited knowledge in perinatal mental health and students may lack practice opportunities to develop the knowledge and clinical skills. For these reasons, the use of alternative learning resources within perinatal mental health education is vital.

Objectives To explore the use of visual media in perinatal mental health education.

Aims Against the background of increasing concerns about the ability of professionals to assess women with PND, this paper will consider how using dramatisation as a teaching approach can enable students to develop their knowledge and guide clinical skill development.

Methods Three separate groups of senior student midwives and health visitors were asked to evaluate a dramatisation developed from women's lived experience of PND. Pre and post verbal evaluation of the drama were undertaken with the use of focus groups guided by semi-structured questions. Ethical approval was granted by the university.

Results Following thematic analysis three issues were identified: –the role of the healthcare professional; –improvements needed in care; –issues of education and training.

Conclusions Against the background of limited placement experience and opportunity for assessment of PND, the use of visual media can improve student healthcare professionals' learning; with the use of structured facilitation, there is a great potential for multidisciplinary learning.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Depression and anxiety among Tunisian medical students “binge viewers”

M. Boudali, M. Hamza, S. Bourgou, L. Jouini*, F. Charfi, A. Belhadj

Hopital Mongi Slim, Child Psychiatry, Tunis, Tunisia

* Corresponding author.

Introduction Since the advent of online streaming television, a new behavioural phenomenon have emerged among millennial, named “binge watching” that is viewing more than two episodes of a TV show in the same sitting. Whether or not this behaviour reflects emotional difficulties has been poorly studied.

Aims Describe the phenomenon and search a possible link with depression and anxiety.

Methods Fifty medical students were recruited. A questionnaire exploring the circumstances, the purpose and the outcome of the binge viewing was fulfilled. The Beck depressive inventory and the

state-trait anxiety inventory were passed for the assessment of depression and anxiety.

Results Among the 50 students questioned, 68% met the criteria of binge viewers and 64.7% of them adopted this behaviour at least once a week with an overall average of screen exposure of 3.8 hours in one sitting. Before the binge watching, 35.3% reported excitement and 29.4% boredom and have used it mostly to pass time (47.1%) and for fun (44.1%). Participants have felt more relaxed and happier after the viewing. Mild depression was found in 10 cases and moderate depression in 5 cases. Anxiety scores averaged 35.38 for state anxiety and 40.32 for trait anxiety. An inverse relationship was found between depression and anxiety scores and the frequency of the binge watching and its exposure duration. The correlation was however non significant.

Conclusions Could it be that the binge watching is a means of fighting against anxiety and depression rather than an evidence of emotional difficulties? Further studies are needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Emotional and personal development of preschool age children with speech disorders: Drawing test study

N. Burlakova^{1,*}, Y. Fedorova¹, L. Pechnikova¹, V. Oleshkevich²

¹ Lomonosov Moscow State University, Faculty of Psychology, Department of Neuro and Pathopsychology, Moscow, Russia

² Applied Research Center for Child and Adolescent Mental Health named after G.E. Sukhareva, Research Department, Moscow, Russia

* Corresponding author.

Introduction Drawing tests provide good opportunity to research potential risks in emotional and personal development of a child with speech disorder, because drawing tests almost do not involve speech.

Aims and objects The research was aimed at detecting potential risks in emotional and personal development of children with speech disorders. The study involved 28 children (15 girls and 13 boys) with moderate speech disorders and 30 normally developing children. All the children attended kindergarten and were of age 5.5 years at the moment of the research.

Methods The following methods were used: non-participant and participant observation, expert assessment, structured interview with educators, individually conducted family drawing test.

Results Most children (86%) expressed willingness to perform a task, in some cases (14%) children failed to perform a task because of emotional numbing. The children's perception of a specialist was marked by increased anxiety and stress, in some cases it was expressed in a drawing by filled areas (38%) or by barely visible figures (62%). Most children (87%) tried to demonstrate their abilities and were diligent, but their drawings were generally poorer than that of normally developing children. This phenomenon reflects deficit of skills, imagination deficit and low level of aspiration. Quality of drawings and their visible from differ from the drawings of normally developing children that indicates low self-esteem and feeling of personal incapacity formed by speech disorder.

Conclusion Increased anxiety, constriction and imagination deficit characterize children with speech disorders. Their emotional attitude to speech behavior influences their graphical self-fulfilment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Mental health of roofless and squatter population in north Catalonia

F. Calvo^{1,*}, C. Giral², X. Carbonell³

¹ FPCEE Blanquerna, Universitat Ramon Llull, Cas Girona, Girona, Spain

² Institut d'Assistència Sanitària, Spain

³ FPCEE Blanquerna, Universitat Ramon Llull, Psychology, Barcelona, Spain

* Corresponding author.

Introduction Homelessness is a phenomenon, which is hard to limit, as it contemplates different situations including roofless and squatters.

Objective To determine the presence of these homeless categories in the city of Girona and examine the prevalence of diagnosed mental pathology and its principal socio-demographic characteristics.

Methods Transversal, observational and analytic study of the population of roofless people and squatters. The registers of the outreach street work team, the local police and the public shelter were used in order to detect the cases and their basic socio-demographic characteristics. The clinical record of the mental health and addiction public network was accessed to determine their diagnosis.

Results During the 6 years of registers, 781 cases of people in situation of roofless and squatters were detected. In total, 83.2% ($n=630$) of the cases were men and 16.8% ($n=131$) women. The average age was 44.8 (ED=11.2) and no differences were found regarding gender (Men=45.3, ED=11.0 vs. Women=42.9, ED=12.2; $t=1.7$, $df=405$, $P=09$). However differences were found regarding origin (Immigrants= 42.2 years, ED=10.3 vs. Natives=46.8 years, ED=11.4; $t=-4.2$, $df=402$, $P<.001$). A total of, 52.9% of the cases ($n=412$) displayed diagnosed mental pathology and 15.8 ($n=123$), dual pathology.

Conclusion Mental pathology is more prevalent among this typology of homeless people than in general population, as other studies prove.

What happened with the homeless during economical crisis? Evolution of the prevalence of homelessness in north-Catalonia (2006–2015)

F. Calvo^{1,*}, C. Giral², X. Carbonell¹

¹ FPCEE Blanquerna, URL, Psychology, Barcelona, Spain

² Institut d'Assistència Sanitària, CAS Girona, Girona, Spain

* Corresponding author.

Introduction There exists a great number of empirical studies which refer as causes of homelessness not only individual factors such as mental disorders or addictions, but also structural factors such as poverty rates or unemployment.

Objective To describe the evolution of the prevalence of homelessness in Girona from 2006 to 2015, and compare it with the evolution of unemployment in the same region.

Methods The absolute number of homelessness is obtained from the official records in the city of Girona, which include the data of the open medium intervention team, the local police, and the specific municipal hostel. The rates are calculated on the annual totals of population. Correlations are used to compare quantitative variables.

Results The yearly homelessness rates increased progressively from 2006 to 2014, the year in which they began to decrease. Similarly, unemployment both in Spain and in the city of Girona in particular evolves in a similar way, with the burden of the world-

wide economic crisis. There exists a positive correlation between the evolution of homelessness in Girona and unemployment both in Spain ($r = 9.4, P < .001$) and in Girona ($r = 9.5, P < .001$).

Conclusion The effect of the economic crisis affects the people who are socially excluded in a direct way. These results prompt the investigation of the causes of homelessness, which in many cases are attributed to the responsibility of the individuals.

Disclosure of interest The authors have not supplied their declaration of competing interest.

“It is safer to sell marihuana than heroin or cocaine and you make more money” qualitative study about drug traffic and consumption in Girona (eastern sector)[☆]

F. Calvo*, C. Giralt

Institut D'assistencia Sanitaria, Cas Girona, Girona, Spain

* Corresponding author.

Introduction Font de la Pólvera is a neighbourhood located on Catalonia, which has been one of the most important points of sale of heroin and cocaine in the country. The sale of drugs was also affected by the economic crisis, changing the behaviour pattern of patients with drug dependence.

Objective To describe the changes in drug trafficking in this region and how these influence their consumption.

Methods The investigation is carried out by the harm reduction outreach team, who selected, with a non-probabilistic method, a sample of 6 drug users. An in-depth semi-structured interview was conducted.

Results From 2006 to 2012, there existed up to 19 points of drug sale of heroin and cocaine. There are currently 2. The reasons behind the decrease are:

- the demand for cocaine decreases;
- the sporadic consumption of heroin decreases;
- with the decrease in demand, drugs lose quality.

With the housing bubble in Spain and the rise in foreclosures on behalf of banks, empty flats proliferated in the area, which were eventually occupied illegally. This fact prompts the production of cannabis.

Conclusion Many of the strictly punitive actions in the control of narcotics lead to the dealers coming up with new ideas and new patterns of consumption which complicate the intervention of the teams working in the territory.

Disclosure of interest The authors have not supplied their declaration of competing interest.

[☆] The inverted commas refer to a sentence uttered by an interviewee during the investigation.

Characteristics of 23 cases of animal hoarding in Catalonia (Spain)

C. González¹, P. Calvo^{1,*}, J. Bowen², A. Bulbena¹, R. Cirac¹, A. Holloway¹, J. Fatjó¹

¹ Universitat Autònoma de Barcelona, Psychiatry and Forensic Medicine, Barcelona, Spain

² Royal Veterinary College, Behavioural Medicine, London, United Kingdom

* Corresponding author.

Introduction Animal hoarding is considered an under-reported problem, which affects the welfare of both people and animals. Few reports on animal hoarding are available in scientific literature, particularly outside North America.

Objectives We designed a study to analyse cases of animal hoarding in Catalonia.

Aims We wanted to expose the presence and consequences of this disorder in our area and to check for cross-cultural similarities with previous studies in other countries.

Methods Data was obtained retrospectively from 23 case reports of animal hoarding in Catalonia collected by city councils and the Catalanian police from 1992 to 2015.

Results Thirty-three people (20 women and 13 men) and 1521 animals, mainly dogs and cats, were involved. Most cases ($n = 13$) involved a sole animal hoarder. Most cases ($n = 14$) were chronic (lasting longer than 5 years). Object hoarding co-morbidity was found in most cases ($n = 17$). All hoarders were over 40-years-old, with half of them aged over 65. Only in 4 cases was an intervention by the healthcare system reported. Most of the hoarders (9 out of 13) actively opposed animal removal. In more than 50% of cases, the hoarder's personal care, health and financial situation were precarious. No awareness of the impaired welfare of the animals was found in most cases.

Conclusions To the author's knowledge, this is the first study on animal hoarding in Catalonia and one of the few available in Europe. Our results are aligned with previous research, adding evidence of cross-cultural common elements of animal hoarding.

Huntington disease, to have or not to have: That is the question – the importance of psychiatric symptoms

L. Carvalhão Gil*, M. Lázaro, L. Queiroz

Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisboa, Portugal

* Corresponding author.

Introduction Huntington's disease (HD) is an autosomal dominant inherited neurodegenerative disorder, beginning in adulthood. HD represents the majority of patients who present the triad of motor, cognitive and psychiatric symptoms. The last two may be early manifestations, but the clinical diagnosis is based on motor symptoms and a positive genetic test for CAG repeat extension. The remaining patients that are negative for the HD genetic mutation may have HD phenocopies.

Objectives Illustrate the role of psychiatric assessment, discuss the psychiatric and behavioural manifestations, and management.

Aims Illustrate the challenge of diagnosing HD in psychiatry.

Methods A literature search was performed on PubMed database. The patient clinical record was reviewed.

Results We report a case of a 49-year-old male with a family history of HD (mother, uncle, cousin). He was diagnosed with a psychotic disorder fifteen years ago, hospitalised twice and thereafter treated as an outpatient with fluphenazine long-acting injection. He was a symptomatic for ten years. During the last year, he started showing dysphoria, marked irritability, stammering, inappropriate behaviour, poorly structured paranoid delusions, mild cognitive impairment and lack of insight. This was correlated with the beginning of functional impairment, both professionally and socially. Further assessment was performed: neurological evaluation, head CT scan and the genetic test was negative. He is clinically stable under haloperidol long-acting injection.

Conclusions HD is a rare condition which is frequently under diagnosed, especially in early stages, due to lack of recognition of psychiatric symptoms. HD-like disorders should be considered if the clinical picture is obvious, but HD gene test result is negative.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Frontal meningioma and bipolar disorder: Etiopathogenic link or co-morbidity? A case report

I. Chaari*, H. Ben Ammar, R. Nefzi, N. Mhedhbi, E. Khelifa, A. Aissa, Z. El Hechmi

Razi Hospital, F Psychiatry Department, Mannouba, Tunisia

* Corresponding author.

Introduction Frontal meningiomas are benign brain tumours known for their late onset. They may be presented by only psychiatric symptoms. Thus, the diagnosis at early stages can be missed or overlooked until the tumour causes neurological deficit.

Case report We report the case of a 61-year-old man, receiving a treatment and a follow-up for bipolar disorder for 11 years. He has history of 3 major depressive episodes, 2 suicide attempts and a manic episode. The symptoms were initially well controlled by medication. Since 6 months, the patient started to experience atypical symptoms: he had presented disinhibited and aggressive behaviour, psychomotor instability, pyromania and self-neglect. The patient did not respond to treatment despite repeated adjustments. A frontal syndrome was suspected. Cerebral CT scan revealed an unexpected mass measuring 6.8 cm × 5.6 cm at the right frontal area, suggestive of a giant meningioma (Fig 1).

Conclusions Generally, once diagnosed, psychiatric disorders are rarely revised. Consequently, “silent” tumours such as frontal meningiomas can be overlooked. Neuroimaging should be considered in case of new-onset psychiatric symptoms, atypical or change in clinical presentation.

Fig. 1 The tumor was totally resected and the frontal syndrome disappeared. The mood disorder is again controlled by usual treatment

Development of a preliminary tool to assess care-giving practices by family members with Schizophrenia: A report from India

S. Das

Assistant Professor, Department of Psychiatry, Government Medical College and Hospital, 160030 Chandigarh, India

Introduction Care-giving practices by family members have inherent value and importance in the provision of care for patients

with schizophrenia. There is dearth of assessment tools that focus on practices followed by caregivers' while dealing with their relatives with schizophrenia, especially from India.

Objective To develop a tool for the assessment of 'care-giving practices' followed by family members while caring for their patients with schizophrenia.

Aims (a) To construct a reliable and valid tool on 'care-giving practices' followed by family members while caring for their patients with schizophrenia; (b) To determine the various 'good' and 'bad' practices within this tool.

Methods Initial detailed literature (Pubmed, Goggle search with input by the caregivers generated a list of 24 commonly used practices; which was shortened to 17 statements whose face validity was tested by 14 mental health professionals. Hindi translation with 'test-retest' reliability was conducted. Finally, 'Consensus based approach' was adopted by the mental health professionals to arrive at objective (b) i.e. statements reflecting 'good' or 'bad' practice.

Results Final questionnaire comprised 15 statements with adequate face and content validity and high test-retest reliability (Cronbach's alpha = 0.747). 6 items reflected 'good' and 9 reflected 'poor' practice respectively with maximum score of 15; and categorization from 'very poor' to 'very good' practices.

Conclusion This preliminary yet simple and easy to use tool will give better understanding about how family members provide 'care-giving' practices for patients with schizophrenia. However, this needs further validation, replicability, and possible modifications in a multi-cultural, multi-linguistic country like India.

The effectiveness of emotion regulation and distress tolerance skills on improving coping strategies and reduce perceived stress in prisoners

R. Davoodi^{1,*}, S. Ghahari²

¹ Psychology, Clinical, shaft, Iran

² Psychology, Clinical, Tehran, Iran

* Corresponding author.

Objective The aim of this study was the effectiveness of emotion regulation and distress tolerance skills on improving coping strategies and reduce perceived stress in prisoners in Foman city in Iran.

Method The study population was consisted of 200 prisoners of Foman Penitentiary in 2016. Then, 30 prisoners were selected randomly in two groups (15 persons each group) were replaced. Emotion regulation and distress tolerance training was given to the experimental group for 12 sessions and the control group were in waiting list. Both groups at baseline and end of intervention phase filled coping responses inventory Bellinger and mouse and Cohen perceived stress questionnaire – version 14 questions (PSS-14). Data were analysed by using the software spss22.

Findings Emotion regulation and distress tolerance skills have been effective on Improving problem-focused coping strategies and reduce perceived stress in prisoners ($P < 0/001$).

Discussion and conclusion emotion regulation and distress tolerance skills can improve problem-focused coping strategies and reduce the use of emotion-focused coping strategies and perceived stress in prisoners.

The compare of early maladaptive schemas, emotion regulation and general health in offender prisoner men and normal group men

R. Davooodi^{1,*}, S. Ghahari², M.R. Pirmoradi²¹ Clinical Psychologist, Department of Mental health in Azad University Tonekaboon, Shaft, Iran² Clinical Psychologist, University of Medical Science, Tehran, Iran

* Corresponding author.

Object The aim of this study was to compare early maladaptive schemas, emotion regulation and general health in offender prisoner men and normal group men.

Methods The study method was causal – comparative (ex post facto). Participants included two groups: (1) all of offender prisoner men ($n=47$) in Fooman jail and (2) normal group men ($n=47$) in Fooman. Both groups were matched for age, occupation and education. All of the participants completed Young maladaptive schema questionnaire (Y MSQ), cognitive emotion regulation questionnaire (CERQ-P) and general health questionnaire (GHQ-12) individually. Data were analysed using independent t-test and multivariate analysis of variance (MANOVA).

Finding There was significant difference between two groups in total score of early maladaptive schema questionnaire and also in its subscales included abandonment, impaired autonomy/performance, impaired limits, other – directedness, over vigilance/inhibition, emotional inhibition ($P<0/01$). The general health was different between groups, too. In addition, while groups showed significant difference in total score of emotion regulation and one of the subscales (rumination), no significant difference was explored between groups in self-blame, acceptance, positive refocusing, planning refocusing, positive re-evaluation, perspective taking, catastrophizing and others blame.

Conclusion Significant differences between the two groups in terms of general health, schema dimensions and emotional regulation dimensions suggest that dysfunctional schemas, maladaptive emotional strategies and low general health could be involved in criminal behaviour.

Keywords Early maladaptive schemas; Emotion regulation; General health; Offender men

CADASIL case report: Psychiatric symptoms as first manifestation of a neurological process

N. De Uribe-viloria^{1,*}, M. De Lera Alfonso², M. Gomez Garcia¹, M. De Lorenzo Calzon¹, A. Alonso Sanchez¹, H. De La Red Gallego¹, G. Medina Ojeda¹, F. De Uribe Ladron De Cegama¹¹ Hospital Clinico Universitario De Valladolid, Psychiatry, Valladolid, Spain² Hospital Clinico Universitario De Valladolid, Neurology, Valladolid, Spain

* Corresponding author.

Introduction CADASIL (Cerebral Autosomal-Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy), the most common form of hereditary stroke disorder, is characterized by headaches, transient ischemic attacks and psychiatric symptoms which include mood changes, behaviour disorders and variable levels of dementia.

Objectives and aims To emphasize the necessity of discarding somatic and neurological processes before a psychiatric diagnosis is reached.

Methods We present a case initially followed in psychiatry and derived to neurology, and compare it with articles no older than ten years, found in a bibliographic search in Medline (PubMed), fitting the next keywords: CADASIL, autosomal dominant encephalopathy, psychiatric symptoms.

Results The most frequent manifestation of CADASIL is the early age onset of cerebrovascular ischemic attacks, nonetheless, a fair percentage of patients debut with insidious psychiatric symptoms, especially mood changes, behavioural disorders and even mutism. Independently of the age of onset, these symptoms are present at some point of the illness in most cases.

Conclusions Psychiatric symptoms can be found in a vast number of somatic and neurological disorders, even being the first manifestation of such processes. This challenges diagnosis, and given than the line between brain and mind is blurred and not always clear, cooperation among different specialities is of utmost importance in order to correctly treat the illness as a whole, and not just the sum of the parts.

Job satisfaction, burnout and coping strategies: Comparison between medical and surgical specialties

C. Derbel*, A. Braham, A. Souilem, A. Ben Romdhane, R. Gallala, S. Ben Nasr, A.S. Bannour, B. Ben Hadj Ali

CHU Farhat Hached, Psychiatry, Sousse, Tunisia

* Corresponding author.

Introduction Doctors have many constraints in their professional practice, which influence negatively the quality of their performance. This causes a psychological distress.

Aim To compare job satisfaction (JS), burnout (BT), anxiety, depression and coping strategies among doctors of medical (DMS) and surgical specialties (DSS).

Method Comparative and cross-sectional study conducted among 33 DMS and 63 DSS with different grades, in the university hospital Farhat Hached Sousse, Tunisia. We used job satisfaction scale (JSS) to determine the degree of JS, hospital anxiety and depression scale (HADS) to evaluate anxiety and depression, the Maslach burnout inventory to assess the BT and the brief cope to determine coping strategies.

Results DMS were older than the DSS ($P=0.005$). The MSC had more unsettled family life ($P=0.04$) and more monthly guard (5.87 vs. 4.96, $P=0.03$). DMS had more days of outpatient ($P=0.00$), were more satisfied with the work schedule ($P=0.00$), conditions of the guards ($P=0.02$). Relationships with colleagues were more satisfactory among DMS ($P=0.001$). DMS were less confronted to violent events ($P=0.03$). The average score of JSS was higher among DMS ($P=0.014$). The BT was more reported in the DSS ($P=0.049$). An average sub-score HADS-D (depression) was higher in the DSS ($P=0.00$). An avoidance-focused coping was more adopted by the DSS ($P=0.02$).

Conclusion DSS were generally less satisfied in their work than DMS with obvious psychological repercussions. This incites to intervene in factors that interfere with job satisfaction to improve the quality of physicians' performance.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0846

Factors associated with job satisfaction among physicians in a university hospital

C. Derbel*, A. Braham, A. Souilem, A. Ben Romdhane, R. Gallala, S. Ben Nasr, A.S. Bannour, B. Ben Hadj Ali
 CHU Farhat Hached, Psychiatry, Sousse, Tunisia
 * Corresponding author.

Introduction Several professional and personal factors determine the degree of job satisfaction (JS) which is a necessary condition to ensure good quality work, especially for physicians working in university hospitals (UH).

Aims To determine the degree of JS in a population of physicians working in UH and to determine the factors associated with the JS.
Method Cross-sectional, descriptive and analytical study involving 96 physicians with different grades in Farhat Hached University Hospital, Sousse, Tunisia. We used Job Satisfaction Scale (JSS) to assess the degree of JS, Hospital Anxiety And Depression Scale to assess anxiety and depression, Maslach Burnout Inventory to determine burnout (BT).

Results The average age was 28.15 ± 4.10 years. Doctors with medical specialty were the majority (65.6%). Most doctors were dissatisfied with their work (67.7%). The socio-demographic factor associated with ST was the young age ($P=0.00$). Occupational factors associated with JS were: shorter time worked in the department ($P=0.02$), lack of outpatient day ($P=0.01$), a lower number of outpatient day ($P=0.02$), dissatisfaction with the work schedule ($P=0.004$), lack of safety ($P=0.00$), salary ($P=0.00$), non-operating skills ($P=0.00$), the distribution of tasks ($P=0.00$), the conditions of the guards ($P=0.00$), ignorance of the laws governing the department ($P=0.00$), BT ($P=0.01$) and depression ($P=0.00$).

Conclusion The majority of our subjects were dissatisfied with their work. Several factors, especially the professional ones contribute to this state. It is necessary to take steps on these factors to improve the performance of doctors working in university hospitals to provide better care for patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Oxytocin and early and current trauma: A systematic review and meta-analysis

M. Donadon^{1,*}, R. Martin Santos², F. De Lima Osório³

¹ Medical School at Ribeirão Preto, Neuroscience and Behavior, Ribeirão Preto, Brazil

² Universidade Autònoma de Barcelona, Universitat Autònoma de Barcelona, Barcelona, Spain

³ Faculdade de Medicina de Ribeirão Preto, Neurociências e Ciências do comportamento, Ribeirão Preto, Brazil

* Corresponding author.

Introduction Oxytocin has been related to traumas and sociability.

Objective To do a systematic review on the relationship between oxytocin and early (ET), current trauma (CT) and PTSD.

Methods The Pubmed, Psycinfo, Web of Science, Lilacs and Scielo database were researched until to April 2016, using the keywords: oxytocin, early trauma, childhood maltreatment, emotional trauma, emotional stress, neglect, adversity, sexual abuse, emotional abuse, physical abuse and PTSD, and Boolean operators. We used a priori protocol based on PRISMA to select observational and quasi/experimental studies in both gender subjects, who suffer ET, CT, or PTSD. A full review was done, and meta-analysis was carried out when possible to estimate the strength of the

association. Strobe, trend and consort statements were used for qualitative assessment.

Results Twenty-eight studies were included: 15 observational, 3 quasi/experimental and 10 RCT. Quality assessment was 60–70%. Due heterogeneity between studies we analysed them in four groups. Meta-analysis of studies of oxytocin endogenous concentration showed a negative correlation with ET ($r=-0.35$; 95%CI = -0.46/-0.22). Association studies of genetic polymorphism of oxytocin gene receptor (rs53576) showed that subjects with ET, CT and GG genotype had higher vulnerability to develop later psychopathology ($P < 0.05$). Quasi/experimental studies measuring pre/post oxytocin concentration after a stress reactivity test in subject with ET, CT or PTSD showed any significant results. Finally, RCT studies showed that acute administration of oxytocin increased the levels of anxiety and flashback in subjects with CT; and decreased in PTSD or ET. These results were in parallel with brain and connectivity activation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Political abuse and forensic psychiatry in communist Romania

S. Hostiuc¹, O. Buda², E. Drima^{3,*}

¹ Carol Davila University of Medicine and Pharmacy, Legal Medicine and Bioethics, Bucharest, Romania

² Carol Davila University of Medicine and Pharmacy, History of Medicine, Bucharest, Romania

³ Clinical Hospital Of Psychiatry "Elisabeta Doamna", Psychiatry, Galati, Romania

* Corresponding author.

Psychiatry was often used for political reasons in the second half of the 20th century, especially in the former communist countries. According to the global initiative on psychiatry, political abuse of psychiatry is defined as the incorrect usage of diagnoses, treatments, or psychiatry admissions in order to limit fundamental rights of persons or population groups in certain countries. Most studies regarding political abuse as a repressive measure analysed it in either USSR or China. Romania is one of the countries from the former communist block in which psychiatry was proven to be used as a form of repression against political dissidents. One of the psychiatry "tools" used against political dissidents was the widespread usage of mandatory, non-voluntary admissions. They were seen as preventive measures, whose purpose was to prevent an individual to act antisocially. The purpose of this article is to analyse the characteristics of the patients that were non-voluntarily admitted in psychiatry hospitals, based on studies published by the forensic psychiatry researchers in the communist period. The main conclusions of this study are: (1) the presence of a disproportionate number of patients admitted with schizophrenia, especially the paranoid type; (2) patients that performed acts against the state were more often diagnosed with schizophrenia; (3) patients that performed acts against the state were more often considered to have no judicial responsibility; (4) the non-voluntary admission/treatment were more often removed for crimes against persons, and less often in crimes against the state.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0849

Can psychopathy be treated?

D. Durães*, R. Borralho

Centro Hospitalar Barreiro-Montijo, Mental Health and Psychiatry Department, Barreiro, Portugal

* Corresponding author.

Introduction Psychopaths are incapable of feeling empathy and guilt, being responsible for most violent crimes. To date, confinement has been the option of choice to minimize the harm they inflict. However, a deeper understanding of the neurobiology of psychopathy may lead to new insight on possible treatment approaches.

Aims This work aims to review the current knowledge in psychopathy treatment.

Methods A literature search of MEDLINE (2000–present) was conducted using the search terms “psychopathy”+“treatment” and “drug therapy”.

Results Defects in the amygdala and the prefrontal cortex have been implicated in the pathological basis of psychopathy. The most affected areas are the ventromedial prefrontal cortex (VMPC) and the associated anterior cingulate cortex. Alterations in connectivity between the amygdala and the VMPC with other areas of the brain have been demonstrated and seem to be responsible for the non-empathetic, unemotional, and amoral features of psychopaths. Also, they present an increase in dopamine turnover and metabolism and a serotonin dysregulation.

As not all individuals with the biological substrate for psychopathy become violent, it seems that plasticity in forebrain circuits may allow the development of more prosocial responses, especially in youth. Some authors emphasize the need to address other behaviours that can be responsible for violent actions, namely, impulsive aggression. Some drugs have shown efficacy in controlling impulsive aggression.

Conclusions Pharmacological approaches to treating psychopathy have been disappointing. A more reasonable goal would be to focus on impulsive aggression, for which treatment effectiveness has been demonstrated. Additional research is needed if we hope to design rational therapeutic strategies for this disorder.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Misophonia is a complex neurobehavioral syndrome phenotypically characterized by heightened autonomic nervous system

arousal and negative emotional reactivity, in response to specific sounds [1–3]. Research from basic and applied fields are synthesized with studies explicitly designed to investigate misophonia in an effort to more specifically conceptualise this syndrome. The purpose of this study is to review the emerging misophonia research and to integrate cross-disciplinary research in order to inform conceptualisation of this recently defined syndrome. Recently published case studies, descriptive studies, and laboratory-based psycho-physiological and neurobiological research are reviewed within a transdiagnostic and multi-disciplinary perspective. Finally, a brief discussion of updated neuroscience paradigms of emotion, including defence/fear circuitry related to the amygdala, is included to help more clearly contextualise findings from previous research and inform future studies investigating misophonia. From this perspective misophonia may be considered a central nervous system dysfunction associated with threat cue responding. Clinical implications should first stress coping skills, as there is no evidence-based treatment for misophonia. Ideally, clinicians would work together in cross-disciplinary teams to assist in individualizing coping skills plans for patients. However, for each clinician understanding the neurophysiological, emotional and behaviour manifestations of misophonia is essential, as a practitioner cannot simply apply one specific known therapy at this point, or haphazardly integrate what is known without up-to-date in depth knowledge of the research in so far as it is currently understood, as well as the impact on individual's lives and that of their families.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychogenic polydipsia: A case report

G. Erzin*, K. ozdel, H. Karadağ

Diskapi Yıldırım Beyazıt Education and Research Hospital, Psychiatry, Ankara, Turkey

* Corresponding author.

Introduction Psychogenic or primary polydipsia characterized by excessive thirst and compulsive water drinking is a common problem among psychiatric populations, affecting 6% to 20% of patients. It is frequent in chronic psychiatric diseases, particularly schizophrenia. We report a patient with excessive thirst and diagnosed as PIP syndrome.

Case A 54-year-old, married, female patient had normal vital signs. She has excessive water intake (10–12 L/day). She did not have edema, signs of dehydration or fever. The neurological examination, CT, MRI, and EEG was normal. The laboratory tests were normal. She had started using sertraline 100 mg, 7 months ago due to anxiety disorder. There is not any disease except the anxiety disorder, which is in remission due to the treatment. A total of, 2 µg desmopressin I.M. is applied in fluid restriction test. The urine density is determined as 1.008 mg/dL initially, 1.011 mg/dL one hour later, and 1.013 mg/dL two hours later in the urinary test. The diagnosis is psychogenic polydipsia (primary) according to patient history, the clinical examination, and the test results. The patient is recommended to continue the sertraline 100 mg treatment, and also assigned with fluid restriction behaviour.

Conclusion Since excess water intake periods are correlated with psychotic exacerbations; psychosis and polydipsia might have similar pathiopathologic mechanisms. Polydipsia might be due to anti-cholinergic side effect of some psychiatric drugs. The pathiopathology of the polydipsia and polyuria is not totally enlightened in the psychiatric disorders. In some cases, the fluid intake occurs completely voluntary. Therefore, we decided to present this case.

New method and new access to the grieving and clinical tool of the thanatology

S. Färber*, M. Färber

VIVER Psicologia e Tanatologia, Tanatologia, Cascavel, Brazil

* Corresponding author.

Introduction Educational advice for coping with loss and resolution of grief: VIVER[®], proposes new method of research and action in the field of thanatology and grief psychology through systematic meetings, group in which the intervention takes place under the simultaneous care professionals of thanatology and psychology.

Objective To present the principles that underlie the research typology and grief subject, its implications in the grieving process and the service to the mourning proposed by VIVER[®] assistance.

Methods Thanatological hermeneutics and literature review were used to develop this work.

Results The educational assistance VIVER[®] offers a useful tool in the care of the mourning by the method, created by Färber and Färber, composed of two pillars: the presentation of educational content about loss and grief, and artistic, playful and expressive experiences.

Conclusion The work on operational groups listening and intervention assists the development of losses and reinterpretation of the history of the participants.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Thanatology as a resource in the care of addicts and people with mental disorders

S. Färber^{1,*}, M. Färber²

¹ VIVER Psicologia e Tanatologia, Tanatologia, Cascavel, Brazil

² VIVER Psicologia e Tanatologia, Psicologia, Cascavel, Brazil

* Corresponding author.

Introduction The purpose of this research is to present multidisciplinary and relevance of Thanatology in coping of addictions and other mental disorders.

Objective The aim of this paper is to analyse the scientific connections that thanatology establishes with other knowledge. With this postulate we present the thanatology and its relations with other disciplines, especially psychiatry, considering that addictions and mental disorders often have as triggering events of loss, death and mourning.

Methods To develop this research we use the systematic literature review, following the process of research, cataloging, careful evaluation and synthesis of the documentation.

Results Thanatology is multidisciplinary shares and receives information from other sciences or sectors of knowledge without these modified or enriched. It is interdisciplinary because it originated disciplinary specialty of a mother discipline: Anthropology; and it is transdisciplinary, thence its relevance in research on the realities that revolve around mental disorders and addictions (Fig. 1).

Conclusion It is important to research on thanatology position in the scientific panorama, given the emergence of this reflection and the relevance of research for its interrelationship with other disciplines.

Psychological and physical impact of violence in psychiatric nurses

L. Fattah Moghaddam^{1,*}, A. Memari², M. Bamdad²

¹ Islamic Azad University, Department of Psychiatric Nursing, Tehran, Iran

² University of Social Welfare and Rehabilitation Sciences Tehran, Psychiatric nursing, Tehran, Iran

* Corresponding author.

Introduction Violence in therapeutic centers, especially psychiatric wards is much higher than other units. In healthcare provider groups, nurses are at high risk of patient's aggression in the workplace.

Aims The aim of this study is to evaluate the effect of violence on the health of nurses in Razi Hospital in Tehran, Iran.

Method In this cross-sectional study a total of 312 nurses working in psychiatric hospitals completed a GHQ28 questionnaire.

Results The results demonstrated that there is a statistical significant correlation between violence of patients (including physical violence and disrespect) to physical symptoms, anxiety and sleep disorder in nurses ($P < 0.05$). Also, increased frequency of disrespect by family of patient correlated to higher physical symptoms, anxiety, and sleep disorder in nurses. However, there was not any significant correlation between symptoms of depression, social function with aggressive patients.

Conclusion Patients and their relative's violence affect the health of nurses. Therefore, it is necessary the therapeutic interventions for the prevention of physical and mental diseases in nurses and decreased desire to leave the organization.

Protagonist-patient and servant-doctor: A medicine for the sick doctor-patient relationship

I. Ferraz*, A. Guedes

Clinica Veritas, Ambulatorio, Curitiba, Brazil

* Corresponding author.

The doctor-patient relationship (DPR) is very ill; it is in need of emergency assistance. Although there have been change in this relationship, no current model is satisfying. In 1972, Robert Veatch defined some models of DPR. Likewise, Pierloot, in 1983, and Balint, in 1975 and ultimately, Mead and Bower, 2000 with the model of Person-center-care (PCC) medicine.

Objective Evaluate the different kinds of DPR described in the literature and propose an abduction-based model of the Servant DPR, in which patients are protagonists in their treatment.

Methods Pubmed literature review of the last forty years with the keyword 'physician-patient relations'.

Discussion While nursing care advanced in its professional efficacy through Watson's human care and through the leader servant model, the DPR models demonstrated that the doctors are lost in their posture, even feeling as abused heroes. Models that include the patient in decision-making and that value the patient as a person (PCC) promise a revolution in the medical realm. Nevertheless, the PCC model is not enough to heal the DPR itself, because the role of the doctor must be changed to adapt to the relationship, otherwise, the PCC by itself can increase the burden upon the doctor. Doctors with a role of remunerated servant (not slave), like any other professional who delivers a service with excellence, focusing in the main actor, the patient, can heal the DPR.

Conclusion The Servant DPR gives a positive counter transference, increasing the doctor's motivation and giving him back the sense of purpose in medicine, increasing the health system's effectiveness.

Asenapine in the treatment of trichotillomania with comorbid bipolar disorder: A case report

B. Francis*, S.T. Jambunathan, J.S. Gill

University Malaya, Department of Psychological Medicine, Kuala Lumpur, Malaysia

* Corresponding author.

Trichotillomania has been found to be associated with mood disorders, particularly bipolar disorder. Trichotillomania has shared similarities with bipolar disorder by virtue of phenomenology, co-morbidity, and psychopharmacologic observations. In the past, trichotillomania with comorbid bipolar disorder was treated with lithium and sodium valproate. There has been little, if any, literature on using asenapine to augment treatment in patients with trichotillomania with comorbid bipolar disorder. A patient presented with hair-pulling episodes for a year, resulting in bald scalp patches. She had no mood symptoms prior to this. She developed low mood, anhedonia, poor sleep and poor appetite subsequently as she could not stop pulling her hair. She was started on escitalopram 10 mg daily for her depressive symptoms. Three years later, she developed hypomanic symptoms such as irritability and spending sprees. Her hair pulling behaviour worsened at this time. At this point, a diagnosis of bipolar disorder type 2 was considered and she was started on lithium 300 mg daily. Her escitalopram was discontinued. As her mood was still labile 10 months later, asenapine was added to augment lithium in the treatment of the bipolar disorder. With asenapine, her hair pulling frequency started to decrease rapidly.

Asenapine was increased to 10 mg daily and her hair pulling ceased. Her mood also stabilized and she no longer had erratic periods of mood lability. In conclusion, asenapine augmentation of lithium has potential to be used in patients who have trichotillomania with comorbid bipolar disorder due to its unique receptor profile.

A case for considering differences between organic and psychogenic amnesia

R. García López*, J.M. Gota Garcés, J. García Jiménez, J.E. Muñoz Negro, L. Gutiérrez-Rojas

Complejo Hospitalario Universitario de Granada, Mental Health, Granada, Spain

* Corresponding author.

Introduction Medical record, general examination, laboratory findings, neuropsychological interview and multidisciplinary consideration are essential to establish differential diagnosis and correct approach in amnesic episodes.

Aim To describe differences between organic and psychogenic anterograde amnesia.

Methods Single case report and literature review.

Results A 51-year-old man with only diagnosis of DM I, single, a good relationship with his family, without any personal or familiar psychiatric or neurological history, came to the hospital emergency department brought by his sisters referring disorientation, acute memory loss and mood changes, prevailing indifference to the situation for the last three days. After general exploration, including psychopathological examination and higher brain functions study, we arrived to the conclusion that the patient suffered from anterograde short-term severe amnesia as the only symptom, with evident conservation of autobiographic memory. The family referred as a possible stressor factor his mother's recent transfer to a different city, which had caused constant repeated questions about her location. Given the questionable presentation and trigger we shared the case with the neurologist, who ordered an array of tests to rule out any organic cause (LP, CT, MRI...), obtaining as a final result a diagnosis of limbic encephalitis, treated and effectively solved in two weeks with high-dose glucocorticoids.

Conclusion Certain features of the symptoms exploration in amnesic episodes such as reiterative questioning about a specific topic, a non-modified autobiography or the absence of a clear traumatic precipitant factor, are essential for a correct approach and may lead the clinic to an organic evaluation.

Mental flexibility and problem solving in adult patients who present non-suicidal self-injury

A.K. Garreto*, J. Giusti, M. Oliveira, H. Tavares, D. Rossini, S. Scivoletto

University of São Paulo School of Medicine, Department and Institute of Psychiatry, São Paulo, Brazil

* Corresponding author.

Introduction Non-Suicidal Self-Injury (NSSI) is considered a dysfunctional way of dealing with problem situations.

Objective This study aimed to investigate the problem solving capacity in adults with NSSI compared to controls.

Methods Thirty-three patients who sought treatment for NSSI (NSSI group) were compared with 33 individuals without psychiatric disorder (control group). We also investigated Axis I disorders, executive functions and problem solving capacity.

Results In both groups, the majority were women (77.25%) with a mean age of 30 years, and the beginning of NSSI behavior of 16 years. The most common NSSI behaviour was skin cutting, and the most common reason given for engaging in that behaviour was “to stop negative feelings”. The most common psychiatric comorbidities were major depressive disorder (60.6%). Compared to controls, the group with NSSI showed lower results in relation to problem solving capacity ($P=0.000$) and mental flexibility ($P=0.007$). Deficits in problem solving capacity may be a reflection of low mental flexibility of adults with NSSI. This may be a risk factor for the beginning of NSSI and the persistence of it in adulthood.

Conclusion Early identification and treatment focused on problem solving capacity during the adolescence may prevent the chronicity of NSSI.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Associations between gender and obesity among adults psychiatric outpatients in the town of Gabes (Tunisia)

L. Ghanmi^{1,*}, K. Zitoun¹, I. Hachaichi¹, S. Hamrouni¹, O. Salem¹, L. Zouari², M. Maalej²

¹ Psychiatry Department, Regional Hospital of Gabes, Gabes, Tunisia

² Psychiatry “C”, University Hospital Hedi Chaker, Sfax, Tunisia

* Corresponding author.

Background Patients with severe mental illness (SMI) suffer from two to three times higher rates of obesity, and this has translated into much higher rates of obesity-related morbidity and premature mortality in this population.

Aims Measuring the frequency of obesity and its associations with gender, and others socio-demographics factors among 115 adults psychiatric outpatients.

Methods A cross-sectional study, was conducted to assess frequency of obesity among 115 adults attending public mental health department in the regional hospital of Gabes (south of Tunisia). For the diagnosis of mental disorders, we used the diagnostic and statistical manual of mental disorders (DSM-V). Obesity was estimated by body mass index (BMI). This index is defined as the ratio of weight (kg) to squared size (m²). Overweight is defined as a BMI between 25 and 29.9 kg/m² and obesity by a BMI ≥ 30 kg/m². BMI was measured directly and other information was gathered by interview.

Results The mean BMI was 25. In our patients, 40.9% were overweight, 49.6% ($n=57$) were obese including 8.7% ($n=10$) who were morbidly obese. Obesity was significantly more frequent in women (63.8% vs 39.7%, $P=0.009$), living in a couple (60.9% vs 42%, $P=0.03$) and having a medium or high socioeconomic level (53.3% vs 30.4%, $P=0.03$). There were no differences between obese and non-obese regarding age, level of education and professional status.

Conclusion The high prevalence of obesity among women suggests that targeted approaches are needed to promote optimal physical health in this population.

Does listening to Mozart's music influence visuospatial short-term memory in young adults?

V. Giannouli^{1,*}, S. Popa²

¹ Aristotle University of Thessaloniki, School of Medicine, Drama, Greece

² State University of Moldova, Faculty of Psychology and Educational Sciences, Chişinău, Moldova

* Corresponding author.

Introduction Music is claimed to improve mental function and many researchers claim that this effect related to Mozart's music is limited to enhancement of the spatial temporal reasoning and not to other cognitive functions.

Objectives To explore the influence of Mozart's music on visuospatial memory.

Methods Sixty adults (37 women and 23 men), with $M_{age} = 21.83$, $SD_{age} = 2.38$, $M_{education} = 14.03$, $SD_{education} = .99$, and without any formal musical education were examined through an experimental process. Participants in groups of ten listened to Mozart's sonata for two pianos in D major, K.448, to Mozart's violin concerto No.3 in G major, K.216, and to a no sounds condition in varying order. The participants after listening to each 10-minute condition were presented with a series of randomly generated patterns made up of black squares on a chess-like surface. This was used in order to test the storage capacity of their visuospatial memory. After 3 seconds of presentation for each drawing, they were asked to reproduce by drawing these patterns that progressively got bigger.

Results Results revealed for all three conditions that the number of correct grid drawings made by the participants was not significantly statistically different ($P>05$), and therefore their visuospatial memory retention was not influenced by any kind of music.

Conclusions Future research could examine in more detail the retention and manipulation of visuospatial information not only in tasks similar to the visual patterns test, but also in different tests used for clinical and non-clinical populations.

⁶ Centro de Salud Mental 2, Adults, Gijón, Spain

⁷ Hospital Universitario Central de Asturias, Unidad de hospitalización psiquiátrica, Oviedo, Spain

* Corresponding author.

Introduction Psychiatric patients tend to have severe metabolic alterations of multifactorial causes, lifestyle, diet, drug use and psychopharmacological treatment, especially antipsychotic drugs which act as risk factors for cardiovascular disease, strokes, infections and complications of diseases basal negatively influencing its evolution and prognosis.

Objectives Rating the profile lipid and the prevalence of obesity in patients registered as disorder mental severe in treatment with antipsychotics.

Aims/methods A descriptive study was performed taking as variables to take into account levels of cholesterol, triglycerides, weight and size.

Results Of the 28 patients included in the study 7 refused to perform the corresponding measurements. Of the 21 remaining, 3 showed values higher than 150 mg/dl triglycerides and cholesterol figures higher than 200 mg/dl. Other 3 patients presented hypercholesterolemia without alteration of triglycerides and 2 hypertriglyceridemia without elevation of the cholesterol. Concerning the IMC, found that 7 patients presented overweight (BMI >25 and <30) and 5 patients obesity (BMI >30). Of the 8 patients with lipid disorders, 2 had prescribed treatment with risperidone (oral or injectable) more quetiapine, 2 oral risperidone as monotherapy, risperidone 1 more amisulpride, 1 quetiapine more aripiprazole, quetiapine 1 in monotherapy and 1 injection invega more oxcarbamacepina.

Conclusions We found lipid alterations in a 38.1% of patients and a BMI greater than 25 in a 57.14% of 21 patients who agreed to the study. The most prescribed antipsychotic among these patients were risperidone (5 patients) followed closely by quetiapine (4 patients).

Waiting for the child cleft lip and/or palate surgery: Differences between mothers and fathers' experiences

V. Guerriero^{1,*}, A. Gnazzo¹, G. de Campora¹, E. Vegni², G.C. Zavattini¹

¹ Sapienza University of Rome, Department of Clinic and Dynamic Psychology, Roma, Italy

² University of Milan, Department of Health Science, Milano, Italy

* Corresponding author.

Introduction Literature on parents of children affected from cleft lip and/or palate has described the risk of higher levels of stress and anxiety during the pre-surgery period. To the best of our knowledge, just one study has empirically investigated the differences in the psychosocial adjustment of both mothers and fathers, but information on the pre-surgery period were not given. Given that, the aim of the current study is to evaluate the psychological functioning of both parents waiting for the child operation.

Method Data from 34 Italian parents (F=18; M=16; Mean age = 36.62, SD = 6.07) of children affected by cleft lip and/or palate (Mean age = 12 months; SD = 13.75 months) were collected during the pre-hospitalization visits. The following questionnaires were administered, respectively to mothers and fathers: PSI-SF, MSPSS, PACQ, DAS and FACES-IV.

Results Data shows no significant differences between fathers and mothers on the total score of each variable taken into account. Differently, significant differences emerge on the "Self Blame" PACQ subscales.

Conclusions Mothers and fathers seem to share the same psychological experience during their child pre-surgery period. To note, our preliminary data highlight the maternal perception as featured by a greater sense of guilty for the child's disease. The feeling of guilt may be a risk factor for the parental ability to cope with the experiences of the child's illness, influencing parental care giving and parent-child relationship.

Couple satisfaction and parenting stress in parents of children with ASD

V. Guerriero^{1,*}, I. Fioravanti¹, M. Petrillo², M. Di Renzo², G.C. Zavattini¹

¹ Sapienza University of Rome, Dynamic and Clinical Psychology, Rome, Italy

² Istituto di Ortofonologia, IdO, Rome, Italy

* Corresponding author.

Introduction Literature on parents' adjustment in families with autism spectrum disorder (ASD) children highlights on one hand that raising a child with ASD represent a higher stressful experience comparing to families of children with other disabilities and families of children with typical development. On the other hand, a recent systematic review on relationship satisfaction of these parents stressed the very lower levels of couple satisfaction in parents raising a child with ASD. Given that, the aim of this study is to investigate the association between relationship satisfaction and parental stress in a sample of parents of ASD children.

Method 70 parents were recruited (34 = M and 36 = F) to sign the following self-reports: Parenting stress index-short-form (PSI-SF), to assess stress relative to parental role, and dyadic adjustment scale (DAS), to assess couple satisfaction.

Results The analysis showed no differences between mothers and fathers respect to investigated variables. Negative correlations between almost all subscales of the PSI-SF and the subscales of DAS emerged. Moreover, from the regression analysis performed, it can be concluded that the values of the total score of the DAS predicts the PSI-SF total score.

Conclusions In accordance with and building on the achievements of previous studies, these data illustrate a positive influence of couple adjustment on parental stress in parents of ASD children, supporting the hypothesis that relationship satisfaction emerge as a protective variables in the process of parental adaptation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0864

Justinus Kerner and mesmerism

S. Häfner

CELENUS German Clinic of Integrative Medicine and Rehabilitation, Behavioral Medicine and Psychosomatics, Bad Elster, Germany

Introduction The German physician and poet Justinus Kerner (1786–1862), Swabian public health officer in Weinsberg, is well known as an allround, even an epoch-making personality in his time and a natural scientist typical for late romanticism. His greatest merit is not due to his poetic scripts, but to his scientific work. This begins with his medical dissertation "Observata de functione singularum partium auris", a mine of experimental behaviourism.

Objectives The aim of this study is to evaluate the influence of Franz Anton Mesmer (1734–1815) on Kerner's way of treating patients.

Methods A literature research was done on Kerner and mesmerism.

Results Kerner's first contact with animal magnetism was in 1797, when he was magnetized and healed by Dr. Eberhard Gmelin, one of the first mesmerian doctors in Germany, because of his nervous stomach. With the "Seeress of Prevorst" the author ventured to advance into deep layers of the soul unknown so far. During the years 1826–1829 Justinus Kerner treated Friederike Hauffe (1801–1829), the "Seeress of Prevorst", at his Weinsberg domicile. In the year 1829 he published the description of her life and disease with the title "The Seeress of Prevorst, being revelations concerning the inner-life of man, and the interdiffusion of a world of spirits in the one we inhabit".

Conclusions Kerner was very much influenced by Mesmer and left volumes of psycho-pathological case histories that helped to prepare a way for a medicine more psychotherapeutically founded.

Anxiety and depression in patients with gastroesophageal reflux disorder

S.A. Haji seyed javadi

Qazvin university of medical sciences, Psychiatry Psychiatry, Qazvin, Iran

Introduction Evidence shows an influence relationship between described symptoms of gastroesophageal reflux disorder (GERD) and emotional state.

Objectives/aims The current study aimed to evaluate the relationship between anxiety and depression with GERD in the patients referred to the endoscopy unit of Bouali-Sina hospital of Qazvin.

Methods Two hundred individuals (100 patients with GERD and 100 healthy individuals as control group) were enrolled into the current study. All subjects completed the hospital anxiety and depression questionnaire. GERD was diagnosed based on Los Angeles classification system. Demographic and socioeconomic characteristics in addition to clinical history of subjects were collected and analyzed using proper statistical methods.

Results Among the recruited patients, 50 subjects had erosive esophagitis (ERD) and 50 had non-erosive esophagitis (NERD). The anxiety score was significantly higher in the NERD group than ERD and control groups ($P < 0.001$; $P = 0.017$). In addition, the anxiety score was significantly higher in the ERD group than the control group ($P = 0.014$). The score of depression was higher in NERD group than ERD and the control groups, but not significant regarding the ERD group ($P < 0.001$). There was no significant difference among the groups regarding age, gender and body mass index (BMI). The number of smokers was significantly higher in the ERD group than the ERD and control groups ($X^2 = 39.59$, $DF = 6$, $P < 0.001$).

Conclusion The current study showed that mental factors (anxiety and depression) play important roles in the development of GERD, especially NERD; therefore, it is recommended to consider these factors to select suitable treatment plan.

Psychiatric causes of unfitness for military service

H. El Kefi^{1,*}, M.A. Medeb², C. Bechikh Brahim¹, I. Bouzouita¹, W. Krir¹, S. Eddif¹, A. Oumaya¹

¹ Hôpital militaire principal d'instruction de Tunis, PSYCHIATRY, Tunis, Tunisia

² Hôpital Maamouri Nabeul, Forensic medicine unit, Tunis, Tunisia

* Corresponding author.

Introduction The national service is a duty for every Tunisian citizen. The knowledge of psychiatric causes of unfitness for military service would enable developing standardized procedures for selecting and psychiatric assessment of young candidates.

Objectives Determination of the diagnostic categories, frequency and factors associated with psychiatric causes of unfitness for military service.

Method This was a retrospective, descriptive study, performed on medical files of candidates examined between the 1st of January and the 31st of December 2015 at the military hospital of Tunis.

Results Eight hundred and seventy-two subjects were examined as a part of an assessment for mental fitness for military service. They were male, single, with an average age of 23.73 ± 3.5 years. Alcohol was consumed by 17.9% of subjects, cannabis by 12.8% and psychotropic by 4.7%. Fourteen percent had self-mutilation, 8.5% had criminal record and 5.3% had tattoos. Military unfitness was found in 80.8% of cases. The main causes of unfitness were anti-social personality disorder (40.6%), hysterical neurosis (14.9%), adjustment disorders (14.5%) and limited intellectual level (7.5%). The average length of service before found unfit was 9.14 months for anti-social personality, 5.94 months for adjustment disorders and 1.78 months for psychotic disorders. This period was significantly longer for the personality disorders (8.62 months) compared to psychotic disorders ($P = 0.013$) or to non-psychotic disorders (5.05 months, $P < 0.001$).

Conclusion The evaluation on the mental ability of military personnel must be performed at an early date, given the financial, material and human consequences that would result from a delayed diagnosis.

¹ Cardiff University School of Medicine, Medical School, Cardiff, United Kingdom

² Cardiff and Vale University Health Board, General Adult Psychiatry, Cardiff, United Kingdom

³ Cardiff University School of Medicine, MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff, United Kingdom

* Corresponding author.

Introduction Venous thromboembolism (VTE) is a potentially fatal condition. Hospital-associated VTE leads to more than 25,000 deaths per year in the UK. Therefore identification of at-risk patients is crucial. Psychiatric in-patients have unique factors which may affect their risk of VTE (antipsychotic prescription, restraint) however there are currently no UK guidelines which specifically address VTE risk in this population.

Objectives We assessed VTE risk among psychiatric inpatients in Cardiff and Vale university health board, Wales, UK, and whether proformas currently provided for VTE risk assessment were being completed.

Methods All acute adult in-patient and old age psychiatric wards were assessed by a team of medical students and a junior doctor over three days. We used the UK department of health VTE risk assessment tool which was adapted to include factors specific for psychiatric patients. We also assessed if there were concerns about prescribing VTE prophylaxis (compression stockings or anticoagulants), because of a history of self-harm or ligature use.

Results Of the 145 patients included, 0% had a completed VTE risk assessment form. We found 38.6% to be at an increased risk of VTE and there were concerns about prescribing VTE prophylaxis in 31% of patients.

Conclusions Our findings suggest that VTE risk assessment is not being carried out on psychiatric wards. Staff education is needed to improve awareness of VTE. Specific guidance for this population is needed due to the presence of unique risk factors in psychiatric in-patients and concerns regarding VTE prophylaxis.

Sensation seeking and religious orientation: Correlation study

S. Hatam^{1,*}, D. Lea Baranovich¹, M. Shahbazi-Fard²¹ University of Malaya, Faculty of Education- Educational Psychology and Counseling, Kuala Lumpur, Malaysia² Islamic Azad University, General Psychology, Yasooj, Iran

* Corresponding author.

Introduction Religious orientation is a tendency to religious thoughts and performances, which contain the attitudes, beliefs and religious practices. Sensation seeking is a personality trait whereby seeking new feelings and experiences, innovative, complex and intense desire for taking physical and social risks.

Aim The purpose of the study is to predict the religious orientation based on emotional intelligence.

Method The current study utilized Alport's religious orientation questionnaire and Zukerman's sensation seeking questionnaire and applied the correlation method that provides an illustration of anticipating religious orientation. Of all the population of one university in IRAN, 116 participations were selected by using a multistage random sampling method.

Result The finding indicates that based on the emotional intelligence and its components, religious orientation is predictable.

Conclusion It is found that a significant positive correlation holds for emotional intelligence with external religious orientation. In addition, it is showed that a significant negative correlation holds for emotional intelligence with internal religious orientation.

The relationship between parent perfectionism and childhood anxiety of their children in female Refah bank employees in Tehran

S. Heidari

Tarbiat Modares University, Humanity, Tehran, Iran

Although many studies have investigated the relationship between perfectionism and anxiety among the adults, little is known about the manifestations of the effects of parent perfectionism on anxiety of children in Iran. This study was conducted to examine the relationship between positive and negative perfectionism of mothers whist anxiety of their children in an Iranian sample. Besides the study of effects of mother's perfectionism and how can make serious problems for their children is another aim of this research. The study was consisted of 150 women of Refah Bank employees and their 8–15 years old children, which were selected by a multi-stage random cluster sampling. In order to evaluation, the positive and negative perfectionism scale and the revised children's manifest anxiety were assessed. After data collection, Pearson correlation and stepwise regression, using SPSS were conducted. Results showed that positive perfectionism of mothers was not correlated significantly with their child's anxiety. However, mothers' negative perfectionism was associated positively with children anxiety which was significant at 0.01 probability level. Analysis of stepwise regression showed that mothers' perfectionism predicted anxiety of their child. It can be concluded that negative perfectionism of mothers can directly and indirectly have negative effects on children and provide serious problems for them. Our findings indicate that although we must take care of unhealthy and neurotic consequences of negative perfectionism but positive striving for perfection can help us to improve in some aspects.

“Dangerous relationships”: Family dynamics among members with severe mental illness. about a case

G. Hernandez Santillan^{1,*}, E. Martin Ballesteros²¹ Hospital Universitario Príncipe de Asturias., Resident Physician Psychiatry, Madrid, Spain² Hospital Universitario Príncipe de Asturias, Psychiatry, Madrid, Spain

* Corresponding author.

A 51-year-old woman from a Mediterranean location with a history of a brother diagnosed with schizophrenia, moved thirty years ago, away from her family of origin, when marrying a man suffering from severe untreated OCD, who in turn, has two brothers, both with OCD, and a nephew with OCD. She says that her husband is very unsociable, spends most of the day at work and comes home at night to clean for a long time until he does not see lint on the floor or a crumb on the table literally. They have a fifteen-year-old son, with needy materials, very attached to the mother and very little to the father. The patient consults, motivated by a former sister-in-law and a friend, because they have noticed deterioration in their self-care and tendency to isolation, which the patient explains because in the last year she has noticed exacerbation of the comments by her neighbours and even unknown people that tell her “look how dirty, your husband has to come after work to clean your house, and makes noise.” The companions are also concerned that the child has had school and social problems and admits hearing the same as his mother. Now, What possible diagnoses do we propose in this patient: Folie a deux, delusional disorder, paraphrenia, other? (Figure 1)

Needs assessment of people with severe mental illnesses and their families in Azerbaijan

J. Ismayilova

National Mental Health Center, Consultation and Treatment Department, Baku, Azerbaijan

Needs assessment of people with severe mental health problems and their family members provides important information necessary for developing effective interventions at both population and individual level. The study aimed to determine various

needs perceived by patients with SMI and their family members, as well as to find out possible relations between the needs and socio-demographic and clinical variables. Similarly the study was intended to evaluate family burden and users' satisfaction with services.

Fifty dyads of a patient and family members applying for outpatient services were participated in the study. Sociodemographic questionnaire, Brief Psychiatric Rating Scale, Camberwell assessment of needs, involvement evaluation questionnaire and verona service satisfaction scale were used as assessment tools.

The most unmet needs reported by people with SMI and their relatives were psychological distress, social activities and welfare benefits. The study showed significant burden in families caring for people with SMI, which correlated with their views about patients' needs and had a negative impact on the psychological well-being. Evaluation of satisfaction with services pointed out the gap between provided and desired services reported by patients and their relatives. Most of study participants wished to have sheltered work, or receive help in finding employment.

The study results suggest that in order to achieve better outcomes, services for persons with SMI should be developed in accordance with patients' most prominent needs. With this regard needs assessment should become an integral part of routine clinical practice. The results may be used for mental health service planning, development and evaluation.

Work memory and inhibition in abused children

M.C. Jimenez Martinez

Universidad pedagógica y tecnológica de Colombia, Grupo Desarrollo Humano Cognición y Educación Escuela de Psicología, Tunja, Colombia

Introduction It has been shown that children with a history of abuse tend to have a deficit in both their academic and cognitive abilities. Mesa-Gresa, P., & Moya-Albiol, L. (2011) [1]. This study aimed to identify the relationship between abuse (psychological, neglect, custody and abandonment) and the performance of executive functions of memory of verbal work and inhibition.

Method The Executive Function battery (Gonzalez, M., & Ostrosky, F., 2012) [2] was applied to 38 preschoolers 4–5 year olds who have experience abuse and to 36 preschoolers who have not. Data was analysed using the test t for independent samples and the Chi-cuadrado from Pearson.

Results Inhibition was affected in children with psychological abuse and negligence. It means that children presented difficulty in controlling their behaviour. Children victim of abandonment showed lower performance of executive functions of memory of verbal work. Such function allows them to carry on daily activities efficiently. Conversely, children without previous history of abuse showed higher performance in both tests especially in inhibition.

Conclusion Findings suggest that child abuse in preschoolers can influence the performance in their executive functions without difference in gender.

Keywords Executive functions; Child abuse; Preschoolers; Inhibition; Memory of verbal work

* Corresponding author.

Introduction Akathisia is commonly known for its objective components such as rocking while standing or sitting and lifting feet. However, little is known about its psychiatric impact that can even lead to suicidal attempts.

Objectives The aim of this study is to investigate the main psychiatric symptoms associated with akathisia in a Tunisian sample of patients under treatment for Schizophrenia, Schizoaffective or Bipolar Disorder.

Methods Fifteen patients were diagnosed with akathisia using the Barnes Akathisia Scale. Psychiatric symptoms related to akathisia such as mood lability, sadness, anxiety, aggressivity, suicidal ideation, insomnia and social and professional impairment were assessed.

Results The average age of the sample was 47 years. The average antipsychotic chlorpromazine-equivalent total dosage was 1756mg. All patients reported at least one psychiatric symptom imputed to akathisia. These were: mood lability ($n = 11$), inner restlessness ($n = 10$), anxiety ($n = 10$), sadness ($n = 10$), aggressivity ($n = 6$), and insomnia ($n = 12$). Eight patients described suicidal ideation and five confessed having committed a suicide attempt. Four and ten said akathisia had professional and social impact respectively. The prevalence of psychiatric symptoms did not differ according to sex, age, diagnosis, illness duration, presence of a comorbid anxiety disorder, the number and types of antipsychotics used, the antipsychotic chlorpromazine-equivalent total dosage or the reported drug compliance.

Conclusions Psychiatric symptoms resulting from Akathisia remain frequently undetected. Special interest by the clinician is required to elicit these symptoms.

⁴ European University of Tirana, Department of Education, Tirana, Albania

* Corresponding author.

Introduction Anxiety and depression is becoming an increasingly important public health issue. The adolescents' population is among affected seriously.

Objectives The objectives of the study was to investigate the level of anxiety, depression and self-esteem among adolescents and explore links between.

Methodology Participants were 99 adolescents randomly selected in school, aged between 12 to 19 years ($M=14.88$; $SD=2.09$); in terms of gender composition, there were girls 41.1% and boys 58.9%. The measures used included the Albanian versions of depression self-rating scale for children, the revised children's manifest anxiety scale, and the rosenberg self-esteem scale. All data has been analysed by SPSS 21 and Excel 2007.

Results Results showed that clinical significant levels reported 10.3% of participants for anxiety and 22.4% for depression. With low self-esteem scored 16.3% of participants. Self-esteem is significantly negatively correlated only with depression ($r = -.433, P < .00$). Mann-Whitney Test didn't found significant differences in anxiety based on self-esteem levels. Mann-Whitney Test found significant differences in depression levels based on levels of self-esteem ($Md_{low\ self-esteem} = 15; n = 16; Md_{normal\ self-esteem} = 10; n = 81$) as adolescents with low self-esteem had significantly higher depression as compared to adolescents with normal self-esteem ($z = -2.876, P < .004$).

Conclusions Findings suggested that self-esteem and depression links are present but not links self-esteem and anxiety. It is important to investigate these relationships in future research aimed identification/interventions programs.

Diagnoses among students, patients of psychiatric outpatient ambulatory in student health centre of ljubljana university

E. Kajin

Student's Health Centre of Ljubljana University, Aškerčeva 4, 1000 Ljubljana, Slovenia

Introduction Health care for students in Slovenia was organized immediately after the WWII. It slowly developed and in late 1960's extended with specialist ambulatories, including psychiatric.

Objectives Survey of primary psychiatric diagnoses in one school year.

Method Research of patient's primary psychiatric diagnoses of the school year 2015/2016.

Results During 1.9.2015–31.8.2016, there were 1126 patients diagnosed in the age group younger than 29 years, while number of diagnoses was 90 (see Table 1).

Conclusions Most patients were diagnosed with one among anxiety disorders, followed by one of the mood [affective] disorders while the third most common diagnosis was one of schizophrenic spectre. The findings are at least approximately consistent with data elsewhere.

Table 1

Blocks of diagnostic classifications	No. of diagnoses in certain blocks	No. of patients	% of patients
Mental disorders due to PAS use (F10-F19)	1	1	0.1
Schizophrenia, schizotypal and delusional disorders (F20-F29)	16	111	9.9
Mood [affective] disorders (F30-F39)	24	273	24.3
Neurotic, stress-related and somatoform disorders (F40-F48)	21	543	48.3
Behavioural syndromes . . . (F50-F59)	7	31	2.6
Disorders of adult personality and behaviour (F60-F69)	11	96	8.5
Disorders of psychological development (F80-F89)	2	2	0.2
Behavioural and emotional disorders . . . (F90-F98)	2	60	5.3
Other non-mental disorders	2	2	0.2
Z71.x (Counselling and medical advice)	4	7	0.6
	90 diagnoses	1126 patients	100

Malingering and medicalization in Israeli higher education: A critical inquiry of students feigning learning disorders

O. Katchergin

Oranim academic college, sociology and anthropology, Kiryat-Tivon, Israel

This lecture stimulates new thinking about learning-disorders. Previous research in Israel regarding students with learning-disorders did not analyze the social processes through which students acquire the disability label. Therefore, the scenario of some students seeking the learning-disorder label in order to gain academic advantage has not been discussed in the professional literature within this context. The lecture is based on forty in-depth interviews conducted with self-testified malingering students who, nonetheless, were diagnosed as learning-disordered. Using sociological and naratological frameworks, the lecture discusses the strategies used by the students prior to, and during, their formal diagnoses, in order

to influence the diagnosis outcome and convince the diagnosticians that they were genuinely “learning-disordered”. The strategies are divided into three clusters corresponding to the pre-diagnostic, diagnostic, and diagnostic-interview stages. The students’ stories challenge a number of assumptions that are embedded in the educational–academic and medical discourses regarding students with learning-disorders. Moreover, the lecture maps the reasons used by the interviewees in order to justify pretending to be learning-disordered. Prominent among these rationalizations are claims of “equal opportunity”, “objective science”, “lack of choice”, “everybody does it” and “it’s a unique situation”, as well as minimizing statements. Finally, the clinical cases described are placed within the current Israeli educational and cultural context characterized by medicalization trends as well as the negative images of “effort” on the one hand, and the meritocratic ethos of “success” on the other. It is suggested that these may shed some light on the ever-growing number Israeli learning-disordered students.

Perfectionism is related with academic stress in medical student

C. Kim*, C. Seockhoon, L. Suyeon, Y. Soyoun, P. Boram
Asan Medical Center, Department of psychiatry, University of Ulsan
College of Medicine, Seoul, Republic of Korea

* Corresponding author.

Objective Especially medical students set high academic standard, and try hard to achieve because they are requested to studying medicine perfectly. Multidimensional perfectionism scale (MPS) is used to measure perfectionism in medical student. The purpose of the present study was to investigate the relationships between stress and various factors including perfectionism.

Methods We enrolled 159 medical students from University of Ulsan college of Medicine. We used the Medical Stress scale (MSS), the Multidimensional Perfectionism Scale (MPS), the patient health questionnaire-9 (PHQ-9), the academic motivation scale (AMS), the insomnia severity scale (ISS), and The revised neo personality inventory.

Result To analyze data, we used Pearson’s correlation and logistic regression analysis. In the first step- Pearson’s correlation analysis, a motivation, PHQ-9, ISI, perfectionism and neuroticism traits of NEO-PI significantly correlated with stress level ($P < 0.001$). In the second step, logistic regression analysis indicated that students who feel high level of academic stress (MSS score ≥ 28) are also related to a motivation, insomnia, perfectionism and neuroticism traits of NEO-PI ($R^2 = 0.389$, $P < 0.05$).

Conclusion Student who tend to be perfect feel more academic stress. The high level of stress related to insomnia and a motivation in medical student. Moreover, personality trait also can influences their psychological stress level.

Internet addiction in adolescents and staying at a dormitory: A controlled study

Y. Kivrak^{1,*}, İ.C. Kivrak²

¹ Medical Faculty, Psychiatry, Kars, Turkey

² Alpaslan Anatolian High School, 4A, Kars, Turkey

* Corresponding author.

Introduction Internet addiction can have important consequences in adolescents. Many adolescents have to live apart from their families for their education during high school. Some of these students stay in dormitories. Despite the many studies on Internet addiction, none of them clarify the Internet addiction status and quality of life of dormitory residents.

Aims Our aim in this study was to determine the internet addiction scores of dormitory residents and evaluate whether a difference was present with students who lived at home.

Methods The subject group consisted of randomly chosen dormitory students. The control group consisted of another randomly chosen student at the same class who was staying at home. The sociodemographic data forms the pediatric quality of life inventory (PedsQL), children’s depression inventory (CDI) and internet addiction test (IAT) were administered.

Results We found lower Internet addiction scores and total psychosocial scores in dormitory students compared to students who lived at home. There was no difference between the groups regarding depression score, physical health total score and quality of life total score.

Conclusions Our results indicate that dormitory students suffer less from Internet addiction than those staying at home while the quality of life is similar. Staying at a dormitory may be protective against and therapeutic for Internet addiction without decreasing the quality of life and missing school for internet addict adolescents as it makes it more difficult for them to access the internet.

The phenomenon of psychological adaptation to the professional activities of doctors

A. Kozhyna*, V. Mykhaylov, V. Viyun
Kharkiv National Medical University, Psychiatry, Kharkiv, Ukraine

* Corresponding author.

Disorders of adaptation of young doctors and students to their the professional activities.

The study was designed to develop a system of psychological adjustment and psychoprophylactic support during professional training based on a systematic approach to the study of the mechanisms of formation of psychological adaptation to the professional activities of doctors.

It was conducted comprehensive examination of 405 interns and of 615 last year’s students of medical universities in Ukraine. 211 interns had adaptation disorders. The data demonstrated individual and personal, social and psychological factors, mechanisms and conditions of psychological adaptation to medical work.

The necessary components of psychological readiness for independent productive activities on the basis of high value professional identity, a positive attitude to the profession, perception of the patient as a personality in a certain psychological state, choice of interpersonal relationships and the use of ethical and deontological knowledge and skills at different stages of treatment process.

The results showed that females have a higher level of disorders of adaptation to professional activity, compared with males. High level of disadaptation, which requires using of emergency measures was founded at 9.2% of men and 12.5% women; moderate level of desadaptation, which requires mandatory intervention of psychologists, conducting rehabilitation programs - 10.3% men, 14.0% women; mild level of desadaptation, in which the useful work of advisory experts - 36.2% and 42.1% respectively.

* Corresponding author.

Introduction The income hospital represents a rupture in the continuity of life of the patient. It would be advisable to determine those variables that help to reduce them. Some studies are running to a paper protector of the treatment injection in the relapses and number of hospitalizations.

Objectives Compare the risk of decompensation, measured in terms of income hospital or consultations to emergency, between patients to treatment injection versus oral.

Aims/methods He is a descriptive study which assesses the number of hospital admissions and consultations to emergency departments in the period of one year (between September 2015 and September 2016) of a sample of 28 patients registered as TMS and the results are compared with the type used for antipsicótico treatment via.

Results We start from a sample of 28 patients, of which 17 are still a treatment intramuscular and 11 have all your guideline prescribed in oral. Patients injection treatment group needed to be admitted to a psychiatric inpatient unit at least on one occasion in the past year, 7 patients and 11 patients to oral treatment, only 2 patients were admitted and other 2 came once to your referral hospital emergency department.

Conclusions Of the 17 patients to treatment with injectable ingestion or needed care urgently a 41.18%, facing the 36.36% of those patients to treatment by via oral. These results do not have a protective role of injectable treatment compared with decompensation measures according to need hospitalization or urgent attention.

Academic burnout and personality traits in Korean medical students

H. Chae¹, S.J. Lee^{2,*}

¹ Pusan National University, School of Korean Medicine, Yangsan, Republic of Korea

² Kyungil University, Department of Psychotherapy, Gyeongsan-si, Republic of Korea

* Corresponding author.

Objectives Personality was shown to play an important role for well being under academic stress. The purpose of the present study was to evaluate how temperament and character traits predict academic burnout in Korean medical students.

Methods One hundred and seventy-eight Korean medical students completed the Cloninger's temperament and character inventory (TCI) at the beginning of semester and Maslach burnout inventory-student survey (MBI-SS) was also measured around the final exam when academic stress and burnout is at the highest. The correlation between TCI and MBI-SS was examined and stepwise regression analysis was performed to measure how well personality traits predict academic burnout level.

Results The MBI-SS total burnout score was correlated positively with harm-avoidance ($r = 0.247, P < 0.05$) and negatively with self-

directedness ($r = -0.296, P < 0.001$) and Cooperativeness ($r = -0.169, P < 0.05$) scores. The regression analysis showed that the harm-avoidance ($\beta = 0.269, P < 0.001$) accounted for exhaustion score and the self-directedness explained the Total burnout score ($\beta = -0.296, P < 0.001$) and Inefficacy score ($\beta = -0.284, P < 0.001$). The Cynicism score was accounted for high Novelty-Seeking ($\beta = 0.150, P < 0.05$) and low Cooperativeness ($\beta = -0.182, P < 0.05$).

Conclusion This study showed that the Cloninger's temperament and character might explain the burnout level from the stressful medical education. The temperament of novelty-seeking and harm-avoidance could provide the susceptibility to the academic burnout and the character of self-directedness and cooperativeness might determine the resilience to the negative influence of academic stress.

Community behavioral health care linkages for youth

C. Leukefeld^{1,*}, M. Tilson², E. McNeese-Winston², R. Seaver², M. Dickson²

¹ University of Kentucky, Behavioral Science, Lexington, USA

² University of Kentucky, Center on Drug and Alcohol Research, Lexington, USA

* Corresponding author.

Introduction and objective behavioral health (BH) agencies have care linkages for youth including juvenile justice (JJ). However, there are few studies on youth care linkages. This study focuses on six sites with the objective of examining BH and JJ staff perceptions about information exchange on screening, assessment and treatment.

Methods We developed an index to quantify BH and JJ staff perceptions of information exchange on youth screening, assessment and treatment. After Informed Consent, staff rated past year interactions from agree to disagree on a 7-point Likert scale. Chi-squares and T-tests were used.

Results All 64 staff consented 17 (26.5%) BH staff and 47 (73.5%) JJ staff. Significant differences included BH staff were more likely to be licensed ($P < .001$) and had a masters degree or higher ($P = < .01$). Professional experience ranged from 9.8 to 15.8 years. However, there were no statistically significant differences. BH staff was somewhat higher from 5.7 for "shared assessment results" to 6.8 for "been easy to talk to" while JJ staff were from 5.1 for "shared screening results" to 6.1 for "treated youth with respect".

Conclusions This pilot study found high rates of staffs agreement including ease of talking and listening, sharing screenings and assessments information, and helping begin, continue, and complete treatment. This high agreement was not expected with confidentiality restrictions and traditions. Future studies should target care linkages including letters of agreement, case conferences, and guidelines.

The study is supported by the National Institutes of Health.

The reality of domestic violence in the US

J. Gonçalves¹, C. Lima^{2,*}

¹ Psychology, USA

² Desenvolvimento Pessoal e Bem, Estar, Unipessoal, Lda, Psicologia, Porto, Portugal

* Corresponding author.

According to the United States department of justice, domestic violence is defined as “a pattern of abusive behaviours in any relationship that are used by one partner to gain or maintain power and control over another intimate partner”. It involves a pattern of coercive behaviour in intimate relationships whereby the behaviour is controlled through humiliation, intimidation, fear, and often intentional physical, emotional or sexual injury. Domestic violence crosses all ethnic, socioeconomic and age groups, and is also prevalent in same sex relationships.

Over six million children are severely assaulted by family members every year in the United States; a man beats a woman every twelve seconds; women who leave their batterer are at 75% greater risk of being killed by their batterer than those who stay; and one third of police time is spending on answering domestic violence calls.

In domestic violence situations the intervention is frequently in crisis, where the victims “fight” for survival, and it is necessary to give proper answers according to the victim’s needs. The professionals that work directly with domestic violence assume that there is a strong bond connecting the domestic violence with mental health. In the United States 90% of domestic violence survivors report extreme emotional distress; 47.5% report having been diagnosed with post-traumatic stress disorder; 14.7% report anxiety; 20% depression. Mental illnesses are frequently observed in domestic violence survivors.

Psychiatric picture of encephalitis: Stigmatisation of psychiatric patient

A. Hrnjica¹, I. Lokmic- Pekic^{1,*}, S. Bise², B. Kurtovic²

¹ Psychiatric Hospital, Intensive Care Sarajevo- Bosnia and Herzegovina, Sarajevo, Bosnia and Herzegovina

² Psychiatric Hospital, Women Department- Sarajevo- Bosnia and Herzegovina, Sarajevo, Bosnia and Herzegovina

* Corresponding author.

Background Psychiatric symptoms/disorders in brain diseases are not specific and may have the same clinical presentations as functional psychiatric disorders, so they can compromise early diagnosing of disease.

Objective This paper’s objective is to show (negative) influence of stigma in a diagnostic process of patients with predominantly psychiatric symptoms in their clinical pictures.

Materials and methods The subject is a 46 year-old female patient with no history of psychiatric disease. Her symptoms includes: confusion, disorientation, perseveration, visual and auditory hallucination, lack of motivation, inability to understand questions, developed following a 10-day long period of febricity. During the outpatient care, she has been examined by a neurologist, a specialist of urgent and internal medicine, and a psychiatrist. As the CT scan made in that stage was interpreted as normal, the patient was hospitalised in a psychiatric hospital. She was treated both with typical and atypical antipsychotics but no therapeutic effects have been reached. Thinking of organic etiology, advanced diagnostics have been made (MR, LP). MR scan showed lesion that is a characteristic for herpetic meningitis, which is also confirmed with positive serological tests.

Conclusion In patients with a sudden onset of psychiatric symptoms, patients with unexpected changes in mental status or suddenly developed headaches, as in the therapy-resistant psychiatric disorders, it is important to keep in mind the possibility of the coexistence of brain disease. Removing the stigma from psychiatric patients is important in order to be able to give every patient the chance of getting the correct diagnose on time.

Women’s personal and political identities in selected Middle East countries

S.F. Lu

University of the Philippines Manila, Department of Social Sciences, Manila, Philippines

Introduction Women’s personal and political identities are significant in defining their roles and eventual contribution to society in contemporary society both in the private and public spheres.

Objectives This research study focuses on the effect of Islam on women’s personal and political identities.

Aims This research aims to highlight the existing ideology relating to women’s treatment in regards their identities and public roles, and hence to contribute to women’s emancipation.

Methods This study utilizes quantitative and qualitative methods in analysing women in eight Muslim-majority countries, namely, Iran, Turkey, Egypt, Saudi Arabia, Jordan, Yemen, Cyprus and Kuwait, in the Middle East. For the quantitative data, statistical dataset was culled from Inter-university consortium for political and social research of the university of Michigan.

Results The overall results show that historical constructions of gender spheres are still palpable in the Islamic landscape. Woman’s question is identified as a complex personal and social problem, and cannot be rejected as a valid search for gender sameness or equality. This study also shows the interpolation of Islam with other factors such as patriarchy, modernization, and state formations. Some Muslim scholars argue that Quran’s fundamental mooring is geared towards equality between men and women, and women’s enhanced status, and it is patriarchy that has confined women to the domestic sphere.

Conclusion Gender is embedded within culture, and structures of power in families, communities, and states, which have gender in itself, as an organizing principle.

Keywords Women’s identities; Middle East; Patriarchy; Gender; Culture

The investigation of nurses’ burnout levels in the context of emotional habitus

B. Malak Akgün^{1,*}, F. Öz²

¹ Ardahan University School of Health Sciences, Department of Nursing, Ardahan, Turkey

² Hacettepe University Faculty of Nursing, Head of Psychiatry Nursing Department, Ankara, Turkey

* Corresponding author.

Introduction The concept of Bourdieu’s habitus effects nurses’ approach to patients. Habitus is the site of nurses’ internalizations of the rules in the field of care work, where nurses acquire emotional habitus that corresponds to ethical values and feeling rules of care work. If nurses do not manage their emotions in accordance with the moral disposition, social suffering will be occur. Determining social suffering helps to understand how a tension between the field of care work and emotional habitus can violate nurses’ well-being and cause burnout.

Objectives To determine the emotional habitus of nurses’ with the high level of burnout.

Methods Clinic nurses of Hacettepe university hospitals constituted the population of this study. Firstly, Nursing Information Form, Maslach Burnout Scale were applied to participating 350 nurses. Secondly, semi-structured thorough individual interviews were made with 39 nurses of 201 with the high level of burnout.

Results With content analysis emotional habitus, problem areas for emotional habitus, results of these problem areas, optimal behavior in expressing feelings of nurses and related to suggestions to gain these statements total twenty themes were reached. Nurses suggested proposals to gain optimal behavior in expressing feelings. These are individual development, obtaining professional knowledge, role modeling, experiencing. Also, nurses wanted to see value by patients and hospital administration and respect patients.

Conclusions To prevent and cope with burnout; it has been proposed that awareness training programmes and course contents about emotional habitus, management emotions should be arranged.

Keywords Nurse; Emotional habitus; The field of care work; Burnout

The evaluation of emotional labor and emotional self-efficacy on burnout among nurses

B. malak akgün^{1,*}, F. Öz²

¹ Ardahan University School of Health Sciences, Department of Nursing, Ardahan, Turkey

² Hacettepe University Faculty of Nursing, Head of Psychiatry Nursing Department, Ankara, Turkey

* Corresponding author.

Introduction Nurses are required to manage their emotions, like being empathetic. Emotion management requires emotional self-efficacy and emotion labour, because learning how to it takes effort. If emotional labor is not managed effectively by nurses, burnout will occur among nurses.

Objectives To evaluate the emotional labor, emotional self-efficacy and burnout levels of nurses.

Methods Clinic nurses of Hacettepe university hospitals constituted the population of this study. Nursing information form, emotional self-efficacy scale, emotional labour Scale and Maslach Burnout Scale were applied to participating 350 nurses.

Results It was found out that nurses went through high level “emotional exhaustion”, medium level “depersonalization”, low level “personal accomplishment” and had medium level emotional self-efficacy sense. It was determined that there was a positively relationship between emotional labor and its sub-dimensions surface acting and emotional effort and depersonalization levels, also there was same relationship between surface acting and emotional exhaustion. There was a negative relationship between emotional self-efficacy sense and emotional exhaustion and depersonalization but there was a positive relationship in personal accomplishments. There was a positive relationship between emotional self-efficacy sense between deep acting, emotional effort and suppression of real emotions. Additionally, discrepancies were found in burnout levels of nurses according to sociodemographic, their working and choice of profession characteristics ($P < .05$).

Conclusions To prevent and cope with burnout; it has been proposed that awareness training programmes and course contents about emotional management, emotional self-efficacy and emotional labour should be arranged.

Keywords Nurse; Emotional labour; Emotional self-efficacy; Burnout

Comparison of noise effects to state anxiety levels of patients and nurses

B. Malak Akgün^{1,*}, M. Akgün²

¹ Ardahan University School of Health Sciences, Department of Nursing, Ardahan, Turkey

² Ardahan University Faculty of Engineering, Environmental Engineering, Ardahan, Turkey

* Corresponding author.

Introduction An quiet environment is comfortable and peaceful. Also, healthy and safety environment is a human right. But, exposure to noise may cause negative effects on psychology and performance. Also, it is a problem in public hospitals, because, noise is an important issue for both nurses and patients.

Objectives The study was designed to determine decibel levels on the hospital's four unified clinics and compare noise effects to state anxiety levels of patients and nurses.

Methods Information Form, Spielberger State-Trait Anxiety Inventory (STAI) were applied to participating 40 patients and 14 nurses. A measurement of the sound level of unified clinics was performed for two days in the morning and after lunch for two days.

Results The range of minimum to maximum decibel levels was significantly greater in nurses' station (38.66 dB versus 82.48 dB) than patient rooms (24.61 dB versus 74.2 dB) ($P < .05$). 25 patients and 14 nurses stated that there was noise in the clinic. 19 patients and 10 nurses expressed that it caused a headache. The state anxiety levels were 39.29 ± 5.61 for nurses and 45.4 ± 4.86 for patients. The state anxiety level of patients were 44.83 ± 3.86 in 1. Clinic, 48.8 ± 4.37 in 2. Clinic, 43.82 ± 4.9 in 3. clinic, 44 ± 5.57 in 4. Clinic.

Conclusions We should reduce the noise level to reduce the level of state anxiety. This study describes one reason to reduce peak noise levels on unified clinics. Standards applied across studies to measure and characterize acoustic environments are urgently needed.

Keywords Noise; Anxiety; Patients; Nurses; Nursing

The investigation of nurses' sociotropic-autonomic personality features levels in the context of emotional habitus

B. Malak Akgün

Ardahan University, School of Health Sciences, Department of Nursing, Ardahan, Turkey

Introduction Researchers who plan to debate the nursing practice habits and nurses' professional-individual self and identity can study out nurse habitus. Habitus affects how the nurses understand care needs of patients. Also, sociotropy-autonomy is important for both the personal and professional development of nurses. According to researchers, professional criteria are autonomy, commitment to the profession and unity consciousness.

Objectives The study was designed to investigate of nurses' sociotropic-autonomic personality features levels in the context of emotional habitus.

Methods Information form, sociotropy-autonomy scale were applied to 10 nurses. Also, semi-structured thorough individual interviews were made with them.

Results Seven nurses have voluntarily chosen their profession and the others are not. Nurses' sociotropy levels were 59.2 ± 22 . Sixteen and autonomy levels were 83.9 ± 22.41 . According to the results of the MWU test ($U = .0 P < .05$), anxiety about disapproval of eight undergraduate nurse ($MR = 4.5$) is lower than two graduated from health school nurse ($MR = 9.5$). Five nurses stated that nursing is appropriate for their personal character. Six nurses stated that nursing influenced the positive development of personal character. With content analysis, similarities and differences between nursing identity and social identity, optimal behaviour in expressing feelings of nurses and emotional habitus themes were reached.

Conclusions Nurse habitus is developed by both of individual and structural factors which are complex and diversity. So, it affects nurses' career and motivation to provide services. That the researcher assesses them from this aspect affects positively the quality of care.

Keywords Nurse; Nursing; Emotional habitus; Sociotropy-autonomy; Personality feature

* Corresponding author.

Introduction The drivers are a central component of traffic system, and their limitations, constraints, needs, motivation, level of alertness, and personality define their behaviours on the road. Understanding the determinants of the driver's behaviour is crucial to find solutions for the serious problem of road accidents.

Objective This study aims to investigate the reliability and the construct validity of the Portuguese version of the driver behaviour questionnaire (DBQ; Reason et al., 1990; Portuguese version: Correia, 2014), using exploratory and confirmatory factor analysis (EFA and CFA) in a sample of Portuguese population.

Methods Participants answered an online survey including socio-demographic questions and the DBQ. Inclusion criteria were: driving license and regular driving for at least three years and age lower than 75-years-old. The sample is composed of 747 participants [417 (55.8%) women; mean age = 42.13 ± 12.349 years; mean driving license years = 21.30 ± 11.338 ; mean years of regular driving = 20.33 ± 11.328]. The total sample was randomly divided in two sub-samples. Sample A ($n = 373$) was used to EFA and sample B ($n = 374$) was used to CFA.

Results The most acceptable model was the three-factor model found with EFA, excluding items 1 and 24 ($\chi^2/df = 2.01$; TLI = .86; CFI = .88; RMSEA = .05, $P = .315$). The internal consistency analysis resulted in: infractions and aggressive driving, $\alpha = .77$; non-intentional errors, $\alpha = .73$; lapses, $\alpha = .71$; total DBQ score, $\alpha = .84$.

Conclusions These results suggest that the Portuguese version of the DBQ is a valid and reliable measure to assess self-reported driver behaviour in the Portuguese population.

* Corresponding author.

Introduction Glucocorticoids are widely prescribed for a variety of diseases and are known to cause neuropsychiatric as well as somatic side effects.

Objective To review the incidence, clinical characteristics, course and treatment of neuropsychiatric effects of glucocorticoids.

Aim We have described the case of a 86-year-old woman. She had no personal and no psychiatric medical history in her family. She presented wrist arthritis requiring high doses of an oral corticoid treatment (prednisona 20 mg/d). After a week, she started with symptoms characterised by persecutory and surveillance delusions. Organicity was ruled out. The patient got a progressive recovery after starting anti-psychotic medication and progressive reduction of the steroid drugs.

Methods We have performed a literature review of the neuropsychiatric complications of glucocorticoids using the PubMed database.

Results Neuropsychiatric effects of glucocorticoids involve affective, behavioural, and cognitive manifestations. The incidence is variable, between 2 and 60% of patients who receive steroids. Although the effects of glucocorticoids are unpredictable, the administered dose is the most significant risk factor for the development of neuropsychiatric symptoms. Dosage reduction typically results in clinical recovery. Although the limited data on this subject, it is a problem that clinicians face on their regular basis. The administration of anti-psychotics or mood stabilizers may be beneficial in the prevention and treatment of this syndrome.

Conclusion The neuropsychiatric effects of glucocorticoids are unpredictable and non-specific. More controlled trials are needed in order to perform evidence-based clinical guidelines for the treatment with glucocorticoids and for the prevention of neuropsychiatric manifestations.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁵ Miguel Torga Institute e Faculty of Medicine of the University of Coimbra, Portugal, Coimbra, Portugal

* Corresponding author.

Introduction Aging is a very heterogeneous and dissimilar process, full of asymmetries. There is evidence that socio-economic differences determine disadvantages and inequalities in old ages. Older people face particular inequalities in healthiness especially with more complex and vulnerable long-term conditions, being more likely to need support from social care services.

Aim To evaluate the quality of life (well-being) related to the health of the elderly according to socio-economic indicators.

Method Cross-sectional quantitative study was performed. A total of 316 elderly people ($M = 74.78$; $SD = 9.78$ years of age) was interviewed with the Portuguese version of the EQ-5D-3L scale for health-related quality of life.

Results The interaction between income and the type of residential follow-up (alone vs. accompanied) was not statistically significant [$F(2,310) = .910$, $P < .407$; $\eta^2 = .006$]. Differences in health status index were statistically significant for income [$F(2,310) = 5.518$, $P < .004$; $\eta^2 = .034$]. Post-hoc comparisons indicated that the mean score for those with insufficient income for their expenses ($M = .39$, $SD = .27$) was significantly different from those with income reaching their expenses ($M = .50$, $SD = .25$) as well as those with income covering their expenses sufficiently ($M = .60$, $SD = .21$). The main effect for the type of follow-up (alone vs. accompanied) did not reach statistical significance [$F(2,310) = .224$, $P < .636$, $\eta^2 = .672$].

Conclusions Income has an impact on health-related quality of life. Health in aging as a social phenomenon is not neutral to economic differences and is exposed to these structural disadvantages.

Alexithymia and coping strategies among medical students

N. Messedi*, I. Feki, B.N. Saguem, R. Masmoudi, J. Masmoudi
Hedi Chaker University Hospital, Psychiatry A, Sfax, Tunisia

* Corresponding author.

Introduction University life is stressful for the student, which is characterized by disturbed emotional regulation or alexithymia. To face these stressful events he must use certain coping strategies.

Objectives Studying the prevalence of alexithymia and exploring coping strategies among medical students, and establish the relationship between these parameters.

Methods It was a cross-sectional study of 97 students in Sfax university medicine (Tunisia). We used:

- a questionnaire containing demographic and clinical data;
- Toronto alexithymia Scale (TAS-20): a score ≥ 61 indicates alexithymia;

- WCC (Ways of Coping Checklist-r Folkman) with 3 factors: problem-focused, emotion-focused and social support coping.

Results The average age of participants was 24.07 years (± 2.71); the sex ratio (M/W) was 0.4. They were smoking in 36.1% and sedentary in 43.3% of case. They had a nibbling activity in 57.7%. The average score of TAS-20 was 50.92 10.46 and alexithymia was found in 16.5% of students. Alexithymia was significantly correlated with smoking ($P = 0.003$) and physical inactivity ($P = 0.025$). Most students (72.2%) opted for problem-focused ways of coping with a highest score at WCC = 29.21. A significant correlation was found between alexithymia and coping strategy with emotion-focused ($P = 0.02$). The TAS score was significantly higher among students who resort to this ways of coping = 26.11. ($P = 0.002$).

Conclusion This study explored the role of alexithymia in stress management ubiquitous in university life. A high level of alexithymia could be a detrimental factor in stress management. Psychological support aimed specifically alexithymic dimension is indispensable.

¹ Federal University of Alagoas, School of Medicine, Maceio, Alagoas, Brazil

² Federal University of Bahia, Instituto de Humanidades Artes e Ciências Professor Milton Santos, Salvador, Brazil

* Corresponding author.

Introduction Maternal mental health is very important to manage children with chronic health problems.

Objective To evaluate the role of maternal common mental disorders (CMD) in the control of asthma in children by taking the maternal stressful life events (SLE) into account.

Aims To improve the management of childhood asthma by using a psychosocial approach.

Methods Cross-sectional study involving mother-asthmatic child dyads assisted in paediatric pulmonology outpatient clinics. To characterize maternal CMD, the Self-report questionnaire (SRQ-20) with cut-off 7/8 was used. The global initiative for asthma control (GINA) questionnaire was used to define controlled and uncontrolled patients. The SLE questionnaire was also used.

Results Table 1 suggests association between uncontrolled asthma with asthma severity and SLE, and a borderline association between uncontrolled asthma and maternal CMD. Table 2 indicates that, considering all independent variables simultaneously, asthma severity is the only variable statistically significant. It is also possible that with a larger sample size, maternal CMD and SLE would also become statistically significant.

Conclusions The frequency of uncontrolled asthma is associated with asthma severity and tended to be higher in children whose mothers had CMD and were exposed to SLE.

Table 1 Crude odd ratios (OR) for the association between asthma control in children, and selected variables ($n = 272$).

VARIABLES		Uncontrolled	Controlled	CRUDE	CI 95%
		asthma	asthma		
		N	N	OR	
Asthma Severity	Moderate and severe	49	36	1.98	1.15–3.41
	Mild	59	86

How much does love really hurt? Psychopathology and romantic relationships: A meta-analysis

A. Mirsu-Paun^{1,*}, J.A. Oliver²

¹ "Carol Davila" University, Department of Medicine, Bucharest, Romania

² Duke University School of Medicine, Department of Psychiatry & Behavioral Sciences, Durham, NC, USA

* Corresponding author.

Introduction Romantic relationship quality (RRQ) and break-ups (RRB) among young adults have been associated with the onset of a first major depressive episode or suicide attempts. However, the size of these associations varies across studies and the relative weight of RRB versus RRQ needs to be understood.

Objectives To investigate (1) the size of the association between adolescent RRQ/RRB and psychopathology (i.e., depression, suicide ideation, deliberate self-harm, and suicide attempt); and (2) the role of potential moderators (e.g., gender, age, and nationality).

Methods A meta-analysis of 20 manuscripts reporting on 21 studies ($n = 19623$) was conducted, focusing specifically on adolescents and young adults. Studies focused on physically abusive relationships were excluded.

Results A model combining relationship quality and break-up yielded a highly significant association between relationship measures and depression/self-harm but the strength of this relationship was modest ($r = .229$). The strength of the association between depression/self-harm and RRQ ($r = .279$) was statistically different from RRB ($r = .145$) ($P = .006$). Location (US vs. Non-US) had no effect. Age was not significant, $B = -0.005$, 95% CI [-0.026, 0.016], $P = .647$. Gender was a weak moderator ($B = .160$, 95% CI [-0.021, 0.340], $P = .083$).

Conclusions The association between psychopathology and RRQ/RRB was statistically significant but relatively small. RRQ was a stronger predictor of depression compared to RRB. This association was slightly stronger for women than for men. Implications for practice and future research will be discussed.

⁵ School of Population and Public Health, Vancouver, Canada

* Corresponding author.

Introduction Fear of childbirth (FOC) is a problematic mental health issue during pregnancy and postpartum period. It is essential to identify the most effective approaches to reduce the problem.

Objective Using meta-analyses, we aimed to examine the most effective intervention for reduction of FOC.

Method We searched the Cochran central register of controlled trials, PubMed, Embase and PsycINFO databases since inception till January 2016 without any language restriction. The reference lists of all included studies were checked for additional published reports and citations of unpublished research. We included randomised control trials and quasi-randomised control trials comparing interventions for treatment of FOC. Two review authors independently assessed trial quality and extracted data. The standardized mean differences (SMD) were pooled using random and fixed effect model. The heterogeneity was determined using the Cochran's test and I^2 index and was further explored in meta-regression model and subgroup analyses. Egger's regression and funnel plot were used for assessing publication bias.

Results Ten studies totalling 3984 participants were included from two quasi-experimental and eight randomised clinical trials. Eight studies investigated education and two studies investigated hypnosis-based intervention. The pooled SMD of FOC for the education intervention and hypnosis group in comparison with control group were -0.46 (95% CI -0.73 to -0.19) and -0.22 (95% CI -0.34 to -0.10), respectively.

Conclusion Interventions were effective on reducing FOC; however educational interventions reduced FOC twice as high as hypnosis. This result highlights the roll of antenatal education in enhancing childbirth expectations and experiences to enhance maternal and neonatal well-being.

Migration, women and education: Iran case study

M. Mohammadi

Education organization, physics, Tehran, Iran

Short description migration of villagers to cities can be damaging the women's status in social affairs and promotion of family. Long description, one of the most controversial problems of rural dwellers' migration to big cities, is the occupation of women in low-level jobs. The villagers mostly have little skills and women are deprived of knowledge and skills to cope with the new situation so that they cannot find good jobs to meet the family needs. The low-level jobs and income by men in black market after having migrated to the cities force women to adopt to work in dirty jobs or work as maid at homes to increase the financial capacities of the family and provide educational facilities for children. This can bring about many dangers for the family. First, children are deprived of

family interaction most part of the day and most of them become trapped with illegal gangs of drug distribution. Second, women can be exploited with the burglary and shoplifting groups who use low educated and poor women. The destiny of most of these women is prison and being away from the family, which in turn worsens the situation. Vocational skills provided by NGOs have helped women to sustain their life but they are not enough. The factors involving with the situation of these women are the main focus of this paper.

² University of Coimbra, Faculty of Medicine, Coimbra, Portugal

* Corresponding author.

Introduction Most mental disorders begin during adolescence and early adulthood (18–24-years-old), highlighting the importance of understanding the onset and progression of mental disorders among youths. Although progress has been made, namely by creating youth mental health transition services, gaps continue to exist. Locally, our recently constituted young adults unit aimed to minimize discontinuities in care.

Objectives/aims To characterize a population of young adult psychiatric outpatients, regarding socio-demographic and clinic variables.

Methods Socio-demographic and clinic characterization of young adult psychiatric outpatients observed during 1st January 2015–30th July 2016.

Results Two hundred and fifty-five outpatients were observed: 64.3% females and 35.7% males, average age 20.56-years-old (median 20). Most lived in urban areas (59.4%), with their parents (27.8%), were students (80.4%), attending secondary school (36.1%). A total of, 27.5% were referenced by an emergency department, and adjustment disorders (ICD-10 F43.2) were the most frequent diagnosis (21.6%). Regarding suicidal behaviours and self-harm, 9.8% did self-cutting. A vast majority did not have previous psychiatric hospitalizations—only 5.9% outpatients had at least one. In total, 39.8% were medicated with antidepressants (1/3 of which in association with other drugs), and about 38.8% received cognitive-behavioural interventions. About 2/3 of patients (66.3%) remained in care and only about 1/6 (15.7%) were discharged.

Conclusions Our typical youth psychiatric outpatient was of female gender, student, living with its parents. Adjustment disorders were the most frequent diagnosis, and antidepressants were the main psychopharmacologic option, often combined with other psychotropic drugs. In the future, psychotherapy interventions should be more widely available, namely group psychotherapy.

Effectiveness of the structural approach components on the marital quality, and problem solving of couples

M. Nafian Dehkordi^{1,*}, S.A. Kimiaee², T. Zandipour¹, H. Hassanabadi²

¹ Alzahra University, Department of Education and Psychology, Tehran, Iran

² Ferdowsi University Of Mashhad FUM, Department of Education Faculty of Education and Psychology, Mashhad, Iran

* Corresponding author.

The aim of this research is investigating the effect of training structural-systematic approach components on marital quality and problem solving of couples. General plan of research is a quasi-experimental with pre-post test and control group. Statistic population includes all clients of psychology and counselling clinic of Ferdowsi Mashhad University couples with marital conflicts and issue in problem solving in 2014. Sample size includes 10 couples in each control and examination group. Examination group has received 10 couple-therapy structural-systematic group meetings. Research tools were two questionnaires; revised marital quality scale and family problem solving (2010). To analyse data ANCOVA method has been used. For analysing data SPSS software has been used. Results have indicated that structural-systematic approach results in significance increment of marital quality and couple problem solving in comparison to control group. It can be said that structural-systematic approach may has a significant effect on family structure having a systematic and comprehensive approach and tries to solve happened problems and defects changing family structure. It is hoped that can progress in couple-therapy and family therapy using this approach.

¹ Centro hospitalar psiquiátrico de Lisboa, psiquiatria, Lisboa, Portugal

² Centro Hospitalar Lisboa Norte, Psiquiatria, Lisboa, Portugal

* Corresponding author.

Introduction HIV (human immunodeficiency virus) infection is related to several neuropsychiatric complications, such as dementia, encephalopathy, psychosis, as well as, opportunistic infections of the central nervous system (CNS). The discovery of antiretroviral therapy (ART) has limited these conditions and extended the life span of infected patients into a chronic illness, but it is also associated with neuropsychiatric adverse effects.

Objectives To review the literature on the most common neuropsychiatric complications of the ART, since it can be difficult to distinguish drugs toxicity, the effects of the virus, immune system and psycho-social events.

Methods The authors have conducted an online search in PubMed with the terms: “Psychiatry”, “HIV”, “adverse effects” and “antiretroviral drugs” from 2011 until 2016. From the outcome were collected, analyzed and summarized the articles considered to be relevant.

Results The antiretroviral therapy (ART) are associated with a numerous adverse effects on the central and peripheral nervous systems, as well as, metabolic, gastrointestinal, cardiac, and other toxicities. The neuropsychiatric effects are common and highly variable, including depression, cognitive impairment and sleep disturbance. The nucleoside reverse transcriptase inhibitors and the

non-nucleoside reverse transcriptase inhibitors are one of the two classes of antiviral drugs most frequently associated with neuropsychiatric complications.

Conclusions The occurrence of new-onset conditions related to ART makes it difficult to determine the association between psychiatric disorders and ART adverse effects, and given the fact that patients commit to lifelong therapy, as well as, they can diminish quality of life; it makes these assessment important in treating these conditions.

Sex differences in psychiatric inpatients: Demographics, psychiatric diagnoses and medical co-morbidities

P. Oliveira*, M. Coroa, N. Madeira, V. Santos
Psychiatry Department, Coimbra Hospital University Centre,
Coimbra, Portugal

* Corresponding author.

Objectives There are few published studies on the relationship between gender and psychiatric disorders. We assessed sex differences in a sample of first-admission psychiatric inpatients to identify possible risk factors and targets for sex-tailored treatment interventions.

Methods A retrospective study of admissions to the psychiatry department, Coimbra hospital University Centre, Portugal, in 2015 was accomplished ($n=924$). The two groups were compared for demographic features, psychiatric diagnoses and medical co-morbidities.

Results Male patients were significantly younger (age average = 47.7 vs. 53.3). Differences in employment, educational, and marital statuses were found between male and female psychiatric patients. Having a degree was a protective factor for males, whereas it was a risk factor for females. Being divorced and single were both risk factors for medical co-morbidity in females. A higher proportion of men among patients hospitalized for schizophrenia (14.9 vs. 5.5%) or substance use disorder (10.3 vs. 2.1%) and a higher proportion of women among those admitted for affective disorders (43.3 vs. 25.9%), including bipolar disorder (13.4 vs. 9.0%), were found. No significant differences in duration of hospitalization between the two groups (22.8 in male vs. 22.2 days in female)

Conclusions The differences between the two groups of inpatients were very pronounced. A better understanding of these differences may help to establish more effective treatment strategies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Who are the Europeans admitted to psychiatric hospital in Tunisia?

U. Ouali*, K. Ben Neticha, R. Jomli, A. Ouertani, F. Nacef
Razi Hospital, Psychiatry A, La Manouba, Tunisia

* Corresponding author.

Introduction A large number of foreign travellers and expatriates visits or lives in Tunisia.

Objectives To explore socio-demographic, clinical and therapeutic characteristics of European patients admitted to psychiatric care in Tunisia.

Methods This is a retrospective, descriptive study on all European patients admitted to Razi psychiatric university hospital, which is

situated at the outskirts of the capital Tunis, between 2000 and 2015.

Results A total of 44 Europeans was admitted. Most frequent nationalities were: French and Germans (19 and 16 patients). The stay in Tunisia was mainly due to pathologic travel (17 subjects) and tourism (13 subjects). In total, 25 patients travelled without being accompanied. Average age was 51.3 years with extremes from 16 to 78 years. A history of psychiatric disorder was found in 15 patients, of whom almost all had stopped treatment. A majority (19 patients) was diagnosed with bipolar I disorder, and 8 patients suffered from schizophrenia. Average duration of hospitalization was 19 days. A total of, 22 patients were repatriated for medical reasons. Major difficulties during hospitalization were the language barrier, difficulties to contact family members or former treating psychiatrists for further information on the patient and his medical history, and the lack of insurance covering repatriation for medical reasons.

Conclusion Psycho-education and early action on the precipitating factors could help to prevent psychiatric illness or relapse in these patients. Furthermore, attention of public authorities should be drawn to incomplete insurance coverage in many psychiatric patients.

New psychiatric service – fresh nurses experiences

A. Pardal*, N. Correia, C. Santos, A. Matos Pires
ULSBA, Psiquiatria, Beja, Portugal

* Corresponding author.

The year 2015 started a new assistance in the cycle of mental health care ending the gap that existed in the district of Beja in the last twenty years, in this area. The aim of this presentation is to give the data of nursing activity in the first six months inpatient psychiatric service. The population studied was 98 inpatients, 53% male and 47% females aged between 16 and 87-years-old, diagnosed with depression, schizophrenia, personality disorders, bipolar disorders, dementias and others. Descriptive statistic of collected data. We rated the gender, marital status, aged and main disorders as well as the nursing therapeutic activities performed with the patients. Six different kinds of activities were done. The total of interventions were 148: relaxation, ludic activities, physical activity, art therapy, health education and music therapy. Nursing intervention in the treatment of people with mental disorders improves the compliance to the treatment (adherence, self-care, useful occupation, stress career and insight of the illness) during the hospitalization time, aiming to avoid the worsening situation and the social isolation of the patient, and promote the recovery and quality of life. These objectives begin on hospital stay during the acute crisis. We are aware of the fact that this is just the beginning of this approach and for more and better results we have to have a bigger sample and a longer time of intervention as well as better methodology, namely the use of scales to measure some parameters that can provide more consistent and objective findings.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychosis and/or Lyme disease: There is more than meets the eye

M.J. Peixoto^{1,*}, S. Timóteo¹, I. Moreira², C. Cochat³, A. Silva⁴, A. Bastos-Leite⁵, C. Silveira⁶

¹ Department of Psychiatry and Mental Health, Coimbra, Portugal

² D.^a Estefânia Hospital, Centro Hospitalar de Lisboa Central, Portugal, Lisboa, Portugal

³ Magalhães Lemos' Hospita, Porto, Portugal, Porto, Portugal

⁴ Infectious Diseases' Department, Centro Hospitalar de São João, Porto, Portugal, Porto, Portugal

⁵ Medical Imaging, Faculty of Medicine, University of Porto, Portugal, Porto, Portugal

⁶ Clinic of Psychiatry and Mental Health, Centro Hospitalar de São João, Clinical Neurosciences' Department, Faculty of Medicine, University of Porto, Portugal, Porto, Portugal

* Corresponding author.

Introduction Lyme disease (LD) caused by the spirochete *Borrelia burgdorferi* (Bb) results from human contact with rural environments and is transmitted by infected ticks (*Ixodes* spp.)

Objectives/aims To report a case with LD and to highlight the importance of differential diagnosis in a first psychotic episode.

Methods Case report and systematic review of the literature.

Results We report a case of a 19-year-old man that was admitted because of strange behaviour with alienation, perplexity and persecutory delusions. He had one previous admission to an inpatient unit two years prior and was diagnosed with psychosis not otherwise specified. After being admitted to the psychiatric ward a medical work up was completed. The patient had had a long stay in a rural environment; so anti-body specific to Bb was ordered and came positive. LD was diagnosed based on cerebral magnetic resonance imaging (MRI) findings and the presence of Bb in the cerebrospinal fluid. During treatment with anti-psychotic and antibiotic there was a noticeable clinical amelioration correlated with improvement of MRI's perfusion patterns.

Conclusions LD is relatively rare, but physicians need to be aware of typical neuropsychiatric symptoms, given that they may occur months to years after the initial infection. Prompt diagnosis and effective treatment are crucial to avoid the possibly irreversible mental illness. In the evaluation of a first psychotic episode LD should be considered and excluded, principally if there's an epidemiological context and no psychiatric family history. MRI may be another useful asset in the diagnostic evaluation of this condition.

The relevance of Paraphrenia: Case report

M. Peixoto^{1,*}, M.M. Oliveira², M. Bragança²

¹ Psychiatry and Mental Health Clinic of Centro Hospitalar do Porto, Coimbra, Portugal

² Clinic of Psychiatry and Mental Health, Centro Hospitalar de São João, Porto, Portugal

* Corresponding author.

Introduction Paraphrenia is a chronic psychotic disorder with a better-preserved affect and minimal disturbances of emotion and volition and a much less cognitive deterioration and personality changes.

Objectives/aims To report a case with probable Paraphrenia and to highlight the importance of the differential diagnosis in a first psychotic episode.

Methods Case report and systematic review of the literature.

Results We report a case of a 41-year-old man without a past psychiatry history that was led to the psychiatry emergency department (PED), by officers, because of strange behaviour and aggressiveness towards his family. In the PED the patient said that his real father was his father-in-law and that his ex-wife was his sister. His mental exam revealed disinhibition, disorganized speech with slightly mood elation, persecutory, mystic

and influential delusions with various delusional interpretations. After being admitted to the psychiatric ward, in compulsory care, he began treatment and a medical work up was completed. According to the family the patient had begun this strange behaviour four years prior. During the hospitalization it became clear that the patient was experiencing imaginative-confabulatory multi-thematic delusions, sometimes interviewer guided, without showing cognitive deterioration and retaining his personality.

Conclusions The diagnosis of atypical psychosis or psychosis not otherwise specified is not satisfactory since it agglutinates different conditions together. Paraphrenia is a well-established concept and should be used in order to define a group of psychotic patients who exhibited characteristic symptoms of schizophrenia, minus personality impairment and slower cognitive decline.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A systematic report review of Ganser syndrome: 118 years of case studies

S. Petrykiv^{1,*}, L. De Jonge², W. Sibma³, M. Arts⁴

¹ UMC Groningen, Department of clinical pharmacy and pharmacology, Groningen, The Netherlands

² Leonardo Scientific Research Institute, Department of Geriatric Psychiatry, Groningen, The Netherlands

³ GGZ Friesland, Department of Clinical Psychiatry, Leeuwarden, The Netherlands

⁴ UMC Groningen, Department of Old Age Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction Ganser syndrome was first described by a German psychiatrist Ganser in 1898, in a patient who showed a peculiar twilight state. Ganser syndrome is defined as the presence of approximate answers, somatic conversion symptoms, clouding of consciousness, and pseudo-hallucinations. The etiology of this disease remains a subject of debate. While the DSM-IV-TR classifies Ganser syndrome under the heading of dissociative disorder, it is not listed as a diagnosis in the DSM-V.

Objectives and aims The purpose of this paper is to review available literature on Ganser syndrome, published in Dutch, English, German, and French for examining the etiological debate, in order to gain insight into the etiology of this disorder.

Methods The study design was a retrospective case series of all published cases since 1898. For this purpose we used the electronic databases PubMed and Embase.

Results Over a period of 118 years, we found 79 papers, describing 117 case reports on Ganser syndrome. It generally occurs in patients who are exposed to somatic disorders or to psychological stress, however, often in absence of a psychiatric disorder.

Conclusions Ganser syndrome remains a controversial disorder in terms of its etiology. Ganser syndrome has been associated with organic disorders, as well as with stressful and intolerable life events. Based on this report, it is noteworthy that this syndrome predominantly occurs in the absence of co-morbid psychiatric disorders and is often associated with stress factors and underlying somatic diseases.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Serotonin syndrome with SSRIs augmentation of amisulpride: Two case report and literature review

M. Preve*, A. Ruccia, R. Traber, R.A. Colombo
Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

* Corresponding author.

Introduction Serotonin syndrome is a potential adverse reaction to drugs increasing serotonergic activity in the nervous system, some of them being frequently prescribed, such as antidepressant drugs. The association of myoclonus, diarrhea, confusion, hypomania, agitation, hyperreflexia, shivering, in-coordination, fever and diaphoresis, when patients are treated with serotonergic agents, could constitute a “serotonin syndrome”. The purpose of this report is to review the clinical evidence of serotonin syndrome with SSRIs augmentation of amisulpride. We propose two case report and literature review.

Method We conducted a systematic review of the literature with the principal database (PubMed, Enbase, PsychInfo) and we present two case report [1,2].

Results We describe two different case report with SSRIs augmentation of amisulpride.

Discussion and conclusion To our knowledge this is no report about the emergence of serotonin syndrome due to the use of SSRIs augmentation of amisulpride. Serotonin syndrome symptoms include high body temperature, agitation, increased reflexes, tremor, sweating, fever, dilated pupils, and diarrhea. Further research is warranted to replicate our clinical and qualitative observations and, in general, quantitative studies in large samples followed up over time are needed. Methodological limitations, clinical implications and suggestions for future research directions are considered.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Health screening audit – south Barnet PCMH pilot

H. Rahmanian
Camden and Islington NHS Trust, Primary Care Mental Health, Sutton, United Kingdom

Physical health monitoring is an integral part of caring for patients with mental health problems. It is proven that serious physical health problems are more common among patients with severe mental health illness (SMI), this monitoring can be challenging and there is a need for improvement.

Aims The aim of this project was to improve the physical health monitoring for patients with mental health illness. The patients group was under the care of south Barnet primary care mental health pilot (SB PCMH Pilot). SB PCMH pilot is a multidisciplinary team that includes: consultant psychiatrist mental health nurse and psychologist.

Results Between November to December 2014, 60 patients were discharged from SB PCMH and the electronic case notes of 38 of them who had an assessment/intervention by the service were reviewed. Results showed that 82% of the records verified that discussion and screening of physical health, smoking, drugs and alcohol had been completed. The data was discussed in team meetings with all team members. After thorough team discussions and brainstorming; the team agreed that an improvement in the process of monitoring was needed to work towards ensuring these matters are discussed with 100% patients and that this is accurately recorded. It was agreed to re-audit in 3 months.

Re-audit A re-audit completed between January to April 2015 confirmed an improvement as 98% of patients seen for an assessment by SB PCMH pilot have had their annual health checks and appropriate health screenings discussed and recorded routinely.

Personality traits and emotion recognition abilities in two samples of Romanian medical students

A.M. Romosan*, L. Dehelean, R.S. Romosan, M.O. Manea
University of Medicine and Pharmacy “Victor Babes”, Neuroscience, Timisoara, Romania

* Corresponding author.

Introduction Personality traits and social cognition are important predictors for the future performance, success, adjustment and mental health of medical students.

Objectives The purpose of the study was to assess and compare personality traits and emotion recognition abilities of two medical student samples: general medicine (GM) and general nursing (GN) students.

Methods The study was conducted between 2015–2016 on 173 Romanian medical undergraduates from the Timisoara “Victor Babes” university of medicine and pharmacy: sixth-year GM students ($n=96$) and fourth-year GN students ($n=83$). Personality traits were evaluated with the 60-item NEO five-factor inventory (NEO-FFI). Emotion recognition abilities were assessed with the revised version of the “reading the mind in the eyes” test.

Results The GM sample consisted of 31 (32.3%) males and 65 (67.7%) females, with a mean age of 24.65 years ($SD=1.81$). The GN sample was comprised of 13 (15.7%) males and 70 (84.3%) females, with a mean age of 23.84 years ($SD=2.12$). Overall, compared with female students, males gave considerably less correct answers in the “eyes test” ($P=0.002$) and had lower mean scores in “agreeableness” ($P=0.005$). GM students scored significantly higher than GN students in “neuroticism” ($P=0.01$), obtained lower mean scores in “agreeableness” ($P=0.015$) and had poorer emotion recognition abilities ($P=0.03$) than their GN colleagues.

Conclusions GN students appear to be more emotionally stable and with better emotion recognition abilities than GM students. Results of the present study represent a starting point for other studies that may use larger and diverse student samples.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A Study of empathy in Romanian general nursing students

F. Romosan*, R.S. Romosan, A.M. Romosan

“Victor Babes” University of Medicine and Pharmacy, Neuroscience, Timisoara, Romania

* Corresponding author.

Introduction Empathy is of most importance in the medical field. The ability to comprehend and connect with the emotional state of another person is essential for establishing a successful interaction between patients and health care professionals.

Objectives The aim of this study was to assess empathic response in general nursing (GN) students.

Methods The study was conducted between 2015–2016 on 75, sixth-year Romanian GN undergraduates from the Timisoara “Victor Babes” university of medicine and pharmacy. To evaluate the level of empathy, we used the empathy quotient (EQ), a 60-item self-report inventory with 40 questions empathy-related and 20 filler questions.

Results We included in this study 12 (16%) males and 63 (84%) females, with a mean age of 23.48 years (SD = 2.17). Female GN students had significantly higher EQ mean scores than the general female population. Compared to female students, males obtained significantly lower EQ mean scores. There were no significant differences between male and female students regarding age distribution.

Conclusions Female GN students showed greater empathy than their male colleagues, as well as than the general female population. These results support the theory on women’s understanding of others mental states, vital to the provision of a worthy nursing care.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0912

Cognitive emotional regulation in Romanian general medicine students

R.S. Romosan*, A.M. Romosan, V.R. Enatescu, I. Papava, C. Giurgi-Oncu

“Victor Babes” University of Medicine and Pharmacy, Neuroscience, Timisoara, Romania

* Corresponding author.

Introduction During medical school, students experience significant amounts of stress. Since certain emotion regulatory strategies are known to be maladaptive, the way in which students are capable to regulate their emotions becomes very important, because it can affect their physical and mental welfare.

Objectives The purpose of this study was to assess cognitive emotion regulation strategies in Romanian general medicine (GM) students.

Methods The study was conducted between 2015–2016 on 86 sixth-year Romanian GM undergraduates from the Timisoara “Victor Babes” university of medicine and pharmacy. In order to identify the cognitive emotion regulation strategies (or cognitive coping strategies) that students use after experiencing negative situations or life events we used the Romanian version of the cognitive emotion regulation questionnaire (CERQ).

Results The sample consisted of 30 (34.9%) males and 56 (65.1%) females, with ages ranging between 24 and 31 years (mean age = 24.97 years, SD = 1.74). Compared to female students, males obtained significantly lower mean scores in “umination” ($t = -2.84$,

$P = 0.005$, 95% CI = -1.64; -0.29), “positive refocusing” ($t = -2.09$, $P = 0.037$, 95% CI = -1.42; -0.04) and “catastrophizing” ($t = -3.17$, $P = 0.002$, 95% CI = -1.31; -0.3). Both male and female GM students had significantly higher mean scores in “blaming others” than their respectively gender-related general population.

Conclusions Results of this study suggest that GM students, when facing stressful or negative events, are more inclined in using “blaming others” as a coping strategy. Female students seem to be more inclined than males to use “rumination”, “catastrophizing” and “positive refocusing” as cognitive coping mechanisms.

Antipsychotic-induced hyperprolactinemia

S. Khouadja*, R. Ben Soussia, A. Bouallagui, I. Marrag, S. Younes, M. Nasr

University Hospital, Psychiatry, Mahdia, Tunisia

* Corresponding author.

Introduction As antipsychotic agents are increasingly used, many patients are at risk for antipsychotic-induced hyperprolactinemia.

Aims of the study Estimate the prevalence of hyperprolactinemia in patients treated by a single antipsychotic and identify the risk factors for its occurrence.

Methods This is a prospective study carried out at the psychiatric department of psychiatry of university hospital of Mahdia during 24 months. We have included all patients with a follow up and treated by single antipsychotic for at least 12 weeks. A pituitary MRI has been requested for patients with a prolactin level higher than 100 ng/ml.

Results We have collected 92 patients. Hyperprolactinemia was found in 34.8% of patients among which 7.6% have had prolactin level greater than 150 ng/ml. Pituitary MRI have revealed 2 cases of macro-adenoma. The decrease of the antipsychotic doses has significantly improved prolactin levels. The switch of antipsychotic with another less inducing hyperprolactinemia has significantly decreased prolactin levels. 7 factors were correlated significantly to hyperprolactinemia: sex (female), substance use, presence of side effects, combination of psychotropic drugs, atypical antipsychotics, type of antipsychotic: Haloperidol and amisulpride, antipsychotic dose greater than 1000 mg Chlorpromazine equivalent.

Conclusion Hyperprolactinemia must be carefully identified, through a pre-therapeutic assessment and monitoring of patients.

Hyperinsulinism as evidence of munchausen syndrome by proxy: A case report

S. Khouadja*, S. Younes, S. Fathallah, R. Ben Soussia, L. Zarrouk, M. Nasr

University Hospital, Psychiatry, Mahdia, Tunisia

* Corresponding author.

Introduction Hyperinsulinism is one of the most important causes of hypoglycemia. Rarely, drug toxicity can be a reason. In the context of Munchausen syndrome by proxy (MSBP), toxicity usually occurs in children due to drug administration by a parent or caregiver.

Methods we report a case of a 2-year-old girl with hyperinsulinemic hypoglycaemia due to insulin injections by her mother.

Case report Mrs. W. is a 28-year-old mother of three children. In her medical history, she was diagnosed with gestational diabetes and treated briefly with insulin. She was hospitalized several times for hypoglycemia and she was diagnosed with factitious disorder. Lately, her youngest daughter aged 2 years old was hospitalized in the pediatric department for repeated unexplained loss of consciousness. The hospitalization lasted 2 months with recurrence of severe hypoglycemia. A full metabolic screen revealed no abnormalities. The mood of the mother appeared quite discordant with the situation. Strict monitoring of maternal behavior showed that the mother gives insulin injections to her daughter. She denied deliberately injecting insulin, and then she accused the health workers. She was referred to our psychiatric department and we diagnosed the MSBP.

Conclusion MSBP should be considered particularly in patients who have been evaluated by more than one hospital and have discordant test results.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Which one is the best anaesthetic agent for Ect?

H. Saiz Garcia^{1,*}, L. Montes Reula¹, A. Portilla Fernandez¹, V. Pereira Sanchez², N. Olmo Lopez³, E. Mancha Heredero¹, A.S. Rosero Enriquez¹, M.E. Martinez Parreño¹

¹ Complejo Hospitalario Navarra, Psychiatry, Pamplona, Spain

² Clinica Universidad Navarra, Psychiatry, Pamplona, Spain

³ CSM Salburua, Psychiatry, Vitoria, Spain

* Corresponding author.

Introduction The most frequently used anesthesiologic agents are methohexital, thiopental, etomidate, propofol, ketamine, and sevoflurane. The objective is to clarify the differences on recovery, cardiovascular variables, cognitive functions, and response to treatment showed by these drugs.

Methods A review was conducted aiming to clarify the differences between anaesthetic agents used in ECT. The literature search was conducted in PubMed data reviewing articles dating between 2015 and 2016.

Results – Propofol seems to have better hemodynamic effects in comparison with etomidate in patients with schizophrenia and depression;

– The seizure duration was significantly shorter with propofol, but this did not cause a difference regarding clinical improvement;

– The seizure duration was longer with etomidate in many studies. It did not decrease in a dose-dependent fashion with etomidate in a study comparing methohexital, etomidate, and propofol;

– The most frequently observed adverse effects were arrhythmias and nausea and they occurred more frequently in patients who were given thiopental. The pain at the injection site was more frequent in patients who were given propofol;

– Etomidate seems to have better clinical improvement than thiopental. Thiopental seems to have better results than propofol, which has an anticonvulsant feature effects.

Conclusions In order to figure out which anaesthetic agent was the most indicated for undergoing ECT, we found that both EEG-based seizure duration and motor seizure duration showed the sequence etomidate>methohexital>thiopental>propofol. These items are directly related with clinical improvement. When a drug is chosen, it is important to individualize the treatment according to the patients' comorbidity.

EV0916

Neuroacanthocytosis syndromes and neuropsychiatry symptoms associated

H. Saiz Garcia^{1,*}, L. Montes Reula¹, A. Portilla Fernandez¹, V. Pereira Sanchez², N. Olmo Lopez³, E. Mancha Heredero¹, A.S. Rosero Enriquez¹

¹ Complejo Hospitalario Navarra, Psychiatry, Pamplona, Spain

² Clinica Universidad de Navarra, Psychiatry, Pamplona, Spain

³ CSM Salburua, Psychiatry, Vitoria, Spain

* Corresponding author.

Introduction Neuroacanthocytosis is an infrequent cause of both neurological and psychiatric manifestations, and acanthocytes, which are a special form of spiculated red blood cells. Clinically significant psychopathology, ranging from behavioural disturbance to frank psychiatric illness, has been reported to occur in up to 60% of ChAc patients.

Methods A review was conducted aiming to clarify the physiopathology of this illness and its clinical features in order to distinguish neuroacanthocytosis from other neurological or psychiatric diseases. The literature search was conducted in PubMed data reviewing articles dating between 2010 and 2016.

Results – Neuroacanthocytosis autosomal recessive disorder associated with mutations or deletions in the VPS13A gene on chromosome 9q, which codes for the membrane protein chorein. Chorein is strongly expressed in the brain. Chorein loss particularly affects the basal ganglia, especially the caudate nucleus and putamen;

– Dysexecutive syndromes, OCD, depression and possibly psychosis, which may precede the frank motor and cognitive impairment;

– The most recently developed treatment for neuroacanthocytoses is the use of deep-brain stimulation (DBS), with stimulation of the globus pallidus internus.

Conclusions While conducting a neurological exam, secondary causes of psychosis have to be included in the differential diagnosis. It is important to notice the possible confusion between tardive dyskinesia and a primary movement disorder. It should be necessary to investigate all de novo movement disorders in psychotic patients in order to eliminate etiologies other than iatrogenic ones.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A review about comorbidity between obsessive-compulsive symptoms and huntingong disease and a case report

L. Sánchez Blanco^{1,*}, M. Juncal Ruíz¹, G. Pardo de Santayana Jenaro¹, M. Gómez Revuelta², R. Landera Rodríguez¹, O. Porta Olivares¹, D. Abejas Díez¹, N.I. Núñez Morales¹

¹ Hospital Universitario Marqués de Valdecilla, Psychiatry, Santander, Spain

² Hospital Universitario de Álava-sede Santiago, Psychiatry, Vitoria-Gasteiz, Spain

* Corresponding author.

Introduction The concept of obsessive-compulsive disorder (OCD) as a disorder that affects the basal ganglia arising to the phenomenological similarities found between idiopathic OCD and other conditions associated with basal ganglia disease such as Huntington's disease (HD) and Sydenham's chorea. Huntingong's disease is characterized by cognitive, motor and neuropsychiatric symptoms.

Aims A review of articles published from 1989 to 2016 in PubMed and UpToDate about relationship between HD and obsessive-compulsive symptoms.

Methods Case report of a 56-year-old male who was admitted at the acute unit of psychiatry with obsessive-compulsive symptoms marked by hypochondriac obsessive thoughts. He also had cleaning rituals in relation with meals and we observed an important functional impairment and depressive mood. No previous history except family chorea without cognitive impairment in study by neurology department.

Results Affective disorders are the most common psychiatric disorders in HD. Less frequently it can be found other psychiatric symptoms as obsessive-compulsive behaviour with prevalences between 10% to 52%. Psychiatric symptoms do not correlate with duration of disease or presence of dementia or motor symptoms.

Conclusions It is necessary to complete the study of the patient to provide a more appropriate therapeutic option. The neurological signs of basal ganglia disorder should be evaluated when considering OCD diagnosis, especially in atypical presentation ages. Longitudinal studies are needed to determine the pathogenesis, disease progression and future therapeutic options.

Violence as object of interdisciplinary research: Characterization of a Brazilian group of studies

E. Scherer^{1,*}, Z. Scherer², J. Rodrigues², L. Cavalin², D. Silva², N. Camargo², N.P. Scherer³

¹ Ribeirão Preto Medical School Hospital of the University of São Paulo, Neurosciences and Behavioral Sciences, Ribeirão Preto, Brazil

² University of São Paulo at Ribeirão Preto College of Nursing, Psychiatric Nursing and Human Sciences, Ribeirão Preto, São Paulo, Brazil

³ Neurosciences and Behavioral Sciences, Ribeirão Preto Faculty of Medicine of the University of São Paulo, Ribeirão Preto, São Paulo, Brazil

* Corresponding author.

Introduction The interdisciplinary group of studies on violence (GREIVI), created in 2006, develops teaching, research and community extension activities related to violence and its impact on individuals' mental health (victims or perpetrators).

Objective To describe the subjects studied, the participants and the activities developed in the GREIVI in the period of 8 years.

Aims Knowing the GREIVI's activities.

Method Qualitative exploratory documentary study. Analysed 90 group monitoring reports from 2009 to 2016. The records were subjected to content analysis.

Results Production: completed 11 research projects of undergraduate and postgraduate students; 7 in progress; presented 9 works in international scientific events; published 9 articles; 1 extension project in elementary school (2009 to 2016). Established partnership with international research and education institution to articulate and implement new projects. Topics discussed: definition, types and nature of violence; ecological model of violence; violence against women; and school violence. Activities: directed reading; discussions and exchange of experiences between the participants; presentation, discussion and advice on research and community extension projects; production and dissemination of scientific papers; technical visits and activities' structuring and planning. Participants: professionals and undergraduate and graduate students from different areas (nursing, psychiatry, psychology, social work, education, biology and political advisor who works with the theme of violence).

Conclusion The GREIVI have provided interdisciplinary space for discussion of different aspects of violence and the construction of research and extension projects to the community.

Issues of self-regulation of children with mental retardation

E. Sedova^{1,*}, T. Goryacheva^{1,2}

¹ Pirogov Russian National Research Medical University RNRMU, Psychologico-Social Faculty, Moscow, Russia

² Moscow University of Psychology and Education MSUPE, Clinical and Special Psychology Department, Moscow, Russia

* Corresponding author.

Matured self-regulation system is considered to be one of the crucial factors for the success in life and that explains the interest to this issue from researchers, belonging to varied psychological disciplines.

According to the Nikolaeva's (1991) model, self-regulation system consists of three levels: the level of self-regulation of mental states, the level of activity self-regulation and the motivational level.

The research aim was to describe maturing of self-regulation of children with mental retardation comparing with their normally developing peers.

The sample consisted of 39 children with the slightest degree of mental retardation in the age from 7 to 10 years, attending public school, and of 59 their normally developing peers.

The research methods included the Luria's neuropsychological test battery, adapted by Semenovitch (2008) for the first level of self-regulation, analysis of school results for the second level and Guinsburg's and Louskanova's tests of learning motivation for the third one.

According to the test results all the subjects were referred as having high, medium and low degree of self-regulation. All the children with mental retardation had the low degree.

The research shown that for normally developing children the defects of the first self-regulation level were compensated by maturing of the third one. As for the children with mental retardation, they had more severe defects in the first level, and maturing of the third level also delayed, so there was no compensation of their problems. That fact should be considered when working out intervention program for those children.

Magnitude of resource and reputational concern impact generosity and deception in children

M. Shayesteh Far

Tehran University of Medical Sciences, Neuroscience Institute, Tehran, Iran

Introduction In a bargaining process, there are factors impacting the outcome (i.e. gain versus loss). Of the important factors is the informational asymmetries between bargainers which could provide a more powerful position for whom has information that the other partner has not as well as magnitude of resource.

Objectives Thus, in a modified two-round, 4 trials (different magnitudes) bargaining paradigm, we investigated deception in children when there is no chance of deception revelation (first round) and when there is a chance of deception revelation (second round).

Methods One hundred and forty one healthy schoolchildren (90 boys and 51 girls) between age of 7 and 12 participated in the current study. We designed a modified version of the bargain-

ing paradigm based on the experimental design by members of the junior faculty workshop in the conflict management division at the 1995 academy of management meetings in Vancouver, BC. Variables included earning amount, deception frequency, real generosity and pretend generosity.

Results Using paired-samples T-test we showed that there were significant differences between two rounds in earning amount, deception frequency and real generosity. We administered separate one-way ANOVA with repeated measure on 4 different conditions (bank amounts). We found that, the main effect of condition was significant for real generosity (in both round), for pretend generosity (in first round) and for deception amount (in both round).

Conclusions We found that revelation (reputation concerns) decreases deception and increases generosity. Moreover, lesser magnitudes increase generosity and decrease deception and vice versa.

Clinical profile of patients hospitalized for delirium

F. Smaoui*, M. Frikha, I. Bouchhima, O. Hdiji, N. Farhat, H. Haj Kacem, M. Dammak, C. Mhiri

CHU Hbib Bourguiba Sfax, Tunisia, Neurologie, sfax, Tunisia

* Corresponding author.

Introduction Delirium is a common clinical syndrome characterized by acute disruption of all cognitive and behavioural functions. **Objectives** – Draw up an epidemiological and clinical profile of patients hospitalised for delirium;

– Assess different pathologies involved.

Methods We conducted a retrospective and descriptive study, in the neurology department at Habib Bourguiba university hospital, Sfax, Tunisia, at the period from 2009 to 2013. We included 52 patients hospitalised for delirium. Socio-demographic and clinical data were collected from patient files.

Results The mean age was 66.5 years. The majority (73.1%) were elderly patients (>=60 years). Sex-ratio (M/F) was 1.73. It was the first episode in 96.2%.

Medical histories were cardiovascular in 55.8%, endocrinal in 25%, neurological in 11.5% and psychiatric in 13.5%. The beginning of the signs was brutal in 55.8% of cases. The reported symptoms were: disorientation in time and space (76.9%) and behaviour disturbance (63.5%), memory disorder (23.1%), headaches (26.9%) and hallucinations (17.3%). Organic etiologies were noted in 75% of cases: vascular 42.30%, metabolic 11.50%, infectious 11.5%, tumoral 3.9% and iatrogenic 3.8%. Delirium grafted on dementia was retained in 5.8% of cases.

Conclusion Delirium is associated with increased mortality. Its prevention is essential and requires recognition of risk situations.

EV0922

Hydrocephalus and psychiatric disorders: About a clinical case

H. Snene

Military hospital of tunisia, psychiatry, Tunis, Tunisia

Introduction Hydrocephalus is a neurological disease caused by excessive accumulation of cerebrospinal fluid following an abnormal secretion, circulation and absorption. It is considered the most common reversible cause of dementia but still an underestimated cause of psychiatric disorders.

Objectives Highlighting the possible association of hydrocephalus in some psychiatric disorders and know how to adapt the management of this co-morbidity.

Clinical Vignette He is Mr O.Y, aged 27, unmarried, his parents divorced, lives with his mother. He had surgery in 2012 to the orthopedic service for disabling scoliosis. No significant psychiatric family history. Discovery of a tri ventricular hydrocephalus in 2011 requiring regular monitoring neurology.

Indeed Mr O.Y followed the CMP for a mood disorder requiring antidepressant treatment based. The evolution of disorder was marked by the installation of a hallucinatory and delusional syndrome motivating several hospitalizations and relapses iterative partial response to various therapies.

Mr O.Y was received a ventricular shunt within the sound hydrocephalus.

The postoperative course was marked a progressive amendment acoustic verbal hallucinations and delusions of persecution.

The conduct was to gradually reduce the dose of antipsychotic (Risperdal) to the stop. No recurrence pathological productions.

Conclusions Psychiatric disorders may mark the evolution of hydrocephalus. Share against the indications and side effects of some psychotropic drugs, the management of this co-morbidity may be difficult. Further studies are needed to better elucidate causality for this association and to develop appropriate therapeutic consensus.

Alcohol consumption, smoking and substance use in first and final year of nursing school

D. Soria^{1,*}, L.D.S.P.D. Magalhães², F.A.M.D. Souza¹, E.J. Domingos¹, C.C. Ribeiro¹, S.V. Chagas³, T.V.C. Vernaglia¹

¹ Federal University of State of Rio de Janeiro, Nursing Medical Surgical, Rio de Janeiro, Brazil

² Adão Pereira Nunes State Hospital, Pediatric Emergency Care, Duque de Caxias, Brazil

³ Public Ministry of State of Rio de Janeiro, CAO Cidadania, Rio de Janeiro, Brazil

* Corresponding author.

Aims To describe the use and abuse of alcohol, cigarettes and street drugs in nursing degree students of Alfredo Pinto nursing school at federal university of state of Rio de Janeiro.

Methods cross-sectional and descriptive data of first and final year students enrolled in a nursing degree course. One hundred and seventeen students took part in a questionnaire, providing sociodemographic information and completed the alcohol smoking and substance screening test (ASSIST). A double variant and chi-squared analysis and Fisher's exact test was performed.

Results One hundred and seventeen students participated. Of the first year students 82% (n=73) were woman; 61% (n=54); 18–20 years old; 43% (n=38) were white and 40% (n=36) had parents that identified as Roman-Catholic. The students in their last year: 89% (n=25) woman; 54% (n=15) aged between 21–23 years old; 70% (n=20) are white and 71% (n=20) have roman-catholic parents. That is a high prevalence of alcohol use: 84% (n=75) in the first year and 78% in the last year had used alcohol. 24% (n=21) had smoked during their first year and 18% (n=5) during the last year. It was found that the consumption of street drugs during early years of university is correlated to the age (P=0.033) and the religious orientation by parents (P=0.047).

Conclusion Universities responsibility towards their students, and students involvement with their learning process are factors that lead to changes in attitudes, beliefs and knowledge that are so

important in maintaining healthy habits and lifestyle in line with what is taught in a nursing degree.

Integrated identification of new substantial gadget addiction: With selfie-mania phenomenon model

I. Sosin^{1,*}, Y. Chuev², O. Goncharova²

¹ Kharkov medical academy of postgraduate education, Narcology, Kharkov, Ukraine

² Kharkiv Medical Academy of Postgraduate Education, Narcology, Kharkiv, Ukraine

* Corresponding author.

Introduction Modern selfie-infatuation extent went far beyond fashion and subculture causing distinct tendency to non-chemical addiction state transformation requiring evidential scientific identification.

Aims and objectives To develop clinical-psychological and classification basis for new type of gadget addiction (selfie-mania), prevention and approaches to mental correction and rehabilitation.

Method Selfie attitude testing of 157 respondents-students, and internet resources topical data analysis were done.

Results Behaviour models were rubricated, design and content, causes, clinical-psychological description, selfie-phenomenon prevalence were clarified. It allows to state selfie-addiction specific key symptoms, conforming to ICD-10 diagnostic criteria for addiction states:

- psychological and emotional supercomfort feeling during realizing selfie-interventions (substantial analogue of euphoria phenomenon caused by psychoactive substances in narcology);
- desire for permanent updating and layouting in social networks selfie-portraits, selfie-positions (impulse control disorder analogue);
- selfie-modifying need causing adrenaline extreme and life threat (analogues: compulsive craving, megadoses, overdosages, amnesias);
- obsessive craving to increase daily number of selfie-shots (tolerance syndrome analogue);
- constant foreshortening change of selfie-interventions (analogue: experimentation with different psychoactive substances, searching behaviour);
- selfie-destruction psychopathological consequences (neurotism, mental and behavioural disorders, group pattern of behavioural selfie-deviations);
- formation of associated comorbid chemical and other substantial addiction forms;
- selfie-deprivation syndrome (analogue: alcohol or drug withdrawal syndrome);
- interdisciplinary range of problems (professional sphere of study for sociologists, psychologists, neurologists, psychiatrists, narcologists, psychotherapists, sexopathologists, lawyers).

Conclusions Selfie-addiction problem recognition is necessary on the level of inclusion to ICD, that will allow to develop scientific, legal and clinical base for integrated prevention, rehabilitation and treatment.

EV0925

Selfie as a method of perception of the virtual environment

M. Sulaimanova¹, R. Sulaimanov^{2,*}

¹ Kyrgyz-Slavic University, Medical Psychology- Psychiatry- and Psychotherapy, Bishkek, Kyrgyz Republic

² Osnabrück University, Institute of Cognitive Science, Osnabrück, Germany

* Corresponding author.

Nowadays selfie is one of the significant communication methods in the conditions of the developing internet space.

Goal The study of psychological mechanisms motivating perception of internet space via selfie.

Objectives The identification of:

- The personal-social necessity in selfie, as a method of the virtual world perception;
- The factors of personal-social necessity of the virtual communication via selfie;
- The personal features, which contribute to self-presentation in virtual space via selfie.

Research methods One hundred and thirty-four respondents aging between 16–28 (1st group: 68 respondents fond of selfie (50.8%), 2nd group: 66 respondents not fond of selfie (49.2%)) were studied using standardized scales of anxiety (Spilberger-Hanin), depression (Zung), ego-defense mechanisms (EGMs) (Plutchik-Kellerman-Konte), and life quality (WHO, 1991).

Results Desire of high evaluation dominates in 47.8% of respondents ($r = 0.3$; $P < 0.01$). Fifty point seven percent of the 1st group and 13.4% in 2nd group have heightened anxiety ($r = 0.3$; $P < 0.01$). Forty-three point two percent in 1st group and 23.9% in 2nd group don't have depression.

Subdepressive level dominates in 19.4% of 2nd group ($r = 0.36$; $P < 0.01$), against 11.9% of 1st group.

In 1st group dominate: denial (17.9%), projection (16.4%), regression (7.5%); in 2nd group: denial (17.9%), intellectualization (13.4%), projection (7.5%) ($P < 0.05$). Forty-four point eight percent in 1st group and 40.3% in 2nd group have a high level of EGM stress ($P < 0.05$). Forty-six point eight percent in 1st group have high level of subjective life quality, 0% had low one; in 2nd group: 26.9% have high level, 13.4% low one.

Conclusions Personal-social necessity of virtual space perception via selfie reflects the severity of narcissistic tendencies. Selfie in conditions of illusory reality increases the subjective level of life quality. Isolation of narcissistic personality from communication through selfie suggests subjective decrease of life quality. Effects of the selfie should be considered in the development of rational methods of use of internet-technologies and in the psycho-correction of people with low life quality.

* Corresponding author.

Introduction The interest for academic background and investigational activities are essential in psychiatry. Several European-wide, early career psychiatrists-driven studies have been carried out completely independently, leading to high quality publications, where all the co-authors are junior researchers.

Objectives To further elaborate the European federation of psychiatric trainees (EFPT) platform of promoting the experience of collaborative work and research lead by psychiatric trainees in different countries all over Europe.

Methods A review of EFPT collaborative trainee-led research initiatives since the beginning with the focus on published articles and their impact on psychiatric community in Europe.

Results Main topics of trainee research are related to postgraduate psychiatric training schemes in Europe raising awareness on enhancing and harmonizing standards of psychiatric education and training across Europe. Other research topics are related to treatment strategies while being a psychiatric in Europe, to migration and "brain drain" phenomenon of psychiatric trainees in Europe, to access to information in psychiatric training.

Conclusions International cooperation's in research should be promoted since the training. Joining professional associations provides opportunities for participating in research activities and establishing networks with other colleagues. Collaboration between psychiatric trainees ensures a more effective use of individual talents and a quick way of accessing and transferring new knowledge and research expertise. Moreover it provides a supportive framework for multi-center research.

The influence of the emotional burnout on the relational maintenance strategies

L. Kato¹, O. Radchuk¹, S. Tukaiev^{2,*}

¹ Università della Svizzera italiana, Institute of Communication and Health, Lugano, Switzerland

² National Taras Shevchenko University of Kyiv, Department of Social Communication, Department of Physiology of Brain and Psychophysiology, Kiev, Ukraine

* Corresponding author.

The syndrome of emotional burnout is developed in people whose profession requires a lot of communication, and the effectiveness of their work depends on its quality. The aim of our study was to determine the influence of burnout on relational maintenance strategies. 8 professors of università della Svizzera italiana, Lugano, Switzerland participated in this research. We used Maslach Burnout Inventory and The relational maintenance strategies scale. Moderate level of emotional exhaustion was detected in the majority of the participants. This condition is characterized by the urge towards finding a place to stay alone and get some rest from everything and everybody. It is accompanied by the feeling of emptiness, depression, and apathy. These indicate pronounced

tiredness, disappointment, and unwillingness to work among our participants. The high level of Lack of personal accomplishments phase is being developed in all the participants. It indicates the pronounced doubts in the necessity to keep performing the work and in the fact that the work is needed and recognized by other people. We demonstrated that among the professors with burnout such strategies as conflict management, openness, assurances and positivism are the most widespread. Our data indicate that the readiness to work together on certain project or scientific problem (Openness), the willingness to support a student (Advice Giving) and the help to find necessary support outside of current academic environment (Social Networks) decreases with the development of emotional burnout. Understating the level of one's self-appraisal, observed during the development of burnout, ruins effective collaboration between professors and their PhD students, and formalizes their relationships. Thus, burnout is an important mediating variable between interpersonal aspects of work environment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0928

Adjustment of the German prospective payment system for psychiatric and psychosomatic facilities: Does PEPP provides a suitable basis? Results of a descriptive comparative study

B.S. Voigtländer*, T. Barth

Klinikum Chemnitz gGmbH, Psychiatry, Behavioural Medicine and Psychosomatics, Chemnitz, Germany

* Corresponding author.

Introduction In Germany a consistent, performance-oriented, flat-rate remuneration system based on per-day payments for inpatient and day patient hospital services for psychiatric and psychosomatic facilities (PEPP) is developed. The Klinikum Chemnitz gGmbH decided in 2013 to participate in the optional PEPP introducing phase and acts as a PEPP cost accounting hospital.

Objectives Due to a controversial discussion by the psychiatric experts, an adjustment of the hitherto only performance-based to a budget-oriented system based on PEPP is planned in 2017.

Aims This paper discusses if the current PEPP remuneration system enables an appropriate recognition and measurement of services.

Methods Descriptive analyses were performed by comparing inpatient and day patient treatment at a therapy oriented psychiatric unit and the emergency psychiatric unit in 2015. The evaluation primarily focused on the criteria of "staffing level and structure", "imaging of services by German procedure classification (OPS) according to PEPP", "PEPP remuneration".

Results Our findings (Table 1) show that in 2015 the PEPP remuneration system provided an appropriate recognition of unit-specific services in emergency psychiatry (e.g., 1 to 1 care, intensive care treatment), but services of board certified therapeutic staff were recognized inadequately in consequence of the definition of therapy by the OPS catalogue.

Conclusion Further development of payment system should implicate changes in the definition of therapy according to scientific guidelines and the pay for performance concept.

Table 1

Criterion	Therapeutically oriented unit 2015	Emergency psychiatric unit 2015	Significance Chi-squared test*
Staffing level in total (full time equivalent)	100%	158%	
Service time of board certified therapeutic staff/ Service time in total*	34.4%	16.6%	p<0.01
Mean daily cost weight with regard to PEPP remuneration by using a hypothetical base rate	0.89	1.09	
PEPP remuneration in total p.a.	100%	120%	
Service time imaged by OPS procedures/ Service time in total*	21.3%	57.4%	p<0.001

The integration of yoga theory and practice into a general practice of psychiatry

R. Weininger

Reuben A. Weininger- M.D., Psychiatry, Santa Barbara, USA

Introduction Yoga is an ancient system of concepts and practices designed to address problems of the mind and body, codified during the few centuries BCE in India. Yoga has become increasingly popular in the West during the past half century, and its practice in various forms is now widespread. Along with mindfulness-based techniques, yoga is increasingly seen as compatible with Western therapeutic methods of approaching physical and mental illness.

Objectives To introduce the audience to the yoga model of the mind, and to show how it is both compatible with and complementary to Western models, including psychoanalytic and cognitive behavioral.

Aims We will explore how this ancient system can be introduced into clinical practice, and in what ways it can accelerate the process of psychotherapy and psychological change.

Methods This talk will include a review of yoga theory, including the causes of suffering and its resolution. We will explore road-blocks in treatment and how daily practices can accelerate the process of growth and change.

Conclusions Yoga can be a very helpful adjunct to a psychiatric practice, in addition to medications and psychotherapy.

Protective effect of saikosaponin B₂ on damage of cultured SH-SY5Y cells in vitro introduced by hydrogen peroxide

Y. Zhang*, F. Liu, Z. Dai, Q. Wu

Xi'an mental health center, pharmacy lab, Xi'an, China

* Corresponding author.

Objective To investigate the effect of saikosaponin B₂ on the damage of cultured SH-SY5Y cells.

Methods 10% calf serum including volume fraction 0.05, 0.10, 0.20 saikosaponin B₂ (10^{-4} mol·L⁻¹) were added respectively into the SH-SY5Y cells, which were then treated with 140 μmol·L⁻¹ hydrogen peroxide (H₂O₂). 10% calf serum group and blank serum without H₂O₂-treated group were as the model group and the control group. The effect of saikosaponin B₂ was observed by morphological identification, colorimetric MTT assay.

Results Both saikosaponin B₂ of 10^{-6} mol·L⁻¹ and 2×10^{-6} mol·L⁻¹ can relieve the damage of SH-SY5Y cells and increase the survival of the cells.

Conclusion saikosaponin B₂ can protect the cultured SH-SY5Y cells from damage induced by H₂O₂.

EV0931

Procrastination as a personal factor in young patients with mental disorders

M. Zvereva

Mental Health Research Center of RAMS, Clinical psychology, Moscow, Russia

Introduction Many of contemporary studies of procrastination were conducted with healthy students. Only a few investigators analyzed procrastination's connection with personal features (self-esteem), socio-psychological parameters (aggression, well-being). Researchers do not consider procrastination as a personal factor in patients with different mental disorders. Most of procrastination's researches are related to affective spectrum disorders (depression), often found in the student's environment.

Objectives Male and female students (aged 18–25). Normal group–61. Experimental group – 54 patients of psychiatric clinic, divided to diagnosis: schizophrenia F20.01, bipolar disorder F31 and personality disorder F60.

Aims Study of procrastination combined with personal characteristics (self-esteem, aggression) on young people: normal and with endogenous pathology.

Methods Procrastination assessment scale-students (PASS) by L.J. Solomon, E.D. Rothblum; Rosenzweig Picture Frustration Test; E. Wagner's The Hand Test; Warwick-Edinburgh Mental Well-being Scale; Rosenberg Self-Esteem Scale; Self-esteem by Dembo-Rubinstein. Multiple linear regressions were used as method of data assessment.

Results Assessment of obtained data allowed to distinguish some different models of connections parameters of PASS and other tests. These models differ in comparing groups. Healthy students: multidimensional model of communication procrastination and personality parameters harmoniously combined personal and socio-psychological parameters. Schizophrenia: fewer models, mostly one-dimensional structure (identified only communication based on personal parameters). Bipolar disorder: one or two dimensional model (include mainly characteristics of aggression and self-rated health). Personality disorders: some mono and multi-dimensional models, their structure and content are very close to normative sample.

Conclusions Procrastination is considered as a common phenomenon at young people.

Connections PASS and personal features differ according to disease.

Depression Among Chronic Pain Patients

I. Berrahal*, B. Ayadi, M. Haddad

La Rabta Hospital, Pain management ward, Tunis, Tunisia

* Corresponding author.

Introduction Patients with chronic pain are more likely to develop depression, which is associated with decreased function, poorer treatment response and poor quality of life.

Objective This study aimed to determine the prevalence of depression in patients with chronic pain.

Methods This descriptive cross-sectional study was conducted among clinically diagnosed chronic pain patients from the pain management ward of La Rabta hospital in Tunisia over a period of six months.

Sociodemographic and clinical data were obtained from patients' interviews and medical records.

The Beck depression inventory (BDI) was used for screening depression diagnoses and the Visual analogue scale (VAS) to assess the severity of pain.

Results The sample included 102 patients with a mean age of 46.4 ± 10.4 years. The majority of the patients were females (72.5%, $n = 74$), married (83.3%, $n = 85$) and being employed (58.8%, $n = 60$). The prevalence of depression was (40.1%, $n = 41$). The mean duration of pain was 3.6 ± 1.5 years. The severity of pain was mild in 28 cases (19.3%), moderate in 36 cases (31.3%) and severe in 38 cases (49.4%). Depression was significantly associated with the duration of pain ($P < 0.01$). A positive correlation was observed between pain severity assessed by VAS and BDI ($r = 0.521$, $P = 0.001$). Depression was significantly associated with the duration of pain ($P < 0.01$).

Conclusions Depression is frequent in patients who suffer from chronic pain and it was significantly associated with the duration and the severity of pain. Antidepressants and psychological therapies can be effective and should be delivered as part of a multidisciplinary pain management plan.

Treatment of pain: Results of a behavioral intervention

M. Palomo Monge^{1,*}, J.F. Calvo Mauri², M.F. Alcocer Lanza³

¹ Psychiatry, 45600, Spain

² Hospital Nuestra Señora del Prado, Psychiatry, Spain

³ Hospital Nuestra Señora del Prado, family and community medicine, 45600, Spain

* Corresponding author.

Introduction Chronic pain and its estimate in general population varies widely depending on the area and population studied. It is concluded that exerts effects on both physical and mental health, either in the patient or his family, in addition to its social cost

to influence activities of daily living, employment and economic welfare of a significant proportion of the general population, constituting one of the main reasons for medical consultation.

Aim Hypothesis: The painful perception is an operant behaviour. Subjects Six subjects (S): 5 females and 1 male, aged between 56 and 72 years Diagnosis ICD-10: R52.2 chronic pain of neuropathic origin. Material soundproof booth with audiometer Maico MA52.

Methods design Experimental single case.

Independent variable: behaviour modification treatment by differential molding using auditory stimulation as discriminative stimulus. Dependent variable: pain perception scale of 0-100%. Analysis comparisons using non-parametric test, significance at $P < 0.05$.

Results Table 1. M (Media), SD (Standard deviation)

Conclusions Six replications of behavioural experiment were performed. All show statistical significance. Generalization occurs in 83%. The hypothesis is confirmed and effectiveness of the treatment protocol was concluded; however the line of work should continue.

Study of the interactions between magnesium, ketamine and morphine on acute nociception in rats

K. Savic Vujovic^{1,*}, A. Vujovic², S. Vuckovic¹, B. Medic¹, M. Prostran¹

¹ Faculty of Medicine- University of Belgrade, Department of pharmacology- clinical pharmacology and toxicology, Belgrade, Serbia

² KBC Dragisa Misovic, Hospital for ENT, Belgrade, Serbia

* Corresponding author.

Objectives Study is aimed at evaluating the effects of ketamine and magnesium sulphate on acute nociceptive pain in rats and examining whether magnesium sulfate added to ketamine or morphine-ketamine combination produces higher level of analgesia.

Methods Analgesic activity was assessed by tail-immersion test in male Wistar rats (200–250 g).

Results Magnesium sulfate (2.5–60 mg/kg, s.c.) and ketamine (2.5–30 mg/kg, i.p.) given alone did not produce any effect on antinociception. However, there is a synergistic interaction between ketamine (2.5, 5 and 10 mg/kg) and magnesium sulfate (5 mg/kg). Both ketamine and magnesium sulfate, as well as their combination potentiated the antinociceptive effect of morphine (2.6 mg/kg, i.p.).

Conclusion This study revealed potentiation of ketamine and morphine-ketamine combination by magnesium sulphate in tail-immersion test in rats with higher activity when ketamine is given before magnesium sulfate. It is first time to demonstrate the synergistic interaction between magnesium sulphate and ketamine in lowering body temperature and in antinociception with statistical confirmation.

Lists of demographic details and psychiatric diagnoses of patients diagnosed with FMS in physical therapy and rehabilitation outpatient clinics

C. Tüz

Erenköy FTR Hastanesi, Psychiatry, Istanbul, Turkey

Objective In this study, a list of demographic details and a list of psychiatric diagnoses of patients who presented to physical therapy and rehabilitation outpatient clinics of Erenköy state hospital for physical medicine and rehabilitation and were diagnosed with fibromyalgia were investigated.

Method The study sample included patients who presented to outpatient clinics of the department of physical therapy and rehabilitation and the department of psychiatry in the hospital in 2015 and patients who were diagnosed with fibromyalgia (FMS) in the outpatient clinic of department of physical therapy and rehabilitation and also presented to the outpatients' clinics of psychiatry department. SCID-Mood Module and HAM-D were used during psychiatric assessment of the patients.

Conclusion It was determined that a total of 5225 patients diagnosed with fibromyalgia were examined in physical therapy and rehabilitation outpatient clinics in 2015. Of these, 183 patients also presented to the psychiatric outpatients clinic and were diagnosed with a psychiatric diagnoses. In this study, a list of demographic details and a list of psychiatric diagnoses of these 183 patients were made. The results were compared with the literature.

Personality traits and specialty choice among Oman medical specialty board residents

M. Al Alawi^{1,*}, H. Al Sinawi¹, S. Al Huseini²

¹ Sultan Qaboos University Hospital, Behavioral Medicine, Muscat, Oman

² Oman Medical Specialty Board, Psychiatry, Muscat, Oman

* Corresponding author.

Introduction Understanding factors that determine the choice of a specialty among junior doctors are crucial for career counseling and candidates selection. Most studies focused on working hours, income and other lifestyle factors. However, few studies have explored the role of personality traits of the doctors in influencing specialty choice.

Aims To examine the relation between personality traits and specialty choice among residents at Oman Medical Specialty Board (OMSB).

Methodology Residents from different specialties were invited to participate in this study by completing Eysenck Personality Questionnaire – Revised (EPQ-R) and Behavioral Inhibition System (BIS) & Behavioral Activation System (BAS) scale.

Results A total of 255 residents participated in the study ($M=40\%$, $F=60\%$). Surgical residents scored significantly higher on the Psychoticism sub-scale (P -value, 0.002) and the Behavioral Activation System (BAS) scale compared to nonsurgical residents (P -value, 0.05). On the other hand, medical residents scored higher in Behavioral Inhibition System sub-scale suggesting a tendency towards avoidance of anxiety-provoking situation ($P=0.023$). Concerning neuroticism trait, psychiatrists had the lowest score indicating more emotional stability. Residents from diagnostic specialties score the highest in BAS-Fun seeking with a difference reaching the level of statistical significance.

Conclusion The findings of this study suggest a possible correlation between career choice and personality traits. Therefore, adapting a well-constructed, efficient and standardized selection approach is of great importance. A reasonable framework for conceptualizing specialty choice would be recognizing one's own personality traits along with exploring social and technical factors related to a particular specialty.

Portuguese validation of the Psychological Entitlement Scale

A.I. Araújo^{1,*}, A.T. Pereira², C. Cabaços³, M.J. Brito³, L. Mendonça³, A. Macedo²

¹ Faculty of Medicine, University of Coimbra, Department of Psychological Medicine, Macieira de Cambra, Portugal

² Department of Psychological Medicine, Faculty of Medicine, University of Coimbra, Coimbra, Portugal

³ Faculty of Medicine, University of Coimbra, Faculty of Medicine, University of Coimbra, Coimbra, Portugal

* Corresponding author.

Introduction Psychological entitlement can be conceived as a disposition to believe that one deserves or is entitled to more than others. This pervasive sense has a wide impact on social behaviour, namely undesirable social outcomes. Given these theoretical implications on self-concept and interpersonal functioning, Campbell and Bonacci developed a shorter questionnaire of the Psychological Entitlement Scale (PES) to evaluate this construct by reducing from the original version from 57 to 9 items.

Objective To investigate the psychometric properties of Psychological Entitlement Portuguese version.

Methods A community sample composed of 286 university students (69.2% females; mean age = 21.09 ± 2.133 ; range: 17–33) answered the Portuguese preliminary versions of the PES, of the Dirty Dozen and of the honesty-humility dimension from the HEXACO-100.

Results The PES Cronbach alpha was “very good” ($\alpha=0.75$). Following Kaiser and Cattell Scree Plot criteria, only one factor was extracted (explained variance = 35.46%), meaning that the scale is unidimensional. Pearson correlation coefficient of between PES and narcissism ($r=0.36$), psychopathy ($r=0.21$) and Machiavellism ($r=0.24$) were positive, moderate and significant ($P<0.01$). Pearson correlation between PES and honesty-humility was negative, moderate and significant ($r=-0.43$ $P<0.05$).

Conclusions The Portuguese version of PES present good internal consistency and convergent-divergent validity. Because we consider that psychological entitlement reflects a stable disposition, it is our intent to analyze PES temporal stability within the ongoing research project on the relationship between perfectionism and

other personality traits. PES could be very useful both in clinical and research contexts.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV0938

Personality dark triad: Portuguese validation of the dirty dozen

A. Macedo¹, A.I. Araújo^{2,*}, C. Cabaços³, M.J. Brito³, L. Mendonça³, A.T. Pereira¹

¹ Faculty of Medicine, University of Coimbra, Department of Psychological Medicine, Coimbra, Portugal

² Faculty of Medicine, University of Coimbra, Department of Psychological Medicine, Macieira de Cambra, Portugal

³ Faculty of Medicine, University of Coimbra, Faculty of Medicine, University of Coimbra, Coimbra, Portugal

* Corresponding author.

Introduction The Dark Triad is a term used to describe a constellation of three socially undesirable personality traits: narcissism, psychopathy, and Machiavellianism. Contrary to Altruism (the desire to help others with no personal reward or gain), these traits are harmful to others. Given the increased scientific interest on the dark triad, Jonason and Webster developed a shorter questionnaire to evaluate these three independent-yet-related constructs with only 12 items – Dirty Dozen (D12).

Objective To investigate the psychometric properties of the Portuguese version of the Dirty Dozen.

Methods A community sample composed of 286 university students (69.2% females; mean age = 21.09 ± 2.133; range: 17–33) answered the Portuguese preliminary versions of the Dirty Dozen and of the Altruism dimension from HEXACO-100. To study the temporal stability, 30 participants (66.7% females) answered the D12 again after six weeks.

Results The EA Cronbach alpha was “very good” ($\alpha = 0.72$). Following Kaiser and Cattell Scree Plot criteria, three meaningful factors were extracted which explained variance (EV) was of 54.64%: F1 Machiavellianism (EV 32.07%; $\alpha = 0.73$), F2 Narcissism (13.665%; $\alpha = 0.74$), F3 Psychopathy (8.90%; $\alpha = 0.64$). The test-retest correlation coefficients were high, positive and significant for the total D12 and its dimensions ($r > 0.70$; $P < 0.001$). Pearson correlations of D12 total and dimensional scores and Altruism were negative, moderate and significant ($r @ - 0.30$).

Conclusions The Portuguese version of Dirty Dozen has good reliability and validity. It could be very useful both in clinical and research contexts, namely in an ongoing project on the relationship between dark triad and perfectionism traits.

Suffering of the spouses of narcissistic perverts: About two cases

S. Ben Saadi*, O. Moula, O. Zerriaa, S. Chebli, R. Ghachem Razi Hospital, Department B, Mannouba, Tunisia

* Corresponding author.

Introduction The narcissistic perversion is a psychoanalytical term resulting from the association of 2 Freudian notions: perversion and narcissism. The concept of narcissistic pervert has no clinical validity. The companions of the narcissistic perverts undergo moral suffering, often unknown by their entourage.

Objectives We suggest studying the trajectory of life of two wives of narcissistic perverts.

Aims Emphasize the peculiarities of the narcissistic perverse personality.

Methods We are going to postpone 2 clinical cases of spouses of narcissistic perverts.

Results Case 1: Mrs. A., 60-year-old, divorced once. Mother of a girl. She met her current husband during the marriage of her daughter. At the beginning of their common life, Mr. M. was loving and in the small care with his wife. After three months of the marriage, Mrs. A. reported the change of character of her husband who became aggressive, decreasing her and taking her away from her family. He seized all her goods. She is actually getting a divorce.

Case 2: Mrs. R., 27-year-old, married Mr. C. after 9 months of knowledge. At the beginning of their marriage, they had a good agreement. Forced to stay at home to take care only of domestic spots, she reported a real-life experience of neglect and emotional carelessness, she felt belittled and isolated. At present engaged in a divorce procedure after been physically assaulted threatened with death.

Both women consulted for depression.

Conclusion The narcissistic perversion is a personality problem which affects as well the person involved but especially his entourage. When you are in connection with a narcissistic pervert, even after leaving him, you never recover from it.

Low compliance to pharmacological treatment of severe chronic illness: Passive suicide ideation in borderline personality disorder?

M. Bonea*, I. Miclutia

University of Medicine and Pharmacy, Psychiatry, Cluj-Napoca, Romania

* Corresponding author.

Introduction The core features of Borderline Personality Disorder (BPD), such as deliberate self-harm, suicide attempts and demandingness in interpersonal relationships persist with age, even though impulsivity decreases. Impairing progressive disease combined with affective instability and chronic feelings of emptiness can lead to a desire for death.

Objectives To present a case of BPD with severe chronic endocrine pathology and liver cirrhosis who refused to take his treatment as prescribed.

Methods A case report is presented and discussed.

Results We report the case of a 61-year-old man with BPD and liver cirrhosis, complex endocrine pathology (pituitary adenoma, diabetes insipidus and primary hypothyroidism), type 2 diabetes mellitus with insulin therapy, essential hypertension and alcohol use disorder. He had a history of 5 suicide attempts caused by marked feelings of rejection and emptiness and a pattern of unstable relationships and lack of commitment, thus his marriage lasted only 2 years. He idealized and was extremely familiar with his clinician and displayed marked affective instability (dysphoria, periods of anger and despair, affective ambivalence towards his parents and recurrent depressive symptoms). Because of his liver disease, the psychotropic medication was ceased by his physician. The patient refused to follow the rest of his treatment plan and diet as prescribed, resulting in the deterioration of his somatic status. The patient denied an active suicidal ideation, but did not explain his non-compliance.

Conclusion The impairment from BPD and the risk of suicide persist even in older age affecting the outcome of co-morbid somatic conditions.

Multidisciplinary approach to several mental disorders: Clinical caseP. Castrillo^{1,*}, R. Guijarro², M. Cerviño¹¹ Complejo Hospitalario Universitario de Granada, Servicio Andaluz de Salud, Unidad de Rehabilitación de Salud Mental, Granada, Spain² Complejo Hospitalario Universitario de Granada, Servicio Andaluz de Salud, Unidad de Salud Mental Comunitaria, Granada, Spain

* Corresponding author.

The research evidence supports multidisciplinary treatment covers the different needs that appear in people with mental health problems, especially with long-term mental health disorders. The aim is to emphasize the importance of integrated treatment. It means to share therapeutic targets among different professionals. We propose that not only the therapeutic relationship between patient and psychiatry is important, but also a collaborative approach among different professionals. This is a descriptive study of a case of personality disorder and an individualized treatment carried out by different professionals from a multidisciplinary point of view. Combined pharmacological treatment, group and individual psychotherapy, and other therapeutic spaces are discussed in the present study as an alternative to individual therapy sessions. She has recovered her social and labour activity 14 years later from her first contact with mental health. Coordination and communication among clinical professionals would help us to improve quality of treatment.

Personality traits of participants of local armed conflicts in the remote post-combat periodE. Epanchintseva^{1,*}, T.V. Kazennyh², V.A. Rudnitsky³, A.A. Ivanova¹¹ Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Clinics, Tomsk, Russia² Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Administration, Tomsk, Russia³ Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Borderline States Department, Tomsk, Russia

* Corresponding author.

Introduction The problem of the psycho-injuring influence of military operations and accidents on mentality of the person is relevant and significant that is connected with existence of emergency situations, local wars and the international conflicts.

Material and methods We examined group of patients of participants of local armed conflicts (69 people) in the remote post-combat period (not less than 15 years). Most examined persons were older than 40 years (92%). Duration of stay in conditions of military operations made 6–7 months in 42.0%, 12 months and more – in 43.0%; 15.0% participated in official journeys. Clinical, clinical-physiological, experimental-psychological examination was carried out.

Results During experimental-psychological examination reorganization of the pre-morbid personality which was expressed in increase in its structure of specific weight of pathocharacterological disorders both as a result of acuteness of qualities of character inherent in patients, and emergence of new forms of personal reaction was revealed. In communication sharpness, maximalism of judgments, rough behavior was typical in combatants. In some cases, we observed existence of permanent mood disorders in the form of a combination of intense affects of melancholy and rage. Behavioural disturbances were expressed to rough demonstration

of affect of anger and rage as a proneness to conflict, with jamming on negatively colored experiences, tendency to destructive actions up to criminal acts, abuse of alcohol took place. In some patients, the desire to return back to a situation of military operations was revealed. In the circle of the family, they showed hostility, aggression, and intolerance.

Personality and defence mechanisms in Takotsubo cardiomyopathyR. Ferrara^{1,*}, N. Renda²¹ École doctorale de Lausanne, Department of Biology and Medicine, Roma, Italy² University of Palermo, Department of Experimental Biomedicine and Clinical Neurosciences, Palermo, Italy

* Corresponding author.

Introduction Takotsubo cardiomyopathy (TC) is an acute cardiologic syndrome, characterized by specific symptoms and ECG, echocardiographic and enzymatic abnormalities, similar to an acute myocardial infarction, with no hemodynamically significant stenosis at coronary-ventriculography.

Objective To assess personality in TC patients in order to find common psychopathological elements.

Methods A series of consecutive patients suffering from TC hospitalized at the Cardiology Unit of “Ingrassia” Hospital in Palermo in 2013–2014, were included in the study. We used Structured Clinical Interview for Axis I and II, according to DSM-IV TR criteria. Further, the Defense Mechanisms Inventory (DMI), used in order to explore defensive strategies: turning against self (TAS), projection (PRO), principalization (PRN), turning against object (TAO), and reversal (REV).

Results Eight women (mean age + SD: 57 ± 5 years) have been included in the study. A common element of them was a stressful event immediately preceding the onset of TC, in particular bereavement (4), armed robbery (1), infarction of a family member (1), estrangement of a family member (1), and separation from a partner (1). Although the patients did not fulfill any diagnostic criteria for Axis I or Axis II disorders of DSM-IV-TR, they showed scores at the SCID-II close to the limit values for avoidant and dependent personality. DMI showed, unequivocally, the common use of TAS-type defence style.

Conclusions Although the sample size was too small for complex statistical analyses, nevertheless our initial findings would indicate the presence of a common, defensive style in TC patients, and how this syndrome may be related to stressful life events.

Object Identity style and locus of control are of the most important strategic variables in determining the characteristics of people personality. So, this study was conducted to investigate the relationship between identity style, locus of control and self-efficacy among teachers of Khodabandeh city in Iran during the academic year 2014–2015.

Methods Among all teachers in Khodabandeh city during 2014–2015 academic year (419 teachers), 120 were selected using systematic random sampling method. All of them completed identity Style Inventory (ISI), Levenson Multidimensional Scale of Locus of Control and General Self-Efficacy Scale (GSE-10). For data analysis correlation and regression analysis (stepwise) was used.

Finding Data analysis showed a significant correlation between teachers' identity style, locus of control and their self-efficacy ($P < 0.05$).

Conclusion Due to the results, it can be concluded that identity style and locus of control can predict self-efficacy in teachers.

Keywords Identity style; Locus of control; Self-efficacy

² Hospital San Juan Alicante, Psychiatry, Alicante, Spain

³ Hospital de San Juan de Alicante, Psychiatry, Alicante, Spain

⁴ Hospital San Juan de Alicante, Psychiatry, Alicante, Spain

* Corresponding author.

Objective The aim of our study is to outline the demographic characteristics of the patients with a diagnosis of personality disorder that come to the ED. A second objective is to find specific risk factor for this type of patients.

Methods We selected patients that came to the ED with the diagnosis of personality disorder, between October 2015 and February 2016. Data analysis was conducted using SPSS software. Chi² test and *t*-Test were used as appropriate. A *P*-value < 0.05 was considered statistically significant.

Results Sixty-eight of the 402 patients that were attended in the ED met the criteria of personality disorder; 44.92% of these patients presented with suicidal ideation or attempt. We found in the use of drugs, statistically significant differences between men and women, using drugs all the men with a personality disorder that came to the ED except one. The most frequent reason for consult were anxiety, conduct alterations, suicidal ideation, and suicidal attempt, being these consultations the 77%.

Conclusion Anxiety and suicide risk are the most common reasons for a personality disorder patient to go to an ED. We have to be even more careful due to the high rate of suicide conducts in these patients. Also, it is important to think of drug use and dual pathology when assessing these patients.

Psychopathy and twins. A case report

A. Hernandez Dorta^{1,*}, I. González González²

¹ Hospital Universitario de Canarias, Psychiatry, Santa Cruz de Tenerife, Spain

² Hospital Universitario de Canarias, Psychiatry, La Laguna, Spain

* Corresponding author.

Introduction We are going to explain a case of a patient diagnosed with psychopathy and his twin brother with a normal personality.

Objectives To show the controversia about psychopathy and twins.

Methods Description of a case of psychopathy. We evaluated his psychopathology using the Psychopathy Checklist (PCL).

Case A 18-years-old male teenager admitted to a penitentiary facility for several crimes: drug dealing, violent theft and multiple aggressions.

Personal history: early psychological and psychiatric attention for disruptive behaviour as a child: repeated lies, low empathy, defiance to parents and teachers, indifference to punishment, robbery, aggressive behaviour, loitering, escaping from home, cruelty against animals, promiscuity, vandalism and drug abuse. Medium-high class family, well-structured family, none of them with criminal history or mental disorders, his brother is a brilliant student.

Personality assessment: We describe 20 features of his personality according to the PCL and we score them from 0 to 2. Zero if it does not apply at all, one if there is a partial match, two if there is a good match.

Features: Superficial charm, narcissism, pathological liar, manipulator, absence of guilt, superficial affection, absence of empathy, inability to accept responsibility, need for constant excitation, parasitic life, unrealistic goals, impulsivity, irresponsibility, low self-control, conductal problems since childhood, juvenile delinquency, repeal of conditional freedom, criminal versatility, promiscuity and multiple marriages.

Results Out of a maximum score of 40, the cut-off for psychopathy is 30.

This patient has 34 points so we can conclude he is a psychopath.

Conclusions We can conclude there is not a clear relationship between twins and psychopathy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

³ I.M. Sechenov First Moscow State Medical University, Department of clinical medicine, Moscow, Russia

* Corresponding author.

Introduction According to common-sense model illness representation regulates her coping both in somatic and mental illnesses.

Objectives As a personal reaction illness representation should partially depend not only on diagnosis and symptoms but also on personality. Aim is to identify direct and indirect effects of personality and psychopathological complaints in illness representation in mental disorders.

Methods Eighty patients (20 males) from MMPI-2 validation sample (Butcher et al., 2001) filled revised version of Illness Perception Questionnaire and Symptom Checklist 90-R. Eleven patients met ICD-10 criteria for addictions, 28 – for mood disorders, 20 – for schizophrenia and schizotypal disorder, 21 – for acute stress reactions.

Results According to moderation analysis, illness-related beliefs in mental disorders are relatively independent on clinical diagnosis and specific symptoms, but are associated with the overall level

of psychopathological complaints. Regardless of the clinical group and complaints, depressive traits are associated with negative and emotional appraisal of illness. Social introversion and hypomanic activation serve as moderators of the relationship between complaints, illness duration and emotional representations.

Conclusions Personality and overall level of psychopathological symptoms could be stronger predictor of illness-related beliefs than specific clinical factors in mental illness. Preliminary diagnostics of personality in mental illnesses could be used to reveal high-risk group for poor insight and non-compliance due to unrealistic beliefs. Research supported by the grant of President of the Russian Federation for the state support for young Russian scientists, project MK2193.2017.6.

Borderline personality programme in a rural area: The value of a therapy

M. Marin Olalla*, B. Perez Ramirez, A.M. Vidal Lopez, B. Martinez Martinez, R. Maldonado Lozano
AGS Norte Almeria, Mental Health, Huerca Overa, Spain

* Corresponding author.

Introduction An increased incidence of personality disorders (TP) in general, and borderline personality (BP) is currently a significant health problem because of the complexity of the clinic, the difficulty for early diagnosis, often unsatisfactory response to available treatments and the lack of clear proposals on multidisciplinary therapeutic interventions. In more serious cases, people with TP generate a high level of self and family suffering, as well as a high care burden that does not have a proportional impact on the quality of life of those affected and their families.

Aim Establish a stable functional organization of professional and organizational resources of the Mental Health Unit of the North of Almeria that ensuring comprehensive care for people with borderline personality disorder and their families.

Methods The program was structured:

- elemental: BP census, individual sessions with optional nurse reference;
- advanced individual: BP census, individual sessions, Nurse reference;
- advanced individual and group: BP census, Individual sessions, Nurse reference and Therapeutic Group Hospital Mental Health Day weekly applying dialectical behaviour therapy.

Results The census of patients with borderline personality disorder was established in 30 people, 20 of them participating in two editions of therapeutic group. Fifty weekly sessions were carried out continuously, except holiday periods. A multidisciplinary team (nurse and two psychiatrists) were involved. The results indicate that there was an improvement in the quality of life of patients. It had been reduced hospitalisations, emergency assistance, and more than 60% of them got a job after that.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Use of paliperidone palmitate long-acting injectable in a patient with a personality disorder

N. Martinez¹, E. Benitez Cerezo², S. Garcia Marin^{2,*}

¹ Hospital Vinalopo, Psychiatry, Santander, Spain

² Hospital Vinalopo, Psychiatry, Elche, Spain

* Corresponding author.

Patient of 32 years old, sent to the psychiatric unit, because he had an aggressive behaviour after he suffered a car accident with a traumatic brain injury. The patient had a huge amount of problems with family, friends and even with police (even being in jail), due to the impulsive conduct the brain injury had created. It was added a self-referential, which produced a disruptive behaviour that he could not avoid, when someone looked at him in a strange way or was not agreeing with him. After the aggressive response, he regretted of his actions, getting to try to commit suicide in several times. It was decided, reaching to an agreement with the patient, to use the paliperidone palmitate long-acting injectable. After the first dose, the patient began to be more serene and calm, the aggressive conducts were reducing until being disappeared, improving his mood and reaching a normal life, with a better relationships with his family and social environment.

Job satisfaction among employees is a crucial issue in an organization and employer plays a vital role to fulfill their needs. Keeping job satisfaction high among workers can be of tremendous benefit to any organization, as happy employees will be more likely to produce work effectively. It has been assumed that personality traits can play an important role in people's dealing with the environmental issues such as work situations. By assuming this effectiveness, the main aim of this essay is to study the relationship between personality traits and job satisfaction. Explaining job satisfaction by using personality traits can enlighten whether job satisfaction depends only on type of organization or on some personality traits. In this regard, present study has investigated the relationship between job satisfaction and personality traits among Iran Khodro Company expert staff. To do so personality characteristics were measured by NEO-PI-R scale and job satisfaction was measured by Job Descriptive Index (JDI scale) that filled by experts of "Iran Khodro" company (111 men and women). Pearson correlation used to analyze the data. Results show that, neuroticism/emotional stability was associated with low job satisfaction ($r = -0.713$, $P < 0.01$). Also conscientiousness ($r = 0.620$) and agreeableness ($r = 0.476$) was significantly correlated with job satisfaction ($P < 0.01$). But the relationship between extraversion ($r = -0.025$) and openness to experience ($r = 0.061$) with job satisfaction was not significant. In addition, the results of this study emphasis on the effective role of age ($r = -0.301$) and job background ($r = -0.330$) on job satisfaction. But relationship between sexuality ($r = 0.183$) and marriage ($r = 0.125$) with job satisfaction was not significant.

In recent years, mobile phone is a necessary device in life, because it provides much easiness in education, work, business, etc. but extreme use of communication devices, especially among young people are related with mental health problems. So, the aim of this study was surveying of relationships between personality traits with Mobile dependency in high school students. The research method was correlation. The population were included all high school students that 220 students were selected by cluster sampling method. Research data were collected by McCare & Costa's NEO personality traits (Neuroticism, Openness to new experience, Extroversion, Agreeableness, and Conscientiousness) and Jenaro's Mobile dependency inventory, and were analyzed by Pearson correlation formula. The results showed that there is positive and significant relationship between Neuroticism and openness to new experience with Mobile dependency, and positive and significant relationship between extroversion, agreeableness, and conscientiousness with mobile dependency. Thus, it can be concluded that personality traits have main impact on mobile dependency.

Introduction Histrionic personality disorder (HPD) is one of the most common personality disorders diagnosed in Psychiatry. This disorder, although not thoroughly researched, has been known to be present in more than 40 percent of patients. There is also a high tendency for those diagnosed with this disorder to be female.

Objectives The purpose of this case is to show all the difficulties caused by this pathology, since differential diagnosis with other personality disorders, groups of characteristics from different clusters and also, complications produced in daily routine.

Methods The purpose is to study a clinical case of a 27-years-old woman, with a degree in journalism, who began with a depressive episode after a failed relationship. After being diagnosed of infertility, she debuted with dissociative episodes and somatization symptoms. She did not remember what she had done during the dissociative episode. After that, she suffered several depressive episodes, and a pseudo manic episode, making the diagnosis of bipolar disorder, with no pharmacological response to lithium or lamotrigine.

Introduction Obsessive symptomatology can sometimes be worsened when a patient with this personality trait suffers through a period of increased stress.

Aim To review articles in PubMed related to how vortioxetine affects obsessive symptoms in patients with depression.

Methods We review the case of a 45-year-old male with obsessive personality traits diagnosed of recurrent depression. He was going through a period of stress at work that had worsened his obsessive symptoms (primarily obsessive thoughts). In a previous depressive episode, he was treated with an antidepressant that triggered sexual dysfunction as a side effect. Trying to prevent another antidepressant-induced sexual dysfunction, we decided to use vortioxetine because of its low tendency to interact with the sexual function.

Results We started treatment with vortioxetine reaching a dose of 10 mg/day. Three weeks later the patient reported a decrease in his levels of anxiety, a slight upturn of his mood and a relieve of his obsessive symptoms.

Conclusions Vortioxetine can be considered a good therapeutic option in the treatment of obsessive symptoms in a depressive episode with patients with a history of antidepressant-induced sexual dysfunction.

This is a case study of a 27-year-old man with co-morbid congenital communicating hydrocephalus and epilepsy. The patient had multiple hospitalizations in psychiatric clinics due to serious domestic violence caused by compulsive buying demands. Impaired social interaction skills, diminished judgment, planning, insight and temporal organization difficulties were also present and the diagnosis of organic personality disorder was given.

The patient was treated with 1.5 g valproic acid for epilepsy and for the behavioural difficulties multiple antipsychotics, benzodiazepines, SSRI's and beta-blockers were administered, without major benefits. Due to serious aggression and impulsive behaviour, it was administered memantine 20 mg/day according to NMDA receptor antagonist hypothesis and gradually reduced the benzodiazepines and SSRI's.

A significant decrease in the average score of the Barratt Impulsiveness Scale (BIS-11) and to violence incidences was observed. Also, social interaction skills were improved and a slight improvement at patient's judgment was observed.

The patient had good tolerance during the treatment and no side effect was reported. It is the first scientific report on memantine effectiveness in this patient group. Further research is needed.

Shame: An overlooked factor in conceptualizing and treating

borderline personality disorder: Its' powerful role in the lives and suicides of people with BPD

V. Porr

TARA for Borderline Personality Disorder TARA4BPD, EXec Director, NYC, USA

Shame, a central emotion in borderline personality disorder (BPD), has been overlooked despite its' relationship to self-injurious behaviour, chronic suicidality, self-esteem, quality of life, and angry-hostile feelings. Patients describe shame when explaining acute feelings of emotional pain. There is a paucity of research exploring the impact of shame on the person with BPD's sense of self and behaviors. BPD symptoms may be the expression of and defenses against this painful emotion. Shame-proneness is related to anger arousal and the tendency to externalize attributions for one's own behavior by blaming others or not taking responsibility for one's behavior. The relationship between shame-proneness and BPD has important implications for treatment. TARA for BPD, an educational and advocacy organization, developed a Family Psycho-education program teaching how shame is often the common denominator of BPD responses, triggering escalations, emotional shifts, volatile reactions, anger and misperceptions. Shame is the response to perceived negative evaluations (judgment, criticism, or blame) and general misinterpretation of social situations. Shame is an impediment to thinking clearly, exaggerates ambiguity and overwhelms cognitive ability in the moment. As shame is often confused with guilt, raising awareness of shame responses is essential for improving family relationships. Families can learn to recognize shame responses and implement evidence based techniques from dialectic behavior therapy (DBT) and mentalization based therapy (MBT) to decrease its' impact on their loved one with BPD. Demonstration of methodology to address shame in family interactions and data from a TARA Internet survey of The Experience of Shame will be presented.

* Corresponding author.

Introduction Non-psychotic mental disorders of organic register tend to have protracted progressive course, to respond poorly to treatment. Traditionally it is explained by features of cerebral-organic process. However, affective, behavioural and cognitive disturbances can be complicated by medico-social problems including treatment-related.

Objective To analyse efficiency and stability of results of the therapy of organic mental disorders and propose approaches and means of their improvement.

Methods Clinical-psychopathological, epidemiological, clinical-dynamic, catamnestic, experimental-psychological, medical statistics.

Results The most frequent causes of decompensations of organic mental disorders in patients with positive results of the therapy were analyzed. Sixty-four percent (58 patients) after 6 months showed partial recurrence of symptoms and after a year the condition practically returned to the initial one. However, only 12.22% (11 patients) passed recommended course of maintenance therapy to sufficiently full extent, 23.33% (21 persons) have discontinued it due to subjective causes during a month after discharge, about 2/3 of patients during the first two months of the therapy. Patients showed low indicators of therapeutic compliance, low level of therapeutic alliance, little familiarity with the illness and treatment and unrealistic expectations about prospects of the therapy. During insignificant difficulties in the therapy, it usually was discontinued and renewed during relapse of symptoms. A medico-social approach with support of psychotherapeutic and psycho-corrective work and information educational programs were developed.

Conclusion Proposed psychotherapeutic and educational approach heightens efficiency and stability of treatment and can serve a basis for further improvement of psychiatric, psychotherapeutic and medico-social assistance for patients with organic mental disorders.

Working with anxiety and depression from a Buddhism framework

A. Allen

The ADHD Clinic, Psychiatry, Toronto, Canada

Buddhism as a spiritual discipline is concerned with freedom from suffering, conceptualizing suffering as originating in false views about the nature of self and reality. Buddhist psychology conceptualizes emotions and mental habits as being wholesome or unwholesome based on the tendency of these habits to promote or hinder the quest for enlightenment, and contains a rich diversity of methods to transform unwholesome emotional tendencies. Many of these emotions, such as anger, fear, and despair, are commonly dealt with in clinical or therapy settings. Buddhist ideas about the genesis and cessation of suffering can be used as an overarching model to organize a diversity of therapeutic techniques, bridge different therapy models, and select particular techniques at particular times in the treatment of emotional disorders. Learning objectives: after this session, participants will be able to use the Buddhist Yogacara model of mind and karma as a model of how negative emotions are transformed. After this session, participants will be able to describe indirect methods (evoking wholesome feelings) in order to transform negative emotional tendencies and how this overlaps with current therapy models such as supportive and compassion-focused therapy. After the session, participants will be able to conceptualize how Buddhist "direct methods" of mindful awareness and contemplating right view overlaps with methods used in cognitive behavioural therapy, marital therapy, or acceptance and commitment therapy. Self-assessment questions: according to Buddhist psychology, what is the primary cause of neg-

ative emotions? Broadly speaking, what are 3 types of techniques for transforming emotional habits?

With the advent of new technologies, the man begins to experience a significant change in the perception of the other, time and space. The acceleration of time promoted by new technology does not allow the exercise of affection for the consolidation of ties, relations take narcissists hues seeking immediate gratification and the other is understood as a continuation of the self, the pursuit of pleasure. It is the acceleration of time, again, which leads man to present the need for immediate, always looking for the new – not new – in an attempt to fill an inner space that is emptied. The retention of concepts and pre-stressing of temporality are liquefied, become fleeting. We learn to live in the world and the relationship with the other in a frivolous and superficial way. The psychic structure, facing new phenomena experienced, loses temporalize capacity and expand its spatiality, it becomes pathological. Post-modern inability to retain the past, to analyze the information received and reflect, is one of the responsible for the mental illness of today's society. From a temporality range of proper functioning, the relationship processes with you and your peers will have the necessary support to become viable and healthy.

CBT waves through the lens of Complex Systems Theory: A tentative way toward integration and sustainability

S. Cheli

University of Florence, School of Human Health Sciences, Florence, Italy

Introduction In the last 15 years, several new waves have been described within CBT. At the same time, two constraints seem to define the role of psychotherapy: an integrative theoretical trend; an increasing incidence of chronic psychiatric disorders and psychiatric morbidity in chronic conditions.

Objectives We discuss the viability of a Complex Systems Theory perspective in fostering the theoretical integration of the new wave of CBT and in promoting the healthcare sustainability in facing with chronicity.

Aims The aims of the present study are to:

- frame a few recurrent and relevant theoretical dimensions in psychotherapy;
- outline a preliminary cost-effectiveness analysis of a Complex Systems Theory approach to psychiatric chronicity.

Methods We performed a non-systematic review and a meta-synthesis of selected references (identified through a citation analysis per single reference and per single scholar) of the new wave of CBT. We especially focused on theoretical handbooks, meta-analyses and reviews, clinical trials.

Results Complex Systems Theory describes an approach to theoretical and operational models based on adaptability, interde-

pendency and self-organization. In defining a few integrative trends in psychotherapy, we highlighted the focus on:

- interpretation of events vs. events per se;
- processes vs. contents;
- transdiagnostic vs. pathologized models.

Furthermore, we framed economic, organizational, and educational implications of such an approach in promoting the adaptability of psychotherapy-as-a-system in dealing with the so-called double crisis of welfare state: continuous cutbacks in response to recession; longer-term pressures on health and social care.

Conclusions Despite further studies are needed, we maintain that psychiatry may benefit from a Complex Systems Theory perspective.

The experience of time in habitual teenage marijuana smokers

A. Dörr

Faculty of Medicine, Universidad de Chile, Psiquiatria y Salud Mental Oriente, Santiago, Chile

The research is qualitative; it studies the experience of time in young people who smoke marijuana in excess, given the high rate of smoking in the teenage years, a delicate stage regarding the planning of the future. Our objective is to see how the relationship between past and future plans is manifested in their biography, through goals and actions, in light of their ability to anticipate themselves. Our guiding principle is the ability to “anticipate oneself”, proposed by Sutter, a phenomenological psychiatrist. The information was obtained from the analysis of autobiographies of young persons through the hermeneutical phenomenological method developed by Lindseth, based on Ricoeur. The results reveal that in the biographies the past temporal dimension is characterized by poor descriptions, the present is where they extend themselves most, describing tastes, how they visualize themselves, but showing a lack of clarity in their interests. In the future, we see the absence of reference, giving the impression of no progression from the past, and without awareness of the fact that the future possibilities or lack thereof are heavily dependent on present actions.

Psyche in historical context: Identity and existence in Captain Ahab and King Lear

G. Egloff

Heidelberg University, Psychoanalytic Practice, Mannheim, Germany

Introduction What ties Ahab, the notorious captain of the Pequod in Herman Melville's 1851 novel, Moby-Dick, to King Lear, the desperate old regent from William Shakespeare's eponymous play published in 1608, is not only their overabundant quest for meaning, or their obsession with pursuing their targets, but their idiosyncratic experiencing of themselves in their personal realities.

Aims Captain Ahab is put in relation with King Lear, in order to show in what way issues of identity and of existence emerge in the course of their fictional lives. Lear is considered to have had deep influence on Melville the author in creating the character of Ahab. Since, in terms of present-day psychopathology, both fictional characters present with symptoms, their issues when put in historical context can untangle their personal realities.

Methods Through a close reading of the characters' behaviour and experiencing in historical context, issues of identity and of existence are elaborated on in order to advance to the psychodramatic substrate.

Results Whereas at the beginning of the seventeenth century conflicts are newly transposed to characters' minds instead of surroundings, the nineteenth century still sees Ahab's monomania on the outside. Identity and existence have increasingly been placed in individual psyche, though.

Conclusions A paradigmatic change in personality concept at the turn of the modern epoch enables psychiatry and psychopathology to conceptualize the individual and to derive identity and existence from. Collective identity gives way to personal identity. With that, choice, interpretation, and failing are individualized.

Dangerous or vulnerable? A genealogy of “difficult and violent adolescents” in France

Y. Gansel

Hospices Civils de Lyon, Hôpital Femme-Mère-Enfant, Psychopathologie du Développement, Bron, France

Introduction Difficult adolescent is a clinical category, defined by psychiatrists' expertise and referred to psychoanalytical concepts. Since the end of the 1990s, it has been extensively used to describe a marginal population in public institutions managing youth deviancy in France. This success occurs against a backdrop of institutional reforms, converging towards politics of suffering and risk management.

Objectives Contributing to the anthropology of mental health, this communication provides comprehensive elements to this success.

Methods Interconnected networks of 49 documents were analyzed using a genealogical method based on Foucault's late conceptions and Ian Hacking's works on constructivism.

Results Results have shown that the category of difficult adolescents found its ecological niche in the 1960s, revealing a moral tension in the use of constraint. At that time, the introduction of the psychoanalytical notions of transference and counter transference depicted a clear distinction with previous categories such as the “abnormals” or “maladjusted youth”. Since then, it has defined an ambiguous condition, suspended between the trouble of caregivers and the adolescents' individual disorder. In addition, the extension of clinical expertise silences social issues, such as gender discriminations, ethnicity and access to employment.

Conclusions The reforms of custodial treatments represented the initial conditions of detection for difficult adolescents, raising new problems of intractable individual and institutional linkage. Driving towards a biographical personalization, the category allows new forms of regulation in the use of institutional power.

Introduction Love has been one of the topics most discussed by philosophy, literature, anthropology, religion, psychology and medicine. “The feelings of love and hate are present in the background of all psychiatric disorders; love has been associated, in one way or another, in all patients that I have had” Dr. Perez Lanzac Trujillo.

Objectives (1) Analyze the possible relationship between psychotic symptoms and breakup (stressor). (2) Review the neurotransmitters involved in psychotic episodes and in love. (3) Postmodern culture and sexuality (agony of Eros and liquid love).

Methodology A 17-years-old female patient, who presented psychotic symptoms without psychiatric history. We hypothesize that the affair was the symptom and the stressful event was the breakup. We believe that early bond with the mother is a decisive factor in shaping the psychic structure of every human being factor. In this case, it seems that there is an insecure attachment: absent parent + overprotective mother.

True love draws three triangles: records (demand, drive and desire); dimensions (beliefs, significant and encounter) and emotions (pride, hope and desire).

Results Most psychiatric disorders are especially alterations in the way of experiencing emotions. Some neurotransmitters involved in her psychosis and addiction are key players in the neurobiology of love.

Conclusions True love is the neurotic experience closer to psychosis.

Overexcitement in today's society is a trauma for the psychic apparatus and it has consequences on the internal world, psychosexuality and loving bond.

The crisis of art and literature can be attributed to the disappearance of the other, to the agony of Eros.

Leonardo da Vinci: A neuropsychological enigma or an aberration?

S. Kumar

5 Boroughs Partnership NHS Foundation Trust, University of Liverpool, General Adult Psychiatry, Liverpool, United Kingdom

Introduction It has been universally regarded that Leonardo da Vinci was one of the all-time geniuses in terms of his contribution to art and sciences. A number of theories have been proposed to explain his genius that range from neurological, psychological uniqueness, and enhanced functional intelligence.

Aim The primary aim is to explore these theories in detail and register their pros and cons alongside contextualizing their credibility and weightage against the extant evidence in science.

Method A detailed literature search has been undertaken to identify variety of models and theories either:

- dealing with neurological, psychological or neuro-philosophical explanations;
- have been proposed by psychiatrist or psychologist and neurologists pertaining to Leonardo's brain or mind;
- theories around occult and religion have been excluded.

Discussion The results are synthesized and presented in a tabular form. The discussion expand son the various theories and the relevance of Leonardo da Vinci to the merging unified field of neurology, psychology, technology and philosophy (consciousness studies).

Client versus patient – The clinical, economical, moral, legal and other implications of a choice

B. Latecki

Life Empangeni Private Hospital, Psychiatric private practice, Empangeni, South Africa

The presentation discusses the overt and hidden meaning of the terms between “patient” or “client” regarding persons undergoing psychotherapy and implications of using these terms. Some historical and recent opinions and points of view are presented. As the outcome of the discussion, it is concluded that to weigh pros and cons and to decide on which name would be more appropriate, one must resort to taking into consideration the definitions of therapy, suffering, and healing. It is suggested that the criterium should be the level and nature of suffering experienced by the “taker” and the level and nature of care performed by the “giver” (provider). The relations between both parties are also discussed in terms of existential phenomenology—as opposed to dualistic approach – and holism versus atomism. It is the intention of the author to deliver some practical and not only theoretical contribution to clinical practice.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

I choose, therefore I am. The Jaspers concept of choice and implications on the ability to act

A. Riolo, F. Babici, F. Tassi*

ASS 1 Triestina, Department of Mental Health, Trieste, Italy

* Corresponding author.

Introduction According to Jaspers, with the term of choice you should not be understood the possibility to choose between objects but freedom as a choice for themselves. Because I choose, then I am; in fact, I feel my freedom in my mind. Choose what is best for the psychiatric patient in different contexts (relational, occupational, social, therapeutic) is the ability to act. The best practices provide that psychiatrists, nurses, social workers, rehabilitation professionals are committed to enhancing the capacity to choose but the legal protection measures are likely to be a contradiction.

Objective We try to explore the theme of choice based on the capacity to act or failure to act from a phenomenological approach.

Method Through some concrete cases, extrapolated from clinical practice, highlight the contradictions between enunciation of principles and procedures for responding to the problems of psychiatric patients who are not able to choose.

Conclusions Protections of health and individual freedom are the weights of a balance poised, since there is uncertainty about the anthropological paradigm of the mentally ill.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Challenging patient-doctor interactions in psychiatry – Difficult patient syndrome

M. Roque Pereira*, A. Fornelos, A.R. Figueiredo

Centro Hospitalar Trás-os-Montes e Alto Douro, Departamento de Psiquiatria e Saúde Mental, Vila Real, Portugal

* Corresponding author.

Introduction The factors contributing to a challenging interaction between the roles of patient and physician may come from several sources. Each interrelation has its own modus operandis in which one of the individuals may not condone the persona the other individual is portraying. A mental illness or diagnosis is often stigmatised by the burden of stereotypical bizarre associations. That means the patient is generally not guilty and this is not another label they should carry. Though the mental health professional should be impervious to this, some degree of discomfort may throw some shadow on the clinical mediation of the interview and management of the pathology.

Objective To provide an overview of what is beyond the label “difficult patient” in mental health care.

Aims Evaluation of conflicts inside the patient-illness-physician triad.

Methods Search for articles in Pubmed, Athens, Google Scholar databases, along with the hospital library.

Results Characteristics of problematic interactions in psychiatric care were described consistently across our references. Causality for these difficulties is vast and surpasses the patient’s behaviour. Plus they are not unique in psychiatry. They can be explained by individual, interpersonal, and social factors.

Conclusion Situational issues, along with patient and physician characteristics, modulate and frame what should potentially be a productive encounter. To become aware of what contributes to difficult clinical encounters and to be prepared to address them while cultivating good interpersonal communication skills is fundamental.

² University of Oxford, Philosophy, Oxford, United Kingdom

³ George Washington University School of Medicine, Psychiatry, Washington DC, USA

* Corresponding author.

Nowadays, we increasing value the broad physical, ethnic, racial, and cultural diversity of human beings. “How wonderful that humans come in all sorts of sizes, shapes, colors, ethnic groups and cultures.” So long as we conduct our behaviour within sanctioned norms. This presentation will focus upon the above paradox: In stark contrast to our delight in the physical, ethnic and cultural expressions of human diversity, there is, at the same time, a perhaps increasingly narrow tolerance for a variety of behavioural and experiential human differences. In such human realms, present-day cosmopolitan societies increasingly call for behavioural and experiential conformity rather than diversity. And if we cannot conform? We propose that the phenomenon of mental illness arises as a consequence of the phenomenon of human diversity coming up against constraints and limitations in expressed and experienced mental and behavioural realms. This presentation will focus upon the primary role that human diversity plays in mental illness. We will discuss adaptive strengths associated with the extraordinary diversity of humans (and our pets and domestic animals) as well as vulnerabilities accompanying this diversity. For example, diversity associated with skin pigmentation has enabled humans to extend across the globe. A consequence, however, is an enhanced vulnerability to skin cancer for some with fair skin and to Vitamin D deficiency for others with dark skin. Psychological diversities can be viewed in an analogous, pervasively more problematic man-

ner. And furthermore, unlike physical diversities, often increasingly celebrated, mental and psychological diversity are – with notable exceptions, increasingly problematic.

Relations between Minkowski and Levinas, a look beyond the phenomenology in the construction of the psyche

J. Veliz Uribe*, M. Ugalde, P. Catrifi

Clinica Psiquiatrica Universitaria, Universidad de Chile, Psiquiatria y Salud Mental, Sede Norte, Santiago, Chile

* Corresponding author.

Introduction Both Minkowski and Levinas introduced in France phenomenological thinking, psychopathology and metaphysics, respectively.

Objectives It is in this context that interested raise the similarities and differences in relation to the study of time these authors in their link to the construction of the self (soi-même).

Aims Both authors take up the relevance of temporality in the construction of the psychic, overtaking Husserl's phenomenology, the distinction between thinking and intuition discursive and theoretical thinking and sensitivity.

Methods Comparative analysis of the problem of time and its relation to the psyche, Le temps vécu of Minkowski, Autrement qu'être of Levinas.

Results You can set a break with Husserl's phenomenology, inspired by the philosophy of Bergson, based on the living back in the studio. At the same time, among the authors reviewed, there is an irreconcilable discrepancy in the notions of activity and passivity in relation to the construction of the self (soi-même).

Conclusions Phenomenology applied to the psychic needs to return to its original inspiration to go beyond a methodological rigid reading, which ends up betraying its spirit, which leads her to forget the living world in its complexity.

Three forms of intuition in Eugène Minkowski

J. Veliz Uribe*, M. Ugalde, C. Pastén

Clinica Psiquiatrica Universitaria, Universidad de Chile, Psiquiatria y Salud Mental, Sede Norte, Santiago, Chile

* Corresponding author.

Introduction Eugène Minkowski is one of the great authors of structural phenomenological psychiatry. However, it has stressed only its influence on the study of schizophrenia, however, the scope of its investigations is much coarser, while addresses issues that attempt to illuminate the way they are set life and humans.

Objectives It is interesting to pose as the author emphasizes the importance of intuition, on more than one level, giving an epistemologically worthy rank in the constitution of the self (soi-même), in psychopathology and even in the ontology.

Aims It is shown that in Minkowski research on intuition it appears as a study of a symptom called autism, as a psychopathological diagnostic method called empathy, and even as an ontological understanding that purpose of the study time.

Methods Reconstruction of the uses of the notion of intuition in the work of Minkowski.

Results Three ways clearly appear in different planes but complementary, pointing not only to a clinical trial, but take a glimpse metaphysical aspects.

Conclusions The conclusions aimed are highlighting how Minkowski think intuition not only as a dignified way to understand the suffering, or establish a knowledge, but necessary for a clinic and even an approximation of what we are.

Alexithymia in war veterans with post-traumatic stress disorder

E. Becirovic^{1,*}, E. Avdibegovic¹, R. Softic¹,

M. Mirkovic-Hajdukovic¹, A. Becirovic²

¹ UKC Tuzla, Klinika za psihijatriju, Tuzla, Bosnia and Herzegovina

² UKC Tuzla, Poliklinika za laboratorijsku dijagnostiku, Tuzla, Bosnia and Herzegovina

* Corresponding author.

Introduction Alexithymia consider a cluster of cognitive and affective characteristics that include: inability of recognizing and describing emotions, difficulties in distinguishing feelings and physical sensations during emotional arousal, narrowed capacity for imagination and externally oriented cognitive style. Several studies links alexithymia with increased risk for physical and mental damage. Symptoms of alexithymia are documented in persons who develop PTSD in response to different types of traumatic events.

Objectives To examine alexithymia in war veterans.

Aims To determine whether alexithymia is significantly more present in war veterans with PTSD.

Methods Cross-sectional study of 205 war veterans tested by Harvard Trauma Questionnaire and by Toronto Alexithymia Scale (TAS-20).

Results Out of 205 war veterans 89 (43.4%) of them have alexithymia. Significantly more veterans with PTSD (78 or 75%) than without PTSD (11 or 10.9%) has alexithymia ($\chi^2 = 88.955$, $P < 0.001$) was found a statistically significant difference between the two groups in the total score of alexithymia (t -test = -10.676 , $P < 0.001$) statistically significant difference was found in all three domains of alexithymia.

Conclusions Alexithymia is significantly often in war veterans with than without PTSD.

Residual sleep disturbance in Tunisian military patients with post-traumatic stress disorder

H. Belhadj*, W. Krir, H. Elkefi, A. Oumaya

Military Hospital, Psychiatry, Tunis, Tunisia

* Corresponding author.

Introduction Sleep disorders such as nightmares and insomnia are among the most frequently reported symptoms in patients with post-traumatic stress disorder (PTSD).

Objective To assess the prevalence of residual sleep disorders in military personnel with PTSD.

Methods A cross-sectional study was conducted and included 25 military consultants meeting the criteria of DSM-5 for PTSD. Sleep disorders were assessed using the insomnia severity index (ISI).

Results The mean score of the ISI was 14. Fourteen percent of the participants ($n=21$) reported difficulty falling asleep. All patients reported difficulties staying asleep. Nightmares were reported by 48% of the sample ($n=12$). All patients were under hydroxyzine at dosages ranging from 25 to 50 mg per day. More than half of the sample ($n=18$) was under a combination of benzodiazepine and hydroxyzine. Seventy-one percent of patients ($n=15$) considered that their sleep difficulties significantly disrupted their daily lives.

Conclusion Insomnia is one of the most frequent and persistent symptoms in PTSD patients. These sleep disorders can impede remission and may be due in part to co-morbid depression.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Assessment of chronic pain in military patients with PTSD

E. Ben Zina^{1,*}, M.W. Krir², H. Bel Hadj¹, A. Tajmout¹,
C. Ben Cheikh¹, H. El Kefi¹, A. Omayya¹

¹ Principal Military Hospital of Instruction of Tunis, Psychiatry, Ariana, Tunisia

² Principal Military Hospital of Instruction of Tunis, Psychiatry, Tunis, Tunisia

* Corresponding author.

Introduction Patients with post-traumatic stress disorder (PTSD) presents often with several concomitant physical and mental health problems. Recent evidence suggests that pain is one of the most commonly reported symptoms in patients with PTSD, regardless of the nature of their traumatic experience.

Aim of the study To evaluate chronic pain in patients with PTSD in a Tunisian military sample.

Methods Transversal descriptive study of a sample of 22 patients treated for PTSD in the Principal Military Hospital of Instruction of Tunis during the period between August and October 2016.

The PTSD Checklist for DSM-5 (PCL-5), Hospital Anxiety and Depression scale (HAD), and the Brief Pain Inventory Short Form (BPI-SF) were administered for patients.

Results All the patients of the study were male. The mean age of the sample was 29.6 years. Fifty percent presented with a co-morbid major depression and 59.1% with chronic pain symptoms. Locations of chronic pain were as follow: limb pain (69.23%), back pain (38.46%), headache (30.76%) and torso pain (7.69%). Sequelae from combat-related trauma were present in 31.8% of cases.

Conclusion The results of this study illustrate a high rate of chronic pain symptoms among PTSD patients. This suggests that closer attention should be given to the interaction of medical problems, especially pain, with PTSD symptomatology in clinical management and in future research.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Self-esteem in military patients with post-traumatic stress disorder

E. Ben Zina*, M.W. Krir, H. Bel Hadj, R. Lansari, H. El Kefi,
C. Ben Cheikh, A. Omayya

Principal Military Hospital of Instruction of Tunis, Psychiatry, Ariana, Tunisia

* Corresponding author.

Introduction Maintaining self-esteem is a fundamental human motivation. Trauma may lower self-esteem, which contributes to the development and maintenance of Post-Traumatic Stress Disorder (PTSD).

Objectives Assessment of self-esteem in Tunisian military patients suffering from PTSD. Study of correlation between the severity of the PTSD symptoms and the rate of self-esteem.

Methods Transversal descriptive study of a sample of 22 patients treated for PTSD in the Tunisian Military Hospital during the period between August and October 2016.

The PTSD Checklist for DSM-5 (PCL-5), Hospital Anxiety and Depression scale (HAD), and the Rosenberg Self-Esteem Scale were administered for patients.

Results All the patients assessed were male. The mean age of the sample was 29.6 years. Fifty percent of the patients presented with a co-morbid major depression. Based on the score of the Rosenberg Self-Esteem Scale, patients had a self-esteem, which was very low in 45.45% of cases, low in 45.45% of cases, average in 4.54% of cases and high in 4.54% of cases. The results also showed that lower levels of self-esteem are significantly correlated to the severity of the PTSD symptoms as measured by the PCL-5 score.

Conclusions This study highlights the magnitude of self-esteem deficiency among patients suffering from PTSD. It remains unclear as to whether the relationship between trauma and depression is consistently mediated by a negative cognitive schema, such as low self-esteem, or whether trauma influences mood independently of low self-esteem. Further studies are required.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Post-traumatic stress spectrum and adult autism subthreshold spectrum in parents of children with epilepsy: Correlations and gender differences

C. Carmassi, M. Corsi, C. Gesi, C.A. Bertelloni*, V. Pedrinelli,
G. Massimetti, A. Bonuccelli, A. Orsini, L. Dell'Osso
Azienda Ospedaliero, Universitaria Pisana, Department of Clinical
and Experimental Medicine, Pisa, Italy

* Corresponding author.

Introduction Data that assess the co-morbidity between post-traumatic stress symptoms and autism spectrum are scarce. Nevertheless, some authors suggested that subjects with autism spectrum disorder (ASD), due to their difficulty in understanding the codes of communication, empathy, expression, are lower resilience to traumas.

Objectives The aim of this study was to explore in a sample of parents of children with epilepsy, the presence of correlations between the symptoms of post-traumatic stress and adult autism subthreshold spectrum.

Methods Seventy-seven parents completed the Trauma and Loss Spectrum Self-Report (TALS-SR), specifically modified for one's son epileptic disease, and 72 parents completed the AdAS Spectrum (Adult Autism subthreshold Spectrum).

Results Eight subjects (11.1%) presented a total score ≥ 45 at the AdAS Spectrum, corresponding to the satisfaction of a symptomatic ASD criteria and indicative of the Adult Autism Spectrum subthreshold. More specifically, a total score ≥ 45 was found in 7 (15.9%) of mothers and 1 (3.6%) of the fathers, with no statistically significant differences between the two groups ($P=0.139$).

Noteworthy correlations between TALS and AdAS, emerged only in the subgroup of the fathers. In particular, a relevant number of moderate to good correlations emerged between the Domain II (reactions to the events of loss) of the TALS-SR and the AdAS Domain III (non verbal communication), Domain VI (restricted interests and ruminations) and total score.

Conclusions Results indicate that this peculiar psychopathological model could lead to increased vulnerability to effects of the trauma, in particular in male.

Disclosure of interest The authors have not supplied their declaration of competing interest.

DSM-5 PTSD and Post-Traumatic Stress Disorder Spectrum in patients with fibromyalgia: Possible correlations with subthreshold autism spectrum?

C. Carmassi*, C. Manni, G. Cipollone, C. Tagliarini, M.T. Avella, C. Portulano, G. Massimetti, C. Conversano, L. Bazzichi, C. Gesi, L. Dell'Osso

Azienda Ospedaliero-Universitaria Pisana, Department of Clinical and Experimental Medicine, Pisa, Italy

* Corresponding author.

Introduction PTSD is extremely common in patients with fibromyalgia (FM) with rates up to 57%, and it often correlates with increased severity of the disease.

Objectives The aim of this study was to investigate the presence of PTSD, diagnosed according to DSM-5 criteria, and of Post-Traumatic Stress Spectrum symptoms in a sample of patients with FM.

Methods Sixty-one patients, 7 males and 54 females, with FM, diagnosed according to American College of Rheumatology (ACR) at the Unit of Rheumatology of A.O.U.P clinics, were assessed by: SCID-5; Trauma and Loss Spectrum Self-Report (TALS-SR); Adult Autism Subthreshold Spectrum (AdAS Spectrum).

Results Patients with FM with full and partial PTSD reported a significantly higher number of losses and potentially traumatic events in the TALS-SR than patients without PTSD. Significantly, higher AdAS Spectrum scores in almost all domains were reported in patients with PTSD with respect to those with partial or without PTSD. Moderate to good correlations were highlighted amongst most of the TALS-SR and ADAS-Spectrum domains.

Conclusions Significant DSM-5 PTSD rates emerged in our sample of patients with FM. Significant correlations were found between Adult Subthreshold Autism Spectrum and Post-Traumatic Stress Spectrum, corroborating recent hypotheses that indicate autism spectrum symptoms as vulnerability factors for PTSD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Full and partial DSM-5 PTSD in parents of children with epilepsy: Exploring gender differences

C. Carmassi, M. Corsi, C. Gesi, C.A. Bertelloni*, F. Faggioni, E. Calderani, G. Massimetti, D. Peroni, A. Bonuccelli, A. Orsini, L. Dell'Osso

Azienda Ospedaliero-Universitaria Pisana, Department of Clinical and Experimental Medicine, Pisa, Italy

* Corresponding author.

Introduction Increasing literature suggests the need to explore PTSD and post-traumatic stress symptoms among parents and caregivers of children with acute and chronic illnesses but scant data are available on epilepsy.

Objectives The aim of this study was to estimate full and partial PTSD rates among parents of children with epilepsy according to DSM-5 criteria. Further, aim of this study was to examine eventual gender differences between mothers and fathers.

Methods One hundred and thirty-eight parents, 91 mothers (65.9%) and 47 (34.1%) fathers, of children diagnosed with epilepsy were interviewed using the SCID-5.

Results Full and partial DSM-5 PTSD were reported by 10.4% and 37.3% of patients, respectively. Significant gender differences, with the mother more affected, emerged in the rates of partial A PTSD rates ($P=0.048$) and in the endorsement rates of criterion B (intrusion symptoms) ($P=0.047$), criterion D (negative alterations in cognitions and mood) ($P=0.010$) and criterion E (alterations in arousal and reactivity) ($P<0.001$) too.

Conclusions This is the first study to identify post-traumatic symptoms in caregivers of pediatric patients with epilepsy with the use of current diagnostic criteria and the relevance of the results suggests the need for further studies on this risk population.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Post-traumatic stress and subthreshold autism spectrum among divers of the Italian Navy employed in search and rescue activities

C. Carmassi, P. Isabella, C.A. Bertelloni*, M. Corsi, G. Massimetti, C. Conversano, L. Dell'Osso

Azienda Ospedaliero, Universitaria Pisana, Department of Clinical and Experimental Medicine, Pisa, Italy

* Corresponding author.

Introduction Rescue emergency personnel is at high risk to develop PTSD due to possible extreme and repetitive exposition to "cruel details of traumatic events".

Objective This study aimed to explore posttraumatic stress and subthreshold autism symptomatology and their impact on social and working functioning level among sub mariner of Italian Navy, who were employed in the Costa Concordia and Genova tower rescue operation.

Methods Eighty-five subjects were enrolled and investigated by the following instruments: Trauma and Loss Spectrum Self-Report (TALS-SR), Adult Autism Subthreshold Spectrum (AdAS Spectrum) and Work and Social Adjustment Scale (WSAS).

Results The response rate was about 50%. Ninety-five percent of the subjects were employed in recovering corpses and 80% reported at least one rescue operation in the last three years. Full and partial DSM-5 PTSD rates were 8% and 27.5%, respectively. A strong correlation emerged between several TALS-SR and ADAS domain. Furthermore, TALS-SR domain scores were related to WSAS domain.

Conclusion This data showed rescue personnel to be at risk for post-traumatic stress spectrum and related work and social impairment. Further studies are needed to better investigate possible risk and resilience factors associated to PTSD.

Post-traumatic stress disorder, violence and war: A documental exploratory research

M.A. Dos Santos^{1,*}, R.D.C. Soares Junior²

¹ Universidade Católica Dom Bosco e Universidade de Coimbra, Psicologia e Medicina, Porto, Portugal

² Universidade Católica Dom Bosco, Psicologia, Campo Grande, Brazil

* Corresponding author.

Introduction In a globalized world, violence, present in all forms and everywhere, it is a serious public health problem. Violence and war lead to death and leave marks on the bodies and minds, and the post-traumatic stress disorder (PTSD) is a mental disorder that may develop following exposure to a potential event traumatic.

Results In the 3-month period (January 2016 to April 2016), according to typological analysis of the journal cover, the following results were found: the type of prevailing violence was interpersonal, community, committed by a stranger (75%), followed by the violence of the economic type (16.7%), and finally interpersonal violence committed by partner (8.3%). Although not all cases have provided the number of people who perpetrated or suffered violence, most victims of violence were male (8), aged 3 months and 36 years, followed by 2 women, and as a perpetrator of violence the men were in excess (4 men) followed by one woman.

Discussion Violence and war are traumatic stressors and risk factors for PTSD which, in turn, is also a risk factor to perpetrate violence, such as domestic violence. The costs of violence are high and its routinization as a way of life has important effects on the mental health of population.

Considerations Scientific research, including qualitative studies, on PTSD, violence and war are necessary so that we have a better understanding of the phenomenon as well as to promote the mental health of all through early intervention or even in preventing the onset of this disorder.

Deaths and symbolic use of language: Semiotics and thanatological reading of the film *Nell*

S. Färber^{1,*}, M. Färber²

¹ VIVER Psicologia e Tanatologia, Tanatologia, Cascavel, Brazil

² VIVER Psicologia e Tanatologia, Psicologia, Cascavel, Brazil

* Corresponding author.

Introduction Psychiatric disorders may become more severe when the subject is exposed to a hostile environment. Symptoms of mental malaise are expressed by the senses, including speech and language.

Methods The method is used of semiotic analysis and thanatological movie.

Objective To investigate the limit and death as a trigger of a singular mode of use of the spoken language. The problem presented in this paper is the linguistic system created by *Nell*.

Results Partial results show that spoken language in this particular cut, becomes an instrument for dealing with the losses accumulated throughout his life. The life of isolation, restrictions on maternal vocalization, her mother's death and mourning acted as an inhibitor of language.

Conclusion The spoken language works like kaleidoscope of interactions of the individual with their group, with the medium in which it is inserted, with the set of beliefs that nourishes and with the world that she wants there, even if only in your intimate venue. Thus, demonstrating the sociolinguistic approach inalienable role in speech performance.

² Osakidetza, Psychiatry, Vitoria, Spain

³ Marqués de Valdecilla, Psychiatry, Santander, Spain

* Corresponding author.

Introduction Traumatic event related disorders (ASD, PTSD and dissociative disorders) could share a common dissociative psychobiological origin. Patients diagnosed with dissociative identity disorder present a high sexual abuse rate (85–90%), way above the rest of the traumatic spectrum disorders.

Objectives The goal of this study is to analyse the existing relation between different types of trauma, especially sexual abuse, and the onset and continuity of dissociative disorders.

Materials and methods We report the case of a 37 years old woman with a long sexual abuse history. The symptoms appear by age 30, in the form of flashbacks, ushering a persistent identity fragmentation in individual differentiated opposed components, shaping a dissociative personality disorder, which was present for years taking a fluctuating and invalidating nature.

Discussion When a traumatic event occurs, acute dissociative reactions frequently appear, usually briefly, disappearing spontaneously afterwards. In this case, we can discern the persistence of the dissociative symptoms and the repercussion they had in the patient's functionality.

Conclusion The existence of a correlation between the duration of a chronic traumatic event and the persistence of dissociative symptoms in the evolution of a dissociative personality disorder is possible.

Keywords Dissociation; Trauma; Abuse; PTSD

Prevalence study of mental disorders in Georgian military personnel participating in peace-keeping missions

S. Giorgi*, T. Oniani, G. Nino, K. Giorgi, L. Estate

Ministry of Defence of Georgia, Psychological Recruitment and Monitoring Department, Tbilisi, Georgia

* Corresponding author.

Introduction Due to the professional activities acute stress disorder and PTSD are most diffuse disorders among military servants. Number of studies revealed relationships between post-traumatic stress and depression, anxiety or somatic complaints.

Objective Though Georgian military personnel actively take part in the international peacekeeping missions since 2004 and no research was conducted to investigate the prevalence of above-mentioned disorders.

Aims Thus, this study aims to investigate the prevalence of PTSD, depression, anxiety and somatic complaints in the cohort of Georgian military servants.

Method The research participants were 2799 military servicemen who had been deployed on the 6 month long period to the peace-keeping missions and were screened for psychological problems after deployment. All of them were Caucasian males, with average age of 29.3 years. All participants were asked to complete a PTSD Checklist for DSM-5 (PCL-5), as well as a 15-item somatic subscale of the Patient History Questionnaire (PHQ-15), a 9-item depression subscale of the Patient History Questionnaire (PHQ-9), a 7-item anxiety subscale of the Patient History Questionnaire (GAD-7).

Results Prevalence rate of probable PTSD screened by the PCL-5 was 2.7%. Further investigation showed that depressive, anxiety and somatic symptoms among them was 21.6%, 8.7% and 21.7% respectively.

Conclusion Appreciable positive relationship was found ($r=0.65-0.70$; $P<0.001$) between these variables in the deployed military servants. Therefore, it is recommended that military servants should be screened on all above mentioned conditions along with PTSD, in order to see full picture of co-morbid problems.

Predictors of post-traumatic stress disorder in military personnel deployed to peacekeeping missions

S. Giorgi*, N. Guguhshvili, T. Oniani, G. Kanaldarishvili, E. Lelashvili

Ministry of Defence of Georgia, Psychological Recruitment and Monitoring Department, Tbilisi, Georgia

* Corresponding author.

Background The following study shows that PTSD, depression and anxiety present actual and urgent problem in military field. These disorders appear to be highly co-morbid that results in much more complicated treatment process and outcome. Service members of Georgian armed forces participate in various international peacekeeping operations on the regular basis, though there are no researches conducted so far to provide evidence for mental health problem prevalence in Georgian deployed military personnel.

Method Collection of the data took place during the period of 2014–2015 years after six months of service members returning from the international peacekeeping mission back to their homes. The sample for this research were represented by 2799 servicemen who actively engaged in ISAF peacekeeping missions. All of them were male, with average age: $M=29.3$ ($SD=6.3$). The data for the following research were collected using self-administered assessment measures, namely PCL-5 for PTSD screening and PHQ for depression and Anxiety and somatic complaints assessment.

Results PTSD appeared to be significantly predicted by range/level of anxiety and depression symptom urgency, nevertheless after joint/combine integration of these variables in one regression equation, just symptoms of depression remained as statistically reliable explanatory factor for the significant percentage of the somatic symptom range variation.

Conclusion It would be wise to recommend mental health care specialists particularly to bear in mind the possibility of co-existing depression and anxiety symptoms in patients with PTSD.

³ Université de Nantes, laboratoire psychologie des Pays de la Loire, UPRES EA 4638, psychology, Nantes, France

* Corresponding author.

Introduction While research on religious beliefs as an adjustment is on the rise, less is known regarding such process following stillbirth and no study has been conducted on a sample of Moroccan women.

Objectives The aim of the present study is to extend the current literature by:

– identifying a typology of Moroccan women who experienced stillbirth based on several dimension of religious coping strategies;

– examining whether these profile differ on grief, anxiety, post-traumatic stress disorder (PTSD) and posttraumatic growth (PTG) symptoms.

Methods One hundred Moroccan women who experienced stillbirth were recruited through a Moroccan public hospital. At 6 weeks following stillbirth, they completed questionnaires assessing Religious Coping Strategies (RCS), PTSD, PTG, anxious and grief symptoms.

Results Five clusters were identified: one with high level of plead and religious avoidance coping strategies, one with high level of interpersonal coping strategies, one with multiple religious coping strategies, one with discontent religious coping strategies and one with low religious coping strategies. High levels of psychological symptoms were found in the 5 cluster and PTG symptomatology was as associated with increased RCS.

Conclusion Our findings suggest that, while religious beliefs and practices as a coping strategy do not protect from short-term psychopathological symptoms in the immediate aftermath of stillbirth, they play an important role in the development of positive reactions. As PTG symptoms have been reported be a protective factor for long term psychiatric symptomatology further longitudinal studies focusing in this area is warranted.

Post-traumatic mania symptoms: About one case

H. El Kefi*, I. Beldi, W. Krir, C. Benchikh Brahim, S. Eddif, A. Oumaya

Hôpital militaire principal d'instruction de Tunis, Psychiatry, Tunis, Tunisia

* Corresponding author.

Introduction Psychotraumatism can constitute for some people a real existential fracture, a real upheaval of the psychic organization. Immediate psychological reactions can vary from one-off and temporary reactions to far more severe and sometimes enduring reactions.

Material and methods We collected the case of a patient who was hospitalised in April 2015 for manic symptoms in the immediate aftermath of a terrorist attack, with a review of the literature.

Clinical case This is Mr. A. F., aged 38, with a personal history of AVP and a shooting wound following a terrorist attack. He had presented a psychomotor instability and an exaltation of the mood in the immediate aftermath of an ambush.

Behavioural problems were identified by the psychiatric team during the group debriefing conducted at the HMPIT emergency room. During his hospitalisation, a chemotherapy based on thymoregulators, neuroleptics and anxiolytics was introduced.

The evolution was marked by a significant regression of the manic syndrome after ten days, and the installation of a post-traumatic stress condition (PTSD). At the end of eight months, the patient was able to resume his work with long-term thymoregulatory treatment, a ban on weapons and safety posts.

Conclusion Manic episodes are rarely observed as an immediate post-traumatic reaction. Their occurrence does not prevent the subsequent installation of PTSD. Has psychic trauma revealed a latent psychosis? Is it a trauma-induced mood disorder?

Clinical features of PTSD and adjustment disorders in refugees from the zone ATO

H. Kozhyna*, V. Korostiy, V. Mykhaylov
Kharkiv National Medical University, Psychiatry, Narcology and Medical Psychology, Kharkiv, Ukraine

* Corresponding author.

Aim To study clinical features of PTSD and adjustment disorders in refugees from the zone ATO.

Methods We have a complex psychopathological and psychodiagnostic research 156 refugees in volunteer center in Kharkiv.

Results Among the IDPs observed, 75.9% have violations of adaptation: long-term depressive reaction and predominant disturbance of other emotions. The men reactive alarm indicators (average – 37.7 ± 3.0), were higher than trait anxiety (average – 32.6 ± 2.9). On the contrary, women figures trait anxiety (average – 38.6 ± 2.9) were higher than reactive anxiety (average – 34.7 ± 3.0). Severity of depressive symptoms also slightly prevailed in women. The mean score on the Hamilton scale for men was 17.0 ± 2.3 points, women – 18.0 ± 2.3 points.

Test results on a scale of quality of life showed no significant differences between men and women. We have developed a medical and psychological support system to correct the neurotic disorders in refugees.

Conclusions The majority of people who left the ATO zone have psycho-emotional disorders of different severity and require a further correction in the specialized medical institutions.

Introduction Mental health professionals find it very challenging to provide counselling and therapy when confronted with disclosures of ritual, satanic and extreme abuse. Psychometric and muscle testing can facilitate diagnosis and healing in this context. Psychiatrists of renown such as David Hawkins and Colin Ross have embraced and written about energetic medicine in their practice.

Objectives The presentation explains how somatoform dissociations are tell-tale indications of abuse and neglect of early childhood trauma and how 'Energetics' therapy facilitates healing.

Aims Delegates will learn to recognise somatoform dissociation symptoms, understand advances and limitations of psychometric assessment tools, appreciate energetics approaches as an adjunct to other intervention methods and gain an insight into the origins of complex trauma.

Methods Two case studies are used to illustrate causes, impact, diagnosis and healing of complex trauma.

Results A set of psychometric assessments helped to unravel a chilling revictimisation crime series. 'Twice Exceptional' characteristics were very high IQ coupled with Dyslexia, very weak auditory memory and psychic capabilities. In another case that stemmed from extreme abuse of ancient, commercial and high-tech vari-

eties muscle testing and energetics therapy lead to a remarkable recovery.

Conclusions Psychometric and muscle testing can inform diagnosis, therapy and healing. Energetics can be used to bring about profound healing for those who have repressed severe trauma. This method has many advantages in that parts of it are easily learned, it is non-invasive, has no side effects, gives patients control over their reactions, eliminates triggers and offers healing.

Prefrontal cortex neurochemical changes in single prolonged stress as a model of post-traumatic stress disorder: In vivo magnetic resonance spectroscopy at 9.4 T

S.I. Lim*, K.H. Song, C.H. Yoo, D.C. Woo, B.Y. Choe

The Catholic University of Korea, Biomedical Engineering, Seoul, Republic of Korea

* Corresponding author.

Purpose Single prolonged stress (SPS) is an animal model of post-traumatic stress disorder (PTSD). Until now, it has not been known how PTSD develops from the first exposure to traumatic events and neurochemical differences between acute/single stress and PTSD-triggering stress. The object of this study is to determine neurochemical changes in prefrontal cortex of rats using in vivo proton magnetic resonance spectroscopy (1H-MRS) at 9.4 T.

Method and Materials Male Sprague-Dawley rats ($n = 11$; mean body weight: 200–220 g) were used. The SPS was used in this study. Rats were restrained for 2 h and then immediately forced to swim for 20 min in water (20–24 C). After a 15 min recuperation period, rats were exposed to ether until anesthesia occurred. MRS was performed 30 min before SPS, 30 min after the stressors, 3 and 7 days after the stressors to investigate time-dependent changes on metabolites levels in the PFC. Acquisition of MRI/MRS was conducted at four time points using 9.4 T Agilent Scanner. Concentration of metabolites was quantified by LCModel. A one-way ANOVA test with Tukey's HSD post-hoc test was used for statistical analyses.

Results The SPS resulted in altered absolute metabolite concentrations for GABA [F(3.0)=1.450, $P = 0.035$], glutamate [F(3.0)=3.417, $P = 0.026$], glutathione [F(3.0)=3.759, $P = 0.018$], NAA [F(3.0)=3.919, $P = 0.015$], total choline [F(3.0)=7.584, $P = 0.000$], total NAA [F(3.0)=3.760, $P = 0.018$], total creatine [F(3.0)=3.248, $P = 0.032$] and glutamine/glutamate [F(3.0)=3.552, $P = 0.023$] among the four time points.

Conclusion PTSD in human is associated with decreased neuronal activity in the PFC. In this study, SPS decreased glutamate (excitatory) and total choline (membrane turnover) on day 7.

Mental disturbances on anti-terrorist combatants in Ukraine

B. Mykhaylov

Kharkov medical academy of postgraduate education, Psychotherapy, Kharkov, Ukraine

In Ukraine, the significant participants of the "Anti-Terroristic Operation" (ATO) need to provide a system of psychiatric, psychotherapeutic assistance. The 6 groups of disorders:

– non-pathological reaction (Z65.5);

- pathological reactions (F43.0);
- neurotic disturbances (F45);
- psychotic disturbances (F44);
- PTSD (F43.1);
- chronic personality changes (F62.0).

The system of complex assistant was provided. Step 1: emergency psychological assistance. It is carried out on the basis of crisis intervention, that is defined as the emergency and urgent medical and psychological first aid, aimed at the return of the victim to the adaptive level of functioning, preventing prodromal development of mental disorders, reducing the negative impact of a traumatic event. Step 2: medical and psychological support. The purpose is the relief of mental and behavioral disorders, prevention (secondary and tertiary), psychological maladjustment, progressive course of mental disorders, with the purpose, rational, suggestive, cognitive-behavioral (CBT), and others. The aim of psychotherapy is to support the patient's assistance, processing traumatic material reevaluation of the crisis, a change of attitude, increased self-esteem, develop realistic perspectives and active life position. It is important to restore a sense of competence and design future in which you can use a good past experiences. Step 3: the primary goal of treatment is relief of anxiety and fear, stress, adaptation to the human life and activity in conditions of continuing psychogenic. The most effective method of psychotherapy in these cases is CBT. Step 4: supportive. All steps developed by multimodal model of psychotherapy.

Psychotherapies for complex trauma: A combination between EMDR and mindfulness

H. Tounsi, P. Pacioselli, L. Riou, C. Gouret, L. Gross, A. Quaderi, J. Palazzolo*

Université de Nice, Psychology, Nice, France

* Corresponding author.

Faced with the effects of trauma, new psychotherapies are emerging in France, converging especially around awareness, experience and emotion. The hypothesis put forward here concerns the complementarities of the two following approaches: Mindfulness, part of a behavioural and cognitive context. EMDR that uses neuroscience through its ABS. The implementation of a protocol based on EMDR and mindfulness, has shown convincing results on the demented elderly person suffering from complex PTSD. The protocol begins with a session devoted to anamnesis and symptoms evaluation. The second phase consists of desensitization and cognitive restructuring. The principal foundations rely on EMDR but also include mindfulness exercises to reduce anxiety due to the effects of therapy or otherwise allow the possibility to bring new material when it seems to encounter a deadlock. The third phase is the consolidation of therapeutic benefits. For this, ABS are based on the patient's resources and meditation exercises are performed in order to amplify the restructuring. The combination of these two therapies could allow to potentiate their respective effects. The single case study that we conducted allowed us to observe encouraging results: reduction of symptoms of revival, autonomic hyper-activation and avoidance. Effects were also observed for co-morbid symptoms namely depression, anxiety and psychotic manifestations. The combination of these two approaches seems profitable and requires replication.

⁶ Inje University Seoul Paik Hospital, Department of Psychiatry, Seoul, Republic of Korea

* Corresponding author.

Aim Both trauma-focused cognitive behaviour therapy and antidepressant medication are regarded as the first line treatments for post-traumatic stress disorder (PTSD). However, little is known about sequential or combined efficacy of these two different treatment options. This prospective study examined the add-on efficacy of eye movement desensitization and reprocessing (EMDR) therapy among adult civilians with PTSD who continued to be symptomatic after antidepressant treatment.

Method Adult patients with PTSD at a specialized trauma clinic who received treatment doses of antidepressants for more than 12 weeks were recruited; definition of symptomatic PTSD was a total score > 40 on the Clinician-administered PTSD Scale (CAPS). The CAPS and the global improvement from Clinical Global Impression (CGI) were rated prior to EMDR, after termination and six months follow-up.

Results A total of 15 patients underwent an average of six sessions of EMDR and 7 (47%) of 15 no longer met the criteria for PTSD and 10 (67%) were given status of very much or much improved. The CAPS scores and significantly decreased after EMDR therapy (paired $t = 7.38$, $df = 14$, $P < 0.0001$).

Conclusion These results indicate that EMDR or trauma-focused CBT can be successfully added to those who failed to improve after initial pharmacotherapy for PTSD. Further studies are needed to explore the best sequence or components of therapies in the treatment of PTSD.

Impact on new onset stress and post-traumatic stress disorder (PTSD) in relatives of patients admitted to an intensive care unit evaluated by diaries study

K. Sundararajan

Royal Adelaide Hospital, Intensive Care Unit, Adelaide, Australia

Introduction ICU diary is effective in aiding psychological recovery and reducing the incidence of new onset PTSD in patients three months after ICU discharge. The impact of ICU diaries on PTSD in relatives of critically ill patients in Australia has not been fully elucidated.

Aims and objectives To determine the impact of ICU diaries on the incidence of PTSD, stress and family satisfaction in the relatives of critically ill patients.

Methods One hundred and eight consecutive patients, staying > 48 hours in a tertiary ICU were identified. A survey using

DASS-21, IES-R, and FS-ICU questionnaires was performed followed by a repeat survey 90 days post discharge from ICU. An IES-R score of >33 was used to define PTSD. A FS-ICU score <5 was used to define dissatisfaction.

Results Forty subjects refused to participate, eight were excluded, sixty family members were included for analysis on an intention to treat basis which included 36 completed diaries. Whilst there was no association between PTSD at 3-month follow-up and diary use (P -value = 0.9), there was an association with PTSD at baseline (P -value = 0.02) and unemployment (P -value = 0.0045). Medical patients had mean PTSD score 3.0 units greater than surgical (estimate = 3.0, 95% CI: 0.3, 5.7). Families who were dissatisfied (FS-ICU score of <5) were not at more at risk of developing PTSD than families who were satisfied (P -value = 0.74).

Conclusion ICU diaries did not impact on the incidence of stress, family satisfaction with care and PTSD in relatives of patients in this index population.

Repeated programmed hospitalizations (RPH) in the care of French military suffering for war post-traumatic psychiatric disorders: Interests and limitations

G. Thomas*, E. Le Pape, E. Py-Leroy, E. Mele, G. Tourinell
HIA Robert-Picque, Psychiatry Service, Villenave-d'Ornon, France

* Corresponding author.

Introduction The long-term management of psychiatric wounded patients with prolonged disorders requires a rethinking of our practice of care.

Objectives The aim is to propose an integrative model of all valid therapies in the post-traumatic-stress disorder while taking care of co-morbidities and ensuring patient support in the different administrative procedures that permit reconstruction. Repeated short-term hospitalizations can meet this objective by mobilizing resources, creating group dynamics, restoring a space of safety, allowing a rupture with the environment, preventing recurrence of crises, and by encouraging the historicization of trauma by the temporal sequences of intra/extra-hospitalisation repetition.

Method We propose, by means of a review of the literature, to discuss on a psychopathological level the interest and limits of this mode of care.

Results This work reveals the specific therapeutic effects of repeated programmed hospitalizations, which constitute a new modality of institutional psychotherapy.

Conclusion Rethinking the place of hospitalisation in the management of psychiatric illnesses can be useful to all psychiatrists who follow patients with chronic and co-morbid disease.

Impact of terrorist attacks on the profile of consultants at the outpatient department of Razi hospital

R. Trabelsi^{1,*}, A. Bouasker², H. Zalila²

¹ Razi Hospital, Department Psychiatry F, Mannouba, Tunisia

² Razi Hospital, Outpatient Department, La Mannouba, Tunisia

* Corresponding author.

Introduction A trauma is an uncommon experience of violence in which the physical and psychological integrity of an individual or group has been threatened. Intentional violence in general and terrorist attacks in particular are a perfect example of this. It turns out that during the year 2015 Tunisia was shaken by a series of terrorist attacks as sudden as violent. What impact would these actions have on the profile of consultants at the Razi hospital?

Methods A retrospective and descriptive study of the consultants between January 1, 2015 and December 31, 2015, while determining the socio-demographic, clinical and therapeutic profile of the consultants for the first time at the outpatient clinic of the Razi psychiatric hospital, and indicating the different changes during the month following each attack; Bardo 18 March, Sousse 26 June and Mohamed V 24 November.

Results Our study pointed to an increase in the number of consultants at the hospital (31%) and outpatient (128%) levels during the year 2015, without increasing the number of consultants. New consultants. The new consultants are younger with a strengthening of the female predominance (56.8). In the months following the attacks from the same period of the previous year, we found that diagnoses of acute and post-traumatic stress disorders (151%) and (93%) increased in percentage.

Conclusion The impact of terrorist attacks is harmful to people directly exposed but also to vulnerable people. It imposes the necessity of a preventive activity involving multidisciplinary interventions in order to develop the concept of resilience.

Five sessions of in vivo exposure therapy for post-traumatic stress disorder: A case report

T. Tuvia*, S. Rego

Montefiore Hospital, Psychiatry, Bronx, USA

* Corresponding author.

Introduction Prolonged exposure (PE) is recognized in many guidelines as an effective, evidence based treatment for post-traumatic stress disorder (PTSD), with the active ingredients being in vivo and imaginal exposure. Despite this, patients and clinicians are often reluctant to engage in this form of treatment. Imaginal exposure can be perceived as too anxiety provoking, leading to discomfort among both patient and clinician. In vivo exposure alone, however, has also been established as an effective treatment for anxiety disorders that can provide significant results in a rapid manner.

Methods A 31-year-old female with no prior psychiatric history presented to treatment in an acute depressive episode following a motor vehicle accident two years prior. She also met criteria for PTSD. Her Beck Depression Inventory (BDI) and PTSD Checklist for DSM-5 (PCL-5) scores were 42 (severe depression) and 64, respectively. Due to constraints, a modified form of PE was initiated, with five in vivo exposure sessions conducted.

Results After five sessions of in vivo exposure, the patient's PCL-5 score decreased from 64 to 36 and her BDI score decreased from 42 to 13 (minimal depression).

Conclusions This case report underscores the effectiveness of a modified form of PE, using in vivo exposure alone as a treatment for PTSD. This has significant implications in particular for patients or clinicians who are unable to initiate imaginal exposure (e.g., patient finding it too difficult to tolerate/refusing to engage, language barriers, etc.). In such situations, in vivo exposure appears to be an alternate, effective, short-term treatment option.

* Corresponding author.

Background Loss of a loved one is a distressing event that may result in grief characterized by emotional distress, longing of the dead, and dysfunctionality. Persistent complex bereavement disorder (PCBD) is differentiated by extended and damaging bereavement [1], which is being treated by some with EMDR [2]. In this study, the effects of an EMDR session on a patient with PCBD will be analyzed.

Case G.Ö. (45) is a married housewife who had been working, mother of a kid and a baby. She has lived with her family and her mother in a metropolitan city until her mother died a year ago, unexpectedly. Then, she quit her job and they moved in a small city upon her husband's wish. The inpatient had complaints such as active suicidal thoughts, marital dissatisfaction and an ongoing deep sadness. EMDR therapy is applied on her grief and dysfunctional beliefs.

Conclusion After one session of EMDR, her mood improved, her ruminations declined, she sought job, and became hopeful for the future. In our case, even one session of EMDR let remarkable improvements on PCBD. Indeed, as for other trauma-related issues, EMDR therapy can be utilized on PCBD.

Introduction In traditional medicine curriculum, internship is the moment in which students experience medical practice more intensively. Attitudes can be considered predictors of behaviors and actions. Evaluate them contributes to improve medical graduation.

Objective Evaluate medical internship attitudes, considering medical practice and associated factors in a Brazilian public university.

Methods Cross-sectional study with 69 students, using a structured questionnaire and an attitude scale. Descriptive statistic was carried out, classification of the attitude tendency, group analysis ('clusters') and F statistic.

Results The average age was 25.1 and 56.5% were male. Students presented positive attitudes towards four from six aspects and negative attitudes toward death.

Conclusion Results suggest the necessity of educational intervention, which follows the educational objectives.

The impact of parental schizophrenia in the development of behavioral disorders and mental illness in children

M. Alves^{1,*}, A.R. Rodrigues², A.M. Moreira¹, O. Queirós²

¹ Hospital de Magalhães Lemos, Serviço C, Porto, Portugal

² Centro Hospitalar do Porto, Departamento de Psiquiatria da Infância e da Adolescência, Porto, Portugal

* Corresponding author.

Introduction Parental schizophrenia will potentially cause dysfunction in mother-child relationships, and it will also cause difficulty in adapting to motherhood.

Objectives We aim to study the implications of the relationship between mothers with schizophrenia and their children. The psychosocial environment and the impact of dysfunctional relationship in social skills development may cause behavioral disorders in children and further development of severe mental illness taking into account genetic factors and biopsychosocial factors.

Methods Non systematic literature review, through the Pubmed and Medline database, with time constraints.

Results The development of schizophrenia is related to genetic and environmental factors. Children of parents with schizophrenia are at increased risk of developing psychiatric disorder compared to the general population. It was found early behavioral disorders, starting between 5 and 8 years old and the difficulties in social interaction may arise at this age and remain until adulthood.

Conclusions It is important to assess the level of acquisition of social skills in children and families when there is a direct relationship with schizophrenia. It may be important in the future, monitorize the development of these children, as well as be aware of the surrounding social and family environment, to identify and manage early in the presence of behavioral disorders and possible development of serious mental illness. An early intervention at the level of social deficits in children can be a preventive intervention of later schizophrenia development.

The status of early intervention services in Greece

S.I. Bargiota^{1,*}, G. Garyfallos¹, V.P. Bozikas²

¹ Aristotle University of Thessaloniki, 2nd Department of Psychiatry, Thessaloniki, Greece

² Aristotle University of Thessaloniki, 1st Department of Psychiatry, Thessaloniki, Greece

* Corresponding author.

Introduction Schizophrenia and other psychotic disorders usually emerge during adolescence and early adulthood deteriorating the lives of young people. As a result, a lot of early intervention services have been developed worldwide.

Objective This study aims to investigate the status of early intervention services in Greece related to similar programs around the world.

Methods The literature was accessed in order to investigate the status of clinical early intervention services throughout the world. In terms of Greece, a naturalistic research was added to the literature one, since there are not enough published data available.

Results Hundreds of early intervention programs exist in Australia, Europe, North America and Asia, designed to provide early and sustained care with less prescription not only soon after psychosis has been diagnosed but in a prodromal state as well, like the outreach and support in South London (OASIS) team. In Greece, four early intervention services have been established since 2007, without funding, and they still operate in a volunteer basis. Furthermore, the field about ultra-high risk subjects in Greece remains neglected.

Conclusions The specialized services play an important role in the prevention and proper clinical management of the illness and its outcome with a positive impact on the economy. Greece needs to recognize the significance of this issue in order to enhance public health and welfare.

Disclosure of interest The authors have not supplied their declaration of competing interest.

CEVUP program: An analytical epidemiological cohort study

P.F. Bazziconi*, C. Lemey, L. Bleton, M. Walter
CHRU de Brest, Pôle de Psychiatrie, Brest, France

* Corresponding author.

Introduction Over the past few years, several teams have built programs to detect patient at clinical high-risk state for psychosis and to develop interventions at an early stage of psychiatric troubles. The aim of this study is to provide an overview of the functioning and the results obtained by the specialized program developed in Brest, France (CEVUP).

Methods We retrospectively analyzed the medical records of patients addressed to the CEVUP between June 2010 and April 2014. Data were double collected by two different investigators and we tested the inter-raters reliability. We included 49 help-seeking patients, aged from 15 to 30 years old, addressed by psychiatrists and general practitioners. The initial evaluation included a clinical evaluation, CAARMS scale, Rorschach test and neurocognitive tests. Subjects were classified in two groups: not at risk for developing psychosis (NA) or at risk for developing psychosis (AR).

Results The main results at initial evaluation showed that 16 (32.7%) patients were AR and 33 (67.3%) NA. Among AR patients, 8 (24%) developed psychosis in two years against 2 (12.5%) for NA patients. These patients have psychiatric comorbidities, essentially depression or anxiety. Secondly, there are more disturbances of psychomotor and affective development in subjects AR: 14 (41.1%) against 7 (20.5%) in group NA.

Conclusion The present study describes the procedures and the main results established by a specialized program for patient at high risk to develop psychosis. The characteristics of the sample remain consistent with descriptions of such populations worldwide.

Relationship between values of the health care and cognitive beliefs about body, illness and treatment: Is there “hypochondriac discourse” in the society?

M. Kovyazina^{1,*}, E. Rasskazova², A. Tkhostov¹, N. Varako¹

¹ Lomonosov Moscow State University, Department of Psychology, Moscow, Russia

² Lomonosov Moscow State University and Mental Health Research Center laboratory of Medical Psychology, Department of Psychology, Moscow, Russia

* Corresponding author.

Introduction Social values of health and health care are considered as important factors of health behavior as well as sources of self-regulation in health and illness. However, emphasize on medicine, health and body that is widespread in mass media nowadays may increase hypochondriac-like beliefs and behavior as well as the risk for unexplained somatic symptoms in some individuals.

Objectives Analysis of mass media revealed four models of health care value: health as a depletable resource requiring conservation, health as fragile value requiring protection and control, health as a necessary source of success and happiness, health as requiring periodic restoration by alternative medicine.

Aim was to investigate the relationship between these models and beliefs about body, illness and treatment.

Methods One hundred and thirteen adults without history of mental or severe somatic illnesses filled checklist of values of health care, Cognitive Attitudes about Body And Health Scale (Rief et al., 1998), Compliance-related Self-Efficacy Scale (Tkhostov and Rasskazova, 2012).

Results The models of health as a depletable resource and as fragile value are dominated in the sample. Agreement with these models of health care is, on the one hand, related to willingness to seek medical help and follow treatment, but, on the other hand, to an excessive attention to bodily sensations, somatosensory amplification, monitoring and catastrophization about bodily sensations.

Conclusions Possible pathways linking “hypochondriac discourse” in the society in its various forms and cognitive beliefs typical for hypochondria and somatoform disorders will be discussed. Research supported by Russian Foundation for fundamental research, project 17-06-00849.

Assessment the probability of formation burnout syndrome among health care workers

S. Kuzmina*, K. Yakhin, Z. Berkheeva

Kazan State Medical University, Psychiatry, Kazan, Russia

* Corresponding author.

Aim Study of psychosocial risk factors in the formation of burnout syndrome.

Material and method Based on a questionnaire developed by WHO experts for the European model of “health management, environment and security in the workplace”, conducted surveys 246 health care workers. Individual attention was paid to health, physical activity and nutrition.

Results Survey conducted of the medical personnel showed high prevalence among them psychophysical, social and psychological, behavioral symptoms that allows to think of high probability of formation of a syndrome of professional burning out. Part of medical workers who have one complaint in each group of symptoms (psychophysiological, sociological-psychological, behavioral) – 18,7%. Part of HCW with two and more complaints in each group – 39% (Table 1). Prevalence of psychophysiological, sociological and psychological, behavioral symptoms among health care emergency workers is different (Table 2).

Table 1

	City n = 78 (%)	Countryside n = 168 (%)	Chi ²	P	Total n = 246
Complaint in each group of symptoms	16 (20.5)	30 (17.9)	0.01	0.963	36 (18.7)
Two complaints in each group of symptoms	32 (41.0)	64 (38.1)	0.01	0.982	96 (39.0)
Three complaints in each group of symptoms	18 (23.1)	26 (15.5)	0.4	0.549	44 (17.9)

Table 2

	City n = 70 (%)	Countryside n = 150 (%)	Chi ²	P	Total n = 220
Two and more of psychophysiological spts	26 (37.1)	12 (8)	7.8	0.005	38 (17.3)
Two and more of sociological and psychological spts	8 (11.4)	24 (16)	0.1	0.793	32 (14.5)
Two and more of behavioral spts	10 (14.3)	10 (6.7)	0.7	0.414	20 (9.1)

Prevention of specific learning disorders in early stages

I.R. Lupu^{1,*}, V. Lupu²

¹ Emergency Clinical Hospital for Children, Center of Mental Health, Cluj Napoca, Romania

² "Iuliu Hatieganu" University of Medicine and Pharmacy,

Department of Psychiatry and Pedopsychiatry, Cluj Napoca, Romania

* Corresponding author.

Introduction Specific learning disorders as defined in the DSM-5 are frequently diagnosed among children – 4–9% for reading deficits – (DSM-5, 2013). As any deficit can contribute not only to a child's emotional distress, it can also result in academic failure or school abandonment. Therefore, prevention measures should be considered.

Objectives The present study's objective was to compare the influence of a set of primary prevention measures on children's performance in reading and writing and improve their reading and writing.

Aims We aimed to prevent specific learning disorders–dyslexia and dysgraphia in children from the second to their third year in the educational system.

Methods Only children from the second year of school were considered (grade 1). Children with clear potential for developing specific learning disorders were included in the present study. Children with any other comorbidity were excluded from the data analysis. Four experimental groups were considered – one control and three interventional – 1. Control, 2. COPS method, 3. Meixner principles, and 4. COPS method combined with Meixner principles and considering improvement of reading images, image filling, graphical schema orientation and discrimination, spatial and temporal orientation, orientation of objects, fine motor skills, temporal sequences, attention for details, perception of differences.

Results Findings indicated that the use of the combined methods significantly improved children's performance in reading and writing. Though all interventional methods improved children's performance. Results comparison was computed.

Conclusions Early prevention programs which target both reading and writing can improve children's performance in reading and writing.

EV1004

The use of vitamin D3 sublingual tablets versus oral drops in the treatment of patients with COMT Val/Val genotype and major depressive disorder

A.W. Mech

Mech Healthcare Associates, MechMatrix, University of Texas at Arlington, USA

Introduction Vitamin D has been shown to be crucial in the regulation of dopamine and its relationship to major depressive disorder.

A five-year pre-interventional study of 25 hydroxy vitamin D levels in patients with major depressive disorder found values ranging from 17 to 32 ng/mL.

COMT Val/Val genotype has been associated with a 20–40% more rapid breakdown of dopamine in the prefrontal cortex as compared to individuals with a Val/Met genotype.

Methods This retrospective study gathered data concerning outcome measurements in patients who displayed a baseline 25-OH level < 30 mg/mL and initially treated with sublingual tablet form of 10,000 IU vitamin D3. These data were compared to post-interventional depression outcome scores for patients switched to oral vitamin D3 drops at a dose of 10,000 IUs.

Results Scores on the MADRS 1–3 weeks following the vitamin D3 switch showed an improvement in mood with the lowering of scores on the MADRS.

Conclusions Patients with a COMT genotype of Val/Val showed clinical improvement with a switch from oral D3 sublingual tablets to oral D3 drops. Further studies are needed to draw from conclusions. Pre- and post-25-OH vitamin D levels and other dopamine synthesis variables including serum ferritin would be useful as well as prospective double-blind placebo controlled trials. The future use of genotype-specific and supportive approaches deserves serious investigation.

Ultra-high risk psychosis. A case report

G. Pardo de Santayana^{1,*}, R. Landera¹, M. Juncal¹, O. Porta¹, M. Gómez², N. Núñez², L. Sánchez¹

¹ Hospital Universitario Marques De Valdecilla, Psychiatry, Santander, Spain

² Hospital Universitario Alava-sede Santiago, Psychiatry, Vitoria-gasteiz, Spain

* Corresponding author.

Introduction There is much debate on whether patients who are at high risk of developing a psychotic disorder in the near future (such as patients suffering of attenuated psychotic symptoms, brief limited intermittent psychotic symptoms or personality trait vulnerability) should be treated with antipsychotic drugs to prevent possible psychotic breaks from happening.

Aim To review articles from the existing medical literature about treatment of patients in ultra-high risk of developing psychosis.

Methods We describe the case of a 19-year-old male who was hospitalized after a suicide attempt in April 2015. He had been diagnosed of different psychiatric disorders such as mixed anxiety-depressive disorder, adjustment disorder and probable borderline personality disorder. During his stay at the hospital, we observed that he had schizoid personality traits. In the initial anamnesis, he denied ever having psychotic symptoms, but a few days later he admitted that the previous year he suffered through a period of brief self-limiting psychotic symptoms.

Results Prophylactic treatment was started with oral aripiprazole 15 mg/day, which was well tolerated by the patient. He has been free of psychotic symptoms for the last 17 months (from April 2015 to September 2016). No relevant side effects were detected.

Conclusions Oral aripiprazole 15 mg/day can be a good therapeutic option in patients at ultra-high risk of developing a psychotic episode.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Relationship between affective temperaments, traits of schizotypal Personality and early diagnosis in a sample of Italian healthy subjects

F. Ricci*, A. Ventriglio, M. Pascucci, A. Bellomo
University of Foggia, Institute of Psychiatry, Foggia, Italy

* Corresponding author.

Introduction Akiskal et al. [1] examined the relationship between affective temperaments and characteristics of schizotypal personality disorder. Schizotypal personality disorder is becoming increasingly important both in itself as a significant personality disorder and as a condition that can provide important insights into the origins of schizophrenia. Perceptual and interpersonal cognitive disorders, behavior and disorganized speech do the schizotypal personality disorder a kind of mild form of schizophrenia, a premorbid or prodromal phase of this serious disorder.

Aims To analyze, in an Italian sample of healthy subjects, the correlation between affective temperaments and schizotypal traits.

Methods We recruited 173 healthy subjects aged between 18 and 65 years who have completed the following tests:

- BIS-11;
- SPQ;
- SDS;
- SAS;
- HCL-32;
- TEMPS-A.

Results At linear regression analysis between TEMPS-A scores and other rating scales are observed highly significant associations between increasing scores of cyclothymic and depressive temperament, subjective anxiety and depression with scores pertaining to the schizotypal personality disorder.

Conclusions Clinically, a better understanding of the mechanisms that lead to a schizotypal personality could lead to the development of effective preventive and curative treatments in an early stage of symptoms in addition to the identification of subgroups at risk for the development of schizophrenic pathology.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Forgiveness and armed conflict in a Colombian Caribbean region: Differences between genders

A.M. Romero Otalvaro*, M. Munoz, A. Uribe, C. Katia, R. Maria
Universidad Pontificia Bolivariana, Psicología, Monteria, Colombia

* Corresponding author.

The forgiveness within the framework of social-political conflict is a factor that affects the coexistence and welfare. In the Colombian Caribbean, there are a significant number of people who have been victims of land dispossession and/or forced displacement.

The aim of this study is to compare the forgiveness ability between men and women who have been displaced and are in the process of lands restitutions. Displaced and in restitutions process people were participated ($n = 38$), which 20 of them were women and 18 were men (Mean = 57.81; SD = 13.86). The CAPER Scale, was administered. A cross sectional and comparative design was carried out. The comparison was performed using a t -test for independent samples (Table 1).

Conclusions A greater tendency was observed in women for forgiveness himself, nonetheless a statistically significant gender difference was not identified. It was a greater tendency in men toward forgiveness to others, however there are no statistical differences between the two groups. In forgiveness situations, a similar trend is evident in gender. As for beliefs, it was observed that men scored higher, this allowed statistically significant differences were observed [$F(1, 38) = 6.271$; $P > 0.05$].

Table 1

Means and SD – Caper Scale	1. Women; 2. Men	n	Mean	SD	Standard error of mean
Forgiveness himself	1	20	28.00	4.899	1.095
	2	18	26.00	4.229	0.997
Forgiveness to others	1	20	28.35	5.402	1.208
	2	18	29.11	4.129	0.973
Forgiveness situations	1	20	28.00	5.016	1.122
	2	18	28.00	3.757	0.886
Beliefs	1	20	11.80	2.821	0.631
	2	18	13.33	1.188	0.280

Psychiatric Risk Assessment Scale (PRAS)

A. Shoka^{1,*}, C. Lazzari²

¹ University of Essex, School of Health and Social Care, University of Essex, Colchester, United Kingdom

² North Essex NHS University Foundation Trust, General Adult Psychiatry, Colchester, United Kingdom

* Corresponding author.

Introduction The aim of psychiatry is the prediction of risks.

Objectives Creation of the Psychiatric Risk Assessment Scale (PRAS) (Table 1).

Aims To assess psychiatric inpatients for risk to self and others. **Methods** The PRAS comprises 20 risk items that rate five probabilities of occurrence: 0% (nil), 25% (low), 50% (moderate), 75% (high) and 100% (severe). Cut-off score indicates “moderate” risk = 50. The mathematical formulas for the risks are as follows:

- severity of risk (SR) = average for the whole table multiplied by %;
- number of significant risk events (NSRE) = count of risks scored from 50% to 100% divided by 20 (items);
- probability of occurrence of risks (POR = NSRE%);
- range probability of death (RPD) = range score of (overdose + suicide + reckless activities)%.

Two raters assessed independently $n = 8$ patients. Kappa inter-rater statistic was used by dichotomous results (above-below cut-off score).

Results Inter-rater Kappa = 0.60 indicates a moderate inter-rater agreement. In the sample, only 2 patients scored above the cut-off score of 50, indicating a level of moderate-to-severe risk. For the other patients, the average SR = 36%, indicating low-to-moderate risk.

Conclusions PRAS is constantly used to assess the likelihood that the care provided to patients admitted to hospital is sufficient or whether major remedial action is required.

Table 1

Events	0%	25%	50%	75%	100%
Becoming homeless	0				
Alcohol dependence or harmful use	0				
Assault to others	0				
Homicide	0				
Discontinuing medication			50		
Disengaging from services			50		
Exploitation from others		25			
Self-harm by cutting				75	
Overdose of medications				75	
Taking illicit substances				75	
Conflict with others				75	
Conflict with the law				75	
Dangerous to others				75	
Other suicidal attempts (e.g. hanging, self-poisoning, etc.)					100
Relapse in presentation					100
Sabotaging care plans					100
Reckless activities (e.g., risk driving, walking on railtrack)			50		
Theft					100
Social isolation					100
Exploitation of others					100
Total severity of risk (max=100%) is:					
	Nil	Low	Moderate	High	Severe
Number of risk events:	4	1	3	6	6
Final report:					
The total severity of risk (SR) for self and others is:	61.25%				(MAX=100%)
The total number of significant risk events (NSRE) from moderate to severe is:	15/20				(MAX=20/20)
Therefore, the probability of occurrence of risk events (POR) (the maximum being 1.0 or 100%) is:	0.75	or	75	%	
The range probability of death (RPD), accidental or voluntary, by one of the risk events including accidental and deliberate overdoses, reckless activities and active suicidal acts is:	Minimal risk		Range		Maximum risk
	50 %		to		100 %

Probability of Relapse Scale (PRORES) for psychiatric inpatients

A. Shoka^{1,*}, C. Lazzari²

¹ University of Essex, School of Health and Social Care, University of Essex, Colchester, United Kingdom

² North Essex NHS University Foundation Trust, General Adult Psychiatry, Colchester, United Kingdom

* Corresponding author.

Introduction The prediction of relapse in presentation is central to psychiatric prognosis.

Objectives The Probability of Relapse Scale (PRORES) (Table 1) is used by the authors to predict the likelihood of relapse by psychiatric inpatients.

Aims To tailor better care plans by knowing the likelihood of relapse and readmission to hospital.

Methods Eighteen inpatients were diagnosed with the ICD-10 codes. Results were reported on a 5-point probability scale from 0 (less severe) to 10 (most severe). The 5 items are: degree of severity of illness, degree of patient's insight, frequency of readmission into hospital, probability of discontinuation of therapy and probability of relapse in the 4–6 weeks after discharge.

Results With the cut-off score at 25 (score 5 × 5 items), indicating a moderate level of relapse, we ascertained that 100% of patients with a personality disorder (usually borderline) and substance misuse relapse are readmitted shortly after discharge, compared with 85.71% of those with psychoses and 66% of those with mood disorders.

Conclusions The PRORES can help support those patients who are at elevated risks of relapsing due to any of the major causes: discontinuation of treatment, chronicity and poor insight into their own condition (Table 1).

Table 1 PRORES Scale.

Instructions: please report the degree of severity from 0 to 10

1. On a scale from 0 (acute and benign condition) to 10 (chronic and severe condition) what is the degree of severity for this patient's illness?

1 10

2. On a scale from 0 (total insight) to 10 (total lack of insight) what is the degree of insight that this patient shows about the own illness?

1 10

3. On a scale from 0 (first admission) to 10 (very frequent readmissions) what is the degree of readmissions to hospital of this patient for the illness considered?

1 10

4. On a scale from 0 (not applicable) to 10 (almost certain) what is the probability that this patient will discontinue treatment once discharged from hospital?

1 10

5. On a scale from 0 (nil) to 10 (almost certain) what is the probability that this patient will relapse in the 4–8 weeks after discharge from hospital?

1 10

Flourishing: Factors associated with positive mental health among young adults with neuropsychiatric disorders

K. Appelqvist-Schmidlechner^{1,*}, R. Lämsä¹, T.H. Annamari²
¹ National Institute for Health and Welfare, Mental Health Unit, Helsinki, Finland

² Social Insurance Institution, Research Department, Helsinki, Finland

* Corresponding author.

Young people with Asperger's syndrome and/or ADHD face major challenges in their lives affecting their quality of life and general well-being.

The aim of this study was to investigate factors that associate with positive mental health (flourishing) among young adults with neuropsychiatric disorders.

The sample consisted of 188 young adults with diagnosis of Asperger's syndrome (AS) (F84.5) and/or ADHD/ADD (F90). They participated in the one-year "My Way" rehabilitation programme organized and funded by the social insurance institution of Finland. Baseline questionnaires included measures on positive mental health (SWEMWBS), provisions of social relationships (SPS), social competence (MASC) and questions about functional capacity and leisure time activities. Information on diagnosis was received from doctors' statements.

Of the study participants, 35% had a comorbid mood, anxiety or stress-related disorder (F30–F40). Among those, 14% had low, 79% moderate and 7% high positive mental health (flourishing). Higher rate of physical activity was associated with flourishing. Furthermore, flourishing was associated with high level of provisions of social relationships, social competence as well as good general functional capacity. No association was found with engagement in employment or education, or having the diagnosis of AS, ADHD/ADD or a comorbid psychiatric disorder (F30–F40).

People with psychiatric disorders experience high positive mental health, too. Social relations, social competence and general functional capacity play an important role in mental well-being of young adults with neuropsychiatric disorders. Supporting them may help in reaching also other goals set for the rehabilitation, such as capacity to work or study.

EV1011

Resilience, pain and quality of life in people with physical disabilities: A systematic review

P. Aranguren (Student)

Clinical Psychology, Universidad Complutense de Madrid, Getafe, Spain

Introduction More than a thousand million people live with a certain type of disability over the world (more than a 15% of the population worldwide). In Spain, 2.5 millions of people suffer from a physical disability. Disability can be understood as an interaction of the individual's health condition (disease, illness...) and his/her environmental and personal factors. Resilience could be included as a powerful personal factor, which would play a major role in the individual's quality of life. Resilience can be defined as a universal basic capacity to prevent, minimize or overcome life's adversities, even reaching a change in the life of the individual.

Aim To determine the association among resilience, pain and quality of life in people with physical disabilities.

Materials and methods An electronic search of several databases (Psycinfo, Medline, Pubmed...) was performed using the terms resilience, physical disability, and physical illness among others.

Results – Pain and resilience show an important relationship. Factors as acceptance, pain beliefs and self-efficacy are directly related with a lower pain interference.

– Resilience and quality of life show a strong positive relationship.

Conclusion Several factors are related to resilience in people with physical disabilities. Resilience seems to be an important capacity that helps individual with physical disabilities overcome adversities. Further analyses are required.

The therapeutic handling of a mental health promotion group: The therapist role in the Communitarian Mental Health Group

A.P. Craveiro Prado^{1,*}, C.L. Cardoso²

¹ University of Sao Paulo, Psychology Department, Faculty of Philosophy, Sciences and Literature USP, Ribeirão Preto, Brazil

² University of Sao Paulo, Psychology Post-Graduation Program, Ribeirão Preto, Brazil

* Corresponding author.

Within the mental health promotion field, communitarian and group-based interventions are significant and viable approaches. One of the features of group studies is the therapeutic group handling, provided by the group therapist, which influences the therapeutic potential and development of the group. The communitarian Mental Health Group (CMHG) is an innovative intervention for promoting mental health, developed and researched for 18 years, in Brazil. The activity's goal is to promote the attitudes of attention and understanding over day-by-day experiences, as resources of mental health promotion. This research goal was to investigate and understand the therapeutic group handling provided by the CMHG's therapist and its connections to this specific group's characteristics. The corpus was built by the transcriptions of six groups. To each group session, all the therapist's interventions were analyzed in the context in which they happened. Later, those sessions were horizontally analyzed, as a mean to identify common aspects of the CMHG's therapeutic handling, which resulted in the elaboration of three main categories: framing–includes interventions which the therapist organizes the setting; providing keys–includes interventions which the therapist provides key concepts and encourages the participants to adopt certain attitudes, so that they can understand and interact with the assignment; Understanding the gesture–includes the interventions which the therapist stresses the gestures underlying the participant's communication. This research pointed that the therapeutic handling of CMHG is different from traditional models, and that it is related to its theoretical and methodological approach.

EV1013

The Communitarian Mental Health Group: Promoting mental health through daily experiences in Brazil

A.P. Craveiro Prado^{1,*}, C.L. Cardoso², S. Ishara³

¹ University of Sao Paulo, Psychology Department, Faculty of Philosophy, Sciences and Literature USP, Ribeirão Preto, Brazil

² University of Sao Paulo, Psychology Post-Graduation Program, Faculty of Philosophy, Sciences and Literature, Ribeirão Preto, Brazil

³ Universidade de São Paulo, Hospital das Clínicas de Ribeirão Preto, Faculty of Medicine of Ribeirão Preto, Ribeirão Preto, Brazil

* Corresponding author.

In Brazil, the mental health field has been the scenario of many transformations, among them, the recognition of community and group-based interventions as significant approaches concerning mental health promotion. These approaches regard the interpersonal relationships as a resource to individual's mental health care and the construction of a helping network. This study aimed to present and describe the Communitarian Mental Health Group (CMHG), an innovative intervention developed and studied in Brazil for 18 years. To accomplish that, a study of previous researches about this intervention was conducted, including the analysis of a book published in 2014. The activity goal is to promote mental health through the attitudes of paying attention, understanding

and sharing everyday experiences, as resources for personal development and mental health care. It is an open and heterogeneous group, in which participants interact among them aiming mutual help. Each group session lasts 1 h 30, and each session is divided into three phases: sharing experiences with cultural elements considered meaningful to the goals of the group; sharing everyday experiences; sharing what was significant from that session, according to the participants. One of the premises is that taking care of our mental health belongs to the scope of the human being and it is not restricted to patients. Daily experiences are significant resources for mental health promotion and for the construction of a helping communitarian network among participants, bonded through the sharing of their quotidian. The CMHG represents a mental health promotion intervention able to complement other kinds of available treatments.

EV1014

Discrimination and mental health among lesbian, gay and bisexual adults

M.A. Dos Santos

Universidade de Coimbra e Universidade Nova de Lisboa/IHMT, Faculdade de Medicina, Coimbra e Lisboa, Portugal

Introduction Mental health care is indispensable, has an essential role in development, but mental health issues are a major public health concern worldwide. Sexual minorities, lesbian, gay and bisexual, suffer from prejudice and it determines health inequities, especially for their mental health.

Objective To show the relation between discrimination and mental health issues in lesbian, gay and bisexual (LGB) people and to increase understanding of this serious neglected public health problem.

Methods The search was conducted using Science Direct and Scopus, using the following keywords: “discrimination” and “mental health” and “lesbian” and “gay” and “bisexual”. Using the review of literature, documents in English (articles, official documents, editorial, reviews, clinical trials).

Discussion Numerous studies have identified highest risk behavior, as illicit drug use, sexual risk-taking behaviors and mental health issues among LGB people. Some previous studies propose that health and risk disparities between heterosexual and LGB identifying or behaving people are due to minority stress—that is, that the stigma, discrimination, and violence experienced, leading to stress, thus predisposing illness, disease (worse mental and physical health outcomes) and potentially substance use, which may be used to relieve or escape stress.

Conclusion Health professionals and healthcare organizations must cover these unmet mental health needs if they move to more integrated, coordinated models of care. Health educators should attend to the unique needs of each sexual orientation group when presenting sexual health information and health care providers should undergo diversity and sensitivity training to work more effectively with those groups.

EV1015

Pre- and postnatal psychosocial intervention concepts

G. Eglhoff^{1,*}, D. Djordjevic²

¹ Heidelberg University, Psychoanalytic Practice, Mannheim, Germany

² University Hospital, Children's Clinic, Nis, Serbia

* Corresponding author.

Psychiatry, psychoanalysis and infant mental health research of the last decades have led to intervention concepts for pre- and postnatal stages of human development. Such concepts reach from how parents-to-be can be prepared for parenthood to how to intervene in support of relation and attachment in infants, toddlers and older children. Especially the postnatal relation of infant and parents has been examined extensively, as have parental competencies. The expression of intuitive parental competencies (according to Papousek and Papousek) may be compromised by diverse factors, thus putting the infant's psychic development at risk in general. Early intervention concepts may help out to some extent. In German-speaking countries, there are intervention programs focusing on bonding as there are on handling, processing of and coping with trauma, on promoting secure attachment between infant and parents, on relational issues, on bodily contact, on understanding the infant's signals, including those of the preterm infant, as well as on educational practices. From prenatal period onwards up to kindergarten age there are structured interventions, including the involvement of parents and parents-to-be. Yet, some factors of psychic development and of pathology may not necessarily be reached by these. Whereas concepts on an individual level of personality education do exist, nevertheless there might have to be collective measures. There seems to be a need to augment the agenda as there is good reason to assume that in the last decades there has been a motion toward new social deprivation stemming from societal deprivation processes, which might potentiate future deprivation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1016

The impact of emotional acknowledgement and self-esteem on resilience to family dysfunction

C. Fontaine*, C. Connor, S. Channa, C. Palmer, M. Birchwood
University of Warwick, Warwick Medical School, Coventry, United Kingdom

* Corresponding author.

Introduction Family dysfunction can test the resilience of adolescents, specifically those from single parent families and those attending schools in more socio-economically challenged areas.

Objectives To determine what factors are associated with resilience for those from single parent families or attend schools in more socio-economically challenged areas.

Aims To examine the role of emotional regulation and self-esteem as putative resilience factors in the context of single parents status and socioeconomic disadvantage.

Methods Secondary school pupils from single and dual parent families aged 13 to 15 answered questionnaires at three time points on: emotional regulation, self-esteem, depression and anxiety. A total of 434 pupils took part at time 1, 574 at time 2, and 467 at time 3. The secondary schools were categorised into more and less disadvantaged schools.

Results Positive self-esteem [$F(1.205) = 54.568, P = 0.000; F(1.157) = 35.582, P = 0.000$] and emotional regulation [$F(1.205) = 46.925, P = 0.000; F(1.157) = 16.583, P = 0.000$] were both associated with resilience against depression in adolescents from single parent families. Positive self-esteem [$F(1.75) = 102.629, P = 0.000; F(1.355) = 60.555, P = 0.000$] and emotional regulation [$F(1.60) = 34.813, P = 0.000; F(1.73) = 36.891, P = 0.000$] were both associated with resilience against depression in adolescents attending more socio-economically challenged areas.

Conclusions This research suggests that adolescent resilience against depression may be promoted by improving self-esteem and

emotional regulation. Therefore, future interventions could focus on boosting these resilience factors. Further resilience research could include emotional regulation and self-esteem as protective factors for resilience in adolescent mental health. As these variables have been identified, they can help find more pieces to the complex puzzle of resilience.

Introduction Psychosocial functional deficiency of persons with mental disorders covers the most important kinds of activity: work, education, independent living, and interactions with people, family interactions. Important aspect of rehabilitation practice is work with the family, relatives, and the nearest environment of patients due to decrease in the field of marriage or stable cohabitation.

Objective To determine adaptive-preventive potential of the family in the area of mental health.

Material and methods The analysis of multilevel characteristics of adaptation of 414 adult persons (patients with mental disorders and members of their families) with use of system approach and the methodical complex (“The Passport of Health of the Family”) has been carried out.

Results We define the adaptive-preventive potential of the family of mental patient as biological (genetic) and social-psychological opportunities of family system of the individual to compensate the limits of ontogenetic (life) cycle of the family of several generations caused by the illness of the family member. Novelty of the “Clinical-psychological model of anti-relapse behaviour based on interaction of mental patients, their families, persons from the general population and experts in the field of mental health” project consists of scientific justification of development of multilevel (individual, family, society) model of anti-relapse behavior.

Conclusion This multidisciplinary project is aimed at the persons entering into risk groups for development of mental disorder (for example, persons with sub-syndrome symptoms or with biological, and psychological or social risk factors) and the persons entering into risk groups for relapse of the existing mental disorder.

* Corresponding author.

Introduction “The wounded healer” (TWH) is an innovative method of pedagogy that blends art with science that is delivered by an award-winning doctor with first-hand experience of a mental health condition. The aim of this study is to evaluate the effectiveness of TWH at reducing stigma from healthcare professionals and students towards their peers with a mental health condition.

Background TWH has been delivered to more than 30,000 people in 9 countries on 5 continents worldwide and has been integrated into the medical school curricula of 4 UK universities. TWH also featured in the 2015 iMed Congress in Lisbon, Portugal, the largest medical student congress in Europe ($n = 1000$).

Methods We conducted a cross-sectional, mixed-methods study on participants who attended TWH in venues across the UK. Paper questionnaires containing stigma constructs with response items on a Likert-scale were hand distributed to participants. Free-text comments were subjected to thematic analyses.

Results Two hundred and nineteen over 256 participants recruited responded (85% response rate); 207/219 (94%) of respondents agreed or strongly agreed that TWH made them realise that medical students and doctors who experience mental distress can recover and achieve their goals.

Themes that emerged from analyses of free-text comments included, “inspirational”, “merits of blending art with science”, and “benefits of receiving a talk from a doctor with first-hand experience of a mental health problem”.

Discussion Our findings suggest that TWH might be effective at reducing stigma from healthcare professionals and students towards their peers with mental health problems. More robust research in this area is needed.

Student psychiatry audit and research collaborative (SPARC): A new UK initiative to improve recruitment in psychiatry

N. Ellis¹, M. Quraishy¹, C.M. Grubb¹, D. Codling², J. Harrison^{3,*}

¹ Cardiff University School of Medicine, Medical School, Cardiff, United Kingdom

² King's College Hospital NHS Foundation Trust, Clinical leadership, London, United Kingdom

³ Cardiff University School of Medicine, MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff, United Kingdom

* Corresponding author.

Introduction The UK has longstanding problems with psychiatry recruitment. Various initiatives aim to improve psychiatry's image among medical students, but involve research and none are student-led. Providing opportunities to take part in psychiatry research and quality improvement could increase the number of students who choose to enter the speciality.

Objectives We have developed the student psychiatry audit and research collaborative (SPARC), a student-led initiative for nationwide collaboration in high-quality research and audits.

Methods Our model is inspired by the success of the UK Student audit and research in surgery (STARSurg). Area teams, located in medical schools, take part in multi-centre projects. The area teams consist of medical students, who have the main responsibility for collecting data; a junior doctor, to supervise the process; and a consultant, with overall responsibility for patient care. The data collected centrally and analysed by a team of medical students and doctors. Student leads from each site are named authors on result-

ing papers. All other students are acknowledged and are able to present the work.

Results We have completed our first audits in Cardiff and London; other sites will return data in 2017. Student feedback indicated a high level of satisfaction with the project and interest in psychiatry as a future career.

Conclusions This initiative aims to tackle the recruitment problems in psychiatry by giving students a chance to take part in high quality research and audits.

Introduction Economic crises have consequences on labor market, with impacts on mental health (MH) and psychological well-being (PWB). We describe the effectiveness of an intervention among unemployed, performed within EEA Grants Healthy Employment project.

Objectives Evaluate the effectiveness of an intervention for MH literacy, PWB and resilience among unemployed.

Aims MH and PWB promotion, common mental disorders prevention and inequalities reduction linked to unemployment.

Methods A five modules intervention (life-work balance; impact of unemployment on PWB and MH; stigma; depression and anxiety; health promotion) distributed by 20 hours was developed based on literature reviews and a Delphi panel. It was delivered to unemployed from two public employment centers (PECs). Inclusion criteria: 18–65 years old; registration in PEC for less than a year; minimum of nine years of formal education. Control groups from the same PECs received the care-as-usual. Measures of psychological WB, MH self-reported symptoms, life satisfaction, resilience and mental health literacy were collected through an online survey before and one week after intervention.

Results Overall, 87 unemployed participated, 48% allocated to the intervention group (IG); 56% women (21–64 years old), average education was 15 years. Mixed measures ANOVA showed that the interaction between time and group was significant for PWB and MH literacy measures. The IG showed better self-reported PWB and improved MH literacy after intervention, compared to controls. No significant interactions were found for MH symptoms, life satisfaction and resilience.

Conclusions This study shows the contribution of short-term community-based interventions in increasing MH literacy and PWB among unemployed.

Clínica Jorge Jaber, Saúde Mental, Rio de Janeiro, Brazil

* Corresponding author.

Introduction The work describes the benefits of physical activities in patients with dual diagnosis in a psychiatric clinic of Rio de Janeiro city, Brazil.

Objectives Present the benefits of physical activities inside the hospital space. Evaluate the impact of the introduction of regular physical activity practice in patients having dual diagnosis in hospitalization environment.

Aims Demonstrates the decrease of the resistance to treatment in hospitalization regime, the behavioral and social improvement of patients, as well as the physical and mental capacities and the wellness promotion during and after the treatment.

Methods Forty-five patients carrying the dual diagnosis, hospitalized in the clinic for the period of 1 year, were monitored. All the patients were assessed by a general practitioner, a psychiatrist and a physiotherapist, before starting the physical activity, being the classification of mental disorders ICD-10 used for the diagnosis. The patients were treated with psychotropics, according to the diagnosis and the signs and symptoms presented. The therapeutic project offered physical and psychological treatment, promoting the recovery possibility through aerobic and anaerobic ludic physical activities inside the therapeutic environment.

Results All the patients presented improvement in the physical and mental capacities and in socializing. In the physical activities, the patients participated respecting their limitations, respecting the next and having a higher body perception.

Conclusions Through the development of the activities, the patients demonstrated excellent involvement and interaction with the treatment, favoring their psychological and behavioral recovery and impacting positively their response to the treatment of various mental disorders.

² Mackay Memorial Hospital, Department of Medical Research and Development, New Taipei City, Taiwan

* Corresponding author.

Aim To examine the effects of support interventions on anxiety, depression in women hospitalized with preterm labour at admission and 2 weeks.

Background Hospitalized pregnant women with preterm labour have significantly higher anxiety and depression levels. Few studies have explored the effects of support interventions on anxiety, depression in such women.

Methods A randomized, single-blind experimental design was used. The control group ($n = 103$) and intervention group ($n = 140$)

were recruited from the maternity wards of one medical centre in northern Taiwan between January 2013 and April 2015. The control group received routine nursing care. The experimental group received support interventions, which included an interview, distraction methods and assistance with daily living needs. Groups were evaluated with the Beck anxiety inventory, Edinburgh Postnatal Depression Scale and at admission and 2 weeks of hospitalization.

Results There were no significant differences between groups for demographics, obstetric characteristics, or birth outcomes. For the control group, anxiety and depression scores increased significantly decreased 2 weeks after hospitalization. The intervention group had a small, but significant, increase in anxiety and no significant change in depression at 2 weeks. Participants who received 2 weeks of support intervention had significantly lower anxiety and depression scores than the control group.

Conclusions Providing interventional support could reduce anxiety and depression for women with preterm labour during hospitalization.

* Corresponding author.

Introduction As a component of personal characteristics, mental health has always been associated with marital satisfaction. Mental disorders associated with depression and anxiety are common in the workplace. Many studies have found a close link between job satisfaction and these two factors.

Objectives The present study investigated the relationship of the level of job satisfaction, with mental health indicators and marital satisfaction in women.

Aims This study aimed to explain the relationships of job satisfaction (as an organizational key factor) with mental health and marital satisfaction of women at the workplace considering the practical implications for promoting mental health.

Methods To achieve the goal of research, a sample of 100 married women who worked at least for 5 years were selected by randomized sampling method in an organizational setting in Iran. Enrich Marital Inventory, Brayfield and Rothe's job satisfaction scale, and General Health Questionnaire were used for data gathering. Data was analyzed by utilizing hierarchical regression.

Results Findings indicated that most respondents were satisfied with their jobs. In general, subjects with more severe psychological distress and lower level of marital satisfaction reported lower levels of job satisfaction.

Conclusions Factors related to organizational attitudes such as job satisfaction were especially important in overall mental health and severity of psychological distress. Improving job attitudes is a key factor for promoting marital satisfaction and mental health in women.

Effectiveness of stress and burnout management training for employees of an industrial company

P. Salehe^{1,*}, M. Khademi Ashkzari¹, M. Mohebbi², K. Ezzat¹

¹ Alzahra University, Educational psychology, Tehran, Iran

² Tabriz University, Educational Psychology, Tabriz, Iran

* Corresponding author.

Introduction Burnout is a state of physical and emotional exhaustion. It can occur when people experience long-term stress in job, or when they have worked in a physically or emotionally draining role for a long time. There have been numerous studies done showing the results of stress and burnout in the employee's profession across many areas of health care.

Objectives The purpose of this study was to investigate the effectiveness of stress and burnout management training on employees using experimental method to help employees to understand available resources and help them find better ways to manage stress in the workplace.

Aims This study aims to discuss how organizations can assist in combating stress in ways that benefit both the employees involved and the organization itself.

Method A curriculum-based intervention was developed to provide education in a classroom setting. The sample included 14 nurses with various nursing backgrounds who were selected randomly and were assigned randomly in two experimental and control groups, which contained 7 employees in each group. The experimental group received the training while the control group was in waiting list. The instruments were the General Health Questionnaire and Burnout Checklist, and demographic questionnaire. Data was analyzed by covariance analysis method.

Results Result indicated that stress and burnout management training was efficient on reducing stress and burnout symptoms in employee.

Conclusion It is concluded that stress and burnout management training is an effective group intervening method for reducing the dysfunctional effects of stress and job burnout in employees.

Promotion mental health: Healthy habits program in patients with severe mental illness in the north Almeria mental health unit (Activarte)

M. Marin Olalla^{1,*}, A. Vidal Lopez¹, B. Perez Ramirez¹, R. Maldonado Lozano¹, A.L. Ioret Lopez²

¹ AGS Norte Almeria, Mental Health, Huerca Overa, Spain

² Faisem, Almeria Faisem Delegation, Almeria, Spain

* Corresponding author.

Introduction Promoting healthy lifestyles in patients with severe mental illness (balance diet, physical activity, smoking withdraw, adequate oral hygiene, optimal self-esteem and healthy sexuality) help patients to rely on their recovery.

Aims – avoid social isolation and stigma.

– encourage the recovery process, considering as well as the manage of symptoms together the functioning and quality of life of the patients.

– improve the progress and illness prognosis.

Methods – The program is introduced in the North Health Area of Almeria (Hospital Huerca-Overa) and FAISEM-Andalusia foundation to the social inclusion of mental illness patients;

– patients included in the program has been previously assess and informed-therapeutical contract;

– the program started in January 2013, with 10 sessions in the community, and groups sessions.

Results – fifty patients included between a total of 300–initial target 16%;

– the initial target considered was at least 60–75% of participation rate—being the result of 80–95%;

– physical assessment detected 10% of metabolic syndrome being the patients referred to primary medical care to the adequate management.

Program:

– twenty group sessions scheduled being performed 19: 95%;

– ten active sessions in community scheduled being performed 9: 90%—one sessions (beach trip) was cancelled due to budget problem;

– patients level of satisfaction: under assessment;

– broadcasting: 2 press articles, scientific communications, and shared the experience through FAISEM to all the Andalusia Areas.

– research: expecting spreading the experience and improve the results.

Bridging the gap between clinical practice and research: The association for research in psychiatry

G. Mattei*, S. Bursi, R. Bursi, A. Colantoni

Association for Research in Psychiatry (ARPSY), Castelnovo

Rangone, Modena, Italy

* Corresponding author.

Clinical practice and research are frequently seen as two worlds apart, in psychiatry as in the vast majority of medical specialties. In order to bridge the gap between them, economic funds and grants are required, not always easy to obtain. In this contribution we report the birth of the Association for Research in Psychiatry (ARPSY) and its main activities. ARPSY was born in May 2016 thanks to a research prize assigned to dr. Giorgio Mattei by the eight Rotary Clubs of the Province of Modena, Italy (Rotary Club Modena, Mirandola, Carpi, Sassuolo, Vignola Castelfranco Bazzano, Frignano, Modena L.A. Muratori, Castelvetro di Modena Terra dei Rangoni, that altogether make up the so-called “Ghirlandina Group”). Aim of the association is to promote mental health among students and trainees, mental health professionals, patients and their families, and among the general population by means of fund raising, in order to finance research projects, clinical interventions and educational activities.

The impact of animal-assisted therapy in the context of pediatric oncology: Results of an experimental study

F.L. Osório^{1,*}, N.B. Silva²

¹ Medical School of Ribeirão Preto, São Paulo University, Neuroscience and Behaviour, Ribeirão Preto, Brazil

² Pio XII Foundation, Barretos Cancer Hospital, Oncology Post-graduation, Barretos, Brazil

* Corresponding author.

Introduction The use of animals as a therapeutic resource has increased over the past years, especially for patients suffering from chronic conditions associated with high levels of distress, and animal-assisted therapy (AAT) stands out in this scenario.

Objective To assess the impact of an AAT program for children outpatients in oncological treatment according to psychological, physiological, and quality of life indicators.

Methods Children aged 6–12 years attended an AAT program (weekly open group with a duration of three meetings). The activities followed a pre-established script and children were assessed before and after the intervention with instruments that measure stress, pain, mood, and quality of life, in addition to heart rate and blood pressure records. Two trained therapy dogs were used and the program followed the “Guidelines for animal assisted interventions in health care facilities”.

Results Ten children completed the intervention (70% females, 50% with Ewing’s sarcoma/neuroblastoma). There was a significant reduction in anxiety and depression indicators after the intervention (effect size = -0.73 e - 1.27) and a tendency to stress reduction.

Conclusion Despite the small sample size, the partial analyses already provided favorable results regarding the use of AAT in the oncological context. We highlight the total absence of adverse events during the intervention, which speaks in favor of its safety. The expansion of the sample will probably strengthen the results found so far, suggesting that the technique can be an important ally in the management of emotional conditions associated with oncological treatment in childhood.

EV1028

Concerted action by multidisciplinary stakeholders: The development phase of a complex public health intervention in regards to adolescent self-harm

R. Parker

School of Social Sciences, Cardiff University, Centre for the Development and Evaluation of Complex Interventions for Public Health Improvement, Cardiff, United Kingdom

Self-harm has a strong prevalence within adolescent populations in Europe, and a potent relationship with suicide. In the UK, adolescent self-harm hospital admissions are rising each year. These statistics reflect the “tip of the iceberg”, with the majority of incidents hidden from public health networks. This invisibility creates barriers to: epidemiological information; the planning and evaluation of evidence-based support; health management within the complexity of adolescent self-harming behaviours to ensure recovery and healthy adolescent trajectories. It is also a serious health risk for this population group, and accidental death from self-harm is one of the common causes of injury-related adolescent death.

Within the aforementioned context, this paper describes a UK county-wide complex public health intervention (2013 to 2015) in regards to adolescent self-harm, with concerted action by key stakeholders in health, child welfare, education and social science due to concerns about the increasing self-harm rate within the adolescent population group. As self-harm is a complex behaviour, and the evidence-base for effective interventions is sparse, the development of protective factors within education, health and social care environments were targeted. A synergy of theoretical models from neuroscience and social science informed the intervention’s logic model. The intervention’s development phase utilised the Medical Research Council’s guidance on complex interventions to improve public health, which this paper will exposit.

⁴ Institute of Psychiatry and Clinical Psychology, Catholic University of the Sacred Heart, Department of Neuroscience, Rome, Italy

⁵ Section of Hygiene, Catholic University of the Sacred Heart, Department of Public Health, Rome, Italy

* Corresponding author.

Introduction Stigma in mental illness is characterized by discrimination towards people affected by mental disorder. Consequence of the paradigm “stigma-injury-discrimination” is the social exclusion of these patients and the denial of their rights. Medical students, those who should be important reference points for psychiatric patients, are instead one of the categories that contribute to their stigmatization.

Objectives To study the attitudes of medical students towards psychiatric patients.

Aims The present study analyzes gender differences in a sample of Italian medical students towards mental illness.

Methods A total of 339 Italian medical students completed a cross-sectional survey, in Rome and Foggia (Italy). We used the Italian version of Community Attitude towards the Mentally Ill test (CAMI) to analyze the students’ attitudes.

Results There is a substantial difference among the attitudes towards mental disorders in female and male students. Female students have obtained less stigmatizing results in 9 of the CAMI test items ($P < 0.05$), in Benevolence ($P = 0.001$) and Social Restrictiveness subscales ($P = 0.043$) and in the total score ($P = 0.013$).

Conclusions These results are in line with those achieved in scientific literature, confirming that women tend to show more humanitarian attitude towards the mentally ill. Even in the original article of the validation of the CAMI test, the authors found better attitudes in women in all subscales, with the exception of Social Restrictiveness subscale (that in our analysis also correlates with the female gender).

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Institute of Psychiatry and Clinical Psychology, Catholic University of the Sacred Heart, Department of Neuroscience, Rome, Italy

⁵ Section of Hygiene, Catholic University of the Sacred Heart, Department of Public Health, Rome, Italy

* Corresponding author.

Introduction Discrimination and stigmatization cause an important burden for people suffering from psychiatric disorders. The medical doctors, those who should be important reference points for psychiatric patients, are instead one of the categories that contribute to their stigmatization.

Objectives It is extremely important to study and to know the attitudes of undergraduate medical students towards psychiatric disorders, since these individuals will be involved in the care of these patients throughout their careers.

Aims The present study analyzes the attitudes of a group of Italian medical students towards mental illness, highlighting the differences between the students who would choose surgical specialties from those who prefer medical ones.

Methods A total of 339 medical students of different medical schools, in Rome and Foggia (Italy), completed a cross-sectional survey. The Italian version of community attitude towards the mentally ill test (CAMI) was used to evaluate the students’ attitudes.

Results The students that would choose medical specialties reported less stigmatizing responses in 11 CAMI items (including five items with $P < 0.01$), in benevolence and community mental health ideology subscales ($P = 0.003$) and in the total score ($P = 0.003$).

Conclusions It is evident that the students that prefer the surgical specialties have more stigmatizing attitudes towards psychiatric patients. Negative feedbacks on Psychiatry from non-psychiatrist colleagues may have a fundamental role in stigmatizing mental disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Differences in empathy in Italian university students: Are medical students more or less empathetic?

M. Pascucci^{1,2,*}, D. Di Sabatino¹, E. Stella¹, M. La Montagna¹, R. Nicastro¹, P. Grandinetti^{3,4}, R. Testa⁴, P. Parente⁵, G. Pozzi⁴, L. Janiri⁴, A. Ventriglio^{1,2}, A. Bellomo^{1,2}

¹ Institute of Psychiatry, University of Foggia, Department of Clinical and Experimental Medicine, Foggia, Italy

² Azienda Sanitaria Locale della Provincia di Foggia, Dipartimento di Salute Mentale, Foggia, Italy

³ AUSL Modena, Dipartimento di Salute Mentale, Modena, Italy

⁴ Institute of Psychiatry and Clinical Psychology, Catholic University of the Sacred Heart, Department of Neuroscience, Rome, Italy

⁵ Section of Hygiene, Catholic University of the Sacred Heart, Department of Public Health, Rome, Italy

* Corresponding author.

Introduction Empathy is the capacity to understand or feel what another person is experiencing. It is an important quality in the medical profession, since it is fundamental in interpersonal relationships with patients. Nevertheless, many studies have found that over time medical students (MS) become less empathic and more detached from patients.

Objectives and aims To determine MS loss of empathy and to study the differences in empathy between MS and other university students who are not involved in healthcare.

Methods We enrolled 244 MS (120 of the 1st year and 124 of the last year) and 125 other university students not involved in healthcare, in different universities in Rome and Foggia (Italy). They anonymously and voluntarily completed a socio-demographic questionnaire and Baron Cohen’s empathy quotient test (EQ).

Results We found no differences regarding EQ total score between MS and other students, however there are few differences considering individual EQ items. In particular, MS really like taking care of others ($P = 0.005$) and they are sometimes considered to

be rude, even if only they are only blunt ($P=0.006$). We found no differences in empathy between first year and last year MS.

Conclusions In our sample of Italian students, we have not found MS to be more or less empathetic than other university students, but there are some peculiar differences in empathy that make them better suited to the chosen course of study. Moreover, we found no differences between the different years of medical school.

Owning the brand of psychiatry

A. Peters

The Royal Australian and New Zealand College of Psychiatrists, OPCEO, Melbourne, Australia

In Australia and New Zealand, conversations around mental health are playing out in the public space with increasing frequency. Mental health promotion campaigns and organizations are embraced by mainstream and other forms of media, and supported by government. Whilst public knowledge of mental illness is increasing, the profile of psychiatrists as leaders and medical experts in mental illness is a more difficult brand to sell. With a somewhat tarnished history behind us, the modern evidence-based practice of psychiatry is not always at the forefront of public impression. Furthermore, in Australia, more than half of the population (56%) is unaware that psychiatrists have undertaken medical training as a doctor. This presentation will outline Royal Australian and New Zealand college of psychiatrists (RANZCP) action to improve community information about psychiatry, psychiatrists and treatment experiences.

Prejudice towards people with mental illness

J. Radović*, I. Roncevic-Grzeta, J. Rebic

Faculty of Medicine, University of Rijeka, Psychiatric Clinic, KBC Rijeka, Rijeka, Croatia

* Corresponding author.

This paper reports the results of a medical research that measured prejudice and attitudes towards mentally ill people and towards the mental illness. Three groups of respondents were studied: medical students, psychology students and the general population. Medical students and psychology students represented a population that is educated in regards to mental illness, and the general population was not trained so much about mental illness. The hypothesis was that the respondents who have been working with mentally ill people and had lots of knowledge about mental illnesses were the persons with less prejudice towards people with mental illness. The main objective of research was to examine the differences in prejudice and attitudes between respondents who had experience and knowledge related to mental illness and people with mental illness compared to those without such knowledge and experience. Testing was conducted using an anonymous online survey consisting of thirteen questions. The research confirmed the hypothesis and it could be an incentive for education aimed at specific groups.

The importance of early detection of child neurodevelopment in primary care in Colombia

A.M. Romero Otalvaro*, M. Munoz-Argel

Universidad Pontificia Bolivariana, Psicología, Monteria, Colombia

* Corresponding author.

Introduction The systematic assessment of child development for the first 30 months of age is essential in the monitoring of health outcomes; this requires to have a structured protocol to systematically observe the milestones that have to be achieved at each stage of child development, and prevent deficiencies related to risk factors, reduce and prevent special needs arising from a deficit of the neurodevelopment.

Objective Describe the results of the evaluation of early detection of neurodevelopment problems in subjects from 0–30 months of age who assist to child developmental centers in municipalities located in the Colombian Caribbean region; the main need for intervention was characterized with different neurodevelopment problems.

Methods A cross-sectional study was developed. Childs from 0–30 months of age who attended to the child development centers were tested. Exclusion criteria were not stipulated. The ASQ-3 and a demographic survey (Graffar's survey) were administered, in order to correlate the social level and the overall results.

Results The study included 750 boy/girl. The maturational development for each age group was determined, an analysis of each neurodevelopment area was conducted and the results were correlated with the demographic survey.

Conclusions High levels of suspicion of possible neurodevelopment problems and the referral to diagnostic evaluation were observed for access to appropriate treatments. Early detection is highlighted as a tool in primary care that optimizes health sector resources and act in the appropriate periods of plasticity of child development.

Psychiatric treatment-associated stigmatization as viewed through eyes of rural health clinic patients

D. Sendler^{1,*}, A. Markiewicz²

¹ University of Lublin Medical School, Department of Psychiatry and Sexual Consultation Clinic, Lublin, Poland

² Private practice, Community mental health, Lublin, Poland

* Corresponding author.

Introduction Having a mental disease is frequently a stigmatizing experience for patients. We know little about urban inhabitants who travel to rural health clinics to receive mental treatment.

Objectives Recruit and interview urban-based psychiatric patients who, to avoid stigmatization; travel to rural community clinics with the intention of receiving treatment.

Methods Study included participants ($n=32$) who exchanged treatment in government subsidized city clinics for rural community centers. Qualitative interviews lasting thirty minutes were recorded and transcribed for content analysis. MAXQDA, version 12, was used to annotate transcripts with topic specific nodes, followed by cluster theme and trend analysis.

Results Trend analysis yielded three areas of concern for subsidized urban psychiatry: cost/insurance, lack of staff professionalism, and family-driven ostracism. Seven respondents cited cost as the main factor, influencing the choice of rural-based care over city clinic. Patients with stable income, but without insurance ($n=14$), felt unwelcome in city clinics as their ability to pay

was frequently questioned by supporting staff. Lack of trained social workers caused additional distress, as participants could not receive access to additional resources. Only four patients said that their psychiatrists acknowledged poor clinic environment and encouraged remaining in treatment. For 18 respondents, family demanded that they receive treatment in rural clinic so that no one finds out about their mental disease.

Conclusion In large urban clinics, stigma in psychiatry comes in many flavors, especially projected by unprofessional clinic staff and ashamed family. Lack of support forces patients to travel to rural premises to receive unbiased, stress-free care.

Introduction Cognitive behavior therapy (CBT), which is used by mental health professionals including occupational therapists (OT) is a time-sensitive, structured, present-oriented therapy directed toward solving current problems and teaching clients skills to modify dysfunctional thinking and behavior.

Objectives Supporting the development of CBT theory and efficient use by mental health professionals are vital.

Aim To present the results of CBT training for OTs, which was funded by “European Union technical assistance for increasing the employability of people with disabilities” project (Europe Aid/136449/IH/SER/TR).

Methods Using a basic CBT theoretical framework the participants attended 96 hour face to face training modules with written materials including fundamental features, preconditions and methods used in CBT. A Turkish CBT book was published for course. Participants trained their skills under supervision and send the results to educators. Pre-post of training CBT knowledge and quality of training (plan-contents, educators, and environment) were evaluated by 5-Likert scale.

Results Thirty OTs (f = 23, m = 7) mostly 43.3% PhD; 20–25 (30%) and 45–50 (26.7%) years age period were included. Total mean score for quality of education was 109.4 ± 29.4 with 23.63 ± 4.34, 47.36 ± 6.41, 38.40 ± 21.61 for plan-contents, educators, and environment subscores, respectively. CBT knowledge was increased from 15.70 ± 6.08 to 45.06 ± 4.59 ($P < 0.001$).

Conclusion Training increased CBT awareness and practice skills of OTs. Teaching OTs CBT may increase their understanding of person-environment-occupation approach, psychological problem solving, occupational engagement and participation of individuals. Our result supports that mental health professionals should collaborate to share ideas, develop guidelines and promote good practice examples in client-centered and holistic rehabilitation care.

Background Chronic non-communicable diseases (NCD) are a public health problem in Brazil. In addition, NCDs is more strongly associated with common mental disorders than was each NCD individually. This study is about the implementation and execution through the university extension project “harm reduction and mental health: hypertension control and health education” developed at Images of the Unconscious Museum, Brazil.

Aims Measure the prevalence of hypertension, verify the association with chronic NCDs, educate about risk behavior and improve to psychosocial rehabilitation.

Methods A socio-demographic and blood pressure profile was constructed. We identify hypertension on 33 patients. After the diagnosis, the family health unit was contact to construct a clinical care plan. We distribute health educational material about clinical diseases.

Results Thirty-six percent patients was identify with hypertension; once had high blood pressure and rejected any intervention; 68% have family rates of hypertension and 100% referred low salt on diet. A book storytelling was constructed to give orientations about health lifestyle. We conducted therapeutic workshop to highlighting the creative, imaginative and expressive potential of the users on health behavior.

Conclusion We identify low blood pressure after the activities and a new health style after the orientation process.

Demonstrating the methodology of a pilot programme for establishing a system for mental health promotion in Hungary

R. Wernigg*, Dr. M.D. Toth, Dr. A. Sumegi

National Public Health and Medical Officer Service, Office of the Chief Medical Officer, Norway Grants Mental Health Promotion Project, Project Directorate, Budapest, Hungary

* Corresponding author.

Introduction A 12 month long mental health promotion pilot programme in Hungary, funded by the Norway Grants, will finish on 30th April 2017.

Aims To launch six community mental health promotion centers (MHPCs) located in various economic environments, supervised by one Methodological Center plus expert teams and carrying out studies on the effectiveness of the launch of the system. The final recommendations will constitute a basis for setting up a national network for mental health promotion.

Objectives To develop a sustainable model for establishing a national network of MHPCs; to map and record the mental health problems and the stakeholders of the area; to find and assess the local best practices; and to raise public awareness in the following mental health problems: depression, suicide, stress and dementia.

Methods (1) Models for inducing changes in the knowledge and attitudes upon mental health in the communities were reviewed in a systematic literature search. (2) Based on the results, a model of mental health promotion centers was outlined for problem identification, stakeholder mapping, assessing local best practices, organizing and supporting local networking activities for synergis-

tic effects. (3) In the new MHPCs, on-site TTT education programme and organisational development have been in place. (4) The activities of the MHPCs have been monitored for knowledge transfer and attitude changes in the local networks. (5) Based on the results, recommendations are being made for the national extension of the model.

Results and conclusions The first data ready for analysis will be available by April 2017.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A comprehensive training program for professionals working in mental health promotion centers in Hungary

M.D. Toth*, R. Kallaine Harangi, A. Sumegi, R. Wernigg
National Public Health and Medical Officer Service, Office of the Chief Medical Officer, Norway Grants Mental Health Promotion Project, Project Directorate, Budapest, Hungary

* Corresponding author.

Background In a 12 month long mental health promotion pilot programme funded by the Norway Grants, 6 mental health promotion centers (MHPCs) are being set up in various locations in Hungary, employing 2 mental health professionals each, whose main commitment is to develop a local network of key stakeholders. The aim of the project is to enable MHPC professionals to perform network building tasks involving knowledge transfer and attitude changes regarding the following key areas: depression, suicide, dementia, stress and risk assessment.

Objective To measure the effectiveness of the training and education process by using indicators for feedback, knowledge transfer and attitude changes.

Methods The comprehensive TTT (train the trainers) process of MHPC professionals targets 3 main domains:

- improving presentation skills;
- knowledge transfer (measured with tests);
- elaborative workshops about mental health problems (measured by attitudes at baseline, post-training and 3 months post-training).

Results The satisfaction assessment of the initial 3 days long training averaged 4.73 on a 5-point Likert-scale. Altogether, 12 (2/centres) knowledge transfer trainings are being delivered evaluated by attitude change and general satisfaction questionnaires. One elaborating workshop per center has been delivered during the study period. Being a process still underway, the outcome results will only be available by the conference.

Conclusion This procedure enables professionals to disseminate trainings and build networks for mental health promotion in their micro-regions. The optimized version of this pilot program will be delivered on a national level in future projects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Oxidative stress, inflammation and mild cognitive impairment

N. Cherbuin^{1,*}, K.J. Anstey¹, B.T. Baune²

¹ Australian National University, Centre for Research on Ageing, Health, and Well-being, Canberra, Australia

² University of Adelaide, School of Medicine, Adelaide, Australia

* Corresponding author.

Introduction Oxidative stress (OS) and inflammation are processes known to be implicated in neurodegeneration. Moreover, risk factors for dementia (depression, obesity, sedentary lifestyle, diabetes, etc.) are associated with up-regulation of pro-inflammatory cytokines. OS has been found in animal models to contribute to cerebral amyloid angiopathy. However, investigations of the associations between OS, inflammation and MCI, typically in small clinical samples have produced mixed results.

Objectives Clarify associations, between OS, inflammation and MCI in a large cohort of community-living individuals.

Methods Cognitively healthy individuals ($n=211$, 44% female, 75.2 years) and with MCI ($n=23$, 44% female, 75.2 years) from a population sample were included. MCI diagnosis was established based on a detailed neuropsychological assessment. Inflammatory (IL1b, IL4, IL6, IL8, IL10, TNF-a) and OS (total anti-oxidants, NO, neopterin) markers were assessed in plasma samples. Associations between biomarkers, MMSE, and MCI status were tested with multiple linear and logistic regression analyses.

Results Univariate analyses showed that log IL4 (estimate: -0.175 , SE: 0.085, $P=0.041$) and NO (estimate: 0.015, SE: 0.006, $P=0.017$) were the only markers associated with MMSE scores. MCI status was predicted by log IL4 (estimate: 0.822, SE: 0.357, $P=0.021$) and total anti-oxidants (estimate: -0.007 , SE: 0.003, $P=0.014$). Controlling for pro-inflammatory conditions (T2D, BMI, depression, hypertension) removed the associations with inflammation but not with OS.

Conclusions These results indicate that increased systemic inflammation and increased OS were associated with lower MMSE scores and higher odds of having MCI. This confirms that systemic pro-inflammatory processes are associated with impaired cognition and should be specifically considered in treatment and risk-reduction interventions.

Effect of original anticonvulsant meta-chloro-benzhydryl-urea on behavioral and immune parameters in mice with active and passive behavior types in experimental alcoholism

E. Markova^{1,*}, M. Knyazheva¹, I. Savkin¹, T. Shushpanova²

¹ State Research Institute of Fundamental and Clinical Immunology, Russian Academy of Sciences, Novosibirsk, Russia

² Tomsk National Research Medical Center, Russian Academy of Sciences, Mental Health Research Institute, Tomsk, Russia

* Corresponding author.

Objective Violation of the functional activity of the nervous and immune systems is an essential link in the pathogenesis of chronic alcohol dependence. The search for new psychopharmacological agents whose action is directed to correction of neuroimmune interaction opens new perspectives for the treatment of alcohol dependence.

Methods (CBAx57Bl/6) F1 mice with active and passive behavioral types in a state of chronic alcohol dependence owing to 6 month 10% ethanol exposure were undergoing intragastric administration of original anticonvulsant meta-chloro-benzhydryl-urea. Animal's behavioral and immune parameters, brain cytokines synthesis before and after anticonvulsant receiving were estimated.

Results In the formation of experimental alcohol dependence in animals the most pronounced changes in motor and exploratory

activities in open field test, brain cytokines synthesis and suppression of immune response were registered in mice with passive type of behavior. Daily consumption of ethanol solution in mice with chronic alcohol dependence decreased sharply starting from 2 days of anticonvulsant administration and led to the cessation of ethanol consumption by the 5 day. After anticonvulsant administration for 10 days behavioral parameters in mice were comparable with those in the control group of healthy animals. It also restored brain cytokines synthesis and significant stimulated humoral immune response, estimated by the relative number of antibody-forming spleen cells.

Conclusion Behavior and immune changes following chronic ethanol exposure depended on the behavior status of animals; administration of the original anticonvulsant meta-chlorobenzhydryl-urea may correct both immune and behavior disorders in mice with chronic alcohol dependence, so it has promise in the treatment of alcoholism.

EV1042

Lymphocytes with Fas-receptors of readiness to apoptosis in non-psychotic mental disorders

V. Nikitina^{1,*}, T.P. Vetlugina¹, O.A. Lobacheva¹, V.A. Rudnitsky², M.M. Axenov²

¹ Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Department of Psychoneuroimmunology and Neurobiology, Tomsk, Russia

² Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Borderline States Department, Tomsk, Russia

* Corresponding author.

Introduction Apoptosis is a complex physiological process of the organism which supports cellular homeostasis, provides important aspects of development and functioning of the immune system. In various pathological conditions the process of apoptosis can be impaired that leads to decrease or increase in pro-apoptotic activity.

Materials and methods We conducted investigation of relative and absolute number of CD3⁺CD95⁺-lymphocytes in groups of patients with adjustment disorders ($n=90$), PTSD ($n=100$), organic emotionally labile (asthenic) disorder ($n=232$), organic personality disorder ($n=93$). Clinical verification was conducted according to ICD-10. Control group included 190 practically healthy persons. Fas protein (CD95) expression on CD3 lymphocytes surfaces was detected using flow cytometry. Cytometric measurements were conducted on flow cytofluorimeter FacsCalibur (Becton Dickinson, US).

Results In the control group relative number of CD95⁺-lymphocytes was 11.6%, absolute $-0.21 \times 10^9/L$. In all examined patients as compared with control the reliable increase both in relative and absolute number of lymphocytes of CD3⁺CD95⁺-phenotype was identified. So, in persons with adjustment disorder content of this indicator made 17.0% and $0.28 \times 10^9/L$ ($P=0.0015$), in PTSD-18.0% and $0.33 \times 10^9/L$ ($P=0.0007$) and in patients with organic asthenic disorder-19.0% and $0.32 \times 10^9/L$ ($P=0.0048$), respectively. The highest content in blood of CD3⁺-lymphocytes, expressing on the surface of membrane the basic marker of apoptosis CD95 is observed in patients with organic personality disorder: 26.0% and $0.44 \times 10^9/L$ ($P=0.0003$).

Conclusion In case of intensification of psychopathological symptoms especially in persons with non-psychotic organic mental disorders a receptor-mediated signaling pathway of apoptosis is activated – process of programmed cell death.

Inflammatory markers in mild cognitive impairment and anxiety disorders in middle-aged subjects with metabolic syndrome

V. Piotrovskaya*, N. Neznanov

First State Pavlov Medical University, Psychiatry, St. Petersburg, Russia

* Corresponding author.

Anxiety disorders are increasingly being associated with metabolic and cardiovascular burden, in contrast with depression; the role of inflammation in anxiety has sparsely been discussed. A number of reports of elevated inflammatory markers in mild cognitive impairment (MCI) suggest that inflammation may be a potential early marker of the pathological cascade associated with dementia. The aim of this study was to evaluate a possible association between peripheral blood concentrations of inflammatory factors in patients with MCI and mental processes such as, cognitive impairment and anxiety in obesity.

Methods and results The data collected from 271 patients with MetS according IDF criteria, (aged 30–60 years) have been analyzed. Lifetime diagnoses of depression (D), anxiety (A) was self-reported. Current D and A were confirmed by psychodiagnostic interview according to the criteria of ICD-10. All patients passed through: MMSE test, Wechsler memory scale, symbol coding and category Fluency test, scales HADS, HAM-A. Inflammatory markers included CRP, IL-6, IL-1 and TNF- α . Subjects were divided into group A–with D and/or A (139) and group B–without affective disorders (132). Using Mann–Whitney test significant connection between presence of MCI and high levels of inflammation is associated with simultaneous presence affective disorders. High correlations in subjects with A/D were between IL-6, IL-1 and MCI. In-group B, there was no significant correlations between inflammatory markers and MCI.

Conclusion There is link between affective disorders and levels of inflammatory markers. Increased levels of IL-6 and IL-1 provoke co-morbidity of MCI and depression or anxiety.

Autoimmune limbic encephalitis: When psychiatric symptoms are not what they seem

A. Samico*, Á. Venâncio

Vila Nova de Gaia Hospitalar Center, Psychiatry and Mental Health Service, Vila Nova de Gaia, Portugal

* Corresponding author.

Introduction The autoimmune (AI) limbic encephalitis (LE) can manifests as changes in neuropsychiatric functions and can even occur with isolated psychiatric symptoms. Many times it is a manifestation of paraneoplastic syndromes and it is lately diagnosed.

Objectives Our objective is to increase awareness to this pathology, since initial contact with these patients is often performed by a psychiatrist and its early detection and treatment greatly improve the prognosis of the patients.

Aims The aim of this presentation is to address the AI LE as a differential diagnosis in patients with psychiatric symptoms.

Methods Presentation of a clinical case of AI LE and syndrome revision.

Results The clinical case involves a 62-year-old man, with no psychiatric history, who begun to present depressive symptoms, emotional lability, aggressiveness and amnesic deficits with 4 months of evolution. After realize an exhaustive clinical evaluation, a cerebral MRI and LCR analysis, the results were consistent with seronegative AI LE. The patient was treated with corticoid therapy and presented a favorable evolution, with remission of the symptoms.

Conclusions Even though it is a rare pathology, AI LE is an important differential diagnosis to consider in patients with psychiatric symptoms and it is essential to enhance the early detection and treatment of this pathology. This condition also reinforces the role of AI diseases in psychiatric disorders in general, an area, which requires further investigation. With this clinical case, we expect medical professionals to be able to recognize the importance of this diagnosis.

Behavioral disorders: Within the limits of psychiatry or neurology? About a case

P. De Jaime Ruiz (Resident Medical Intern)*, J. Fernández Logroño (Psychiatrist)

Hospital Universitario Granada, Psychiatry, Granada, Spain

* Corresponding author.

E-mails addresses: pilareina@hotmail.com (P. De Jaime Ruiz), jflogrono@gmail.com (J. Fernández Logroño)

It has been a clinical case of a polymorphic psychotic disorder in a male of 26-year-old, affected by brain palsy, previously with adequate cognitive function, undergoing remarkable confusional fluctuations and a waking state apparently well-preserved. As possible comorbidities or triggers we could count on a tonsillitis and/or a depressive reaction a few days before. Serious consideration must be given to a differential diagnosis with an encephalitis but, despite the presence of an intermittent febricula, it was rejected by both units: internal medicine and neurology, after performing some complementary tests, albeit some more specific tests are still pending. His psychiatric background was also checked, which initially was orientated as a questionable bipolar disorder. At all events, symptoms stopped progressively until, almost complete remittance in the moment he was discharged from the hospital. He recovered his normal functionality. The treatment given was risperidon 2 mL/day, quetiapine 50 mg/8 h and baclofen 10 mg/12 h. This can be used as an example of how many difficulties we usually found to catalogue an acute disorder in first phases, even to encompass the clinical profile within the limits of psychiatry or neurology.

The role of dissociation in patients with a diagnosis of borderline personality disorder and adverse attachment experiences

D. Galletta*, N. Vangone, A.I. Califano, S. De Simone, V. Suarato, A.M. Mastrola

University of Naples Federico II, Neuroscience, Naples, Italy

* Corresponding author.

In literature, the link between childhood abuse stories, trauma, unresolved attachment and psychopathological manifestations characterized by the presence of significant dissociative symptoms are well documented. The treatment of this kind of clinical pictures is very problematic because of dysfunctional relational dynamics acted by patients. As we know, borderline personality disorder patients and those with unresolved attachment show poor emotion regulation. About that, a very recent study found an alteration of the neural mechanism involved in the top-down control process of emotional distress both in BPD patients and in those with unresolved attachment. In this context, to make an accurate psychological assessment is essential to define and understand the overall patient functioning and identify the most appropriate therapeutic strategies. In this study, we have selected 22 women characterized by a diagnosis of borderline personality disorder, dissociative experiences and childhood abuse stories. The psycho-diagnostic examination of this sample involved the use of the following tools: Rorschach, MMPI-2, WAIS-R and drawing tests. Consistent with the literature, the outcomes confirmed the presence of response patterns related to trauma, abuse stories and dissociation in both Rorschach and MMPI-2. At the same time, in a significant portion of the sample, we have found an intact cognitive functioning; this aspect, as showed by other authors, highlights the adaptive function of the defensive mechanism of dissociation.

Psychopathology of depersonalization and de-realization. What is the limit between normal and pathological?

G. Hernandez Santillan

Gina Asunta, Hernandez-Santillan, Hospital Universitario Príncipe de Asturias, Madrid, Spain

A 21-year-old woman, distance-learning psychologist with a history of parent violence during her early childhood in the context of her father's alcohol poisoning, describes experiences of depersonalization and de-realization, of which she is aware since the age of five years, in situations of stress or out, for example, when looking in the mirror or even playing. She consulted to psychiatry, seven months after his father died of lung cancer, he frequently smoked tobacco and cannabis at home, had been diagnosed a year before his death. The patient described increased anxiety symptoms, with panic attacks, hypnopompic and hypnagogic hallucinations, and increased depersonalization and de-realization phenomena. She denies the use of psychoactive substances in addition to tobacco and alcohol, occasionally. Likewise, the depressive symptomatology was objectified in relation to the grief for the loss of his father. She received treatment with SSRIs and two months later, referred partial remission of symptoms, with persistence of dissociative symptoms. In addition, she presents emotional instability, feelings of emptiness, self-defeating ideas without structured suicide ideation. In recent months, he has presented avoidant behaviors and isolation with affectation in his habitual functioning. Now, in this case: are depersonalization and de-realization normal, part of the anxiety crisis, a sign of a high-risk mental state, or a prelude to a serious mental illness?

Psychiatric patients show different coping styles during aggression compared to controls

S. Orlando, G. Callovinì, B. Altavilla, L. D'Ambrosio, F. Iasevoli*
 University of Naples Federico II, Department of Neuroscience,
 Reproductive Sciences and Odontostomatology, Naples, Italy
 * Corresponding author.

Introduction Aggression and violence are common phenomena, potentially experienced by everyone.

Objectives To demonstrate that coping patterns to face aggression and violence may exhibit differential group features.

Aims To find differences in coping styles during moments of high aggression in psychiatric patients compared to non-affected controls.

Methods We evaluated 34 outpatients from the section of psychiatry of university Federico II of Naples by two psychometric scales: AQ to evaluate aggression levels and Brief-COPE for coping patterns. Outcomes were compared with that of 34 non-affected controls, recruited from the university student population. Pearson's correlation was used to find relationships between aggression levels and coping skills in these two groups.

Results We found significant differences between groups in multiple scale items and in the correlation measures, e.g. the use of expression was completely reversed in this two samples according to aggression levels.

Conclusions These results show that aggression is experienced differentially and with different coping styles by psychiatric patients compared to non-affected controls.

Cognitive dysfunction in acute psychosis

O. Mulligan*, W.T. Tan, G. Lowry, D. Adams
 Sligo Mental Health Services, Psychiatry, Sligo, Ireland
 * Corresponding author.

Introduction Patients with psychosis often present with cognitive dysfunction during the course of their illness. Inflammatory markers such as cytokines and neurotrophins have been investigated, as they are relevant to the change in cognitive function.

Objectives To evaluate the cognitive function between patients with acute psychosis and those without. Moreover, this study also investigates cytokines and neurotrophins levels in acute psychosis and their relation with cognition, severity of psychosis and trajectory of their levels across time and under treatment.

Methods Longitudinal, observational, pilot study, of psychiatric inpatients. Participants were assessed on the first day using brief psychiatric rating scale, CAGE, trail making test B and Wisconsin card sorting test. These assessments were repeated weekly until patients were discharged. Blood samples were also collected on the same day for cytokines and neurotrophins analysis. However, the result on cytokines and neurotrophins levels is still pending, therefore only clinical findings will be presented.

Results Thirty-one patients (mean age: 43.7, SD: 18.9, 14 females and 17 males) were recruited. Eleven were acutely psychotic. Generalized estimating equations modelling were used to compare these two groups based on cognitive and demographic variables. Patients with psychosis are more likely to have significantly lower scores for CAGE (Wald- $\chi^2=6.268$, $df=1$, $P=0.012$), significantly more abnormal scores in Trail Making Test B (Wald- $\chi^2=7.338$, $df=1$, $P=0.007$), failure to maintain set (Wald- $\chi^2=8.323$, $df=1$, $P=0.004$) and perseverative errors

(Wald- $\chi^2=4.385$, $df=1$, $P=0.036$) although they have more years of education than those without psychosis.

Conclusions These data show individuals with acute psychosis have impaired cognitive function compared to others.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Insomnia and aggressiveness in affective disorders: Self-assessment versus clinical examination

M. Nascimento^{1,*}, M. Lázaro¹, J. Reis², G. Pereira³, F. Bacelar¹, A. Nobre¹

¹ Centro Hospitalar Psiquiátrico de Lisboa, Clínica 5, Affective Disorders and OCD, Lisbon, Portugal

² Centro Hospitalar do Algarve, Psiquiatria, Faro, Portugal

³ Centro Hospitalar Psiquiátrico de Lisboa, Clínica 4, Lisbon, Portugal

* Corresponding author.

Introduction Although, disturbances of sleep, as well as aggressiveness, have been described in patients with mood disorders, these patients may not be aware of them.

Objectives/aims To access the personal perception of sleep, disturbances and aggressiveness in patients with mood disorders, admitted to an acute psychiatric ward.

Methods Diagnostic data (ICD-10: F31–33), including mood evaluation, were prospectively collected for all patients admitted at the affective disorder ward at Centro Hospitalar Psiquiátrico de Lisboa (Portugal), during the third trimester of 2016. Then, 2 auto-questionnaires – Athens insomnia scale (AIS) and Buss and Perry aggression scale (both validated to the Portuguese population) – were applied to these patients. Statistical analysis was performed for possible correlations between patients' mood and the questionnaires' scores, using R software.

Results Thirty-eight patients admitted were enrolled in this study: 28 with bipolar disorder (19 manic, 4 depressive and 5 mixed episodes), and 10 with depressive disorder. Depressed patients presented statistically higher values in the AIS (average = 20), compared to manic (14) and mixed ones (17.2) ($P=0.031$). However, there were no statistical differences found between depressed patients (bipolar versus non-bipolar). Even though manic patients presented an increased average score in the Buss and Perry questionnaire (both total-65; but also sub-scores), these values were not significantly different than depressed (60) or mixed patients' scores (57.4).

Conclusions Even though some symptoms (like sleep or aggressiveness) seem to be relevant to the clinics, patients with affective disorders do not seem to be aware these disturbances, and therefore are not able to acknowledge their relevance.

Disclosure of interest The authors have not supplied their declaration of competing interest.

¹ University of Thessaly, Medicine, Larissa, Greece

² University of Applied Sciences of Thessaly, Nursing-Postgraduate Program in Mental Health-Research Laboratory of Care, Larissa, Greece

³ University of Applied Sciences of Epirus, Nursing-Research Laboratory Psychology of Patients Families and Health Professionals, Larissa, Greece

* Corresponding author.

Introduction Smoking causes many life-threatening diseases and is a major risk factor for several main causes of death. Damage by smoking is also caused to those called “passive smokers”. Passive smoking has been implicated in many adverse effects on health. Very few studies deal with empathy in smokers while smoking in the presence of non-smokers.

Purpose Estimation of empathy and psychological characteristics of Greek smokers.

Methodology For research purposes we used questionnaires Toronto empathy questionnaire (TEQ), symptom check list 90-R, experience of shame scale (EES) and other as Shamer scale – OAS.

Results A statistically significant difference has been observed in the TEQ to gender (2.436, 0.02), with women showing the highest value (3.4 ± 0.4), as well as in the mean in behavioral shame 2. Another statistically significant difference has been observed in behavioral shame between educational level (3.419, 0.026) and the price of characterological shame among those who reported smoking in the workplace and those who did not.

Conclusions The sample consisted of 27 subjects with average age 24 years and standard deviation of 4 years. Smokers accounted for 48.1%, of whom 69.2% stated that smoke in their living space. Respectively, the percentage of smokers in the workplace was equivalent. The largest percentage of smokers, (13 people, 69.2%) think that non-smokers are very annoyed when surrounded by people smoking close to them. The proportion of those who said they are very much bothered when in places where smoking is prohibited but somebody smokes, is large (47.1%).

Cotard syndrome: Pathology review

A. Samico*, J. Perestrelo, Â. Venâncio

Vila Nova de Gaia Hospitalar Center, Psychiatry and Mental Health Service, Vila Nova de Gaia, Portugal

* Corresponding author.

Introduction Cotard syndrome (CS) is a rare neuropsychiatric condition characterized by nihilistic delusions, which may range from negation of existence of parts of the body to delusion of being dead or negation of self-existence, and it requires an urgent and appropriate therapy.

Objectives Our objective is to highlight the importance of CS, reinforcing that medical professionals should be aware of this pathology to prompt clinical description, diagnostic and treatment.

Aims The aim of this presentation is to alert psychiatrists to this remaining syndrome.

Methods Review of phenomenological and theoretical issues regarding SC.

Results CS can be found in numerous psychiatric or neurologic pathologies but it is most seen in patients with severe depression. It is typically divided in three subtypes: psychotic depression, Cotard type I, with nihilistic delusions without mood symptoms, and Cotard type II, with mood symptoms and auditory hallucinations. There are numerous etiological hypothesis mechanisms, including unusual perceptual experiences, which can similarly be involved in Capgras delusion, disconnection from emotional or limbic processes, an impaired belief evaluation or a tendency to excessive self-attribution. Frontotemporoparietal circuitry also seems to have an important role in its pathology. Treatment usually involves electroconvulsive therapy, antidepressants and anti-psychotics and the prognosis depends on the underlying disorders.

Conclusions CS is a rare pathology with self-defeating risk and its clinical recognition and proper treatment are essential to improve the prognosis of these patients. Diagnostic criteria or clinical instru-

ments for assessment of this syndrome should be encouraged, since its lack is a limitation for systematic studies and consequent management advances.

Hoarding disorders: Two different clinical presentations

A. Samico*, D. Mota, Â. Venâncio, L. Ribeiro

Vila Nova de Gaia Hospitalar Center, Psychiatry and Mental Health Service, Vila Nova de Gaia, Portugal

* Corresponding author.

Introduction Hoarding disorders (HD) have increasingly become a public health hazard. It usually emerges during two broad life periods: in early age-of-onset is usually associated with obsessive-compulsive disorder (OCD); in the elderly, it can be due to psychiatric and organic disorders, unrelated to OCD.

Objectives Our objective is to increase medical awareness and to highlight that both young and elderly people may suffer from this condition.

Aims The aim of this presentation is to address HD and its different presentations.

Methods Presentation of two clinical cases of HD and pathology revision.

Results A 30-year-old woman was hoarding litter, food and several items in a systematic way, become aggressive when her family tried to clean the house and was admitted several times in a psychiatric facility for cleanliness of her house. She had a history of depressive symptoms and severe OCD, with obsessive thoughts and several verification behaviors. A 78-year-old woman, with history of cerebral vascular disease, was self-neglected, living in a filthy home, with hoarding of litter and many worthless objects in a disorganized way, become aggressive after her relatives try to enter her house and refused to get help of any kind. Later on, she was admitted in a psychiatric facility and diagnosed with vascular dementia.

Conclusions Timely diagnosis and proper management of these two variations of HD will allow more advanced studies in this matter and more effective pharmacological and psychotherapeutic treatments. These clinical cases reinforce the importance of practical guidelines for appropriate approach of these patients with complex and multidimensional needs.

Fathers' personality dispositions and conduct-disordered children's perception of their fathers

C. Singh

Marwari Relief Society Hospital, Psychiatry and Psychology, Kolkata, India

Introduction Individual's personality profile is one of the major determinants of one's behavior. Thus, poor personality disposition of fathers and the child's perception of father have been reported to be powerful predictors of subsequent delinquency and criminal offences. The externalizers resemble the dimensions of conduct disorder as prescribed in diagnostic statistical manual IV. The essential feature is their repetitive behavioral pattern wherein the basic right of others or major age appropriate societal norms are violated.

Objective This study finds out the relationship between the fathers' personality-disposition, having male children with conduct

disorder (CDC, $n = 30$, experimental group), dysthymic disorder (DDC, $n = 30$, control group), and normal (NC, $n = 30$, control group), by applying the new five factor inventory, and children's perception of their fathers on the parent–child relationship scale.

Method The children were matched on age, sex, socio-economic status and other relevant variables. The CD and DD were selected on the DSM-IV criteria for the diagnosis of conduct disorder and dysthymic disorder. The fathers of each group of children were administered the aforesaid questionnaires.

Result The CDF showed only significantly poor agreeableness compared to the NF. The CDC's perceived their fathers most negatively compared to the DDC and NC. The CDF's conscientiousness was significantly correlated to a number of variables of the children's perception of them as observed on the PCRS.

Conclusion The CDF showed lower agreeableness than the NF. The CDC perceived their fathers most negatively, hence, setting the model for the child to observe and learn socially inappropriate behavior.

Films and fiction leading to onset of psycho-phenomenology: Case reports from a tertiary mental health center, India

S. Soman^{1,*}, J. Parameshwaran¹, J. KP²

¹ Mental Health Centre, psychiatry, Thiruvananthapuram, India

² Government Medical College, Psychiatry, Thiruvananthapuram, India

* Corresponding author.

Mind is influenced by socio-cultural religious belief systems, experiences and attributions in the development of psychophenomenology. Film viewing is a common entertainment among young adults.

Objectives Influence of repetitive watching of films of fiction and horror genres on onset phenomenology in young adults.

Method Two case reports on onset of psychotic features and mixed anxiety depressive phenomenology were seen in two patients aged 16 and 20 years respectively and based on the fantastic imagination created by films. The 28-year-old female patient diagnosed with schizoaffective disorder had onset at 16 years of age and the course of phenomenology was influenced by the fiction movie 'Jumanji' with partial response to medications over 10 years. The depressive and anxiety symptoms of less than 6 months duration of a 20-year-old male patient was influenced by film 'Hannibal' and responded to antidepressant and cognitive behavior therapy.

Conclusions Horror and fiction films can influence the thinking patterns and attribution styles of a young adult by stimulating fantasy thinking which if unrestrained can lead to phenomenology. Viewing films compulsively, obsessive ruminations on horror and fictional themes can lead to onset of psychopathology of both psychosis and neurotic spectrum. Further research on neurobiological, psychological correlates is needed. Parental guidance and restricted viewing of horror genre films with avoidance of repeated stimulatory viewing of same genre movies in children, adolescents, young adults and vulnerable individuals is required.

EV1056

Behavioral addictions and the associated mental health issues and psychopathology

V. Starcevic

University of Sydney, Sydney Medical School Nepean, Discipline of Psychiatry, Penrith, Australia

Introduction Behavioral addictions are conceptually controversial and their relationship with mental health problems and psychopathology is poorly understood.

Objectives To review the relationships between personality traits, mental health issues and mental disorders on one hand and several behavioral addictions on the other. The latter include problematic Internet use, Internet gaming disorder, hypersexual disorder/compulsive sexual behavior disorder, compulsive buying and exercise addiction.

Methods Literature review and conceptual synthesis.

Results Mental health issues, personality dimensions and mental disorders are commonly associated with behavioral addictions. Although some relatively specific associations were found (e.g., between Internet gaming disorder and attention deficit/hyperactivity disorder, between compulsive buying and pathological hoarding and between exercise addiction and eating disorders), the specificity of most associations was low. Most studies were cross-sectional and the direction of causality, if any, was uncertain. Therefore, it is unknown under what circumstances certain mental health issues predispose to the particular behavioral addiction or represent a primary problem and when they are a consequence of behavioral addictions. This review also underscores the importance of distinguishing between certain behavioral addictions and overlapping conditions, e.g., between compulsive buying and bipolar disorder (mania/hypomania).

Conclusions These findings suggest that proper conceptualization of behavioral addictions as distinct conditions or a manifestation of an underlying psychopathology will have to await results of the prospective studies. In the meantime, there are implications for treatment in terms of the importance of identifying and addressing the underlying or associated mental health problems in individuals with behavioral addictions.

The role of personality and trait affectivity on delusional ideation

M. Tonna*, F. Paglia, R. Ottoni, P. Ossola, C. De Panfilis, C. Marchesi

University of Parma, Neuroscience, Parma, Italy

* Corresponding author.

Objective The relationship between personality and delusional ideation is still debated. The present study was aimed to evaluate the role of personality features and trait affectivity on the severity of delusional beliefs, through the lens of a dimensional approach. In fact, robust evidence suggests that delusional experience presents a dimensional structure rather than an all-or-nothing fashion with a severity gradient of delusional beliefs from general population to full-blown delusional disorder (DD).

Method Forty-nine inpatients affected by DD and 42 non-delusional outpatients were administered the structured interview for DSM-IV Personality Disorders, the Pathological Narcissism Inventory–Italian Version, the Positive and Negative Affect Schedule and the Peters et al. 33–Italian version.

Results Severity of delusional ideation was positively related to “hiding the self” (HS) domain of narcissistic vulnerability and to paranoid traits and negatively related to “positive affect” (PA). Para-

noid traits and HS significantly interacted in influencing delusional dimension severity (Fig. 1). Low PA represents a trait affectivity of sadness and lethargy whereas HS is closely related to the experience of shame. We speculate that lower levels of PA and higher levels of HS may grasp the “asthenic” pole of Kretschmer’s “sensitive character”.

Conclusion The study findings suggest that the severity of delusional ideation depends, at least in part, on a complex interplay between specific affective and paranoid dispositions within personality. Delusion may constitute the superficial shell, which develops from and covers inner affective vulnerabilities of personality.

² Thomas More University College, Applied Psychology, Antwerp, Belgium

³ University of Antwerp, StatUA, Antwerp, Belgium

⁴ Windesheim University of Applied Sciences, Research Centre Human Movement and Education, Zwolle, The Netherlands

* Corresponding author.

Introduction A recent cohort study in the Netherlands and Belgium showed that 38% of children experienced psychological violence, 11% physical violence, and 14% sexual violence in sport (Vertommen et al., 2016). This study aims to explore the long-term consequences on anxiety, depression and somatic complaints in adults who experienced psychological, physical or sexual violence in the specific context of organized youth sport.

Methods A web survey in a representative sample of adults, pre-screened on having participated in organized sport before the age of 18 ($n=4043$) was conducted. In this sample, depression, anxiety and somatic problems were assessed using the brief symptom inventory. A generalized linear model was used to quantify the

impact of experiencing severe interpersonal violence in sport on psychopathology.

Results All three types of severe interpersonal violence (psychological, physical and sexual) were significantly associated with the total score and the subscales of the brief symptom inventory. The effect remains significant after controlling for socio-demographics, as well as disability, sexual orientation, adverse childhood experiences outside sport, recent trauma and family history of psychological problems.

Conclusions Experiencing interpersonal violence against in youth sport is associated with mental health problems in adulthood. This is an important finding to consider in child protection policy in sport.

Chlorpromazine-induced lupus with circulating anticoagulant. A case report

W. Abbes^{1,*}, B. Imen¹, A. Hanene², S. Mouna³, K. Kamilia², B. Zouheir², M. Jawaher¹

¹ Hédi Chaker University Hospital, Psychiatry “A”, Sfax, Tunisia

² Faculty of Medicine of Sfax, Regional Pharmacovigilance Centre, Sfax, Tunisia

³ Hedi Chaker University Hospital, Department of Internal Medicine, Sfax, Tunisia

* Corresponding author.

The drug-induced lupus erythematosus (DILE) is an autoimmune disorder caused by chronic use of certain drugs, including chlorpromazine. Chlorpromazine-induced lupus associated to circulating anticoagulant antibodies (CAC) would be even less frequent. Our observation is an illustration of this association.

We report the case of Mrs. H., 33-year-old, without medical or surgical history, who has been followed in psychiatry since the age of 20 for bipolar disorder type 1. This patient was initially stabilized by an association of fluphenazine, sodium valproate and levomepromazine. The introduction of chlorpromazine in June 2015 induced a leuconetropenia, which was corrected after stopping this drug. During subsequent decompensations, rechallenge with chlorpromazine and administration of other phenothiazines (levomepromazine, fluphenazine) or atypical anti-psychotics (olanzapine, risperidone, aripiprazole) induced a leuconetropenia reversible after drug withdrawal. Within the etiological investigation of this leuconetropenia, physical examination was normal; inflammatory tests (erythrocyte sedimentation rate, serum protein electrophoresis) and serology for hepatitis B and C and HIV were negative; antinuclear antibodies (ANA) titre was positive (1: 160) with a negative antibodies screen; rheumatoid factor and complement levels were normal. Activated partial thromboplastin time (APTT) was prolonged (47/29 s) and not corrected by addition of normal plasma. Lupus anticoagulant antibodies were positive. ANA became negative six months after cessation of implicated drugs. Thus, the diagnosis of “chlorpromazine-induced lupus with CAC” was retained. The pathophysiological mechanism of this association remains a subject of discussion. This induced autoimmunity, involving several anti-psychotics, is a real therapeutic challenge in our patient’s case.

Comparison of efficacy between risperidone and aripiprazole in combination with sodium valproate in patients with acute manic or mixed episodes

N. Amanat^{1,*}, A. Nazeri Astane², B. Dieji², O. Rezaie², A. Biglarian³

¹ University of Social Welfare and Rehabilitation Sciences, Health in Emergency and Disaster, Tehran, Iran

² University of Social Welfare and Rehabilitation Sciences, Psychiatry Department, Tehran, Iran

³ University of Social Welfare and Rehabilitation Sciences, Biostatistics Department, Tehran, Iran

* Corresponding author.

Today, despite of the improvement in the psychological therapeutic approach, mania still remains as a challenging problem for health system. The aim of this study is comparison efficacy of risperidone and aripiprazole in combination with sodium valproate in bipolar patients with acute manic or mixed episodes who hospitalized in Razi psychiatric hospital in Tehran. This study was conducted as a double blind randomized clinical trial in two groups of bipolar disorder patients with manic or mixed episodes (18–65 age). Patients randomly set in two groups who received valproate with aripiprazole or risperidone. Clinical response was assessed with young mania rating scale (YMRS) and weight gain at 3 and 6 weeks. Data was analyzed with Chi² test, paired *t*-test and analysis of covariance and repeated measurement. Evaluation of treatment response after 3 and 6 weeks (50% reduction in Young's scale) in both groups did not show any significant difference between the two therapeutic combinations. The combination of sodium valproate and risperidone showed higher weight gain in comparison with the combination of valproate and aripiprazole at the end of week 6 ($P < 0.001$). The mentioned combination in bipolar I disorder with manic or mixed episode has similar therapeutic effect, so that both of them are effective and usable. There was no difference in their efficacy, and both treatments can be used. Due to the less weight gain, the combination of valproate and aripiprazole in patients who prone to weight gain, this approach is recommended as more safe and effective therapy.

Bupropion induced hyponatremia: A review of literature

M. Arts^{1,*}, S. Petrykiv², J. Fennema³, L. De Jonge⁴

¹ University of Groningen, University Medical Center Groningen, Department of Old Age Psychiatry, Groningen, The Netherlands

² University of Groningen, University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands

³ GGZ Friesland, Geriatric Psychiatry, Leeuwarden, The Netherlands

⁴ Leonardo Scientific Research Institute, Geriatric Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction For over 20 years, bupropion has been used as an antidepressant by inhibiting the norepinephrine-dopamine reuptake. Hyponatremia is a relatively rare condition that has been

associated with the use of antidepressants including selective serotonin reuptake inhibitors (SSRIs), serotonin norepinephrine reuptake inhibitors (SNRIs), and tricyclic antidepressants (TCAs). However, a few case studies have reported that bupropion was associated with hyponatremia.

Objectives and aims To review available literature on bupropion-induced hyponatremia and its possible underlying mechanisms.

Methods Case studies are presented and discussed followed by a literature review.

Results Hyponatremia has been reported with the use of many antidepressants, however, studies on bupropion induced hyponatremia has been limited. In literature only four case reports have been presented. Typically, this condition is only seen in frail or elderly patients. Possible mechanism is that bupropion may cause hyponatremia by the noradrenergic stimulation of vasopressin release.

Conclusion Clinicians should be aware of increased risk of hyponatremia associated with antidepressants, including bupropion. Especially in the elderly, clinical symptoms of hyponatremia can be misinterpreted and may lead to a life-threatening condition.

Off-label prescriptions of quetiapine for sleep disturbances

M. Arts^{1,*}, S. Petrykiv², J. Fennema³, L. De Jonge⁴

¹ University of Groningen, University Medical Center Groningen, Department of Old Age Psychiatry, Groningen, The Netherlands

² University of Groningen, University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands

³ GGZ Friesland, Geriatric Psychiatry, Leeuwarden, The Netherlands

⁴ Leonardo Scientific Research Institute, Geriatric Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction Quetiapine, a short-acting atypical anti-psychotic drug for the treatment of bipolar I disorder and schizophrenia, is increasingly used off-label for the treatment of sleep disturbances or insomnia. However, data supporting this off-label prescription of quetiapine are limited.

Objectives and aims To report and discuss the effects of “off-label” use of quetiapine for the treatment of sleep disturbances.

Methods An English-language literature search was conducted using Pubmed, EMBASE and Cochrane library (December 1980–December 2015) using the search terms quetiapine, insomnia, sleep disorders, sleep disturbances, and sleeplessness.

Results During the last decade, there is an enormous increase in prescribing quetiapine. This anti-psychotic drug is among the best selling drugs worldwide. For the approved indications, the usual therapeutic dose range is 400–800 mg/day. However, off-label use of quetiapine was most evident for the 25 mg/day to 100 mg/day. In some countries, off-label uses are promoted to non-psychiatrists for the treatment of insomnia, dementia, agitation, and aggression. Inappropriate anti-psychotic use may lead to serious health problems, including metabolic effects, increased sudden cardiac death, and age-related side effects with increased risk for orthostatic hypotension, fractures, pneumonia, cognitive impairment, and stroke.

Conclusion There is growing concern regarding the potential harm from off-label prescription of anti-psychotics, particularly quetiapine. There is little evidence supporting the enormous off-label uses of quetiapine. In addition, prescribing quetiapine for indications that are not evidence based has ethical, financial, and safety implications, especially in the older population.

Disclosure of interest The authors have not supplied their declaration of competing interest.

SSRIs and QT interval prolongation management. A review

A. Ballesteros^{1,*}, H. Saiz², Á.S. Rosero², A. Portilla², L. Montes², R. Elorza²

¹ Osasunbidea, Psychiatry, Madrid, Spain

² Osasunbidea, Psychiatry, Pamplona, Spain

* Corresponding author.

Introduction In 2011, the FDA issued an alert recommending not to prescribe citalopram high doses, due to QT prolongation risk. We explored the clinical background of QT interval prolongation related to serotonin selective reuptake inhibitors (SSRI) use and the clinical implications of safety issues.

Methodology A review was conducted to clarify the mechanisms associated with the occurrence of TdP when using SSRI and investigating therapeutic measures to avoid/minimize these effects. The literature search was conducted in PubMed data reviewing articles between 2001 and 2016.

Results (1) Related to risk factors/intraclass differences: risk factors are increase in QTc interval ≥ 60 ms from the pretreatment value, advanced age, female sex, acute myocardial infarction and electrolytic abnormalities among others. Citalopram appears more likely than others to induce this phenomenon but its importance is under current debate. (2) Related to dose: drug-induced QTc interval prolongation and TdP was associated to citalopram in doses > 40 mg/day. However, psychotropic drug-induced sudden cardiac death may be an outlier in the absence of identified risk factors for QTc interval prolongation and TdP. (3) Related to poly-pharmacy/management: there is an additive effect when using SSRI and antipsychotics (EKG control is recommended in those cases). Cross-sectional studies showed that SSRI use was not associated with QT interval prolongation. This could be explained by the EKG intra-intersubject variability.

Conclusions There is little evidence that drug-associated QTc interval prolongation by itself is sufficient to predict TdP. Future research needs to improve its precision to better understand the factors that facilitate/attenuate that progression. Clarifying this may lead to a safer SSRI use.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Lithium and EKG abnormalities. A review

A. Ballesteros*, Á.S. Rosero, H. Sáiz, E. García-Parreño, G. Carlos, E. Manrique

Osasunbidea, Psychiatry, Pamplona, Spain

* Corresponding author.

Introduction The literature concerning possible cardio-toxic effects of lithium therapy in man is reviewed.

Methodology A review was conducted to clarify the mechanisms associated with the occurrence of conducting abnormalities when using lithium and investigating (if so) whether these alterations depend on the dose. The literature search was conducted in PubMed data reviewing articles between 1982 and 2015.

Results (1) Related to pathopsychology/risk factors: reports indicate T wave morphology changes with lithium therapy. Of particular concern are cases of sinus node dysfunction or sinoatrial block and the appearance or aggravation of ventricular irritability. The incidence of cardiac complications, in general terms, may increase with age. Recent findings (a retrospective study

of bipolar patients) of lithium-associated hypocalcaemia showed that hypocalcaemia resulting from medical diseases and bipolar patients with lithium-associated hypocalcaemia had significantly higher frequencies of conduction defects. (2) Related/unrelated to dose: therapeutic and toxic levels of lithium have infrequently been associated with serious cardiac dysfunction. Several case reports demonstrate two important points about Brugada syndrome unmasking: electrocardiograph abnormality severity may correspond to lithium levels and unmasking may occur in the therapeutic range of lithium. Other report shows a case of lithium induced sinus-node dysfunction in a patient with serum lithium levels in therapeutic range.

Conclusions Lithium abnormalities are rare and mostly not related to dose. Conducting heart anomalies may occur, especially when several factors are present (such as age or co-morbid illnesses that affect calcium serum levels).

Disclosure of interest The authors have not supplied their declaration of competing interest.

Prolactin levels in patients with severe mental disorders: Are we doing well? An observational study of Seville area population

P. Blanco Ramón*, N. Gomez-Coronado Suarez de Venegas, I. Martinez

Hospital Universitario Virgen del Rocío, Psychiatry, Sevilla, Spain

* Corresponding author.

Introduction It is well known that hyperprolactinemia increases the risk of hypogonadism, osteoporosis and cardiovascular diseases. Atypical anti-psychotics are directly related with its development. Despite its importance, pharmacological hyperprolactinemia it is not considered and treated by psychiatrists as much as expected. Nowadays, long-acting aripiprazole is one of the main treatments that barely increase the prolactin (PRL) levels.

Objectives To determine the number of cases in which PRL levels are detected. To quantify the reduction of PRL levels with patients treated with long-acting aripiprazole.

Methods Observational, descriptive study, from February 2015 to July 2016, of 52 patients treated with anti-psychotics, in two Sevillian community mental health centers.

Results In 56% of cases, PRL level was measured at least one time: in 77% of cases with prescription of long-acting aripiprazole, PRL levels are reduced.

Conclusion First step to reduce the impact of hyperprolactinemia in patients is to determine the PRL levels in a systematic way being this practice a must to be considered. In the study carried out and described in this abstract, reduction of PRL levels in target populations using long-acting aripiprazole is observed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Eosinophilia associated with clozapine – A case report

T. Abreu, A. Carvalho*, O. Von Doellinger

Centro Hospitalar Tâmega e Sousa, Psychiatry and Mental Health Department, Porto, Portugal

* Corresponding author.

Objectives Clozapine is an atypical anti-psychotic used in the treatment of schizophrenia and other psychotic disorders. It is associated with several side effects, namely, hematologic disorders, the more common being agranulocytosis. Some cases of

eosinophilia have been described. This work describes a case of transient eosinophilia caused by clozapine.

Methods Description of a clinical case.

Results A 22-year-old female patient, with a treatment resistant psychotic disorder initiated clozapine in a slow titration to 300 mg. Ten days after initiating clozapine, the patient presented with eosinophilia (started with $6.6 \times 108/L$ and peaked at $10.0 \times 108/L$). Two weeks later, the patient presented with a skin rash in the arms and legs. The case was discussed with internal medicine service and other causes of eosinophilia were excluded. Since the eosinophilia was mild, the rash was not severe and the patient did not present any other symptoms or signs, it was not considered necessary to stop clozapine. During the next three months, with close monitoring, the eosinophilia and the skin rash slowly resolved.

Conclusions This is a case of a patient who presented mild eosinophilia and skin rash, associated to clozapine, with spontaneous resolution. We draw attention to the need of close monitoring and exclusion of other causes of eosinophilia and rash. Furthermore, other hematologic disorders should be considered besides agranulocytosis, namely eosinophilia, when prescribing clozapine.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Polycystic ovarian syndrome in patients with schizophrenia treated with atypical anti-psychotics: A case control study

V. De Silva^{1,*}, A. Senanayake¹, S.S. Ratnatunga², S. Dissanayake¹, S. Gamage¹, S. De Silva¹, R. Hanwella¹, C. Wijeyaratne¹

¹ Faculty of Medicine, University of Colombo, Psychiatry, Colombo, Sri Lanka

² NHSL, Psychiatry, Colombo, Sri Lanka

* Corresponding author.

Objective Objective was to compare the prevalence of probable polycystic ovarian syndrome (PCOS) in females treated with atypical anti-psychotics with normal controls.

Aims To compare the prevalence of PCOS in patients treated with atypical anti-psychotics and normal controls. To study the hormone profiles in these two groups.

Methods Cases consisted of 102 reproductive age females with schizophrenia treated with atypical anti-psychotics for ≥ 6 months and had gained $\geq 10\%$ body weight. Control group was 123 age and BMI matched females. Menstrual history, physical examination for hirsutism, acne, androgenic alopecia, anthropometrics measures, Ultrasound abdomen and hormone analysis were done.

Results Mean age of cases = 33.17 years (SD 8.9) and controls = 33.08 years (SD 5.6). Mean BMI of cases = 25.92 (SD 5.2) and controls = 25.03 (SD 4.3). Polycystic ovarian morphology of ovaries on ultra sound scan was significantly more in cases 49 (48%) than controls 16 (13%) ($P < 0.001$). Probable PCOS was significantly more in atypical anti-psychotic treated females ($n = 22$, 21.56%) than in normal controls ($n = 10$, 8.13%) ($P = 0.04$). Atypical anti-psychotic treated patients with PCOS had significantly lower mean LH levels 6.69 mIU/L than those without PCOS 10.30 ($P = 0.35$). There was no significant difference in testosterone, FSH, prolactin, TSH and free T4 levels.

Conclusion Treatment with atypical anti-psychotics is associated with higher prevalence of PCOS. This has not been reported previously. The hormonal profile in these patients may be different with low testosterone and LH levels.

Unconventional side effects of antidepressants: Focus on emotional blunting

V. Falaschi^{1,*}, S. Baroni¹, F. Mucci¹, H. Akiskal², D. Marazziti¹

¹ Università di Pisa, Dipartimento di Medicina Clinica e Sperimentale, Pisa, Italy

² University of California, Department of Psychiatry, San Diego, USA

* Corresponding author.

Objectives The aim of this study was to investigate the unconventional side-effects of selective serotonin reuptake inhibitors (SSRIs) and tricyclics (TCAs) antidepressants during long-term treatment of depression, with a special focus on emotional blunting and, in particular, on the possible changes of some features of loving relationships.

Methods Two hundred outpatients (130 women and 70 men, mean age \pm SD: 43.4 ± 11.1 years) were enrolled. They were suffering from mild or moderate depression, according to DSM-5 criteria, treated with one antidepressant for at least six months and involved in a long-term loving relationship. A specifically designed test, the so-called "sex, attachment, love" (SALT) questionnaire was built to assess the possible changes of the loving relationship.

Results The results showed differences between the two genders, in particular women taking TCAs reported more sexual side effects than men, whereas men taking SSRIs complained a reduction of the feelings of love and attachment towards the partner.

Conclusions Antidepressants seem to have a dimorphic effect on some elements of loving relationships, however these results need to be further explored.

Introduction Selective serotonin reuptake inhibitors (SSRIs) are the most prescribed antidepressants worldwide. In older adults, citalopram is generally well tolerated and safe in the therapeutic dose range of 20 to 40 mg/day. In literature, there are cases of SSRI-induced psychosis, but mainly with fluoxetine. There are only three reported cases of citalopram-induced delusions, however, these case-reports did not involve an older adult.

Objectives and aims To provide a case of citalopram-induced psychosis in an older adult, followed by the review of available literature.

Methods A case report is presented and discussed followed by a literature review.

Results A 64-year-old woman without somatic illnesses was referred by a general practitioner with depressive symptoms. One week after initiation of citalopram 10 mg/day she suddenly developed delusions, predominantly in the early morning. No other medical evidence was found that could explain her delusions. After discontinuation of citalopram her delusions quickly resolved.

Conclusion This is the first case report of a SSRI-induced delusion in an older adult. Citalopram has been reported to be one of

the safest SSRIs. Although most SSRI's have a mild side-effect profile, care should be taken when initiating SSRIs since unpredictable adverse effects may occur.

Anti-psychotics: To withdraw or not to withdraw?

C. Ferreira*, S. Alves, C. Oliveira, M.J. Avelino
Centro Hospitalar Psiquiátrico de Lisboa, SETA, Lisbon, Portugal
* Corresponding author.

Introduction Anti-psychotics constitute a class of psychotropic drugs used for the treatment and prophylaxis of several disorders, including schizophrenia, bipolar disorder and psychotic depression. Frequently, clinicians are asked by their patients to withdraw this medication. In some cases, that may be related to notable side effects. However, it may actually indicate an inadequate control of the psychiatric disorder with poor insight.

Aims The goal of this work is to systematically review the scientific literature in order to understand if there are consistent data that support anti-psychotics withdraw in specific clinical situations.

Methods The literature was reviewed by online searching using PubMed®. The authors selected scientific papers with the words "anti-psychotics" and "withdraw" in the title and/or abstract, published in English.

Results and discussion Anti-psychotics improve prognosis and enhance patients' quality of life. There are few data in the literature regarding recommendations that support anti-psychotic withdraw in psychiatric patients. Very specific conditions must exist for withdrawing anti-psychotics, like neuroleptic malignant syndrome, cardiac side effects, and change of diagnosis or prolonged remission after a first and single psychotic event. When that decision is made, it should be done slowly and carefully and both the patient and his family should be involved.

Conclusions There is no evidence in the literature that supports withdraw of anti-psychotics for the majority of psychiatric situations. When specific conditions are present that possibility must then be considered, however, with careful consideration and after discussion with the patient and parties involved in patient's care.

* Corresponding author.

Objective The aim of this study was to investigate the relationship between metabolic factors and use of selective serotonin reuptake inhibitors (SSRIs) combined with olanzapine, quetiapine or risperidone.

Method Data from a cross-sectional study on 1301 patients with schizophrenia or bipolar disorder were analyzed. The main outcome variables were levels of total cholesterol, low- and high-density lipoprotein (LDL and HDL) cholesterol, triglycerides and glucose.

Results One defined daily dose (DDD) per day of an SSRI in addition to olanzapine was associated with an increase in total cholesterol of 0.16 (CI: 0.01 to 0.32) mmol/L ($P=0.042$) and an increase in LDL-cholesterol of 0.17 (CI: 0.02 to 0.31) mmol/L ($P=0.022$). An SSRI serum concentration in the middle of the reference interval in addition to quetiapine was associated with an increase in total cholesterol of 0.39 (CI: 0.10 to 0.68) mmol/L ($P=0.011$) and an increase in LDL-cholesterol of 0.29 (0.02 to 0.56) mmol/L ($P=0.037$). When combined with risperidone, no such effects were revealed. No clear-cut effects were seen for HDL-cholesterol, triglycerides and glucose.

Conclusion The findings indicate only minor deteriorations of metabolic variables associated with treatment with an SSRI in addition to olanzapine and quetiapine, but not risperidone. These results provide new insight in the cardiovascular risk profile associated with concomitant drug treatment in patients with severe mental illness, and suggest that SSRIs can be combined with anti-psychotics without a clinically significant increase of adverse metabolic effects.

Disclosure of interest Co-author Dr. Ole Andreassen has received speakers' honoraria from GSK, Lundbeck and Otsuka.

Introduction Psychosis in childhood and adolescence could be defined as having hallucinations, with the hallucinations occurring in the absence of insight. A broader definition includes symptoms such as delirious thoughts, disorganized speech, disorganized behavior, cognitive and mood symptoms and what is called negative symptoms. Several researches have been done focused in the treatment of first episode of psychosis showing clozapine as a keystone in the treatment of psychosis, especially in refractory first episodes.

Objectives Clozapine has unique efficacy in improving treatment-resistant patients with chronic schizophrenia but the moment of instauration remains unclear. There have always been doubts about the right moment to start clozapine, after two or more previous anti-psychotics or as first option.

Materials and methods We report a 18-year-old woman with family history of severe psychosis. Her mum reasserted patient's symptoms contributing to a longer period of non-treating psychosis (about 10 months). Auditory hallucinations, incongruent mood and

incoherent language appeared for the first time at the age of 17. High doses of two consecutive anti-psychotics were tried without remission and finally clozapine was initiated with clinical improvement.

Discussion In clinical practice, a subgroup of psychotic patients experience, significant ongoing positive symptoms despite of using first line anti-psychotic medication.

Conclusion Most recent research; suggest that clozapine may have an important role in the early treatment of first-episode patients, even becoming a first line option to consider.

Keywords Clozapine; First episode psychosis

Long acting injectable aripiprazole: An observational study

N. Garcia*, J. Brotons, R. Genoves, J. Martinez-Raga, C. Saez, R. Calabuig

Doctor Peset University Hospital, Mental Health Service, Valencia, Spain

* Corresponding author.

Introduction Several trials have shown the efficacy of long acting injectable (LAI) second-generation anti-psychotics compared with other anti-psychotics. LAI aripiprazole is a novel therapeutic tool in the management of patients with schizophrenia.

Aims The present study aimed to evaluate the clinical outcomes of patients who initiated treatment with LAI aripiprazole, by comparing their clinical outcomes prior and after initiating treatment with LAI aripiprazole.

Methods This observational, retrospective, mirror study assessed a series of socio-demographic and clinical variables during the 12 months prior to commencing LAI aripiprazole, while on another anti-psychotic medication, and the first 12 months of LAI aripiprazole. The sample included a series of consecutive patients receiving LAI aripiprazole at the Doctor Peset university hospital health area, in Valencia (Spain). The variables analyzed in the study included: emergency room visits, number and average length of hospitalizations, relapse, rate of abandonment of treatment and number of anti-psychotics needed as maintenance treatment.

Results The preliminary analysis showed a reduction in the rate of emergency room visits and the number of relapse and total hospitalizations while on LAI aripiprazole; however, there is no a reduction of the average length of hospitalizations. A reduction in the number of anti-psychotics as maintenance treatment was not appreciated, however, there was an improvement in treatment adherence.

Conclusions The preliminary results showed that LAI aripiprazole is an useful option that could suppose a benefit concerning treatment adherence, a decreased in number of relapses and hospitalizations and use of health resources.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A pharmacologic option to reduce hospital admissions and relapses of patients with severe mental illness

N. Gomez-Coronado*, P. Blanco, I. Martinez
Hospital Virgen del Rocío, Psychiatry, Sevilla, Spain

* Corresponding author.

Introduction Some diseases relapses involve functional impairment that sometimes takes years to recover. We present our

experience using long-acting aripiprazole as maintenance therapy in patients diagnosed with psychotic episode, acute mania (bipolar disorder) or personality disorder, who were previously treated with another anti-psychotic.

Aims Analyze what treatment were they taking before aripiprazole depot. Determine the number of hospital admissions and relapses before and after long-acting aripiprazole treatment.

Methods Descriptive analysis based on a sample of 37 patients, aged 18–65 years, treated during one year with anti-psychotics at two community mental health units.

Results Reduction of hospitalization average: 0.59/year with non-long-acting-aripiprazole anti-psychotic, 0.18/year with long-acting aripiprazole (66.6%).

Conclusion Long-acting aripiprazole appears to reduce the number of hospitalizations and relapses compared to other anti-psychotics. However, the sample size is small and more studies are needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1075

Tobacco and anti-psychotics side effects

I. González González, A. Hernández Dorta*

Hospital Universitario de Canarias, Psiquiatría, La Laguna, Spain

* Corresponding author.

Introduction It's known that, patients with schizophrenia smoke more tobacco than general population, and that tobacco is a potent inducer of cytochrome P450 isoenzyme 1A2 (CYP 1A2). In addition, clozapine and quetiapine, drugs frequently used in the treatment of schizophrenia, are CYP1A2 substrates. So, tobacco smoking may reduce blood levels of clozapine and quetiapine.

Objective To revisit the influence of changes in tobacco consumption in clozapine and quetiapine side effects.

Methods Case report.

Results A 48-year-old male diagnosed of schizophrenia following DSM IV-TR criteria. He required five hospital admissions from 2008 to 2013 because of psychotic episodes. Since 2013, he was asymptomatic receiving clozapine, 600 mg/day, and quetiapine, 1200 mg/day. Recently, he came to the emergency service due to sudden extreme sedation, thinking impairment, sialorrhea, and walking disability. The patient denied treatment abuse and his family confirmed this statement. When asked about toxics he referred progressive tobacco reduction in the last 3 months (from 60 to 20 cigarettes/day). Bearing in mind the relationship between clozapine and quetiapine metabolism and tobacco, treatment was slowly reduced until the doses of clozapine 500 mg/day and quetiapine 400 mg/day. One week after admission, side effects disappeared, psychotic symptoms were not detected, and the patient was discharged.

Conclusions Inquiring about changes in tobacco consumption may be useful when anti-psychotics side effects appear suddenly without an alternative explanation.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Sex and age factors in neuroleptic malignant syndrome diagnosis frequency

R. Gurrera

VA Boston Healthcare System, Mental Health/Psychiatry, Brockton, USA

Introduction It is not known whether sex and age are risk factors for neuroleptic malignant syndrome (NMS).

Objectives To examine sex and age distributions in NMS patients based on a systematic review of the literature.

Aims Estimate the sex-specific relative risk of an NMS diagnosis.

Methods EMBASE and PubMed databases were searched in November 2014 using broad, unrestricted criteria to identify any published observation of NMS. Any physically (online or hard copy) accessible and interpretable (using language translation software) report published from January 1, 1998 through November 1, 2014 was considered for inclusion. Secondary sources (e.g., reviews) were included when primary sources could not be accessed. All cases for which the patient's sex or the sample's sex distribution was provided were included, except for redundant reports and cases in which NMS was not the most likely clinical diagnosis. Sex ratio and age distributions were examined using standard graphical techniques and measures of association.

Results Twenty-eight independent NMS sex ratio estimates were included. Most sex ratio estimates (75%) indicated male preponderance, with a median of 1.47 (95% CI: 1.20–1.80). NMS incidence peaked at age 20–25 years and declined steadily thereafter; males consistently outnumbered females at all age intervals. Major study limitations are the heterogeneity of case ascertainment procedures and the potential for publication bias.

Conclusions NMS patients are 50% more likely to be males, and NMS is most likely to occur in young adulthood. Men, and all young adults, appear to be at increased risk for NMS.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

EV1077

A Comparison of DSM-IV and international expert consensus diagnostic criteria for N.M.S

R. Gurrera^{1,*}, G. Mortillaro¹, V. Velamoor², S. Caroff³

¹ VA Boston Healthcare System, Mental Health/Psychiatry, Brockton, USA

² Faculty of Medicine and Dentistry, University of Western Ontario, Psychiatry, London, USA

³ Perelman School of Medicine of the University of Pennsylvania, Psychiatry, Philadelphia, PA, USA

* Corresponding author.

Introduction Neuroleptic malignant syndrome (NMS) requires prompt recognition for effective management, but there are no established diagnostic criteria.

Objectives To validate the recently published international expert consensus (IEC) diagnostic criteria for NMS, which assign priority points based on the relative importance of each criterion for diagnosing NMS.

Aims Determine optimal diagnostic cutoff for priority point score.

Methods Data were extracted from 221 archived telephone contact reports of clinician-initiated calls to a national telephone consultation service from 1997–2009; each case was given a total priority point score based on the IEC criteria. DSM-IV-TR research criteria, in original form and modified to accept less than 'severe' rigidity, served as the primary diagnostic reference standard. Consultants' diagnoses served as an additional reference standard. The optimal priority point cutoff score was determined using receiver operating characteristic (ROC) curve analysis.

Results Area under the ROC curve ranged from 0.715 (95% CI = 0.645–0.785, $P < 0.001$) for consultant diagnoses to 0.857 (95% CI = 0.808–0.907, $P < 0.001$) for modified DSM-IV-TR criteria. The latter was associated with 69.6% sensitivity and 90.7% specificity.

Conclusions Agreement was best between IEC criteria with a cutoff score of 74 and modified DSM-IV-TR criteria (sensitivity 69.6%,

specificity 90.7%); this cutoff score demonstrated the highest agreement in all comparisons. Consultant diagnoses showed much better agreement with modified, compared to original, DSM-IV-TR criteria, suggesting that the DSM-IV-TR criterion of "severe" rigidity may be more restrictive than what most knowledgeable clinicians use in practice.

⁴ UFSMA Area Grossetana, Dipartimento Salute Mentale, Grosseto, Italy

⁵ UFSMA Area Grossetana, Dipartimento Salute Mentale, USL sudest Toscana, Grosseto, Italy

* Corresponding author.

Introduction Several studies suggested that second-generation long-acting injectable anti-psychotics (SGA-LAIs) might be effective on preventing relapse and admission/readmission rates among patients affected by schizophrenic and bipolar disorders. Moreover, studies highlighted that SGA-LAIs may reduce costs and healthcare resource utilization (HRU) among community psychiatric settings.

Objectives The objective of the present study was to evaluate whether the increased use of SGA-LAIs among community psychiatric services in southern Tuscany was related to:

– reduced costs and HRU;

– reduced hospital admission/readmission.

Methods Data consisted of both regional registry and data prospectively collected at admission and/or follow up assessments. Patients included were: patients affected by schizophrenia/schizoaffective or bipolar disorders, treated with SGA-LAIs.

Results The increased use of SGA-LAIs was related to a significant reduction of admission and/or readmission rates, as long as a significant reduction in costs and HRU among the community services included in the study.

Conclusions The present findings suggest that SGA-LAIs might have a positive cost/effectiveness profile and could reduce hospitalizations, costs and HRU among a community sample. This could be related to a better tolerability of SGA-LAIs compared to FGA-LAIs, and less adverse effects. More studies on community samples should focus on the cost/effectiveness profile of SGA-LAIs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Clozapine efficiency in tardive syndromes induced by anti-psychotic treatment

L. Jouini^{1,*}, U. Ouali¹, R. Zaouche², R. Jomli¹, Y. Zgueb¹, F. Nacef¹

¹ Razi Hospital, "A" Psychiatry Department, Tunis, Tunisia

² Razi Hospital, Psychiatry Outpatient Unit, Tunis, Tunisia

* Corresponding author.

Introduction Tardive syndromes (TS) resulting from prolonged exposure to dopamine receptor blocking agents are frequent. Clozapine is considered to have a low risk of causing new onset TS and accounts therefore as an interesting option in patients with invalidating TS.

Objectives Our study aims to describe clozapine indications in patients experiencing TS.

Methods Presentation of the clinical cases of five patients, who experienced different kinds of TS secondary to 1st and 2nd generation anti-psychotic treatment.

Results We present the cases of AB aged 41, MJ aged 40, HM aged 31 and AS aged 30, diagnosed with schizophrenia; and FB aged 24, diagnosed with schizoaffective disorder. Adverse side effects to conventional anti-psychotics such as limb and trunk tremors were described for AB, choreic limb movements, axial and segmental dystonia for MJ, AS, FB and oculogyration for FB. All patients were switched to atypical anti-psychotics without improvement of the TS. The switch to clozapine, associated with abotulinum injection for MJ, led to regression of the TS and improvement of clinical signs. In fact, according to several studies, clozapine seems to be an interesting option when invalidating TS occurs. The low prevalence of TS under clozapine can be explained by its low affinity for striatal-D2 receptors, its anti-serotonin and anti-cholinergic effects.

Conclusions Clozapine should be considered in symptomatic patients who develop TS while receiving other anti-psychotics. Further research on mechanism of TS and clozapine effect on TS is needed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Isolated rhabdomyolysis caused by olanzapine: About a clinical case

Y. Laajili^{1,*}, S. Ellini¹, H. Rebhi¹, N. Haloui¹, M. Cheour²

¹ Razi Hospital Mannouba Razi, Psychiatrie Department E, Nabeul, Tunisia

² Razi Hospital Mannouba Razi, Psychiatrie Department E, Tunis, Tunisia

* Corresponding author.

Introduction Atypical anti-psychotics are increasingly prescribed, given their tolerance. Among these anti-psychotic olanzapine, known for its adverse metabolic effects. By against an adverse event type rhabdomyolysis with olanzapine appears uncommon (<1%) and few clinical cases have been reported in the literature.

Aim The aim of our study is to illustrate with a clinical case the occurrence of an isolated rhabdomyolysis with olanzapine.

Materiel and method Starting from the study of the case of a patient with rhabdomyolysis with olanzapine we studied the literature data. Clinical vignette: it is about a patient aged 25 followed for bipolar disorder type I. He responded to the association olanzapine and valproic acid then to valproic acid only. His last hospitalization for manic relapse dating to September 9, 2015 occurred in a context of treatment discontinuation. Upon admission the patient underwent an oral treatment based olanzapine and valproic acid. A dosage of creatine phosphokinase (CPK) done systematically, on September 11 showed high levels of (CPK) to 973 (U/L) without clinical signs of neuroleptic malignant syndrome. The electrocardiogram and biological tests results were normal. Other etiologies can lead to elevated (CPK) were eliminated. The persistent elevation of CPK motivated the arrest of olanzapine. The evolution was marked by a return to normal CPK rates after 15 days. The olanzapine was replaced by haloperidol and vaproic acid maintained. The pharmacovigilance investigation conclude to the accountability of olanzapine in this rhabdomyolysis.

Conclusion Second generation, anti-psychotics are known for their better tolerance compared to conventional antipsychotics. However, they are not devoid of side effects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Rechallenge clozapine after agranulocytosis in refractory schizophrenia. A case report

R. Landera Rodríguez^{1,*}, M. Juncal Ruiz¹, R. Martín Gutiérrez¹, M. Gómez Revuelta², I. Madrazo del Río Ortega¹, L. Sánchez Blanco¹, G. Pardo de Santayana Jenaro¹, D. Abejas Díez¹

¹ Hospital Universitario Marqués de Valdecilla, Psychiatry, Santander, Spain

² Hospital Universitario Álava-Sede Santiago, Psychiatry, Vitoria-Gasteiz, Spain

* Corresponding author.

Introduction Clozapine, is widely prescribed for treatment of refractory schizophrenia, but its use may be limited by potentially serious adverse effects. The most feared complication remains agranulocytosis [absolute neutrophil count (ANC) < 500/mm³], which occurs in 1% of patients. Guidelines recommend immediate cessation until the granulocyte count normalizes, but little is known about the subsequent treatment and the possibility of restoring clozapine.

Objectives To know procedures that allow clozapine rechallenge after induced agranulocytosis in refractory schizophrenia.

Methods We present a clinical case of agranulocytosis and evolution after simple reinstitution of clozapine.

Results A 38-year-old woman diagnosed refractory schizophrenia. After 10 years with clozapine (300 mg/day), we find neutropenia (ANC 1420/mm³) in a monthly control blood count with progression to agranulocytosis (ANC 460/mm³) in the following month. We suspend clozapine and started olanzapine (20 mg/day) with restoration of haematological values in a period of one month. The patient had psychotic decompensation at two months after the change with lack of response to different psychopharmacological strategies for five months. According to the hematology department we decided to re-introduce clozapine (200 mg/day) in combination with olanzapine with complete clinical remission. Between the 3rd and 9th week after rechallenge we observe a progressive decline in ANC, while remaining within the range of normal. From the 9th week and in the last 6 months neutrophil counts remained stable.

Conclusions Although, more research is needed to establish the safety to rechallenge of clozapine after agranulocytosis, it must be an alternative to consider when other treatment strategies fail.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Combination of aripiprazole and olanzapine in first episode psychosis patient with metabolic syndrome: A case report

I. Licanin^{*}, H. Senad

University of Sarajevo Clinical Center, Psychiatry, Sarajevo, Bosnia and Herzegovina

* Corresponding author.

There are numerous factors that predispose patients with schizophrenia to develop metabolic syndrome and become

overweight including: physical passivity, unhealthy diet and anti-psychotic treatment. The prevalence of anti-psychotic-related metabolic disturbances has been reported to vary from 23% to 50% and clozapine and olanzapine had the most pronounced potential to cause metabolic syndrome. We present the case of 32-year-old male who has been diagnosed with first episode schizophrenia spectrum psychosis and has been treated for 3 months in the community mental health center. He was medication-compliant and was prescribed olanzapine 10 mg a day and had initial remission of symptoms. The reason behind referral to our department of psychiatry was development of metabolic syndrome. Immediately upon admission to our department basic panel blood tests (minerals, creatinin, glucose, tryglicerides and cholesterol) as well as complete blood count were done. Patient reported gaining weight of more than 5 kilograms since the initiation of the olanzapine treatment. Results of the performed metabolic tests in addition to abnormal BMI and slightly higher blood pressure have indicated presence of metabolic syndrome. In order to try to reverse metabolic syndrome aripiprazole was commenced adjunctive to olanzapine. During the first week the dosage of aripiprazole was 2.5 mg/day, second week 5 mg/day and then increased to 10 mg a day. Three weeks after adding aripiprazole to olanzapine lab values of holesterol, triglycerides, fasting glucose as well as BMI were significantly lowered and symptoms of the metabolic syndrome were mitigated. Treatment was well tolerated.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Amisulpride-induced agranulocytosis: A case report

H. Maatallah*, H. Ben Ammar, A. Alssa, R. Nefzi, M. Said, Z. El Hechmi

Razi Hospital, Psy F, Tunis, Tunisia

* Corresponding author.

Introduction Agranulocytosis is a potentially life-threatening haematological side effect induced by typical and atypical neuroleptic. When agranulocytosis is associated with a specific anti-psychotic, the medication should be discontinued. This severe side effect is troublesome.

Case report We report the case of a 60-year-old man, treated with amisulpride for schizophrenia, who developed an agranulocytosis. This patient had been treated with first and second generation anti-psychotic drugs during his life and had already been exposed to many neuroleptics without any signs of toxicity. However, after three days of the introduction of amisulpride he presented a rapid onset agranulocytosis (leukocytes 1.2 G/L and neutrophils 0.4 G/L). After discontinuation of amisulpride, blood count returned to normal. The favorable evolution after discontinuation of treatment: the normality of biological and cytological examinations is in favor of a causal relationship between this severe neutropenia and introduction of amisulpride.

Conclusion This case report highlights the risk of amisulpride in inducing agranulocytosis, a risk underestimated in regard of the clozapine risk to induce agranulocytosis or neutropenia. For this reason, it seems reasonable to recommend performing a blood count before introduction and during the treatment by anti-psychotics.

Hepatotoxicity related to anti-depressive psychopharmacotherapy: Implications of quantitative signal detection

M. Gahr^{1,*}, R. Zeiss¹, D. Lang², B.J. Connemann¹, C. Schönfeldt-Lecuona¹

¹ University Hospital of Ulm, Psychiatry and Psychotherapy III, Ulm, Germany

² University Hospital of Ulm, Psychosomatic Medicine and Psychotherapy, Ulm, Germany

* Corresponding author.

Introduction Drug-induced liver injury is a major problem of pharmacotherapy and is also frequent with anti-depressive psychopharmacotherapy.

Objectives/aims However, there are only few studies using a consistent methodologic approach to study hepatotoxicity of a larger group of antidepressants.

Methods We performed a quantitative signal detection analysis using pharmacovigilance data from the Uppsala monitoring center from the WHO that records adverse drug reaction data from worldwide sources; we calculated reporting odds ratios (ROR) as measures for disproportionality within a case-/non-case approach for several frequently prescribed anti-depressants.

Results Both positive controls, amineptine (ROR 38.4 [95% CI: 33.8–43.6]) and nefazodone (ROR 3.2 [95% CI: 3.0–3.5]), were statistically associated with hepatotoxicity. Following amineptine, agomelatine (ROR 6.4 [95% CI: 5.7–7.2]) was associated with the second highest ROR, followed by tianeptine (ROR 4.4 [95% CI: 3.6–5.3]), mianserin (ROR 3.6 [95% CI: 3.3–3.4]) and nefazodone.

Conclusions In line with previous studies our results support the hypothesis that agomelatine and several other anti-depressants may be associated with relevant hepatotoxicity. However, the used data and applied method do not allow a quantitative evaluation of hepatotoxicity or assessment of substance-specific differences regarding the extent of hepatotoxicity.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Trazodone in treatment of interferon-induced anxiety in persons with viral hepatitis C

A. Miljatovic

Clinical Hospital Center "Zvezdara", Psychiatric Hospital, Belgrade, Serbia

Introduction The interferon therapy is associated with numerous adverse psychiatric effects, such as tension, irritability, insomnia, etc.

Goal The goal of this study was to examine the severity and the frequency of anxiety in persons with chronic hepatitis C receiving pegylated interferon alpha combined with ribavirin. We have also tried to assess the efficiency of trazodone in treatment of symptoms of anxiety in patients receiving pegylated interferon.

Method The total of 36 patients whose diagnosis of chronic hepatitis C has been confirmed both serologically and pathohistologically, receiving interferon therapy, ages 22 to 60, participated in this study. The control group consisted of 32 patients, all with same diagnosis, corresponding with those in the study group in terms of gender, age duration of the illness and the level of education. All patients received pegylated interferon alpha 2a, administered subcutaneously once per week, along with oral ribavirin. The research used the following instruments of clinical

assessment: structural clinical interview–SCID, ICD–10; Hamilton anxiety rating scale–HAM–A, and the self-report scale for assessment of anxiety–state-trait anxiety inventory–STAI–Form Y. The testing using these instruments was conducted four weeks after the start of the treatment, then after eight weeks, after 12, 24 and 48 weeks, i.e. at the end of the treatment. The patients in the study group received 150–300 mg of trazodone per day, starting at the week 6 of interferon treatment.

Results The research showed that in the beginning of the interferon treatment approximately one quarter of the patients exhibited symptoms of anxiety in both groups. The administration of trazodone showed beneficial effects in reduction of anxiety induced by the treatment with pegylated interferon.

Effectiveness of long-acting aripiprazole in schizoaffective disorders: A naturalistic longitudinal study

A. Nivoli*, M. Antonioli, L. Folini, L. Floris, G. Meli, M. Paolo, L. Loretta

University of Sassari, Department of Psychiatry, Sassari, Italy

* Corresponding author.

Introduction Intramuscular paliperidone palmitate (PP) is a long-acting, atypical anti-psychotic for once monthly intramuscular (IM) administration in the treatment of patients with schizophrenia.

Objective To study the effectiveness (efficacy and quality of life) of ARP in the maintenance treatment of schizoaffective disorder.

Methods A non-randomized, prospective naturalistic study was performed in out-patients with schizoaffective disorder unsuccessfully treated with oral anti-psychotics. Efficacy of ARP over time was evaluated by using brief psychiatric rating scale (BPRS 24-items), quality of life was evaluated by using QL-Index, both at T0 and at most recent visit (T1). Data were analyzed with Student's *t*-tests and Pearson correlations (α value, two tailed). Paired *t*-test was applied for BPRS and for QL-Index total scores (T0–T1).

Results Data were available for 8 outpatients consecutively prescribed ARP and naturalistically treated attending at the psychiatric clinic, university of Sassari. Mean time on ARP treatment was 207.14 days (sd 137.2). BPRS mean total score at T0 was 57 (sd 13.2) and at T1 was 39.7 (sd 10.8). QL-Index mean total score was at T0 5.43 (sd 1.6) and at T1 7.14 (sd 2.7). Paired sample test showed a statistically significant difference in decreasing symptoms at BPRS over time ($P=0.001$) and QL-Index total score ($P=0.023$). The analyses showed a significant improving at the following BPRS sub-items: anxiety ($P=0.005$), mood elevation ($P=0.014$) conceptual disorganization ($P=0.048$), emotional withdrawal ($P=0.05$), tension ($P=0.02$) and distractibility ($P=0.03$).

Successful treatment of OCD-bipolar co-morbidity with clozapine – aripiprazole combination

U. Ouali*, Y. Zgueb, A. Ouertani, F. Nacef
Razi Hospital, Psychiatry A, Mannouba, Tunisia

* Corresponding author.

Introduction Co-morbid obsessive-compulsive disorder (OCD) in bipolar disorder (BD) negatively affects clinical course and outcome, and considerably complicates its treatment.

Objective To show a therapeutic approach still rarely used in case of resistant bipolar disorder associated with OCD.

Methods Presentation of the clinical case of Mr. M.H., who is treated in our department since 2008 for OCD-bipolar co-morbidity, followed by a literature review.

Results Mr. M.H. is a 29-year-old male patient. He developed BD associated to OCD at age 20. In order to control bipolar symptoms, the patient received several trials of anti-psychotics combined with mood stabilizers with little improvement. Resistant BD was diagnosed, and clozapine 300 mg daily introduced, leading to significant improvement in bipolar symptoms but worsening in OC symptoms. Treatment of OCD with fluoxetine and with cognitive-behavioral therapy (CBT) was unsuccessful. Introduction of aripiprazole 20 mg daily led to decided improvement of OC-symptoms. After one year, clozapine was gradually tapered down to 150 mg daily without reappearance of bipolar symptoms but further improvement of OC-symptoms.

Conclusion Treatment of OCD-bipolar co-morbidity is difficult given the risk of manic switch with antidepressants and the risk of benzodiazepine dependence. CBT could represent an alternative, however, it did not show any efficacy in our patient. Worsening of OCD under clozapine is described in the literature. Adjunction of aripiprazole to clozapine seems an interesting therapeutic option: it diminishes OC symptoms without destabilizing the patient's mood state.

Interactions between SSRI's and statins: Clinical relevance versus statistical significance

S. Petrykiv^{1,*}, L. De Jonge², M. Arts³

¹ University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands

² Leonardo Scientific Research Institute, Department of Geriatric Psychiatry, Groningen, The Netherlands

³ University Medical Center Groningen, Department of Old Age Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction Depression and hypercholesterolemia are two of the most commonly treated conditions in the developed countries, while the lipid-lowering agents and antidepressants are among the most widely prescribed drugs in the world. There is a common concern that selective serotonin reuptake inhibitors (SSRIs) can trigger statin adverse effects, especially myopathy. However, the supporting evidence originates from studies in-vitro and big epidemiological studies. Recent pharmacokinetic insights indicate that the magnitude of pharmacokinetic interaction between SSRIs and statins is likely to be below the threshold for clinical significance.

Objectives and aims Explorative study on pharmacokinetic effects of SSRIs on statin drugs.

Methods We performed a detailed literature review through PubMed, EMBASE and Cochran's Library to assess the clinical relevance of combined SSRIs and statin use. To address pharmacokinetic interactions between two drug groups, we focused on:

- cytochrome P450 enzyme metabolism of statins;
- CYP enzyme inhibition by SSRIs;
- SSRIs–statin drug interactions;
- non-CYP pharmacokinetic pathways.

Results With regard to pharmacokinetic drug interactions and the risk of statin related myopathy, escitalopram, citalopram, and paroxetine are to be safe in co-therapy with all statins. Rosuvastatin and pravastatin are almost certain to be safe in co-therapy with all

SSRIs. Fluoxetine and sertraline are also likely to be safe, even when combined with atorvastatin, simvastatin, and lovastatin.

Conclusion Though the absolute risk of concomitant use of SSRIs with statins seems to be negligible, even this risk can be minimized by using lower statin doses and monitoring the patient.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1089

Hyponatremia associated with selective serotonin-reuptake inhibitors

S. Petrykiv^{1,*}, L. De Jonge², M. Arts³

¹ University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands

² Leonardo Scientific Research Institute, Department of Geriatric Psychiatry, Groningen, The Netherlands

³ University Medical Center Groningen, Department of Old Age Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction Psychotropic agents have been implicated in the cause of hyponatremia, including the majority of selective serotonin reuptake inhibitors (SSRIs). The reported incidence of hyponatremia caused by SSRIs varies widely up to 40%. Important risk factors are older age and concomitant use of diuretics. Though there are numerous retrospective studies available, an update of current knowledge SSRI induced hyponatremia is warranted.

Objectives and aims To review the incidence, risk factors, mechanism, times of onset and resolution, and treatment of hyponatremia associated with selective serotonin-reuptake inhibitors (SSRIs).

Methods An English language literature search was conducted using Pubmed, EMBASE and Cochrane library (December 1980–December 2015) using the search terms selective serotonin-reuptake inhibitor, hyponatremia, syndrome of inappropriate secretion of antidiuretic hormone, citalopram, escitalopram, fluoxetine, fluvoxamine, paroxetine, and sertraline.

Results Numerous case reports, observational studies, and case-controlled studies, as well as one prospective clinical trial, have reported hyponatremia associated with SSRI use, with an incidence of 15%. Risk factors for the development of hyponatremia with SSRIs include older age, female gender, and concomitant use of diuretics, low body weight, and lower baseline serum sodium concentration. Predisposing factors, such as volume status, diuretic use, or concomitant use of other agents known to cause SIADH, may predispose to the development of hyponatremia. In published reports, hyponatremia developed within the first few weeks of treatment and resolved within 2 weeks after therapy was discontinued.

Conclusion Practitioners should be on the alert for this potentially life-threatening adverse event, especially in older adults.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Drug safety warnings in psychiatry: Adverse drug reactions' signaling from 2002 to 2014

V. Prisco^{1,*}, T. Iannaccone¹, A. Capuano², M. Fabrazzo¹, F. Catapano¹

¹ University of Naples SUN, Department of Psychiatry, Naples, Italy

² University of Naples SUN, Department of Experimental Medicine, Section of Pharmacology L. Donatelli, University of Naples SUN, Naples, Italy

* Corresponding author.

Monitoring drug-related side effects in psychiatric patients is highly recommended. In fact, frequent exposure to long-term polypharmacotherapy, poor compliance to pharmacological treatment and co-morbidity with organic illnesses requiring the prescription of other drugs are causes of pharmacokinetic/pharmacodynamic interactions. These vulnerability factors result in a certain increase in ADRs (adverse drug reactions). This study performs an analysis of the Italian medicine agency (AIFA) data, in the section “signal analysis”, to attempt an assessment of the safety warnings among the different psychotropic drug classes, belonging to the ATC class: N03 (anti-epileptics), N05 (anti-psychotics), N06 (psycho-analeptic drugs). Then we analyzed, in a descriptive way, the different association between the drug and the related ADR, evaluating the different safety profiles, in relation to experimental studies, supporting the importance of the signal. In the last years, among the new 25 ADRs, 10 were related to antidepressant drugs (8 SSRI, 1 mirtazapine, 1 agomelatine). In relation to anti-psychotic drugs, 6 new correlations were found between drug and ADR onset, mainly among atypical anti-psychotics. Other correlations (6 above all) were found among anti-epileptic drugs. Among benzodiazepines, a signal linked to rhabdomyolysis onset was found. It is also recommended an evaluation of safety profile in relation to zolpidem prescription. The results of our systematic review are a motivational input, considering the continuous increase of safety warnings, to attentively monitor drug's prescription. Spontaneous ADRs' signaling is a classical system to provide the required attention in relation to a potential risk.

Protection of proteins and lipids of blood plasma by different lithium salts under ethanol-induced oxidative damage

V. Prokopieva^{1,*}, E. Yarygina¹, E. Plotnikov²

¹ Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Laboratory of Clinical Psychoneuroimmunology and Neurobiology, Tomsk, Russia

² Tomsk Polytechnic University, Department of Physical and Analytical Chemistry, Tomsk, Russia

* Corresponding author.

Introduction The creation of new lithium compounds with antioxidant activity is relevant problem for psychiatry. The aim of this work was study of the protective effect of lithium salts against ethanol-induced oxidative damage to proteins and lipids of human blood plasma in vitro.

Methods We used lithium ascorbate and lithium carbonate 0.6 mmol/L which correspond to the therapeutic dose (in terms of lithium ions). Antioxidant carnosine (β -Ala-L-His) was used as comparison drug. We used the blood of 12 healthy donors. The heparinized blood samples were incubated in presence of tested preparations for one hour at 37 °C. The final ethanol concentration in samples was 0.5%. Oxidative modification of proteins was determined as the level of carbonylated proteins with 2,4-dinitrophenylhydrazine, lipid peroxidation products—as the level of TBA-reactive products by spectrometry. Statistical analysis was performed with “Statistika 10” program.

Results The addition of ethanol in the blood led to a significant increase in carbonylated proteins and TBA-reactive products in the plasma (carbonylated proteins: without ethanol 0.26 ± 0.01 nmol/mg of protein; with ethanol 0.33 ± 0.02 nmol/mg; TBA-reactive products: without -3.2 ± 0.1 nmol/mL; with -4.0 ± 0.2 nmol/mL, $P < 0.05$). In the presence of carnosine such increase of oxidized products of biomolecules is not observed, i.e. carnosine had a protective effect against ethanol-induced oxidative

damage. Lithium ascorbate showed a protective effect like carnosine. Lithium carbonate revealed no detectable influence on biomolecules in the conditions of our experiment.

Conclusion Lithium ascorbate has a protective effect on blood plasma proteins and lipids under ethanol-induced oxidative damage of biomolecules.

Drug prescriptions associated with long acting. Pharmacoeconomic aspects

A. Riolo, F. Babici, F. Tassi*

ASS 1 Triestina, Department of Mental Health, Trieste, Italy

* Corresponding author.

Introduction The polypharmacy is a very controversial subject; it brings together problems of interaction between drugs, side effects, and rationality of co-prescriptions, pharmacoeconomic aspects. The long acting is useful to solve adherence to treatment but they are often prescribed in polytherapy.

Method The aim of this studies is to compare long-acting haloperidol, fluphenazine, risperidone and paliperidone regard to prescribing associations and pharmacoeconomy. Also we want to consider for each long-acting which and how many drugs are associated and the implications in terms of pharmacoeconomics. We examined all prescriptions (126 patients) over a period of 12 months in a mental health center, identifying which long acting had the best pharmacoeconomic profile.

Results Despite being the less prescribed and not being associated with other psychiatric drugs, paliperidone palmitate shows the best pharmacoeconomic profile.

Conclusions The costs of a drug are in relationship not only with unit price but also with the question of safety in order to oppose the overmedication.

A rare instance of tardive dyskinesia with SSRI use: A case study

D. Roy

The Prince Charles Hospital Metro North Health Services, Acute Care Team, Department of Psychiatry, Cherrnside, Australia

Introduction Case presentation of a middle aged lady Mrs. C.K., who developed tardive dyskinesia (TD) after a trial of an SSRI.

Case report A 49-year-old Australian aboriginal lady, presented with involuntary movement of her face (bucco-linguo masticatory), movements after a 3 months trial of sertraline (maximum dose of 100 mg daily) for her depressive illness. There was no history of trials with anti-psychotics or any other medications, which may have caused the oral dyskinesias. Routine examinations including cognitive testing, EEG and MRI revealed no pathological findings. Her sertraline was ceased and she was commenced on mirtazapine 15 mg at night, which was hiked to 30 mg after 1 week and continued on this dose over the next 3 months. She exhibited good improvement in her depressive symptoms and a significant attenuation of her TD's. Involuntary movement scale rating: she was rated on the abnormal involuntary movement scale (AIMS) and showed gradual improvement in the severity of her orofacial dyskinesic movement. Her scores were—initial presentation (scored 22/36); at 4 weeks (9/36); 8 weeks (6/36) and at 16 weeks (4/36).

Discussion Although TD's are seen in approximately 1 to 5% of mental health patients treated with anti-psychotics (and some other medications like Levodopa, Metochlorpromide, etc.), research studies on SSRI's causing TD's are rare and few (Leo et al., 1996; Gerber et al., 1998).

Conclusions To alert and educate clinicians about a relatively rare adverse-effect of SSRI producing an involuntary movement disorder.

Sexual dysfunction associated with antidepressants and how to prevent it. Is vortioxetine effective?

H. Saiz Garcia^{1,*}, L. Montes Reula¹, A. Portilla Fernandez¹, V. Pereira Sanchez², N. Olmo Lopez³, E. Mancha Heredero¹, A.S. Rosero Enriquez¹, M.E. Martinez Parreño¹

¹ Complejo Hospitalario Navarra, Psychiatry, Pamplona, Spain

² Clinica Universidad de Navarra, Psychiatry, Pamplona, Spain

³ CSM Salburua, Psychiatry, Vitoria, Spain

* Corresponding author.

Introduction One of the most common, and many times hidden, secondary effects of antidepressants drugs use is sexual dysfunction (SD). It has been noted that as many as 20% of patients will discontinue treatment with an SSRI, with one-third of these patients doing so due to adverse reactions.

Methodology A review was conducted aiming to clarify the pathogenesis of sexual dysfunction in depressed patients or taking antidepressants and how to prevent and manage it. The literature search was conducted in PubMed data reviewing articles dating between 2015 and 2016.

Results (1) the sexual response cycle is negatively affected in individuals suffering from major depressive disorder, even before initiation of any psychotropic medication. The serotonergic system plays a largely inhibitory role on sexual desire, orgasm, and ejaculation with involvement of the hippocampus and amygdala. Tricyclic antidepressants increase the level of prolactin and indirectly suppress the level of testosterone. (2) Bupropion and vortioxetine are the only antidepressants that have level 1 evidence supporting that

they either have a more favorable SD profile. (3) SD with vortioxetine was not statistically higher when compared with placebo, and was statistically lower compared with other SSRIs or SNRIs. (4) There is evidence that antidepressants that are also 5-HT1A receptor agonists (e.g. vortioxetine and vilazodone) may facilitate sexual performance.

Conclusions In case of SD pharmacologic and non-pharmacologic options are available. Vortioxetine seems to be a good pharmacologic option, with better NNH than SNRI and less SD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Aripiprazole once monthly outpatient experience

P. Sánchez Páez*, J.L. Gómez Cano, L. Sánchez Flores, R. González Lucas, P. Artieda Urrutia
Hospital Ramón y Cajal, Psychiatry, Madrid, Spain
* Corresponding author.

Introduction Aripiprazole once monthly (AOM) is one of the most recently introduced antipsychotics with a different mechanism of action, which seems to bring clinical and tolerability implications [1].

Objectives We describe the patient profile that may benefit from AOM treatment.

Methods This is a single-centre, retrospective, one year follow-up study of 13 cases of ambulatory AOM use. We analyze clinical and functional evolution, and the tolerability profile of patients in a real clinical practice basis.

Results Mean age was 53.69; 53.8% were males and 46.2% females. The most frequent diagnosis was Schizophrenia and other chronic psychosis (69.3%). Only 7.7% had co-morbidity with substance use disorder (cocaine); 61.6% were on previous treatment with other injectable anti-psychotics; 84.6% of the sample received AOM as monotherapy. Reasons for switching to AOM are shown on Fig. 1. Events during switching are shown on Fig. 2. Outcomes with AOM long-term treatment were positive in 84.61% of cases and are shown on Fig. 3.

Conclusions Switching to AOM could be considered as a good strategy to improve tolerability, functionality and ultimately adherence to treatment in patients in middle age of life with a chronic psychotic disorder [2].

Clinical vignette – Aripiprazol long acting injection monotherapy as long-term treatment for bipolar disease

C. Solana*, S. Nascimento, M. Duarte, M. Mendes
Centro Hospitalar Psiquiatrico de Lisboa, Psychiatry, Lisboa, Portugal
* Corresponding author.

Introduction Over the last decade a number of effective maintenance treatments for bipolar disorder (BPD) have been developed. Lithium remains the best-established option, but valproic acid, lamotrigine, olanzapine, and quetiapine are also effective maintenance drugs. However, oral administration contributes to lower adherence rates with these drugs. In the United States and Europe,

aripiprazole is approved for the acute management of manic and mixed episodes and maintenance in BPD. It presents the advantage of a low risk of metabolic side effects, sexual dysfunction, and sedation, which can facilitate treatment adherence and help improve clinical outcomes.

Objectives The authors present an illustrative case on which aripiprazol long acting injection monotherapy was effective as maintenance treatment in a patient with long history of BPD with several hospital inpatient admissions and very poor therapeutic adherence.

Methods Case report based on the patient's file. Narrative review of articles available in PubMed about the use of aripiprazol in BPD.
Results For this patient, aripiprazol long acting injection has proved to be an excellent choice for long-term treatment of BPD. The once-a-month injection promotes therapeutic adherence, which in this case was combined with involuntary outpatient treatment, ensuring therapeutic compliance.

Conclusions Aripiprazol has been shown to be safe and effective in the maintenance treatment in BPD. It shows similar efficacy and a superior tolerability profile when compared with other well-established treatments. Further studies are needed, warranted by its potential advantages, particularly on patients with poor insight and adherence.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Treating bipolar disorder in pregnancy

C. Solana*, S. Nascimento, M. Mendes, M. Duarte
Centro Hospitalar Psiquiatrico de Lisboa, Psychiatry, Lisboa, Portugal
* Corresponding author.

Introduction Bipolar disorder is a chronic psychiatric illnesses characterized by alternating episodes of mania/hypomania and major depression, or with mixed features. Acute exacerbations and maintenance treatment with appropriate pharmacotherapy are mandatory. Long-term treatment with mood-stabilizing medications is typically required. The incidence of bipolar disorders in women during the primary reproductive years is very high, and the episodes of mania or depression are thought to occur in an estimated 25%–30% of women with bipolar disorder during pregnancy.
Objectives Provide a clinically focused review of the available information on the effectiveness and safety of the different pharmacotherapies in the treatment of bipolar disorder during pregnancy.
Methods A bibliographic review is made of the pregnancy in bipolar disorder, based on the data published in PubMed.

Results Clinical decision making about the use of mood stabilizers and atypical anti-psychotics by pregnant women can be conceptualized as balancing the competing risks imposed by withholding or stopping pharmacotherapeutic treatment against that of continuing or initiating pharmacotherapy during pregnancy. Some of the most effective pharmacotherapies have been associated with the occurrence of congenital malformations or other adverse neonatal effects in offspring. There is few information about the safety profile and clinical effectiveness of atypical anti-psychotic drugs when used to treat bipolar disorder during pregnancy.

Conclusions Treating women with bipolar disorders during pregnancy is a challenge. There are no uniformly effective or risk-free treatment options. Fully informed decision-making requires the review of the risks of both untreated maternal bipolar disorder and risks associated with potentials interventions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A case report of an acute confusional state related with perampanel

M. Solderdelcoll Arimany^{1,*}, P. Bruguera², P. Guzmán², M. Balcells Oliveiró²

¹ Institute of Neuroscience, Hospital Clínic de Barcelona, Department of Psychiatry and Psychology, Manlleu, Spain

² Institute of Neuroscience, Hospital Clínic de Barcelona, Department of Psychiatry and Psychology, Barcelona, Spain

* Corresponding author.

Introduction Perampanel (PER) is a new selective, non-competitive AMPA glutamate receptor antagonist. PER is generally well tolerated, with dizziness, somnolence, headache, and fatigue as the most common treatment-emergent adverse events, however neuropsychiatric adverse reactions; particularly irritability and aggressiveness can be expected.

Objective We describe a patient who developed and acute confusional state presumably related to treatment with PER.

Aims At the conclusion, the participants should be able to remember that PER is associated with psychiatric side effects.

Methods Collect the data of the clinical history of the patient, who was admitted in the acute psychiatry ward of our hospital.

Results A 32-year-old woman diagnosed with pharmacoresistant juvenile myoclonic epilepsy, was referred to the emergency department because of severe behavioral disturbances, insomnia, irritability and aggressivity after increasing the dose of PER from 6 to 12 mg. Physical exploration, drug screen and blood tests were all normal. No abnormalities were found in CT, EEG and MRI, and then she was referred to psychiatric ward. At her admission, she presented fluctuations of her mental state and level of consciousness. She was diagnosed with acute confusional syndrome induced by PER, and consequently PER was stopped and risperidone was initiated. In the 4th week symptomatology remitted.

Conclusion Anti-epileptic drug's (AEDs) are associated with psychiatric side effects. Patients with epilepsy have higher risk develop psychiatric symptoms and behavioral disturbances. There is evidence to suggest that AMPA receptors are involved in the pathogenesis of psychiatric conditions. Such mechanisms could be responsible of the psychiatric symptoms observed. Neuropsychological profiles of AEDs are important considerations for treatment selection, particularly in children and adolescents.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A retrospective study of drug – drug interactions in patients treated with pharmacotherapy in the biggest Slovenian correctional facility

M. Stuhec^{1,*}, S. Brunec¹, V. Svab²

¹ Faculty of Pharmacy, Biopharmacy and Pharmacokinetics, Ljubljana, Slovenia

² Faculty of Medicine, Department for Psychiatry, Ljubljana, Slovenia
* Corresponding author.

Background Drug-drug interactions (DDIs) are known to lead to treatment failure.

Objectives In most European countries there are no data on DDIs in patients within correctional facilities.

Aim The main aim of this paper is to present the most frequent DDIs in the biggest Slovenian male, Slovenian correctional facility Dob to avoid serious DDIs in future.

Methods A retrospective study was carried between September 2015 and June 2016 on 141 patients on substitution treatment (methadone, suboxone and buprenorphine) and 125 other prisoners with mental disorders in need for psychiatric treatment were

included. All study data were extracted from the patients' medical files of the psychiatric dispensary in the prison Dob. DDIs were determined by different interaction classes with Lexicomp Online™ 19.0 version and only X (major interactions and should be avoided) and D (minor interactions and avoid if it is possible) were included.

Results Together 220 patients were included. Number of patients with at least 1 interaction, were 139 (63.2%). Number of patients with at least 1 X interaction, were 59 (26.8%). Number of patients with more than one (1) X interactions was 15 (6.8%). More than half of the patients (56.4%) were treated by hypnotics and 38.4% with benzodiazepines. The most frequent X DDIs were: buprenorphine, methadone and sulpride with antipsychotics (clozapine and quetiapine) and antidepressants (e.g. escitalopram, fluoxetine).

Conclusions In patients treated with methadone and buprenorphine there are frequent DDIs resulting in contraindications for prescribed combination of drugs. If an antidepressant is to be used in patients prescribed methadone and buprenorphine, sertraline is recommended.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Objectives This was a descriptive study of the prescription trend of anti-psychotics for elderly patients in a general hospital in Singapore.

Methods Elderly patients aged >65 who received at least 1 prescription of anti-psychotics during 2005, 2007, 2009, 2011 and 2013 in Tan Tock Seng Hospital, Singapore, were selected. Data was obtained from the hospital computerized prescription records.

Results The total number of elderly patients who received anti-psychotics increased from 865 in 2005 to 1990 in 2013. Following the official warning issued by the health sciences authority in 2004 regarding the increased risks of cerebrovascular events in elderly patients taking olanzapine and risperidone, prescriptions for risperidone reduced between 2005 to 2013 (20.74% vs. 11.79%, 95% CI: 0.07–0.10, $P < 0.0001$). However, the percentage of prescriptions of other atypical anti-psychotics such as quetiapine increased from 27.47% to 58.48% (95% CI: 0.29–0.33, $P < 0.0001$), in 2005 and 2013 respectively, and prescriptions for olanzapine remained relatively stable at 6.65% in 2005 and 8.94% in 2013 ($P > 0.05$). With the black box warnings extended to typical anti-psychotics 3 years later, the percentage of prescriptions of typical anti-psychotics decreased between 2005 to 2013, e.g. haloperidol (33.19% vs. 13.39%, 95% CI: 0.17–0.22; $P < 0.0001$), sulpiride (6.58% vs. 2.83%, 95% CI: 0.03–0.05, $P < 0.0001$) and chlorpromazine (3.85% vs. 1.85%, 95% CI: 0.01–0.03, $P < 0.0001$).

Conclusions After the first safety warning the percentage of prescriptions for risperidone dropped significantly, and there was a significant increase for quetiapine. The percentage of haloperidol, sulpiride and chlorpromazine prescriptions declined after both warnings. Anti-psychotics use in the elderly continues to be prevalent.

Psychiatrists' opinions on long-acting anti-psychotics drugs: Perceived differences and identification of the ideal patient for each of these medications

V. Verdino*, A. Fagiolini

Azienda Ospedaliera Universitaria Senese, Molecular Medicine and Development, Psychiatry Section, Siena, Italy

* Corresponding author.

Introduction Long-acting anti-psychotic drugs (LAI) are increasingly used in clinical practice, owing to their ability to improve adherence.

Objectives and aims To understand the variables that inform treatment choice, within the LAI anti-psychotics, in the daily clinical practice.

Methods Fifteen attending psychiatrists from the university clinic of Siena and the community mental health service USL 7 Siena and Val d'Elsa were asked to answer a questionnaire comprising 4 questions, and asking for their clinical experience regarding olanzapine, risperidone, haloperidol, zuclopentixol, paliperidone and aripiprazole LAIs.

In particular, they were asked to indicate:

- which LAI has been their mostly used;
- what have been the most relevant side effects;
- an efficacy score ranging from 0 to 5;
- who the ideal patient for each of these medications could be.

The answers were statistically assessed and the final results described as a percentage of the total.

Results The results are shown by the Tables 1 and 2.

Conclusions LAI are still heterogeneously used in the daily clinical practice: their actual use depends on the individual experience with a specific drug as well as on their costs and the availability of resources within the medical service. The most used LAI resulted to be risperidone, although haloperidol LAI is still considered to be the most effective one. Those psychiatrists interviewed had an overall good opinion about the most recent LAI such as paliperidone and aripiprazole. This is due to their good tolerability, which allows them to be administered more safely to the youngest, in order to preserve their good functioning.

Table 1

LAI	% of psychiatrists who said it is the most used	Most relevant side effects	Efficacy score
Olanzapine		Metabolic syndrome (100%)	3,85/5
Risperidone	53,3%	Prolactin increase (100%)	3,93/5
Aripiprazole	20%	<ul style="list-style-type: none"> • no side effects (60%), • akathisia (40%) 	3,26/5
Zuclopentixol		<ul style="list-style-type: none"> • sedation (60%), • extrapyramidal (40%) 	3,4/5
Haloperidol		EPS (100%)	4,13/5
Paliperidone	20%	<ul style="list-style-type: none"> • no side effects (60%) • prolactin increase (40%) 	3,8/5

Table 2

	Ideal Patient	If there are positive symptoms	If there are negative symptoms	If there is relevant organic comorbidity	If young age	If substance abuse	If aggressive
Olanzapine	Schizophrenia, with anxiety agitation and insomnia	60%	14%	7%	21%	7%	60%
Risperidone	Schizophrenia with severe positive symptoms (delusions, hallucinations) and isolated affective symptoms, who could take oral supplementation with Risperdal for 15 days	92%	60%	40%	50%	60%	85%
Haloperidol	Schizophrenia with positive symptoms without affective symptoms	100%	7%	14%	20%	6%	100%
Zuchlopentixol	Psychosis with psychomotor agitation	80%	42%	50%	30%	50%	90%
Aripiprazole	Schizophrenia with obsessive symptoms or comorbidity with Bipolar Disorder or personality cluster b symptoms	42%	85%	85%	85%	85%	0%
Paliperidon	Schizophrenia with severe positive symptoms (delusions, hallucinations)	80%	65%	71%	85%	85%	50%

Genital cenestopathy in psychotic depression responds to augmentation with aripiprazole and pregabalin: A case report

S. Čekerinac^{1,*}, V. Vuković²

¹ General Hospital Sremska Mitrovica, General Psychiatry Ward, Sremska Mitrovica, Serbia

² Special Hospital for Psychiatric Disorders "Dr Slavoljub Bakalović", Acute Psychosis Ward, Vršac, Serbia

* Corresponding author.

Introduction Psychotic depression is a well-known entity, with recent data confirming the use of antidepressant and anti-psychotic co-treatment. Psychotic symptoms can be mood incongruent and present further difficulties for treatment.

Case summary A 51-year-old female presented to our hospital, with symptoms of genital cramping, paresthesiae, feelings of unease in the vulva and depressive mood. In December 2014, the patient was diagnosed with genital polyps, which were successfully removed by curettage. The patient continued feeling various genital symptoms, which she associated with social and family stressors. After short initial outpatient treatment, the patient was admitted to our ward for complete assessment. Psychological assessment revealed psychotic elements, high anxiety and

a passive aggressive personality. Abdominal ultrasound, lumbal spine radiography, psychiatrist exam and computerized tomography of the brain showed no abnormalities. The patient was diagnosed with psychotic depression and referred to further outpatient treatment. Her drug regimen consisted of venlafaxine, risperidone, clonazepam and carbamazepine, which led to slight initial improvement. However, the patient still referred persistent symptoms as well as sedation as an adverse effect, so risperidone was switched to aripiprazole, and carbamazepine to pregabalin. The initiation of this treatment has led to complete withdrawal of symptoms and the patient has since maintained stable remission.

Conclusion Aripiprazole is well suited to the female population because of its lack of hyperprolactinemia, and its combination with pregabalin may be an option for augmenting treatment in psychotic depression with cenestopathy.

Hyperprolactinemia and anti-psychotics: Prevalence and risk factors

B. Walid*, I. Marrag, R. Ben Soussia, F. Ellouze, M. Nasr

Hospital, Psychiatrie, Mahdia, Tunisia

* Corresponding author.

Introduction Hyperprolactinemia is a frequent side effect observed in patients treated with anti-psychotic drugs. The frequency of clinical signs usually correlates with elevated serum prolactin levels.

Objectives To estimate the prevalence of hyperprolactinemia among patients treated with a single anti-psychotic and specify the risk factors for its occurrence.

Methods Cross-sectional study performed in a period of 6 months in the psychiatric department of Mahdia's hospital, for all patients seen in the consultation and treated with a single anti-psychotic for 12 weeks, with a stable dose, and meeting the inclusion and exclusion criteria of the study. Prolactin blood tests have been performed and confirmed by a second one in case of abnormality objectified in the first lab test results. A magnetic resonance imaging (MRI) was intended for patients with prolactin levels greater than 150 ng/mL.

Results Ninety-two patients were gathered. Prevalence of hyperprolactinemia was 34.8% of which 7.6% had prolactin levels greater than 150 ng/mL. Two macroadenomas' cases were detected. The analytical study found 7 factors significantly correlated with hyperprolactinemia, which are: female sex, substance use, the presence of side effects, prescription of atypical anti-psychotics, the anti-psychotic treatment prescribed: haloperidol/amisulpride, doses of anti-psychotic greater than 1000 mg equivalent to chlorpromazine and the combination of psychotropic drugs.

Conclusion Prolactin blood test should be a systematical analysis for all patients treated with anti-psychotics, to prevent the short and long term side effects.

Clozapine treatment of adolescent refractory emergent emotionally unstable personality disorder: Challenges in diagnostics and therapeutics

S. Whitaker^{1,*}, M. Mathe²

¹ Greater Manchester West Mental Health NHS Foundation Trust. . . , Young peoples service, Manchester, United Kingdom

² Priory Hospitals, CAMHS, Birmingham, United Kingdom

* Corresponding author.

Despite recent advances precision diagnostic criteria on how best to diagnose and treat EUPD remains debated. Therapeutic indication and appropriate use of anti-psychotics including clozapine in this patient group remains unclear. It is debated about personality disorder being diagnosed in children and adolescents, overall it is much more acceptable for adolescents to be given a diagnosis of 'emerging' personality disorder if they exhibit clinical features of such. Clozapine has been used (as an off-license treatment) in adults diagnosed with personality disorder improving psychopathology and quality of life. These patients have been tried on numerous other treatments. In a secure unit for adolescent girls who meet the criteria for a diagnosis of emergent personality disorder who posed serious risks to themselves and others three were given a trial of clozapine The off license use of clozapine was tried in all three patients showed a reduction in incidents, reduced need for polypharmacy and improvement in their qualities of life. One cannot account for these changes being the result of clozapine alone; however, these cases add to the growing body of evidence of the benefits of clozapine in patients with emergent personality disorder.

Use of eye-tracker device to detect attention deficits in adults with ADHD

D. Adamis^{1,*}, M. Unal², E. O'Mahony¹

¹ Sligo Mental Health Services, Psychiatry, Sligo, Ireland

² Sligo Mental Health Services, School of Medicine, National University of Ireland, Galway, Psychiatry, Sligo, Ireland

* Corresponding author.

Introduction Adult patients with ADHD may go unrecognized. This can result in psychosocial and functional decline.

Objectives To investigate the use of objective testing, with an eye-tracker device in the diagnosis of adult patients with ADHD.

Methods Case control study. Inclusion criteria were aged 18–65, minimum 5 years of education and literate in English. Exclusion criteria were visual impairment, amnesia and learning difficulties. ADHD was diagnosed with Conners' adult ADHD diagnostic interview (group A, $n=15$) and were matched for gender and age against normal controls (group B, $n=33$). Participants completed four computer-based tasks while their eye movements were recorded. The tests included (i) Stroop effect test, (ii) Stroop effect test with visual aid, (iii) perceptual selectivity test and (iv) Saccadic interference. accuracy (%) and response time (msec) for tests (i–iii) measured while for test (iv), saccade count, average saccade amplitude and average fixation duration.

Results Stroop test accuracy showed a statistically significant difference between group A and group B ($P=0.004$). Stroop response time also showed a statistically significant difference between the two groups ($t=3.228$, $df: 46$, $P=0.001$). For test (ii), there was a significant difference for response time ($t=2.326$, $df: 46$, $P=0.024$) but not for accuracy. For test (iii), the results were statistically significant for accuracy; ($t=2.682$, $df: 46$, $P=0.010$) and for response time ($t=4.028$, $df: 46$, $P=0.001$). There were no significant differences in the saccadic interference test.

Conclusion Adults with ADHD have a longer response time and perform less accurately than controls. Thus, these data demonstrate that there is a use for objective tests (tests i–iii) in the diagnosis of adult ADHD.

Trauma-related dissociation: Psychological features and psycho-physiological responses to script-driven imagery in borderline personality disorder

D. Bichescu-Burian^{*}, S. Jürgen, S. Tilman, T. Stefan
Centre for Psychiatry Südwestfalen, Weissenau, Clinic of Psychiatry and Psychotherapy I, Ravensburg, Germany

* Corresponding author.

Background Defense reactions to threatening situations are vital adaptations to stress that protect organisms from injury and ensure survival. We retrospectively investigated the role of peritraumatic dissociation (PD) in the occurrence of severe psychopathology and dissociative patterns of reactions in borderline personality disorder (BPD).

Methods We recruited 28 patients with a clinical diagnosis of BPD and 15 healthy controls. The BPD group was divided according to the level of PD (low vs. high): BPD and PD ($n=15$) and BPD only ($n=13$). We conducted an extensive investigation of history of trauma, clinical status, and measurements of emotional and physiologic responses to recall of personalized aversive experiences.

Results Participants with BPD and high PD displayed highest degrees of trauma exposure and clinical symptoms. Their significant heart rate decline during the imagery of personal traumatic events was opposed to the heart rate increases exhibited by the other two groups and may indicate a dissociative reaction pattern. Skin conductance responses did not differentiate between groups. Several emotional responses to imagery provided also support of the idea that PD may play a role in memory processing of traumatic events and thus in the aggravation and maintenance of symptoms in particularly severe forms of BPD.

Smooth pursuit eye movements in psychiatric inpatients

L. Mandolesi¹, G. Piraccini², F. Ambrosini¹, F.L. Vetere¹, R.P. Sant'Angelo², R. Raggini², M. Benassi^{1,*}

¹ University of Bologna, Department of Psychology, Bologna, Italy

² Istituto AUSL della Romagna, Cesena, U.O. Servizio Psichiatrico di Diagnosi e Cura, Cesena, Italy

* Corresponding author.

Introduction Eye movements are used in several studies as a biomarker in order to evaluate cortical alterations in psychiatric disorders. Pursuit eye movements' deficits were found both in

schizophrenia and in affective disorder patients. Nevertheless, these findings are still controversial.

Objectives Set up a system to record and evaluate the eye movements in psychiatric patients.

Aims To verify the applicability of a smooth pursuit task in a sample of psychiatric inpatients and to prove its efficiency in discriminating patient and control group performance.

Methods A sample of psychiatric inpatients was tested at psychiatric service of diagnosis and care of AUSL Romagna-Cesena. Eye movement measures were collected at a sampling rate of 60 Hz using the eye tribe tracker, a bar plugged into a PC, placed below the screen and containing both webcam and infrared illumination. Subjects underwent to a smooth pursuit eye movement task. They had to visually follow a white dot target moving horizontally on a black background with a sinusoidal velocity. At the end of the task, a chart of the eye movements done is shown on the screen. Data are off-line analyzed to calculate several eye movement parameters: gain, eye movement delay with respect to the movement of the target, maximum speed and number of saccades exhibited during pursuit.

Results Patients compared to controls showed higher delay and lower gain values.

Conclusions Findings confirm the adequacy of this method in order to detect eye movement differences between psychiatric patients and controls in a smooth pursuit task.

Affective disorders, psychosis and lipid levels: Is there a connection? Linking psychopathology, clinical exams and neurobiology

M. Nascimento^{1,*}, M. Lázaro¹, J. Reis², G. Pereira³, F. Bacelar¹, A. Nobre¹

¹ Centro Hospitalar Psiquiátrico de Lisboa, Clínica 5, Affective Disorders and OCD, Lisbon, Portugal

² Centro Hospitalar do Algarve, Psiquiatria, Faro, Portugal

³ Centro Hospitalar Psiquiátrico de Lisboa, Clínica 4, Lisbon, Portugal

* Corresponding author.

Introduction Published research regarding the relationship between lipid levels in affective disorders has been contradictory. Additionally, most studies correlating psychosis to lipid serum concentrations only concern schizophrenic patients.

Objective To access the relationship between serum lipid levels with the diagnosis and pathophysiology of affective disorders.

Methods Diagnostic data (ICD-10: F31–32), including mood and psychotic features, were prospectively collected for all patients admitted at the affective disorder ward at Centro Hospitalar Psiquiátrico de Lisboa (Portugal), during the third trimester of 2016. Serum concentrations of triglycerides and total/HDL/LDL cholesterol were evaluated using standard laboratory tests. Statistical analysis was performed for possible correlations between serum lipid levels and:

- different stages of bipolar disorder (BD);
- elevated versus depressive mood (unipolar and bipolar);
- depressive mood (BD versus non-BD);
- psychotic features.

Results Sixty-three patients admitted were enrolled in this study: 47 presented with BD (32 manic, 10 depressives and 5 mixed episodes) and 16 presented depressive disorders. Statistical analysis (R software) revealed that depressed bipolar patients had significantly higher triglyceride ($P=0.026$), total and LDL cholesterol ($P=0.525$) levels than other states; mixed episodes presented higher HDL levels ($P=0.542$). Although not significant, manic patients' HDL levels were consistently elevated compared

to depressive ones, whom presented with lower values overall. Finally, when adjusted for age, psychotic patients showed lower levels of total ($P=0.031$) and LDL cholesterol ($P=0.052$) compared to non-psychotic patients.

Conclusions There is a potential link between serum lipid levels and diagnosis/psychopathology of affective disorders. Further research is needed to characterize its pathophysiological relevance.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction According indicators from the OECD in 2015, cardiovascular diseases remain the main cause of mortality in most OECD countries. But main risk factor, as smoking, obesity, hypertension or physical activity do not explain that Slovak republic was the worst from OECD countries with number 404 age-standardized rates per 100,000 population.

Objectives Determine which psychological, psycho-physiological and anthropometrics factors are at risk of cardiovascular diseases: **Aim** The aim is to determine, which risk psychological, psycho-physiological and anthropometrics markers are remarkable in time, when individual subjectively perceives himself as health. Based on the analysis of these correlates will be identified predictors, mediators and moderators of the cardiovascular diseases from the area of psychological variables, which accentuates the clinical picture of a patient with cardiovascular disease. Another aim is to identify specific risk factors for target advice on a lifestyle modification and creation of an interdisciplinary methodology for the prevention of cardiovascular diseases.

Methods Project is aimed to clarify the relation between psychological factors (measuring by personal inventories as temperament predispositions, maladaptive schemes, coping, personality characteristics), balance of autonomic nervous system (by measuring HRV, skin conductance, muscle tension, respiration, and surface temperature), anthropometrics characteristics (BMI, weight, height) with potential symptoms of cardiovascular diseases confirmed in cardiac evaluation (12-lead ECG), blood pressure, examination of pulse wave, and data of arteriographic examination.

Conclusions The results of the study can help to the better understanding of the interface between psychological factors and cardiovascular problems, which help to find new diagnostic, preventive and treatment approaches.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Benefits of the functional ensemble of temperament framework in assessment of mental disorders: Examples

I. Trofimova

McMaster University, Psychiatry and Behavioral Neurosciences, CILab, Hamilton, Canada

Introduction An integration between psychiatry, neurochemistry and differential psychology gives an evidence-based framework for the diagnosis of mental illness rooted both in modern neurophysiology and clinical observations.

Objectives To investigate whether, a neurochemical model of temperament might (FET) provide a better discrimination between major depression (MD), anxiety (GAD), co-morbid depression and anxiety and delusional disorders than existing emotionality-based temperament models.

Methods Three studies compared the profiles on temperament and personality disorder inventories in patients who were diagnosed and treated for named disorders across four adult age groups (17–24, 25–45, 46–65, 66–84).

Results The FET distinguished between MD and GAD in line with the DSM descriptors and showed significant differences for the traits of motor endurance and motor tempo (much lower values in MD), and neuroticism (much higher value in GAD). The results showed benefits of differentiation between physical and social types of fatigue as a symptom of MD and that high impulsivity and low plasticity can be also considered symptoms differentiating between mental disorders. Moreover, high sociability appeared as a symptom associated with high dominance–mania tendencies. The FET framework appeared to be sensitive to age and sex differences: higher anxiety and anti-social symptoms appeared to be more prominent in the younger age (unlike depression symptoms), and declined with age.

Conclusions This study suggest the utility of using a functional approach to both taxonomy of temperament and classification of mental disorders and the benefits of systemic differentiating between 12 functional aspects of behavior, with special attention to non-emotionality-related aspects of behavior.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

* Corresponding author.

Self-transcendence is an important component of mental health and emotional well-being, and associates with everyday stress. The aim of this study was to reveal the relationships between excessive TV commercial viewing and self-transcendence. Forty-two healthy senior pupils aged 14–17 years participated in the study. We used the temperament and character inventory by cloning, cloning tridimensional personality questionnaire, the school anxiety test by Philips, Maddi Hardiness survey, and the emotional intelligence self-evaluation by Hall. We found that excessive TV commercial viewing has been linked to self-transcendence, which directly correlates with empathy and school anxiety. There was an inverse correlation between self-transcendence and self-directedness. We also found interrelations between self-transcendence and reward dependence, mediated by the noradrenergic brain system. We argue that the propensity for watching TV commercials and self-transcendence may determine the activity of monoaminergic brain systems along with the constitutional traits and personality characteristics.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Theory of Mind (ToM) deficit is investigated by psychological and neurobiological methods using a range of social cognitive tests, including the verbal test Hinting Task. However, it remains unclear whether there is a connection between ToM results and the physiological characteristics in norm and in pathology.

Objectives We performed the comparison of Hinting Task performance in patients with schizophrenia and healthy subjects; analysis of correlations between Hinting Task performance with physiological parameters; discriminant analysis in order to classify subject groups according to predictors, including psychological and physiological parameters.

Methods We measured Hinting Task, spectral power of the EEG mu-rhythm (SP) and heart rate (HR) at rest and during a motion imagery task in 114 right-handed subjects, 1st episode patients with schizophrenia (SCH1) $n=29$, chronically ill patients with schizophrenia, duration of illness more than 5 years, (SCH2) $n=23$, and healthy subjects (HC) $n=62$.

Results Hinting Task rate: $HC > SCH2$ ($P < 0.01$), $HC \geq SCH1$ ($P = 0.07$), $SCH1 = SCH2$ ($P = 0.3$). Only SCH1 Hinting Task score was associated with a complex of physiological parameters in the resting state [Multiple $R = 0.78$, $F(3.25) = 13.31$, $P < 0.0001$]. Discriminant function analysis of HC and the combined SCH group [$F(7.106) = 7.078$, $P < 0.0000$]. The samples were classified at 89% and 71%, respectively, including HR ($P < 0.000001$), SP in the resting state in C4 ($P < 0.001$), C3 ($P < 0.01$), SP changes in C3 ($P < 0.05$) and Hinting Task ($P = 0.2$).

Conclusions Hinting Task Hinting Task is a part of classification model of norm and schizophrenia. Patients with first episode and chronically ill patients with schizophrenia do not differ in the studied parameters.

⁴ Leonardo Scientific Research Institute, Geriatric Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction Walter Jackson Freeman II was born the grandchild of William Williams Keen, one of world's most renowned surgeons from Philadelphia and the son of an otorhinolaryngist, which may have been contributed to his interest in medicine. Freeman started his medical career in a psychiatric hospital and over the years, he operated thousands of patients. He was a protagonist in American psychosurgery and therefore, he often has been referred as the "lobotomist".

Objectives To present the scientific papers of Walter Jackson Freeman on psychosurgery.

Aims To review available literature and to show evidence that Freeman made a significant though controversial contribution to the development of psychosurgery.

Methods A biography is presented and discussed followed by a literature review.

Results In this whole career, "the lobotomist" operated more than 3500 patients and performed mainly operations on the frontal areas. However, he operated human brains without due regard for his patient's mental abilities and emotional well-being after their lobotomy. Despite his work was praised, there was also a lot of criticism on his methods.

Conclusion Despite the dubious reputation, Freeman can be remembered as an ambitious doctor who made a significant contribution to the development of psychosurgery. However, unfortunately he crossed medical and legal boundaries.

* Corresponding author.

Autistic spectrum disorders (ASD) are a group of neurodevelopmental disorders that manifest as deficits in social communication and interaction, and restricted, repetitive behaviors and interests. ASD affect at least 1% of the population and are associated with lifelong disability and early death. There are no effective biological treatments for ASD, although non-invasive neuromodulation has sparked great interest as a possibly useful therapeutic approach. Here, we present preliminary results of a systematic review on the effectiveness of transcranial magnetic stimulation (TMS) in ASD treatment. Using appropriate syntax we searched Pubmed, Web of Science, Science Direct, and Educational Resources Information Clearinghouse. Following standard PRISMA statement (Preferred Reporting Items for Systematic Reviews and Meta-analyses) procedures, we selected 12 eligible studies, comprising four controlled and four uncontrolled trials on the effects of TMS on ASD core symptoms, and 9 controlled and three uncontrolled trials on TMS effects on cognitive performance in ASD. The 12 studies totaled 233 subjects. Although combined effect sizes favor TMS in all four groups of studies, conclusions are limited by the high study heterogeneity. Furthermore, only three of the controlled studies used sham TMS as the control intervention, and only two studies followed up the therapeutic effects after the last TMS session. Side effects, none of them serious, occurred in 6.4% of treated subjects. Our main conclusion is that there is currently little evidence that sustains the commercial offer of TMS for treating ASD. Better-designed studies are badly needed to fully elucidate the role of TMS in the treatment of ASD.

Place of electroconvulsive therapy in the treatment of depression in France: A comparative study between clinical practice and international recommendations

T. Charpeaud^{1,*}, A. Tremey¹, P. Courtet², B. Aouizerate³, P.M. Llorca¹

¹ CHU de Clermont-Ferrand, service de psychiatrie B, Clermont-Ferrand, France

² CHU de Montpellier, département des urgences et post-urgences, Montpellier, France

³ Centre Hospitalier Charles-Perrens, Pôle de Psychiatrie, Bordeaux, France

* Corresponding author.

Objectives To study the place of electroconvulsive therapy (ECT) in the treatment of major depressive disorder in France and compare it with international recommendations and algorithms.

Method Multicenter, retrospective study in 12 French university hospitals. Diagnosis, delay between the onset of the episode and the first day of ECT, previous treatments have been identified. Only patients treated for major depressive disorder between 1 January 2009 and 1 January 2014 were included.

Results A total of 754 patients were included (middle age 61.07 years, sex ratio 0.53). The diagnoses listed were: first major depressive episode (14.95%), bipolar depression (38.85%) and unipolar recurrent depression (46.19%). The delay before ECT, was 11.01 months (13,98), and was significantly longer for first episodes (16.45 months, $P < 0.001$) and shorter in case of psychotic symptoms (8.76 months, $P < 0.03$) and catatonic symptoms (6.70, $P < 0.01$).

Conclusions The delay before ECT appears on average, four times longer than recommended by treatment algorithms for the management of major depressive disorder. This long delay could be explained by a very heterogeneous access to this treatment in French territory.

⁴ GGZWNB, Clinical Psychiatry, Bergen op Zoom, The Netherlands

⁵ University of Groningen, University Medical Center Groningen, Department of Old Age Psychiatry, Groningen, The Netherlands

* Corresponding author.

Introduction José Manuel Rodríguez Delgado (1915–2011), a Spanish physiologist, was among the first scientist to perform electric brain stimulation in both animals and humans. His work on brain-stimulation research during the 1960s and 1970s was innovative but also controversial.

Objectives To present the scientific papers of Jose Delgado on psychosurgery.

Aims To review available literature and to show evidence that Jose Delgado made a significant contribution to the development of psychosurgery.

Methods A biography and private papers are presented and discussed followed by a literature review.

Results Delgado showed that with electrical brain stimulation one could evoke well-organized complex behavior in primates. A rhesus monkey was stimulated with an electrode implanted inside the red nucleus, followed by a complex sequence of events. After stimulation of an area three millimeters from the red nucleus, the rhesus monkey just yawned. Delgado also investigated the mechanisms of aggressive behavior in other animals. Stimulation of the caudate nucleus by remote control in a fighting bully resulted in sudden paralysis. In some human patients suffering from depression, euphoria was induced after stimulation of the septum.

Conclusion Delgado pioneered the brain electrode implantation in order to electrically stimulate specific brain areas for treatment epilepsy and of different types of mental illness. He was severely criticized. His studies, however, paved the way for new modulation techniques such as the development of deep brain stimulation.

Manic switch in bipolar patients treated with electroconvulsive therapy for treatment-resistant depression: The experience at the mood disorder unit of Milan (Italy)

D. Delmonte¹, S. Brioschi^{1,*}, B. Barbini¹, R. Zanardi¹, C. Colombo²

¹ IRCCS San Raffaele-Turro, Division of Neuroscience, Milano, Italy

² Università Vita-Salute San Raffaele, Division of Neuroscience, Milano, Italy

* Corresponding author.

Introduction Despite appropriate treatment, 30–40% of depressed patients, both unipolar and bipolar, do not achieve improvement, with high morbidity and mortality. For bipolar patients another risk is the switch into mania due to antidepressant treatment. The concern about the switch, suggests to administer antidepressants at lower doses, in combination with mood stabilizers and second generation anti-psychotics.

Objectives We performed an observational study on a sample of 23 bipolar patients treated with ECT for severe TRD in last 3 years, in order to evaluate the risk of switch.

Methods Twenty-three bipolar inpatients, undergoing bitemporal ECT twice/week, with MECTA spectrum device. Main demographic and clinical data collected. Hamilton rating scale for depression (HAM-D). Clinical response defined as 50% reduction of HAM-D score at the endpoint from baseline; remission as HAM-D score at the endpoint < 8. Young Mania rating scale (YMRS) weekly in order to assess switch into mania.

Results Thirteen (56.5%) females, 10 (43.5%) males, mean age 60.1 ± 10.3 years. Mean age at onset 35.5 ± 13.6 years. Mean number of episodes: 7.1 ± 3.6. Mean duration of current episode: 33.4 ± 24.9 weeks. Mean HAM-D basal score: 30.0 ± 5. Each patient underwent a cycle of ECT (mean No. 6.7 ± 3.3). Pharmacological treatment was administered upon clinical need. Response rate 87%, remission rate 43.5%. Three out of 23 (13.04%) patients had transient hypomanic switch, spontaneous recovery within 7 days after the last ECT.

Conclusions Our experience confirms that ECT is a powerful antidepressant, especially in patients with severe long-lasting depression, refractory to treatment. ECT is also a safe procedure: no adverse effects were reported. The manic switch rate is comparable with antidepressant drugs.

EV1119

From hypomania to mania after correcting severe hypoglycemia: A case report to recall insulin shock therapy

J. Felgueiras*, C. Freitas, A.T. Carvalho

Centro Hospitalar do Tamega e Sousa, Departamento de Psiquiatria e Saúde Mental, Penafiel, Portugal

* Corresponding author.

Introduction In the early 20th century, shock therapies developed worldwide as the most effective means to treat severe mental illness. In 1927, Manfred Sakel introduced the newly discovered insulin as a means to treat opioid-addicted patients, by relieving withdrawal symptoms. After noticing that some psychotic patients notably recovered from their psychotic symptoms after accidental insulin comas, he extended this technique to schizophrenic patients, arguing that up to 70% of his patients improved with this therapy. Insulin shock therapy soon spread all-over the world and became one of the most important treatments for severe mental illness. Regardless of the high-rate complications, insulin shock therapy only declined after the introduction of anti-psychotic drugs.

Objective Description of a clinical case.

Methods Non-systematic review of literature and case report.

Results A 70-year-old female with type-1 bipolar disorder and type-2 diabetes was referred to a psychiatry emergency department (ED) for 2-week behavioral disorder, featuring restlessness, agitation, insomnia, verbiage and persecutory delusions. In the ED, she presented calm, cooperating, with a subtle humor elation and slight disinhibition. The speech was somewhat confusing, but with

normal debit. Delusional thought or hallucinations were not evident. Severe hypoglycemia was first detected by capillary glucose measurement and confirmed by a blood test. After the blood glucose was corrected she became gradually more restless, talkative, disinhibited, with clear humor elation, compatible with a manic state.

Conclusion We discuss if this case might be explained by the severe hypoglycemia and its correction, linking it to insulin shock therapy, reviewing this procedure's history, controversies and current developments.

ECT in major recurrent depressive syndrome with Parkinsonism syndrome

T. Gómez Alemany*, J. Soler Vidal, I. Targa, B. Garcia Alarcon, A. Santoro, O. Alcoverro, J. Sendra Lopez

Complex Asistencial Salut Mental Germanes Hospitalaries Benito Menni, Acute Adult Psychiatry Ward, Barcelona, Spain

* Corresponding author.

A 71-year-old woman with history of major recurrent depressive syndrome responsive to clomipramine (last episode at 50-year-old) with the following medical records: ischaemic stroke with progressive cognitive impairment to the extent of requiring wheelchair.

Current episode Depressive symptoms, with suicidal thoughts, anxiety, tremor and low food intake in the last month (due to choke phobia) with up to 10 kg of weight loss.

Diagnosis Major recurrent depressive syndrome resistant to treatment with Parkinson syndrome.

Treatment Lorazepam 10 mg/day levodopa 150/carbidopa 37.5 mg/day, LART Electroconvulsive therapy (Thymatron SYSTEM IV) was also carried out 3 times a week until 15 sessions were reached.

Discussion This case illustrates the successful response with LART ECT towards major recurrent depression syndrome associated with a pharmacological parkinsonism maintained over the long-term (one year with ECT). There are sufficient evidences showing that the ECT has an effect in the dopaminergic system at different levels: dopamine release, dopamine neurotransmission and linkage with its receptor, and these effects differ between an acute stimulation and when repeated stimulation is carried out. It must be taken into consideration the fact that concomitant existence of depression and parkinsonism could represent another indication for ECT, since the pharmacological management of these patients is highly complex and could even more if we bear in mind that one of the therapeutic options towards the antidepressant potentiation (atypical anti-psychotics) can worsen the symptomatology.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Bilateral continuous theta burst stimulation (cTBS) for treatment resistant auditory hallucinations and synesthesia in schizophrenia – A case report

J. Jakhar*, D.U. Mehta

NIMHANS, Department of Psychiatry, Bengaluru, India

* Corresponding author.

Introduction While 1-Hz repetitive transcranial magnetic stimulation (rTMS) has been found to be effective in reducing auditory

hallucinations (AH), its effects are transient. cTBS, a patterned-rTMS technique induces sustained long-term-depression-like effects. Here, we demonstrate efficacy of twice daily, bilateral-cTBS in a patient with treatment-resistant AH, reflex hallucinations and vision-touch synesthesia.

Method A 25-year-old male with 5 years history of treatment-resistant AH (2nd/3rd person), vision-touch synesthesia and reflex hallucinations. He was on a combination of 200 mg clozapine and 300 mg amisulpride for the last 6 months with no improvement. He received two-weeks of twice daily, bilateral-cTBS [40,1 s-trains (bursts of 3-pulses at 50 Hz every 200 ms) given continuously at 90% motor threshold] over the temporoparietal junctions located using the International 10/20 system. Amisulpride was stopped and clozapine was increased to 300 mg/day. Change in AH and synesthesiae were assessed using auditory hallucination rating scale (AHRS) and clinical interview.

Result AHRS scores reduced from 35/41 to 0/41 at the end of 2 weeks, with substantial improvement being noticed at the end of the fifth day. Synesthesiae and reflex hallucinations also showed similar trends in improvement. No serious adverse events.

Discussion Integration of auditory, visual and tactile perceptions is an important function of the temporoparietal junction. administering cTBS to this region bilaterally reduced our patient's perceptual abnormalities. Increasing dose of clozapine could be a confounding factor, however, the rapidity of treatment response enables us to attribute part of the improvement to cTBS.

Electroconvulsive therapy management in benzodiazepine-resistant catatonic syndrome: A Case report

I.I. Louzao Rojas*, Á. Orosa Duarte, G. Martínez-Alés García, I. Rubio Zavala, A. Fraga Domingo, P. Sánchez Castro, M.V. Bonán, E. Román Mazuecos, A. Flores Martínez, B. Rodríguez Vega, M.F. Bravo Ortiz, E. Jiménez Sola
Hospital Universitario La Paz, Psychiatry and Mental Health, Madrid, Spain

* Corresponding author.

Catatonia is a rare but potentially lethal neuropsychiatric syndrome. Despite its historical association with schizophrenic disorders, it is more frequent in affective ones, and is currently considered an independent pathological entity. The basis of the treatment, regardless of the cause, is the use of benzodiazepines and electroconvulsive therapy (ECT), without a clear consensus on the combined treatment. Regarding ECT, the frequency and number of effective sessions has not been clearly established. Therefore, clinical evolution is the main factor to be considered in order to determinate the appropriate treatment regimen, although the daily application of ECT is preferred, at least for the first week. We report the case of a 41-year-old patient with paranoid schizophrenia, who presented with a benzodiazepine resistant catatonic syndrome. The clinical picture included stupor, mutism, negativism, severe stiffness, catalepsy, waxy flexibility and diaphoresis, with slight CPK increase but with no other extrapyramidal symptoms, fever more than 39 and hemodynamic instability, which allowed to exclude a neuroleptic malignant syndrome. A blood analysis, lumbar puncture, CT, EEG and viral serologies were performed with inconclusive results. The patient required ICU admission and ECT treatment and we used the Bush-Francis Catatonia Rating Scale to evaluate the evolution of symptoms. Six daily treatments with ECT led to an almost full recovery of the patient. Further case series regarding the clinical management of this syndrome are needed, in order to reach consensus on an effective ECT regimen.

Depression and Parkinson's disease: Biological therapies

B. Mures*, N.G. Lluís, A.P. Iñigo, M.H. German, T.G. Miriam, R.Q. José, L.P. Yolanda

Hospital Clinico San Carlos, Psiquiatria, Madrid, Spain

* Corresponding author.

Introduction Depression occurs in approximately 40% of patients with Parkinson's disease. Parkinson's disease is commonly associated with psychiatric morbidity, which includes depression, anxiety, and dopaminergic psychosis. These compound the patient's predicament. Fortunately, a variety of effective treatments are available.

Objective The purpose of this e-poster is to provide an update of the research regarding depression in Parkinson's disease.

Methods Describe a case report. A 56-year-old man, with previous diagnosis of Parkinson's disease. We used SSRIs, but they were not enough to successful treatment so we decided to use ECT.

Results Our patient failed to respond to medication or develop intolerable medication side effects. Electroconvulsive therapy (ECT) should be considered for this group of patients. Contrary to popular belief, ECT is a widely used and safe treatment for depression when medication fails. ECT has been shown to be effective and safe in PD for treating both depression and dopaminergic psychosis. Several studies also report varying periods of motor improvement following ECT in PD. A study is currently underway at UBC to examine this phenomenon in a controlled setting. ECT improves depression, may permit a reduction in antidepressant medications, and has intrinsic antiparkinsonian properties.

Conclusions ECT, has repeatedly been shown to have beneficial effects in PD, but has never gained acceptance as a clinical treatment option. We review the literature on the use of ECT in PD, pointing out that ECT has beneficial effects on both the core motor symptoms of PD as well as the commonly occurring psychiatric co-morbidities.

The role of neuroplasticity in the treatment of cognitive impairments by means multifactor neuro-electrostimulation of the segmental level of the autonomic nervous system

T. Petrenko^{1,*}, V. Kublanov¹, K. Retyunskiy²

¹ Ural Federal University, Research Medical and Biological Engineering Center of the High Technologies, Ekaterinburg, Russia

² Ural State Medical University, Department of Psychiatry, Ekaterinburg, Russia

* Corresponding author.

Introduction Cognitive deficit is a consequence of organic lesions of the central nervous system. Activation of neuroplasticity is a way of effective treatment. There is a suppose that the autonomic nervous system (ANS) involves in the regulation of neuroplasticity.

Objectives We developed a technology for non-invasive electrical stimulate segmental and suprasedgmental parts of ANS [1].

Methods Developed technology is implemented in the "SYMPATHOCOR-01" device. The device produces spatially distributed field of current pulses between two multiple electrodes

located on the neck. The targets of impact are cervical ganglia of the sympathetic trunk and vagus nerve.

Results The restoration of blood supply in artificial ischemia calf muscles and recovery of behavior patterns during acute phase of the adjustment disorder were received as a result of application technology in experiments on rats [2]. An increase global neurometabolic activity on SPECT was shown in clinical studies [2]. Application device for two weeks in children with ADHD led to reduction of inattention and hyperactivity symptoms [2].

Conclusion We suggest that the demonstrated clinical effects are the results of activate of neuroplasticity by impact on ANS structures. It is necessary to conduct fundamental studies by means of neurovisualization methods (fMRI, PET) for the confirmation action of these mechanisms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Modified electroconvulsive therapy in pseudocholinesterase deficiency: A case report

E. Yildizhan^{1,*}, N.B. Tomruk¹, M. Dereli¹, A. Özdemir¹, H. Yıldırım², Ö. Canbek¹

¹ Bakirkoy Research and Training Hospital for Psychiatry, Neurology and Neurosurgery, Department of Psychiatry, Istanbul, Turkey

² Bakirkoy Research and Training Hospital for Psychiatry, Neurology and Neurosurgery, Department of Anesthesia and Reanimation, Istanbul, Turkey

* Corresponding author.

Introduction Pseudocholinesterase (PCHE) deficiency is an inherited condition, in which recovery from anesthetic agents like succinylcholine and mivacurium is slow and complicated with prolonged paralysis of respiratory muscles in susceptible patients. Succinylcholine is used very frequently as a muscle relaxant during the procedure.

Objectives In Bakirkoy research and training hospital for psychiatric and neurological diseases, 24.310 patients were hospitalized for acute conditions and 3490 of these patients were treated with electroconvulsive therapy (ECT) in 3 years. We present a very rare case that we encountered in our practice; a severe PCHE deficiency case that could have complicated the modified ECT procedure unless necessary precautions were taken.

Aims Detection of PCHE levels of all patients eligible for ECT is part of our pre-ECT assessments procedure, and the case presented here shows the benefits of this method.

Methods The patient is a 29-year-old woman, with a 15 year history of schizophrenia. She was hospitalized for homicidal risk and refusal of treatment. Inadequate clinical response with pharmacological interventions and continuous aggressive excitations directed us to consider ECT.

Results After the detection of PCHE deficiency (PCHE level: 126 U/L), we performed the modified ECT with propofol and rocuronium instead of succinylcholine as usual. Sugammadex 100 mg was used for fastening the recovery. Response to treatment, which is recorded with positive and negative syndrome scale, was good and we completed 9 ECT sessions without complication.

Conclusions Screening for PCHE levels in the pre-ECT assessments is efficacious in order to decrease the complications of the ECT procedure.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Electroconvulsive therapy in drug-resistant paranoid schizophrenia on patient with transplanted kidney – Case study

A. Zdanowicz^{1,*}, P. Wierzbinski²

¹ Medical University, Department of Adult Psychiatry, Lodz, Poland

² Outpatient practice, Medsolver, Lodz, Poland

* Corresponding author.

The 22-year-old female patient had her first direct encounter with a psychiatrist in 2009 due to low mood, anxiety, anhedonia, lack of energy and olfactory hallucinations. Diagnosed with delusional depression syndrome, she was treated with SSRI group, and then combined with LLP group. In 2009, she was hospitalized in the Ward of kidney diseases and dialysis due to severe

kidney failure, HA affecting the heart and the kidneys and facial nerve paralysis. In May 2012, she had a kidney transplanted from the deceased donor, which led to graft-versus-host disease. She received immunosuppressive therapy. In October 2012, she was diagnosed with paranoid syndrome. She was initially treated with levomepromazine 75 mg/d and amisulpride 800 mg/d (no results), then Olanzapine 20 mg/d and aripiprazole 15 mg/d (no results). After 10 week hospitalization she was discharged in a slightly improved mental state. Three weeks later, she was hospitalized again in a psychiatric institution where she received olanzapine 20 mg/d and haloperidol 6 mg/d (no results). Due to the severe mental condition, she was qualified for electroconvulsive therapy. In the end, the therapy met with the general positive reviews of consultants of different specialties. After 7 (of the 18) treatments the patient reached a significantly improved mental state with almost no sign of psychotic experiences and with a better day-to-day functioning. To the best of the authors' knowledge, it is the first case of ECT on the patient who was the subject of a kidney transplant, and is one of the very few that have taken place in the entire world.

Cultural reflections in practicing exposure therapy for social anxiety

R. Aly

Egyptian Association of Cognitive Behavior Therapy, Cairo, Egypt

Evidence-based practice of exposure therapy has long been adopted as an effective therapy for treating anxiety disorders including social anxiety. In many situations, it is the chosen therapy for such a debilitating disease. Due to its proven efficacy and readiness applicability, it has proven to be the 1st choice of therapy for social anxiety across different life spans from adolescents to geriatrics. Yet, cross-cultural differences have seldom been considered in the approach towards managing social anxiety. Many differences lie between populations and countries in defining what is accepted and what is not with regard to social interactions. Even across the one country, many differences may color the perception of appropriate social communication. Hence, no one-size-fits all can be adopted here. Some interactions are accepted and encouraged while others are basically banned. Thus, during the application of exposure therapy, therapists should modify the conceptual framework while still trying to abide with the fundamental notion of therapy of exposure experiments. In doing this, many therapists may be challenged in their work. While still lacking a strong body of research, clinical experience can provide us with some helpful innovations for successful practice. Our aim is to provide therapists and psychiatrists across the Arab world with tools for applying successful therapy for social anxiety. A series of case studies are discussed to present some innovations in applying Cognitive Behavior Therapy for patients suffering from social inhibitions. Moreover, essentials of past research are reviewed and needs for further research directions in the field are discussed.

* Corresponding author.

Introduction Complicated Grief (CG) affects 7–10% of the grieving individuals in the general population. However, the incidence is much higher in psychiatric patients, reaching 70% in most samples. These individuals present many risk factors for such condition, demanding a particular attention and treatment approach. Most studies have shown that pharmacological treatment may help relieving depressive and anxiety symptoms, although they do not promote a consistent improvement of the grieving scenario. Several meta-analyses have recognized different psychological interventions as effective in dealing with the loss, decreasing psychological suffering and promoting adaptation. It is accepted that the benefits of the intervention overcome any possible harm.

Objectives To evaluate the impact of a group intervention (12 sessions) in pharmacologically stabilized psychiatric patients presenting with CG.

Methods Patient selection was performed through a clinical interview and the fulfilment of the following psychometric tests: Complicated Grief Inventory; the Impact of Events Scale; Beck Depression Inventory; Social Support Scale. These assessment tools were also used to evaluate the impact of the intervention performed.

Results After the psychotherapeutic intervention, there were significant differences in the levels of depressive and post-traumatic stress symptoms.

Conclusion Group intervention in CG has proven effective in this population, specially regarding depression and post-traumatic stress levels.

Trait mindfulness at baseline predicts increases in telomerase activity over time

F.S. Bersani^{1,*}, A. Gilbert², M. Coccia², C. Saron³, E. Epel²

¹ Sapienza University of Rome, Department of Neurology and Psychiatry, Roma, Italy

² University of California San Francisco, Department of Psychiatry, San Francisco, USA

³ University of California Davis, Center for Mind and Brain, Davis, USA

* Corresponding author.

Introduction Preliminary investigations of cross-sectional samples have linked trait mindfulness with measures related to the hypothalamic–pituitary–adrenal (HPA)-mediated stress response and to the inflammatory system, suggesting that this is one potential pathway linking mindfulness based interventions and health. However, no previous studies explored the association between the trait mindfulness construct and markers of cellular ageing.

Methods In the current study we examined in a sample of healthy mothers ($n=92$) of a child with Autism Spectrum Disorder (i.e. women showing high levels of chronic psychological stress) the prospective associations between a multidimensional scale of trait mindfulness, the Five Facet Mindfulness Questionnaire (FFMQ), and telomerase activity (TA), a marker of cellular ageing and telomere homeostasis. Participants' trait mindfulness and TA were assessed at baseline as well as 9 and 18 month follow-up.

Results Analysis showed that higher levels of baseline mindfulness on FFMQ observation and describe subscales were related to increase in TA from baseline to 9 month ($r=0.27$, $P=0.03$ and $r=0.24$, $P=.04$, respectively). Additionally, the FFMQ Describe subscale was related to increase in TA from baseline to 18 month ($r=.30$, $P=.02$). Results are reported following covariate adjustment of age, BMI, ethnicity, and education.

Discussion Our results showed that higher levels of baseline mindfulness are associated with higher increases in TA after 9 months and 18 months, with increased TA reportedly being associated with decreased oxidative damage, increased telomere length and overall more functional cellular physiology. These findings support a role of mindfulness-related interventions to increase general and mental health.

⁴ Evergreen college, Psychology, Toronto, Canada

* Corresponding author.

Introduction Psychotherapy can ease physical symptoms of patients with skin pathology.

Objectives To study features of social and psychological maladaptation and quality of life in patients with psoriasis.

Aim To study psychotherapy role in quality of life improvement and social rehabilitation of patients with psoriasis and their family members for the period 2000–2015 in the Belarusian population.

Methods One hundred and twenty four patients with cutaneous psoriasis, 12 patients with psoriatic arthritis and 42 healthy persons were studied. Quality of life, types of attitude towards the disease, level of social frustration, depression, level of social maladaptation, psychological defense mechanisms and patients attitudes towards psychotherapy were assessed.

Results There were detected among patients with psoriasis (especially with arthropathy form): social maladaptation, higher level of social frustration and depression ($P<0.05$), decrease in quality of life ($P<0.001$), the wider range of psychological defense mechanisms (negation, regression, substitution, reactive formation, $P<0.05$). Maladaptive types of attitude towards the disease were presented in 24% patients with psoriasis and almost in 41% patients with arthropathy.

Conclusions Psychotherapy can have a high potential for social rehabilitation and quality of life improvement for patients with psoriasis. Obtained data in social maladaptation indicate family therapy as an important therapeutic part for patients with psoriasis. Moreover, knowledge about patients psychological defense mechanisms can help to choose a direction and methods of individual psychotherapy of social maladaptation. This research shows also that psychotherapeutic approach and family psychotherapy remains underestimated in Belarus.

* Corresponding author.

Introduction First wave cognitive behavioural therapy (CBT) focuses essentially on classical conditioning and operant learning and second wave on information processing. They are based on the premise that certain cognitions, emotions and physiological states lead to dysfunctional behaviour and so, by eliminating the first ones, changes in behaviour will take place. Third wave CBT appeared in an attempt to increase the effectiveness of first and second wave by emphasizing contextual and experiential change strategies.

Objectives/Aims To make a review on the actual state of the art of third wave CBT, focusing on MBSR (Mindfulness-Based Stress Reduction), MCBT (Mindfulness-based Cognitive Behavioural Therapy), DBT (Dialectical Behaviour Therapy), ACT (Acceptance and Commitment Therapy) and CFT (Compassion Focused Therapy).

Methods Research on PubMed using the terms “third wave cognitive behavioural therapy”.

Results Methods and targets differ between MBSR, MCBT, DBT, ACT and CFT. Depression, anxiety and borderline personality disorders are some of those targets. However, a transdiagnostic approach is the hallmark of all third wave therapies: mental processes or emotions transversal to many psychiatric disorders such as shame, self-criticism, experiential avoidance or cognitive fusion are the main focus, emphasizing the context and human experience over any categorical diagnosis.

Conclusions Third wave cognitive behavioural therapy is an emerging approach born from the need to improve and complement first and second waves. Although very promising, it is still a recent approach and data to support its superiority over the conventional therapies is missing.

Should I save my marriage?: Addressing couple relationships by means of art therapy intervention

G. Citak Tunc^{1,*}, N. Eren²

¹ Uludag University, School of Health, Psychiatric Nursing Department, Bursa, Turkey

² Istanbul Faculty of Medicine, Department of Psychiatry, Social Psychiatry Service Director of Art Psychotherapy and Rehabilitation Program, Istanbul, Turkey

* Corresponding author.

Objective This study investigates the case of a female patient, who was experiencing marital problems and had separated from her spouse, with whom an art (drawing) therapy process was carried out.

Aim It was aimed to address the relationship of the couple by supporting the ego and increasing self-awareness skills by means of art materials (drawings) in the process of the situational crisis.

Method Case study.

Result With this case study, it was aimed to make emphasis on the impact of drawing sessions as a means of using art in therapeutic relationships for self-awareness and opportunity for development in a situational crisis during marriage.

Conclusion During the process of individual art therapy, nine sessions and eight drawing tasks were conducted. The case patient, OS, had been separated from her spouse for 2 months. In the first session, a personal history was taken, the scores of the state-trait anxiety scale was evaluated and a therapy plan was jointly developed. Each action was carried out by providing specific instructions. Each session was evaluated within the same week in a supervision meeting with an expert experienced in art therapy and the next session was planned. OS, who developed self-awareness as a result of the sessions, evaluated his/her expectations and boundaries in his/her relationship and discovered the connections with her own nuclear family. In a session with OS one year later, she gave the information that she had started to share a house with her spouse.

Doctor-patient relationship: The impact of mindfulness on empathy

S. Darbeda^{1,2,*}, M. Etchevers³

¹ CESP Inserm, U-1018 Addictive Science, Villejuif, France

² University Pierre and Marie Curie, ED 158, Paris, France

³ University Pierre and Marie Curie, Faculty of Medicine, Paris, France

* Corresponding author.

Introduction The doctor-patient relationship has an increasingly important place in medical studies. Empathy is one of the quality criteria of the relationship. The development of mindfulness in medical schools is booming.

Objectives To investigate the relation between empathy and mindfulness among residents and doctors.

Methods Doctors and residents were asked to complete a demographic questionnaire – questions on their personal development

practices – and two scales. The Mindful Awareness Warning Scale (MAAS) is a unidimensional scale measuring attention and mindfulness and Jefferson Physician Empathy Scale (JSPE) is a scale measuring the clinical empathy across 3 dimensions: “perspective taking”, “compassionate care” and “in the patient’s shoes”. Multivariate linear regressions were performed to analyse the correlation between each score of JSPE and explanatory variables.

Results One hundred ninety-three questionnaires were analyzed: 87% were general practitioners, the average age was 34 years old (SD 11) and 69% were women. Regarding personal development practices, 18% practised mindfulness meditation regularly or occasionally (23% for yoga and 31% for relaxation). No correlation between the scores of JSPE and the MAAS score was found. However, doctors who practiced mindfulness had a highest score of “compassionate care” (95% CI [1.26; 4.91], $P=0.0012$).

Conclusions The mindfulness would be an effective tool for the development of the welfare of the doctors, and improving the quality of empathy and therapeutic efficacy. To support these data, it would be interesting to conduct an interventional study by offering French doctors and interns the possibility of following courses of mindfulness.

The effect of art group psychotherapy with photograph in chronic psychiatric disorders: A pilot study

O. Celik Aypak*, N. Eren, U. Cıkrıklı, D. Buyukgok, S. Ucar Isaret

Istanbul University Medicine Faculty, Psychiatry Department, Istanbul, Turkey

* Corresponding author.

Photograph was used as a therapeutic tool for the first time in 1856 by Dr. Hugh Diamond. Photos are considered to be representations of a person’s reality. The possibility of producing visual images when a client has verbal expression difficulties, photography provides a more structured way of expressing ideas and emotions and to be a means of projective-symbolic communication. Photo therapy with chronic psychotic patients may contribute to development of perception of reality, part-whole relationship, integration, distinction of external-internal world, symbolization capacity and improve ego functions. The aim of this study was to determine the effect of phototherapy on symptomatology, functionality, emotional regulation, cognitive skills and coping skills in patients with chronic psychiatric disorders. In accordance with this aim, the study was carried out with 14 outpatients diagnosed as chronic schizophrenic or psychotic disorder. Seven patients received routine medical care plus 28-week psychotherapy with photograph and 7 patients received only routine medical care. Patients were assessed in pre and post-treatment with Beck Depression Inventory, Beck Anxiety Inventory, Difficulties in Emotion Regulation Scale, Global Assessment of Functioning, Ways of Coping Inventory and Neuropsychological Test Battery. Wilcoxon Signed Ranks Test used for statistical analysis. The therapy method resulted in statistically significant reductions in the level of depression and general symptom levels and statistically significant improvement in cognitive abilities and functionality ($P<.05$). There was also statistically significant improvement in positive reappraisal subscale of coping ways. These findings may indicate that photo-oriented art group therapy might show positive effects on the course of chronic psychotic disorders.

Psychotherapeutic interventions in transition unit

L. Asensio, S. Estefania*, L. Nuevo, I. Gomez, C. Rodriguez, V. Muñoz

Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain

* Corresponding author.

Introduction The In-patient units are very closed and highly controlled healthcare resource and then patients have to join the community rapidly, and in sometimes feeling unprotected and with their needs non covered. We created a transition unit with a program of psychotherapeutic intervention, to offer an adequate transition between the acute episode and the incorporation to the community.

Objective We describe the characteristics of the psychotherapeutic group, the aims and the results of the interventions.

Methods Psychotherapeutic transition unit was created to offer intensive attention and control demand that is not possible to control in the community. The objects are to prevent re-admissions and relapse because of abandonment of treatment in patient with personality disorder and suicide attempts, and first episode, affective or psychotic. Patients are selected from the in-patients unit with inclusion criteria, and start going from the unit before discharge. The intervention is once per week, with a duration between 60–90 minutes. There is not a number of sessions, and we have approximately 10 patients per sessions.

Results Since the beginning of the psychotherapeutic interventions, re-admissions have been decreased in patients with diagnosis of personality disorder (most histrionic and borderline disorder) with multiple admissions because of suicide attempt, some had been discharged. In another group of patient we have prevented relapses.

Conclusions Psychotherapeutic interventions will be effective in patients with high risk of re-admissions and relapses. It is early to have solid conclusions, but the preliminary results encourage the continuation of the program.

Objective The present study aims to evaluate the effectiveness of cognitive behavioral therapy (CBT) and spiritual-religious intervention in improvement coping responses and quality of life among women surviving from breast cancer.

Methods This was a semi-experimental study. Forty-five breast cancer survivor referred to cancer research center at Shahid Beheshti university of medical Sciences in Tehran, assigned in 3 groups randomly (CBT group, spiritual-religious group and control group). The interventions were eight sessions cognitive-behavioral therapy and spiritual-religious intervention. The participants were evaluated through quality of life questionnaire published by european organization for research and treatment of cancer (QLQ-30C-ver3) and coping responses inventory (CRI). The data were analyzed using covariance.

Finding Although both intervention groups improved in coping and quality of life, it was not statistically significant ($P < 0.08$).

Conclusion Although both intervention groups improved in coping and quality of life but there is no differences between two groups.

Keywords Breast cancer; CBT; Coping responses; Quality of life; Spiritual-religious intervention

Multiple suicide-attempts in adolescence: Psychodynamic understandings on the process of integration of hallucinated bodily experiences

G. Giacomini*, P. Solano, M. Amore

IRCCS, Azienda Universitaria Ospedaliera San Martino, Dipartimento di Neuroscienze, Oftalmologia, Genetica e Scienze Materno-Infantili, Università di Genova, Genoa, Italy

* Corresponding author.

Introduction Suicidal adolescents have a severely damaged body/mind relationship where issues pertaining to adolescence and psychache are tightly intertwined causing dissociation, hallucinations and concreteness. In this conundrum, the suffering mind swings from being identified and split from the body favouring self-harm and bodily together with visual hallucinations.

Objectives Investigating and working through suicidal concreteness together with the role and meaning of hallucinations in adolescents with a story of multiple suicide attempts.

Aims Achieving a first integration and appropriation of the emotional experience with the establishment of the boundaries between mind/body, inside/outside giving up hallucinations.

Methods Prolonged intensive psychodynamic work focusing on self-representation, the working through of persecutory internal objects causing rage, hostility and attacks on the affective links with the environment allowed a gradual process of integration of the self with the decrease of suicidality.

Results The working through and containment of persecutory internal objects led to the possibility to unconsciously give up hallucinations and integrate the emotional experience in the mind together with the development of first effective boundaries between inside/outside.

Conclusions An intense work of containment and working through of persecution and rage in the early stages of the psychotherapeutic treatment of adolescent multiple attempters can significantly favour the relinquishment of hallucinatory mechanisms and self-harm as a way to cope with intolerable anguish and psychache. This favours the process of in dwelling of the psyche in the soma as described by Winnicott.

Cognitive analytic therapy and mentalizing function

E. Gimeno^{1,*}, C. Chiclana²

¹ Faculty of Medicine, University of San Pablo CEU, Department of Psychology, Valladolid, Spain

² Faculty of Medicine, University of San Pablo CEU, Department of Psychology, Madrid, Spain

* Corresponding author.

Introduction Cognitive-Analytic Therapy (CAT) has settled as an integrative approach from Ryle and Kerr's model in the 70's widely accepted in England and Australia, although increasingly European countries have decided to include this model in their public mental health services. Even though its formulation allows the treatment of almost any pathology ensuring good results, it has been traditionally applied to the treatment of personality and eating disorders. Some authors seem to link this efficacy with training in mental states and reciprocal role procedures identification, justifying the improvement through the increase of the reflexive function.

Aim and objectives The aim of this study is to determine the effect of CAT in mentalizing ability and social functioning in patients attending consultation.

Methods For this purpose a CAT intervention was performed in 6 adults, administering the Inventory of Interpersonal Problems (IIP-64) and the Mindful Awareness Assessment Scale (MAAS) before and after treatment.

Results The results show a statistically significant reduction in interpersonal problems, as well as a non-significant increase in the mentalizing ability.

Conclusions Cognitive Analytic Therapy has shown being effective in increasing social functioning, however we have not been able to demonstrate significantly its efficacy in the reflexive function.

Discussion Implications in the clinical setting are discussed.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Centre Hospitalier Intercommunal Poissy-Saint Germain en Laye, Department of Psychiatry, Poissy, France

* Corresponding author.

Introduction Our two units take care of a rather big number of people (about 170 000). Various activities are proposed for outpatients and the idea was expressed to initiate art therapy.

Objectives We first analysed the possibility of starting this new mediation equally in the two units. A team was formed: a clinical psychiatrist and two registered nurses, one being an art therapist as well. We started this activity with a small group of out patients in April 2016.

Aims The registered nurse – art therapist was provided with appropriate space, art material and furniture by hospital sources. The other unit will send the nurse for training in art – therapy: leave and grant are provided by the hospital. Her project is different and yet complementary.

Methods The group was validated and evaluated by the art therapist and the psychiatrist. The organization of the activity is left to the art therapist. A questionnaire was filled out by art therapist before beginning the art therapy and at regular intervals.

Results Patients are engaged by this therapy and come on regular basis. They chose painting to express themselves and leave their productions in the room after they are finished.

Conclusions The newly opened psychotherapy – art therapy has brought many positive changes in our hospital for working staff as well as for the patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Acknowledgements We want to thank the Chiefs of our Department of Psychiatry, Grandin Pascal, MD and Benzaken-Charlier Catherine MD for their acceptance and support of this project.

Object relations and self-esteem in young adults with schizophrenia in long-term psychodynamic group psychotherapy

M. Grah^{1,*}, B. Restek-Petrović², A. Bogović³, N. Mayer², H. Handl⁴, I. Filipčić³

¹ Psychiatric hospital Sveti Ivan, Psychotherapeutic ward for treatment of affective, anxious and dissociative disorders, as well as personality disorders, Zagreb, Croatia

² Psychiatric hospital Sveti Ivan, Psychotherapeutic ward for treatment of psychosis, Zagreb, Croatia

³ Psychiatric hospital Sveti Ivan, Ward of integrative psychiatry, Zagreb, Croatia

⁴ Psychiatric hospital Sveti Ivan, Day hospital for eating disorders, Zagreb, Croatia

* Corresponding author.

Introduction Psychodynamic concepts describe object relations deficits in patients with schizophrenia originating from their earliest developmental stage, which is due to reduced ability of direct caregivers to adequately stimulate the child, as well as genetic factors. During psychodynamic group psychotherapy, members

through psychotherapy gradually release the old family roles and experiment with new models of behaviour and thus change internalized object representations.

Aim The aim of this study was to investigate changes in object relationships and self-esteem in the psychodynamic group psychotherapy in young patients suffering from schizophrenia.

Subjects and methods The study included a total of 41 patients diagnosed with schizophrenia. Before joining the psychodynamic group therapy and after two years of participation in the treatment, all patients completed a test of object relations and the Rosenberg self-esteem scale.

Results Comparison of the results in two time periods showed downward trend results in all tested dimensions of object relations, a statistically significant difference was found for dimension symbiotic fusion: after two years of participation in the psychodynamic group psychotherapy, patients had significantly expressed less need for symbiotic relationships. Self-esteem was higher in the second period of testing, but without statistical significance.

Conclusion Taking into account the limitations of this study, we can conclude that the results are encouraging. During psychodynamic group processes in young patients with schizophrenia there is a trend of positive changes in terms of object relations and self-esteem and a significant reduction in the need for symbiotic merging.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The effectiveness of three psychotherapies of different type and length in the treatment of patients suffering from anxiety disorder

P. Knekt^{1,*}, O. Lindfors², T. Maljanen³

¹ National Institute for Health and Welfare THL, TERO/TESE, Helsinki, Finland

² National Institute for Health and Welfare, TERO/TESE, Helsinki, Finland

³ Social Insurance Institution, Research, Helsinki, Finland

* Corresponding author.

Introduction Data on the comparative effect of short and long-term psychotherapy in anxiety disorder is scarce.

Aim To compare the effectiveness of two short-term therapies and one long-term psychotherapy in the treatment of patients with anxiety disorder.

Methods Altogether 50 outpatients with anxiety disorder as the only axis I diagnosis, were randomly assigned to long-term psychodynamic psychotherapy (LPP), short-term psychodynamic psychotherapy (SPP), and solution-focused therapy (SFT) and were followed for 5 years. The outcome measures were psychiatric symptoms, working ability, need for psychiatric treatment, remission, and cost-effectiveness.

Results During the first year of follow-up, no significant differences in the effectiveness between the therapies were noted. During the following 3 years, LPP and SFT more effectively reduced symptoms, improved work ability, and elevated the remission rate than SPP. No significant differences between LPP and SFT were seen. At the end of the follow-up, the use of auxiliary treatment was lowest in the SFT group whereas remission rates or changes in psychiatric symptom or work ability did not differ between the groups. The average total direct costs were about three times higher in the LPP group than in the short-term therapy groups.

Conclusions The difference in effectiveness of LPP and SFT was negligible, whereas SPP appeared less effective. Thus, the resource-oriented SFT may be a cost-effective option in this selected patient group, while unconsidered allocation of patients to LPP does not appear to be cost-effective. Given the small number of patients,

no firm conclusions should, however be drawn based on this study.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1143

The use of art therapy in complex treatment on the quality of remission in patients with melancholy in major depressive disorder

H. Kozhyna*, V. Korostiy, S. Hmain, V. Mykhaylov
Kharkiv National Medical University, Psychiatry, Narcology and medical psychology, Kharkiv, Ukraine

* Corresponding author.

Introduction According to studies done in recent years regarding the treatment of patients with melancholy in major depressive disorder, a shift of interest from studies evaluating the effectiveness of therapy to the study of remission is seen. Despite significant progress in the development of pharmacotherapy of depressive disorders, difficulty in achieving rapid reduction in depressive symptoms and stable remission in patients with melancholic depression necessitated the search for new approaches to the treatment of this pathology.

Aims Evaluating the effectiveness of art therapy in treatment in patients with melancholy in major depressive disorder on the quality of remission.

Methods The study involved 135 patients – 60 male and 75 female patients aged from 18 to 30 years old. The main group of patients apart the combined treatment also participated in group art therapy with the use of drawing techniques, while the control group – statutory standard therapy.

Results The results of the use of art therapy in complex treatment in patients with major depressive disorder is detected primarily in reducing of the level of anxiety at the early stages of treatment (60% of patients have noticed decreasing of melancholic state), as well as improving the quality of life in remission period.

Conclusion These results support the use of art therapy in treatment in patients with melancholy in major depressive disorder during period of active treatment, and after achieving clinical remission contributes to achieving and maintaining high-quality and stable remission with full restoration of quality of life and social functioning.

Pollyanna syndrome in psychotherapy-or pseudotherapy. Counseling, consoling or counterfeiting?

B. Latecki

Life Empangeni Private Hospital, Psychiatric private practice, Empangeni, South Africa

Pollyanna syndrome, the name being taken from a book of the same title, means “an excessively or blindly optimistic person.” The occurrence and danger of such attitudes in psychotherapy is discussed. Such attitudes may occur both in patients and their therapists. Either of them may say “things will not be so bad...” attempting to console not him/himself but the other party. The main aim of psychotherapy is to facilitate taking responsibility and decisions. But there are also other aims, identical to those attributed to philosophy in ancient times, namely, “to treat the soul” or, clinically speaking, to provide consolation. This is usu-

ally achieved by attributing meaning and purpose to suffering and set-backs. In the paper, I discuss how the therapist could avoid the trap of being and coercing the patient to be “optimistic, positive, and strong” when the situation does not necessarily warrant such an attitude. Philosophy may be of help here. One may apply theodicy, that is, the philosophical attempt to explain and justify the evil existing in God’s world. Another possibility is Ericksonian approach of utilization, paradoxical intervention, using metaphors and hypnotic techniques in order to let the patient come up with his own, intimate resources facilitating recovery. Logotherapy, which is an existential approach is recommended, either as such or as a part of REBT. In short, the difference between an ineffective and an effective approach is the difference between being optimistic and being realistic.

Attempting reconciliation with cross-examination in couple therapy

B. Latecki

Life Empangeni Garden Clinic, Psychiatric Private Practice, Empangeni, South Africa

Many traps and conflicts can be encountered by the therapist trying to facilitate communication and to promote agreement between couples or between an angry teenager and his/her parent. The cross-examination technique is a useful tool in such situations. It involves humour but it is also confrontational, it shifts the burden of initiating and continuation of the dialog onto the parties involved, it teaches responsibility, respect and sensitivity to the other’s points of view and, after exposing the “sore points”, it leaves the couple in a position to discuss possible solutions. Elements of other psychotherapeutic approaches (mirror technique, paradoxical intentions, empty chair technique, Ericksonian approach) are included as well. Elements of logic aimed at recognizing the fallacies and assumptions between the couple are also used.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

EV1146

Clinical usefulness of confrontations in the initial interview

Z. Barac-Otasevic

Clinical Center of Montenegro, Psychiatry clinic, Podgorica, Montenegro

Principal objective of this work is to illustrate the clinical usefulness of confrontations in the initial interview. Balint, Kernberg, Sullivan, Fromm-Reichmann are the authors, among many of them, who pointed out importance of the initial interview and the consequences of the interview for the future psychotherapeutic work. Initial interview represents two persons; therapist and person who needs help who meet for the first time and do not know anything about each other. Interaction between therapist and the patient through communication is a major source of information about potential patient in the initial interview. The nature of disorder, capacity of motivation for psychotherapy can be evaluated in the current interaction with the person who needs help. Confrontation is a routine technique in psychoanalysis and psychotherapy, unilateral and potentially dangerous, especially when working alliance is not established and that is the case in the initial interview. Purpose of confrontation in the initial interview is to collect information about patient, his psychopathology, his structural personality features, presence of defensive operations, capacity and motivations to work and what kind of psychotherapy is best suited for him.

Confrontation can be very harmful so it requires tact, patience and timing. Incorrect use of confrontations which are poorly conceptualized, premature could stop the flow of the material, make sense of chaos in the interview, increasing anxiety and risk the possibility of leaving interview.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Roll of the third wave therapies in the treatment of schizophrenia

L. Asensio Aguerri*, L. Nuevo, B. Mata, E. Segura, E. Lopez, F. Garcia

Doctor, Psychiatry, Ciudad Real, Spain

* Corresponding author.

Introduction The schizophrenia is a frequent mental disorder. The symptoms affect the emotions, cognition, perception and other aspects of the behaviour. In the last years have been developed different interventions and psychological treatments in order to improve the personal and social functioning of these patients. Among the new proposals is the called “third wave”.

Objectives Determine the efficacy of third generation therapies in the treatment of schizophrenia.

Methods We have performed a systematic review of the existing bibliography in PubMed/Medline, Cochrane and Dialnet, using the combination of different keywords “acceptance and commitment therapy, mindfulness, psychosis, schizophrenia, third wave of therapies, based cognitive therapy”.

Results The based cognitive therapy for the psychosis (CBT) was designed for the treatment of the residual symptoms of schizophrenia, however in the present there are over 30 randomized trial publications were is evaluated the efficacy of CBT in psychosis, on positive and negative symptoms, functionality and affectivity. It is most effective in acute episodes.

Conclusions The treatment with the third generation therapies reduces the positive symptoms of schizophrenia and improves depressive and anxiety symptoms. The CBT and the mindfulness are the most studied. There are scientifically therapeutic options for the treatment of patients with schizophrenia in combination with pharmacotherapy.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1148

The introduction of psychotherapy in psychiatric outpatients in the last four years in a Greek hospital

G. Lyrakos*, D. Menti, I. Spyropoulos, V. Spinaris
General Hospital Nikaia “Ag. Panteleimon”, Psychiatric, Nikaia, Greece

* Corresponding author.

Introduction The use of psychotherapy is an important part of treating psychiatric disorders, in combination with medication taking. However, despite its importance, psychotherapy is still underused from individuals with psychiatric problems in Greece.

Objectives To examine the use of psychotherapy, among psychiatric outpatients, in the last four years.

Aims To investigate whether there are differences in the use of psychotherapy, in combination with medications, to treat psychiatric disorders, from 2012 to 2015.

Methods In this study participated 5,551 patients, 2,760 males (49.7%) and 2,791 females (50.3%). The mean age was 45.54. Convenience sampling method was used and participants were recruited

from the General Hospital of Nikaia, 'Ag. Panteleimon', in Athens, Greece, from 01/01/2012 to 31/12/2015. SPSS software was used to analyse the data.

Results There were significant differences between the four years (2012–2015) with regard to the use of psychotherapy, in combination with medications, from psychiatric patients as χ^2 (21): 753.057, $P < 0.001$. More specifically, only 0.1% of psychiatric patients undertook psychotherapy in addition to taking medications, in 2012, and this increased to 2.7%, in 2013, 13.8% in 2014 and 18.6% in 2015.

Conclusions There was an increase in the use of psychotherapy, in combination with medication taking, during the four last years, from 2012–2015. However, the percentage of patients undertaking both psychotherapy and taking medications is still low. This has important clinical implications as the use of psychotherapy plays a significant role in achieving optimal health outcomes of psychiatric patients.

Countertransference in psychotherapy of paranoid patients

S. Manojlovic*, J. Nikolic-Popovic

University of Nis, Faculty of Medicine, Psychiatry, Nis, Serbia

* Corresponding author.

The complexity of psychotherapy is based on the very nature of the paranoid process. The therapist must not only have a good understanding of the paranoid process, but also needs to be especially careful regarding the transference-countertransference emotions. Long-standing experience in psychotherapeutic work with paranoid patients, in the individual and group setting, has enabled us to systematize countertransference reactions. Dominant projective mechanisms require a high ability to contain emotions from the therapists. The most prominent is aggression, in regard to which the countertransference feelings appear, ranging from aggression to exposedness, impotence, and victimization. The therapist must constantly separate feelings which represent his "blind spot" from those which he perceives as a patient's part in therapist himself. The latter countertransference enables the therapist to experience the internal object of the patient by the mechanism of projective identification. Beside the aggression, the feelings from the narcissistic spectrum related to topics of value, competence, rivalling, idealization, and devaluation represent a significant countertransference problem. The countertransference feelings in group psychotherapy are of lower intensity, and rarely focused on the therapist himself. In the group, there is also the possibility of significant intensification of the projection of aggression, when the whole group is focusing the projections onto the therapist. In the group milieu, commonly emphasized countertransference feelings are related to the position in the group, competence, autonomy, and dependence. The understandings and way of coping with countertransference emotions determine the potential for creating the safe emotional ground in psychotherapy.

Comparisons of narrative psychotherapy to conventional CBT for the psychotherapy of psychosis and bipolar disorder

L. Mehl-Madrona^{1,*}, B. Mainguy²

¹ Eastern Maine Medical Center, Family Medicine Residency, Bangor, USA

² Coyote Institute, Education, Orono, USA

* Corresponding author.

Introduction There is ongoing debate about both the value of psychotherapy in psychotic disorders and the best type of psychotherapy to use if necessary.

Methods We conducted narrative psychotherapy with 18 adults, all diagnosed as having bipolar disorder with psychotic features and/or schizo-affective disorder. Outcome data consisted of the Positive and Negative Symptom Scale, the Clinical Global Impressions Scale, the Young Mania Rating Scale, the Hamilton Anxiety and Depression Scales, the My Medical Outcome Profile, Version 2 (MYMOP2), and the Outcome Rating Scales of Duncan and Miller. We compare the outcomes of our patients to those of a matched comparison group receiving conventional psycho-education and cognitive behavioural therapy. Patients were seen for a minimum of 16 weeks over an average of 22 weeks. Average age was 31.5 years with a standard deviation of 8.1 years.

Results The narrative therapy group showed statistically significant reductions in all outcome measures compared to the conventional treatment group. They continued treatment significantly longer and had fewer re-hospitalizations. They were less distressed by voices.

Conclusions A narrative psychotherapy approach using dialogical theory and therapy ideas is a reasonable approach for the psychotherapy of psychosis. Review of psychotherapy notes showed that narrative approaches allowed the therapist to align with the patient as collaborator in considering the story presented and was therefore less productive of defensiveness and self-criticism than conventional approaches. The therapy included techniques for negotiating changes in illness narratives, identity narratives, and treatment narratives that were more conducive of well-being and recovery.

System of integrative psychotherapy of somatoform and psychosomatic disorders patients

B. Mykhaylov^{1,*}, O. Kudinova²

¹ Kharkov medical academy of postgraduate education, Psychotherapy, Kharkov, Ukraine

² Kharkiv medical academy of postgraduate education, Psychotherapy, Kharkov, Ukraine

* Corresponding author.

The main goal of the investigation was the integrative psychotherapy system established. On the basis of the examined 350 patients with somatoform disorders and 250 patients with chronic psychosomatic diseases, we have elaborated a test that allows to evaluate quantitatively the influence of the disease on patients' social functions. We created the integrative psychotherapy system with cognitive-oriented, suggestive and autosuggestive implementations. Elucidation of peculiarity of personal perception of the disease served as basis of elaboration of purposeful system of psychotherapy, consulting, and psychological support for psychosomatic patients with high-effectiveness 1.5–3 years catamnesis in 85% patients. Psychotherapy should be used first of all as a target-oriented. Our experience showed the necessity of the use the integrative models of psychotherapy, parted on stages. On the first stage, the receptions of cognitive and suggestive psychotherapy are used. There is group therapy on second stage. On the third stage elements of the autogenic training mastered. The system examination high efficacy was shown.

* Corresponding author.

EMDR therapy is a new approach to psychotherapy that uses alternating bilateral stimulation, either through the movement of the eyes or through auditory or cutaneous stimuli, to induce rapid resolution of symptoms related to past events. The protocol of EMDR therapy is based on a set of principles that are essential to a humanistic and integrative approach to medicine and health: confidence in the self-healing capacity of each individual, the importance of history personal approach, a person-centered approach, restored power, the importance of mind-body bonding, well-being and performance improvement. Several controlled studies have demonstrated the remarkable effectiveness of EMDR therapy for post-traumatic stress disorder resolution. Indeed, to date, EMDR therapy is one of the best documented methods of treating post-traumatic stress disorder in the scientific literature. We report here the clinical case of a young lady with post-traumatic stress disorder complicated by depressive disorder, on borderline personality, and as comorbidity a polyaddition to tobacco, alcohol and cannabis, and in whom EMDR therapy proved its efficacy in the management of her disease, enabling her to return to a better life.

Time perspective in multiple sclerosis patients: Looking for clinical targets for psychological interventions

E. Nikolaev^{1,*}, N. Vasil'eva²

¹ Ulianov Chuvash State University, Cheboksary, Russia

² Chuvash Republic Clinical Hospital, Cheboksary, Russia

* Corresponding author.

Introduction Interaction with time is a fundamental human characteristic that varies significantly in situations of severe chronic disease. Multiple sclerosis (MS) refers to medical conditions with severe damage to the nervous system, which have poor prognosis for patients.

Objectives and aims To explore the relation between clinical variants of multiple sclerosis and time perspective in MS patients for goals of psychological interventions.

Methods A total of 104 MS inpatients (25 men and 79 women aged 19 to 64) filled out Russian version of Zimbardo time perspective inventory (ZTPI) developed by A. Sircova, E.T. Sokolova, and O.V. Mitina, 2008. Seventy-three patients were diagnosed for relapsing-remitting multiple sclerosis (RRMS) and 31 patients for secondary progressive multiple sclerosis (SPMS).

Results Analyzing the difference in ZTPI values in MS patients one could notice that RRMS patients showed a greater focus on positive past, while SPMS patients indicated a higher priority on the future. No gender specifics were identified in MS patients with different clinical variants of the disease ($P > 0.05$).

Conclusions The data revealed could be related to the fact that SPMS patients having more severe clinical variant of MS were forced to the issues of living with the disease planning. They were

ready to assess and to prepare for possible negative consequences of the disease. They also sought the most efficient use of available resources for their own future and future of their loved ones. The resulting evidence can be used to determine clinical targets for psychological interventions in MS patients.

Music orchestrating health feelings and senses given to the music present at the hospital during hemodynamic procedures: Cardiac catheterization and coronary angioplasty

S. Paiva^{1,*}, F. Rezende¹, J. Moreira²

¹ Hospital SEMPER Permanent Medical Services, Angiosemper,

Department of Cardiology and Hemodynamic, Belo Horizonte, Brazil

² PUC Minas, Pontificia Universidade Católica de Minas Gerais,

Department of Psychology, Belo Horizonte, Brazil

* Corresponding author.

Several studies indicate that music has soothing effects and is effective for reducing stress and anxiety in coronary patients. The effects of stress on the cardiovascular system have also been proven. However, the meanings assigned to music when used during hemodynamic procedures are unknown, as are the meanings of the experience of these procedures. The aim of this research is to understand the senses and feelings of music for patients undergoing hemodynamic procedures, identify and interpret the fantasies and emotions related to, and study the possibility of deploying in hospitals the "Musical Method for Hemodynamic Procedures", being developed by the author. This research is based on a clinical-qualitative methodology. The sampling method is the theoretical saturation. The semi-structured interview was used in order to obtain data that was submitted to content analysis. The subjects are patients undergoing hemodynamic procedures in hospital SEMPER, Brazil. We conclude that within the experience of listening to music while undergoing catheterisation 100% of the patients claimed they had overcome the experience of stress and felt calm, tranquillity, peace and happiness. Some patients described the music as a companion, as something that diverts their attention from fear, transporting them to an imaginary place, to another dimension. The episodic memory, the capacity to recognize a musical excerpt for which the spatiotemporal context surrounding its former encounter can be recalled, was also important, with surprising results in the case of patients who underwent catheterisation in the presence of music and, later, angioplasty without the presence of music.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1155

The specifics of psychotherapy of nuns

A. Pastuszek-Draxler^{1,*}, M. Jawor²,

B. Bętkowska-Korpała¹, J.K. Gierowski¹

¹ Jagiellonian University Medical College, Chair of Psychiatry,

Institute for Medical Psychology, Cracow, Poland

² Clinic of Psychiatry, University Hospital, Ward for Treatment of Emotion and Mood Disorders, Cracow, Poland

* Corresponding author.

Introduction Nuns undertaking psychotherapeutic treatment are a particular group of patients. As human beings, they experience similar emotions, everyday worries, crises and difficulties as everyone else during social interaction, but at the same time they fill a

special role in society. Presented behaviours, reactions to stressful situations, unaccepted emotional states that appear to be maladaptive, are often intensified by the rules of monastery life.

Objectives The aim of this investigation was to uncover the most significant issues in terms of the specificity of therapeutic work with nuns.

Methods The subjects were 12 patients (nuns) with the diagnosis of depressive-anxiety disorder (F41.2 according to ICD-10 criteria). Over the course of the last 10 years (since 2005) we observed the therapy processes of 12 nuns. The psychotherapy group consists of 12 patients at our ward. Every time there was only one nun in the group.

Results This study gives an overview of issues and problems reported by the nuns: their sex significantly determines their position in the community of consecrated sociality, their obligations to perform specific work, the rules to follow as well as the resulting consequences for the functioning of mental health.

Conclusions In the process of psychotherapy is important and necessary to distinguish between theological and psychological aspects, between what is secular and what is spiritual. The psychotherapy group's as well as the therapist's perception of a nun is of special importance as it is sometimes difficult to distinguish between her social role and her needs, desires, difficulties and conflicts as a human being.

Outcomes assessment: Psychometric properties of the Spanish adaptation of the outcome questionnaire (OQ-45)

P. Penas*, I. Iraurgi, S. Gorbeña, B. Matellanes, M. Montero
University of Deusto, Department of Psychology, Bilbao, Spain
* Corresponding author.

Introduction The outcome questionnaire (OQ-45) has been one of the most frequently used instrument to measure clinical outcomes in psychotherapy. Probably due to its subscale structure, its applicability for a variety of disorders and life struggles, its sensitivity to change by repeated measurements and its predictive ability. Given its popularity, OQ-45 has been translated into several languages.

Objective As the Spanish version has not been published, through this poster it is going to show the reliability and the dimensional structure of the OQ-45.

Method One hundred and thirty-nine patients in clinical settings have completed the Spanish version. Three different confirmatory factor analysis have been calculated to analyze the construct validity.

Results The Cronbach Alpha of the instrument was adequate .92, but also, in the three dimensions: symptoms distress (.90), interpersonal relations (.78) and social role (.66). Through the CFA was proved that the Four-factor bi-level model structure [$\chi^2_{(900)} = 3930.47, P < .001, AGF = .86, CFI = .91, RMSEA = .061 (.049 \text{ to } .073)$] suited appropriately, in fact, more properly than the three-factor correlated or the three-factor with a second order factor models.

Discussion The three-factor bi-level model structure of the OQ-45 is confirmed indicating an empirically and clinically relevant measure of client functioning. In this model each item loaded on one of the three subscales originally created. Besides, each item also captures common variance represented by the general factor of overall maladjustment, where this factor may indicate the degree to which respondents are functionally impaired. Thus, OQ-45 is an instrument that could be used for monitoring treatment efficacy and for making informed decisions about clinically significant changes.

* Corresponding author.

Introduction Most reactions to grief are adaptive. However, there is the possibility that some individuals present a complicated grief disorder, where there is a pathological intensification of symptoms lasting more than 6 months, deserving special treatment.

Objectives/aims Evaluate the effectiveness of two types of intervention in complicated grief: group intervention (GI) and cognitive-narrative (CN) therapy.

Methods Patients in a complicated grief process were selected ($n = 70$), and distributed in three groups: cognitive-narrative therapy group (CNTG), group intervention group (GIG) and a control group (CG). Inclusion criteria: adults, with a reference to mourning situation, with personal meaning, for over six months and results in ICG ≥ 30 points (cutoff). The Inventory of Complicated Grief (ICG), the Center for epidemiologic studies depression scale (CES-D) and the trauma questionnaire (ICD-11) were used. Follow-up was performed 3 months after the end of each intervention. Data analysis was performed using the statistical package from social sciences (SPSS 20).

Results With respect to complicated grief symptoms (CGx) and depression symptoms (Dx) there were statistically significant differences between the CNTG and the CG, but not with the GIG. There was no statistically significant effect in post-traumatic symptoms (PTx), even though both interventions had a slight decrease. When the CNTG and the GIG were directly compared, there was only a statistically significant difference between PTx.

Conclusions In our single center cohort, CNTG was a more effective intervention in complicated grief patients for CGx and Dx reduction. For PTx, no intervention was superior. Larger multi-center studies are needed to validate these results.

EV1158

Cognitive behavioral therapy and acceptance and commitment therapy as augmentation treatment for paediatric autoimmune neuropsychiatric disorders associated with streptococcal infections (PANDAS): A case report

A. Pozza

University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy

Introduction Paediatric autoimmune neuropsychiatric disorders associated with streptococcal infections (PANDAS) are a subgroup of conditions including obsessive-compulsive disorder (OCD), tic disorders, pre-pubertal and sudden onset, temporal association between streptococcal infections and associated neurological abnormalities. Some strategies were developed, including the use of antibiotic prophylaxis to prevent streptococcal-triggered exacerbations, and immunomodulatory interventions for the man-

agement of acute symptoms. Cognitive-behavioral therapy (CBT), which has been demonstrated to be the first-line treatment for OCD, can be a valid adjuvant during the difficult course of PANDAS to target acute symptoms and prevent exacerbations.

Objectives The study presented a case of a patient with PANDAS treated with antibiotic medication and CBT as augmentation.

Methods The 11-year-old patient (Y-BOCS pre-test score = 32), had been hospitalized for three weeks for acute onset of PANDAS. The clinical picture consisted of asthenia, contamination fears and washing compulsions, separation anxiety, severe depression and anxiety. Pharmacotherapy involved risperidone 2 mg/die and sertraline 250 mg/die for five months combined with antibiotic prophylaxis for two years. The CBT intervention started at discharge from hospital and included psycho-education on anxiety, intensive exposure and response prevention (2 hour sessions three times a week) for twelve months, cognitive restructuring, diffusion and mindfulness for the subsequent twelve months.

Results Anxiety and OCD symptoms substantially improved. The patient gradually started school again. Post-test score was 11 on the Y-BOCS.

Conclusions Along with psychiatric and antibiotic medications, CBT may be a valid augmentation strategy for PANDAS to reduce risk of exacerbations and enhance symptom improvement. Limitations are discussed.

* Corresponding author.

Background Supervision is the systematic guidance of a therapist by a supervisor. It is a basic part of training and ongoing education in cognitive behavioral therapy (CBT). Self-reflection and ethical reflection are an important part of supervision.

Method The Pubmed database was searched for articles using the keywords supervision in CBT, therapeutic relations, ethics, transference, counter transference, schema therapy, dialectical behavioral therapy, acceptance and commitment therapy.

Results We discuss conceptual aspects related to supervision and the role of self-reflection and ethical reflection. The task of supervision is to increase the value of the therapeutic process in the client's best interest. Establishing the supervisor-supervisee relationship is based on principles similar to those in the therapeutic relationship. Additionally, supervision is oriented towards increasing the therapist's competencies. The CBT therapist's core competencies involve good theoretical knowledge, professional behavior towards clients, ability to use specific therapeutic strategies for maintaining the therapeutic relationship, sensitivity to parallel processes and accomplishment of changes, and adherence to ethical norms. Given the fact that during supervision, the supervisee may be at any stage of his/her training, supervision must take into consideration where the therapist is in his/her training and development and what he/she has or has not learnt.

Conclusions Both the literature and our experience underscore the importance of careful supervision of cognitive behavioral therapy. Numerous approaches are used in supervision, which is

associated with the abilities to self-reflect and to realize transference and counter transference mechanisms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Educational objectives Psychotherapy is the most preferable intervention for personality disorder patients and group psychotherapy offers the possibility to increase the self-perception through resonance and mirroring processes. When a group is disorganized and emotionally tensioned generates regressive movements, which make it a basic assumption group.

Purpose To highlight the change of a group of patients after the inclusion of a new patient named Margherita.

Methods The patients were included within the group run by two psychotherapists after a cluster B personality disorder's clinical diagnosis (except for antisocial personality disorder), confirmed by SCID II and by a set of individual interviews aimed to prepare the patient to the inclusion within the group.

Results Margherita, from the first sessions, showed the tendency to coercively polarize the attention on herself through themes of discouragement and helplessness, posing a threat for the members' identity and resulting in a disorganization of the work group, which became a basic assumption group.

Conclusions The temporary disorganization of the group with the consequent regression to a worse functioning condition has subsequently allowed to revitalize the group and to avoid its dissolution. After the temporary regression, indeed, the work group was restored and started again to function even based on the new patient's problems.

Why do I have to die twice? EMDR treatment after experience of clinical death

R. Softic*, E. Becirovic, M. Mirkovic Hajdukovic

University Clinical Center Tuzla, Psychiatry Clinic, Tuzla, Bosnia and Herzegovina

* Corresponding author.

Background Clinical death is etiologically non-specific state of reversible cessation of blood circulation and breathing, the two necessary criteria to sustain life. Serious consequences in form of anxiety and/or depression can remain after recovery.

Case report Male patient 55 y/o with no prior history of psychiatric difficulties, who experienced clinical death after cardiac infarction. Reanimation was successful and he was discharged with minimal if any cardiac consequences. During the hospitalization in Coronar unit he reacted with major depression, and aftermath with debilitating anxiety and panic attacks followed by avoidant behavior, obsessive thoughts, social withdrawal, and consequently, very poor quality of life, regardless of the favorable outcome of somatic (cardiac) illness. The patient did not want psychiatric

medications, so EMDR treatment was introduced. We assess negative cognition: why do I have to die twice? “Subjective unit of disturbance regarding the traumatic event (SUD) was 9”. Adhering to the EMDR protocol, the therapist helped the patient to re-process the traumatic event (the very moment when he was told that “he was died”). Complete desensitization and reprocessing were accomplished, SUD was 0, VoC was 7. Patient reached pre-morbid level of psychosocial functioning, doing his demanding job, and enjoying his social life.

Conclusion Near death experience has high traumatic potential with serious psychological consequences. EMDR is efficacious treatment for variety of anxiety disorders caused by psychologic trauma due to physical illness.

Keywords EMDR; Clinical death; Panic disorder

The use of “pliable media” in promoting symbolization in the psychoanalytical psychotherapy of psychosis

P. Solano^{1,*}, L. Quagelli²

¹ *Clinica Psichiatrica, Neurosciences, Section of Psychiatry, University of Genova, Genoa, Italy*

² *Paris VII-Diderot University, Recherches en Psychanalyse, Paris, France*

* *Corresponding author.*

Introduction In psychosis, the capacity of symbolization is lost to different extents and patients live in a concrete world of objects. Moreover, the lack of boundaries between self/other, inside/outside severely impairs the capacity of these patients to understand and recognize reality from the delusional dimension.

Objectives Working through psychotic concreteness and accessing a first subjectivation of this experience, that leads to the development of a first symbolization.

Aims Achieving the possibility to access a first symbolization and begin a delicate process of appropriation of the emotional experience with the establishment of the boundaries between inside/outside.

Methods The use of “pliable media”, such as drawing, as therapeutic mediation allows a partial defraction of the violent transferential dynamics from the therapist and let unsymbolized material to emerge less destructively in the treatment fostering a first figurability.

Results The Squiggle game as “pliable medium” facilitates a first encounter in the therapeutic relationship and represents a primal transitional area that allows a gradual working through process to take place where the establishment of the boundaries between inside/outside could begin.

Conclusions We suggest that the use of “pliable media” in the early stages of the psychotherapy of psychotics can significantly favor a first encounter between patient and therapist and, at the same time, provides the first experience of a transitional space where a working through process leading to first representations can take place.

EV1163

Interoceptive exposure at the heart of emotional identification work in psychotherapy

A. Suchocka Capuano^{1,*}, A. Karar¹, A. Georjin², R. Allek², C. Dupuy², S. Bouyakoub¹

¹ *Centre Hospitalier Intercommunal de Villeneuve Saint-Georges, Consultations de Psychiatrie, Villeneuve Saint-Georges Cedex, France*

² *Université Paris 8, Psychology, Vincennes, Saint-Denis, France*

* *Corresponding author.*

Introduction Emotional avoidance is a target process, offered by modern psychotherapies. Emotional exposure is often difficult to put in place when there is a major cognitive and behavioral avoidance. Education on emotional processes is necessary but often insufficient during individual follow-up.

Objectives The longitudinal study seeks to verify whether work on exposure and emotional identification influences the decreased level of anxiety and depression.

Aims Introduction of interoceptive exposition in psychotherapy decreases the frequency of emotional avoidance.

Method Group psychotherapy composed of two modules: interoceptive exposure and emotional identification was proposed to patients with anxiety and depressive disorders. A group of 6 participants was evaluated at three times: T0 before the start of the group, T1 post-module 1 and T2 post-group. Assessments of HAMA anxiety, MADRS depression, QEC cognitive avoidance, UPPS impulsivity, MCQ-30 metacognition and emotional regulation REQ-21 have been proposed.

Results Significant differences were observed between pre- and post-intervention scores (Friedman test). The HAMA anxiety rate ($P=0.006$) and the MADRS depression ($P=0.047$) decreased. Participants in the group were less likely to use QEC thought substitution ($P=0.009$) and urgency in their UPPS reactions ($P=0.03$). Moreover, their external dysfunction REQ. 21 decreases ($P=0.03$).

Conclusion Faced with emotional avoidance, work on emotional identification requires prior interoceptive exposure. It is a first stage of work that involves sensitizing to the presence of emotional bodily sensations. Group work facilitates exposure to emotion and its identification; deceleration leading to emotional intensity decrease. The work on the interoceptive exhibition facilitates the emotional exposure while participating in the deactivation of the associative emotional network.

Borderline personality disorder – dilemmas and therapeutic challenges

G. Tasic^{1,*}, S. Anakiev²

¹ *Special hospital for psychiatric diseases “Gornja Toponica”, Department of psychosociorehabilitation treatment, Nis, Serbia*

² *Special hospital for psychiatric diseases “Gornja Toponica”, Male admission department, Nis, Serbia*

* *Corresponding author.*

Treatment of borderline personality disorder has some specifics relative to other disorders, which are deriving from nature and structure of those people. Treatment is very slow, often with interruptions, and it presents a special challenge for contratransferal feelings but at the same time offers a possibility of continuous learning, for the patient and the therapist. Main characteristics of this personality disorder are the diffusion of identity, primitive defence mechanisms concentrated around the cleft and relatively preserved ability to rest reality. As classical psychoanalysis and psychoanalytical psychotherapy did not give results in therapy of this

disorder, Otto Kernberg took its basic techniques but used them adjusted for borderline personality disorder, developing so called transfer focused psychotherapy. This paper will present the main principles of this modification, applied in practice.

Keywords Borderline personality disorder; Transfer focused psychotherapy; Therapy principles.

Psychosomatic inpatient treatment achieves in the medium term sustainable clinical improvement as well as a reduction in utilization of medical services-results of a one-year follow-up

J. Valdes-Stauber^{1,*}, S. Merath¹, S. Krämer²

¹ Zentrum für Psychiatrie Südwürttemberg, Department for Psychiatry and Psychotherapy I- University Ulm, Ravensburg, Germany

² General Practitioner, Private practice, Waldburg, Germany

* Corresponding author.

Background The research on sustainability of effectiveness of inpatient psychosomatic treatment is necessary for epidemiological and economic reasons as well as towards their legitimacy.

Objectives and aims To investigate whether the achieved clinical improvement by the inpatient treatment continues one year after discharge and whether the utilization of medical services display a significant reduction post-discharge compared to the year before admission.

Methods Naturalistic 1 year follow-up study of a cohort ($n = 122$). Three measuring time points: T1 (discharge), T2 (6 months after discharge; drop-out rate about 33%), T3 (12 months after discharge; drop-out rate about 49%). Assessment by means of standardized tests of changes in clinical variables, self-efficacy, quality of life, and personality between discharge and one year after discharge. Utilization variables (hospital days, days of incapacity, medication and doctor visits) were compared with ranges in the year before admission.

Results Improvements at discharge in general functionality, psychological and somatic stress, depressiveness, bitterness level, quality of life and self-efficacy remain one year after discharge sustainably. Furthermore, hospital days, days of incapacity, number of doctor visits and of prescribed drugs decreased significantly in comparison with the year prior to admission.

Conclusions Inpatient psychotherapy is effective not only in short-term but also in medium-term. One year after discharge clinically improvement at discharge time-point remains stable and the utilization of medical services decreased significantly. Longer periods of observation, identification of risk groups and of resilient prognostic factors, as well as ensuring post-discharge care are necessary in order to prevent relapses and to made early interventions.

Cognitive behavioral therapy in Internet addiction – A case series

D. Vasile^{1,*}, O. Vasiliu¹, D.G. Vasiliu², F. Vasile³

¹ Central University and Emergency Military Hospital “Dr. Carol Davila”, Psychiatry, Bucharest, Romania

² Coltea Clinical Hospital, Internal Medicine, Bucharest, Romania

³ University of Medicine and Pharmacy Titu Maiorescu, General Medicine, Bucharest, Romania

* Corresponding author.

Internet use increased significantly in the last decade through the development of portable technologies, like laptops, smart-phones, tablets etc. Time spent on Internet could become a problem for many users, some of them reporting a sense of control loss, as they begin to stay more on-line than they initially wanted. Gaming, shopping, gambling, social networking, visiting pornographic sites, e-mailing, all these activities could transform an apparently inoffensive mean of communication into the trigger of a behavioral addiction. We applied individual cognitive-behavioral therapy (CBT) in three cases of Internet addiction, with cognitive re-structuring based on a diary of dysfunctional thoughts, relaxation techniques, and coping skills training, with good results. CBT was structured in bi-weekly sessions, of 30 minutes duration, for 6 weeks. Time spent on-line and daily functioning were the main variables monitored. A very important issue is to address all potential factors that could maintain the disorder, like social skills deficits, personality disorders, other co-morbid addictions, anxiety or depressive symptoms etc. Elements of motivational interview could be helpful especially at first visit, but also during therapy, when danger of relapse surfaces. Cue exposure with prevention of response is another technique that had proven itself useful in several sessions, when automatic thoughts challenge appeared to have reached a dead point. An informant like a close relative of the patient should be involved in the therapy whenever possible, due to the fact that Internet addiction therapy, like any other addiction therapy, need a third party to offer feed-back regarding patient's changes under treatment.

This study is focused on presenting the quality level of the life of parents with disabled children and the determination if there are any differences between parents that are in a treatment process and those that have just started this treatment for their children. Another aspect where this study is focused, are the indicators of life quality. A sample made by disabled children parents ($n = 100$), who are in “QKZHMT” center in Kombinat and PLM in Vlora, underwent the measuring instrument with a total of 40 self reporting allegations as well as, they became part of the focus groups how they present differences in applied conditions of the compound factors of life quality. In this study the research question was: “are there differences in the reported levels of parents with disabled children life quality who have just started the children treatment program with those who have started it six month ago?” Part of the quality focus was: “the differences and similarities exploration of the parenting experience of the parents with disabled children”. These conclusions were reached, affected by the comparative statistical analysis conducted in this study, that there are no

statistical differences reported as well as in the overall life quality level as in its compound factors for both groups. The same result applies for the gender differences.

³ Sismanoglion Hospital, Surgical Department, Komotini, Thrace, Greece

* Corresponding author.

Introduction Quality of life at work has very much to do with educational efforts during medical residence years. Constant changes of work environment for general practice residents, is a strong reason for high levels of stress at work.

Objectives Our study is to present the general rules of work for general practice residents in surgical departments in Greece and the quality of their lives and career motivation.

Methods We use information coming from two hospitals, a large city hospital which covers a population of 780.000 of citizens during all-night duties, and a provincial hospital, which covers a population of 50.000 citizens.

Results In both workplaces, general practice residents spend much of their education time in the emergencies department or the outpatient clinics of surgery. Stress is more intense in the large hospital, based on the number of patients examined per day and the frustration they receive at work. However, the heavy duty to accompany a patient for a transfer to other hospital is much more often in province, and then the stress is much more intense and lasting. Frustration is also often in the urban hospital where the residents of various specialties are more experienced and have more confidence due to their departments expertise. Satisfaction at work varies according to the personality of every doctor.

Conclusions Opportunities for scientific development through participation in scientific meetings was stronger in the provincial Hospital due to a good team of strongly motivated researchers that happened to be there and better work environment.

First episode psychosis service (EPS): Evaluation of implementation in a rural Australian setting

D. Roy

The Prince Charles Hospital Metro North Health Services, Acute Care Team, Department of Psychiatry, Chermside, Australia

Introduction Recent decades, has seen an increasing focus on developing specific early or first episode psychosis services, in various parts of the world. There has been a growing awareness of the emotional impact of psychosis like trauma at onset, suicide and loss of social network. There is also a co relational link between the duration of untreated psychosis (DUP) and outcomes. The first

2–3 years following first episode onset have been argued to be a critical period for treatment.

Method Our study was an evaluation of an early psychosis service (EPS) in a rural Australian MHS 'experiencing' or 'at risk' of experiencing first episode psychosis. The guidelines were based on the Australian clinical guidelines for early psychosis (1998). The audit tool used was a checklist based on 10 treatment guidelines developed by the EPS special interest group evaluation sub-committee.

Results The overall results show that 7 out of the 10 treatment guidelines were well adhered throughout the implementation process. Guidelines strongly adhered to were numbers 2, 3, 5, 6, 7, 8, and 10, whereas guidelines 1, 4, and 9 were poorly adhered to.

Discussion The implementation process was found to be generally effective. The factors that influenced the effectiveness will be discussed in the poster.

Conclusion There were a number of trends when we looked at the overall results which included aspects of the guidelines that were done well and aspects that needed improvement which will be further discussed in the poster.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Introduction Schizophrenia is a severe mental disorder with a relatively high toll on the quality of life of the patient and caregiver. It has a high financial, emotional and psychosocial burden. Surprisingly, optimum academic and educational outcomes in individuals with schizophrenia have been a neglected area of research and service provision.

Objectives Development of an interview schedule assessing the helpful and hindering factors affecting the educational attainment in persons with schizophrenia.

Methods Twenty-one participant were recruited (11 patients and 10 caregivers) from August 2014 to 2015 using purposive sampling and interviewed in a semi-structured qualitative fashion. Patients were between 16–25 years of age. Data collection and interpretation continued iteratively till saturation of factors was achieved. The list of factors (hindering/helping) was compiled and sent to a panel of 14 experts. They rated the schedule and the individual factors on a Likert scale. Reliability and validity parameters were tested and the final schedule was formulated.

Results The final schedule contained 17 hindering and 18 helping factors. Detailed instructions to the interviewer for administration of the schedule are included. The factors have been further subdivided into illness related and illness unrelated. Some of the major hindering factors were symptoms of illness, medication side effects, delay in treatment initiation, perceived conflict in parents, lack of motivation. The major helpful factors were adequate symptom control, withholding inpatient care, spirituality, and peer group acceptance.

Conclusions Service provisions for ensuring optimal educational achievement can be formulated by assessing the felt needs and hindrances of patients and their caregivers.

Applicability and feasibility of the Italian version of the cognitive remediation program circuits: A pilot study

M. Chieffi*, D. Palumbo, S. De Simone, M. Rocco, O.D. Molle, A. Nicita, A. Mucci, S. Galderisi

University of Naples SUN, Psychiatry, Naples, Italy

* Corresponding author.

Introduction Cognitive deficits are considered central and persistent features of schizophrenia and have a significant impact on outcome and quality of life. The computerized interactive remediation of cognition (CIRCuiTS) is a new computerized cognitive remediation program aimed at improving different cognitive domains in patients with schizophrenia. In particular, the program was designed to mainly rehabilitate executive functions, attention and memory by training each cognitive function through several exercises and by improving metacognition.

Objectives In the present study, CIRCuiTS was translated and adapted into Italian. The applicability and feasibility of the Italian version was evaluated. Moreover, preliminary data on the effectiveness of the program were investigated.

Methods Four patients with a diagnosis of schizophrenia were recruited for the study. We investigated the changes in neurocognition, psychopathology, self-esteem and functional outcome at the end of the remediation program. The level of satisfaction of operators and participants was evaluated by means of the client satisfaction questionnaire (CSQ).

For each patient, the entire program took place through 2 weekly sessions of 50 minutes for a total duration of 40 sessions.

Results CIRCuiTS produced an improvement in all domains of neurocognition, disorganization, self-esteem and real-life functioning in the areas "self-care" and "interpersonal relationships". Moreover, high levels of satisfaction were shown by CSQ for both, operators and participants.

Conclusion The Italian version of CIRCuiTS demonstrates high levels of acceptability and feasibility for both, patients and clinicians. Additionally, preliminary data suggest that the use of CIRCuiTS provides an improvement on several aspects of the disease.

Coping skills training intervention on the quality of life of psychiatric patient's caregivers: A randomized controlled study

L. Fattah Moghaddam*, F. Mollasalehi

Islamic Azad University, Tehran, Department of Psychiatric Nursing, Tehran, Iran

* Corresponding author.

Introduction The caregivers of the psychic patients experience decreased quality of life (QOL).

Aims The aim of this study is the determination of the effect of coping skills training on improved quality of life of these caregivers compared to traditional treatments.

Methods The samples consisted of 82 caregivers of psychiatric patients who were admitted in the educational hospital of Tehran for the first time from 2015 to 2016. The caregivers were randomly divided into two groups including Interventional group ($n=41$) who received an educational booklet in addition to coping skills training, and control group ($n=41$) who received usual care. A two-group randomized controlled trial was conducted, including WHOQOL-BREF questionnaire used to collect the data before and after 90 days.

Results The results demonstrated that there were significant changes in the quality of life of family after training ($P=0.05$). But this change was not seen in the control group. The comparison of the two groups after intervention indicated, that the scores of the intervention group were higher than the control group in all dimensions. But these scores were significantly different in the psychological health and the environmental health.

Conclusions To educate the coping skills interventions can have a positive effect on the quality of life of caregivers than usual care.

¹ Islamic Azad University, Tehran, Department of Psychiatric Nursing, Tehran, Iran

² Islamic Azad University, Tehran, Department of psychology, Tehran, Iran

* Corresponding author.

Background Psychiatric patients who live in nursing homes may often feel a loss of autonomy, decision-making, and participation in social activities. They usually had little or no visitors and also they do not have any purpose for living. Pets may decrease this problem and improve their happiness.

Objectives The aim of this study is to evaluate the effects of animal-assisted therapy (AAT) on happiness of chronic psychiatric patients in nursing home.

Method The study design was a randomized controlled trial (RCT) with pre and post-test. Seventy males with chronic mental health disorder who were patients of the nursing homes were randomly divided into a pet therapy intervention group and control group. Patients in the experimental group received pet-therapy with bird as 6 weeks therapy comprising 6 sessions per week. All patients were evaluated by the Oxford happiness questionnaire before and after 6 weeks.

Results Analysis of covariance (ANCOVA) was conducted and pretest was considered as a covariate variable. The result demonstrated that the patients in the experimental group had significantly increased ($P<0.001$) happiness in posttest scores.

Conclusion It is important to consider ways of enhancing happiness in psychiatric patients who live in the nursing homes. Also, it is appearing that AAT can be helpful for them.

Parental stress in autistic parents: The counseling effectsR. Ferrara^{1,*}, M. Esposito²¹ *École doctorale de Lausanne, Department of Biology and Medicine, Roma, Italy*² *Università "Sapienza" di Roma, social medicine, Rome, Italy** *Corresponding author.*

Introduction In parents of autistic children there are high levels of stress. For parents, counseling can help them face the world of autism through the many stressors they experiment.

Objectives To evidence a possible effect of the counseling intervention on parental stress.

Methods The sample consisted of 24 parents (mean age = 38.7) of children diagnosed with autism spectrum disorder related to the treatment centre "Una breccia nel muro". Parents' group was randomly divided into two subgroups, the first (EG experimental group) consists in 12 parents, which were included in a counseling treatment of six months (one meeting of 2 hours every 15 days), while the other subgroup parents, (CG control group) were not included. We used parenting stress index–short form (PSI-SF) before counseling intervention (T0) and after (T1) with every parent. PSI values stress level in following scales: parental distress (PD), parent-child dysfunctional interaction (PCDI) and difficult child characteristics (DC). **Figure 1** shows all the variables in each group at T0 and T1.

Results Then a 2-tail t-test was separately carried out for each group (Counseling Yes; Counseling No). Counseling Yes: PD ($t_{22} = .70, P = .49$); PCDI ($t_{22} = .72, P = .47$); DC ($t_{22} = 2.23, P = .03$); Tot Stress ($t_{22} = 1.04, P = .3$). Counseling No: PD ($t_{22} = .82, P = .42$); PCDI ($t_{22} = 1.7, P = .09$); DC ($t_{22} = .59, P = .56$); Tot Stress ($t_{22} = .72, P = .48$)

Conclusions Our data confirm the positive effects of counseling especially on the difficulties related to children (DC scale).

EV1175

Integrating mental health care and vocational rehabilitation to improve return to work rates for people on sick leave because of common mental disorders

A. Hoff

Psychiatric Centre Copenhagen, Research Department, Hellerup, Denmark

Introduction Sick leave due to common mental disorders (CMD) has major negative influence on society because of the lost productivity, social benefits, and treatment costs, and OECD estimates that the cost is equivalent to 3.4% of the Danish gross domestic product. **Objectives** The Objective is to examine, whether integrating mental health care with vocational rehabilitation, conveys shorter return to work (RTW) time, compared to treatment as usual, after sick leave due to a CMD such as depression, anxiety, and stress-related disorders.

Aims The aims of the intervention of are to provide the shortest possible RTW time. Primary outcome is RTW time, and secondary outcomes are (a) time from RTW until recurrent sick leave and (b) symptom level a six months.

Methods Patients are included in one of two randomized controlled studies (anxiety or depression in one RCT, and stress-related disorders in another RCT), after referral from the municipality vocational rehabilitation (VR) center, after sick leave for at least four weeks. Patients, in both trials, are randomized into one of three groups, in a ratio of 1:1:1: (a) control group, where they receive treatment as usual in primary care and municipally located VR, (b) intervention group: mental health care (MHC) in the research project, and municipally located VR (not integrated), and (c) intervention group: MHC in the research project, integrated with a special project VR.

Results We are currently including, and as of December 2016, more than 300 are included. The total sample will be 1536 patients.

Academic stress and emotion regulation in the Iranian female students with high and low academic performanceS. Piryaee^{1,*}, M. Mohebbi², M. Khademi Ashkzari¹, E. Khademi Ashkezari¹¹ *Alzahra university, educational psychology, Tehran, Iran*² *Tabriz university, educational psychology, Tabriz, Iran** *Corresponding author.*

Introduction This paper examines the similarities and differences between academic stress and emotion regulation and investigates that the association between emotion regulation and academic stress may be explained the level of academic success among female students.

Objectives This research suggests that students vary in their ability to regulate emotions and cope with academic stress, and these abilities may differ across the level of student's academic success. Identifying the academic stress and quality of emotion regulation strategies will lead to practical implications for promoting student's with low or high academic success.

Aims The present study aims to compare academic stress and emotion regulation in the female students with high and low academic performance.

Methods A total of 162 high school students (mean age = 15.26) were selected by cluster random sampling method. They were cat-

Fig. 1

<http://dx.doi.org/10.1016/j.eurpsy.2017.01.1504>

egorized as students with high (87 students) and low (75 students) academic performance by average of their academic performance. Emotion regulation questionnaire, educational stress scale for adolescents and academic performance were administered. One-way MANOVA was conducted on academic stress and emotion regulation.

Results The results of analysis were significant only for emotion regulation, $F(5, 156) = 5.34, P = .001$. Mean score of students with low academic performance in the emotion regulation was significantly lower than students with high academic performance.

Conclusions The extent to which variation in emotion regulation and coping with stress can be considered as a key factor of academic failure/success in educational settings.

Keywords Academic stress; Emotion regulation; High and low academic performance

* Corresponding author.

Introduction Existing polysemy in definitions of human consciousness creates the major difficulty in its understanding. With the development of intensive care modern methods, the number of patients survived after coma and dwelling in disorders consciousness conditions rises.

Aims Among, the most important practical questions of neuropsychology is estimation of the patient's consciousness current condition. The solution of these problems requires precise denotation of consciousness neuropsychological criteria.

Methods All of definitions of consciousness in Russian psychological school, have the binarity as a common feature: in one hand, in view of the world, yourself, and another hand—extraction and differentiation of yourself from the ambient world (self-consciousness).

Results Neuropsychological model of consciousness (in particular, self-consciousness) includes all higher psychological functions (HPF). However, condition of none of them cannot be sufficient criterion of consciousness estimation. In Russian psychology it is suggested to study the consciousness through its own characteristic, among which one can designate reflexivity, which includes cognitions and personal meanings.

Conclusions It is possible to determine the quality of consciousness at a specific instant of time, through the system of human relations, as activity is motivated the knowledge is acquired, the affective side of the activity is determined, the self-consciousness is formed exactly through the personal meaning. Personal meaning can act as that quantity of consciousness (self-consciousness) analyses where the external reality and human attitude to this reality

are differentiated. One can judge about a degree of contact between a human and a real world by indirect difference between them.

Keywords Neuropsychological rehabilitation; Higher psychological functions; Consciousness; Self-consciousness.

Introduction Present article introduces the case of a patient who had traumatic brain injury (TBI) in 2010. During examination V. demonstrated mild sensory aphasia, frontal lobes deficit, memory disorder, limiting beliefs, lack of adequate coping strategies, emotional reactions and disability to describe his feelings and body awareness.

Objectives and aim Neuropsychological, correction and psychological counseling performance, considering neuropsychological deficit profile.

Methods counseling was carried out over six weeks in the form of 2 hour sessions once a week. Speech perception impairment was taken into consideration. The process was started with frontal lobe deficit correction. Goal management training was used in conjunction with external control of distractions. Training in structured organization of information has highly improved memorization. Techniques of CBT were used to work with cognitive distortions, dysfunctional beliefs, and self-restricting behavior. Body-oriented therapy was offered to cope with stress factors and vegetative reactions.

Results V. compensated memory disorder using external sources and motivation. Some adaptive strategies of interaction with people and the outer world were formed. He improved time management skills and learned to follow the priority of current task without distractions. Moreover, he actively started to use body-oriented techniques to regulate his emotional condition. A considerable progress was achieved in understanding his limits and difficulties in everyday life.

Conclusion Implementation of psychological consulting according to neuropsychological deficit profile may be effective in interdisciplinary holistic rehabilitation of patients after TBI.

* Corresponding author.

Introduction In Russia there was a misconception about employment of people with physical or cognitive disability that served as a psychological barrier for both employers and applicants. The situation has recently changed and special vacancies for invalids are open in some companies. A patient in residual period of traumatic brain injury (2010) attended our rehabilitation center with the request for employment. He grew up in orphanage and he had no experience of searching for vacancies by himself, also he had reduced communication skills. Moreover, TBI resulted in strong executive functions impairment.

Objectives and aim Help V with employment.

Methods Holistic rehabilitation program was developed for V. so he had a training in computer skills, CV writing and communication with employer. Cognitive-behavioral therapy methods were used while working on understanding of his limits and acceptance of his disability, and goal management training was applied to reduce frontal lobes dysfunction.

Results After 1.5 months of counseling V. demonstrated significant improvement. He started to use e-mail and the Internet to find job openings. He was able to keep independent control of his activities. V. managed to accept his disability, so he declared it in his CV – it finally became crucial in his successful employment as clerk in a bank.

Conclusion Holistic approach, which includes social work, neuropsychological rehabilitation and psychological support, is promising to overcome psychological barrier in employment of disabled people.

³ CLDS+ Paredes de Coura, Psychology, Paredes de Coura, Portugal

* Corresponding author.

The program “+ Família” part of the activities promoted by CLDS+ from Paredes de Coura in 2015, has enabled to act at the level of strategy development for qualifying families. The perceived quality of life of children and youngsters was evaluated in 2 moments: at the beginning ($n = 23$) and in the end ($n = 11$). We used the scale

kidscreen-10, translated and measured for the Portuguese population. At the first moment, the sample consisted of 65% of women and 35% man; 87% aged between 6 and 10 years old and 13% aged between 11 and 15 years old; 74% attended the 1st cycle of studies and 13% had some type of disability. Based on 4 of the questions, the perception of quality of life has improved, between the beginning and the end of the program implementation. So for the remaining 6 questions, quality of life was perceived in a more negative way in the same period. An intra subject analysis would have to be made in order to measure the results' bias due to the absence of 12 subjects in the final evaluation.

* Corresponding author.

Introduction Family psycho-education is an essential part of the treatment for people with severe mental illness (SMI), however this relevant intervention is underutilized. Shortened variations of family psycho-education have been described in attempts to make it more attractive, efficient, and feasible.

Objectives/aims Considering the lack of manualized intervention for families in Brazil, our study comes up with a proposal to implement and to evaluate the feasibility of brief family psycho-education program (BFPP) during inpatient psychiatric treatment. **Methods** An extensive review using a combination of the words: “family psychoeducation”; “severe mental illness”; “schizophrenia”; “bipolar disorder” was conducted in PubMed/Medline with the aim to select reports of multifamily group psycho-educational programs. Studies involving adults with severe mental illness published until March 2016 were included.

Results After the review of literature and meeting with experts in SMI, the BFPP was developed collaboratively by bipolar disorders' team at Hospital de Clínicas de Porto Alegre (HCPA). The standard BFPP consists of four sessions: (1) causes, symptoms, course, prognosis and stigma of severe mental disorder; (2) treatment; (3) community resources, communication skills and importance of healthy and regular habits; and (4) problem-solving strategies: preventing relapses and establishing plans for crisis. Each session will occur weekly, lasting 90 min, with 8–12 caregivers. The patients did not attend the group.

Conclusion We purposed a standard, brief, cheap and simple intervention to apply. We believe that BFPP is highly suitable for caregivers of patients with SMI. We hope that this program demonstrates feasibility among participants and become a useful and effective intervention.

Quality in community-based day center services for people with psychiatric disabilities from the attendees' perspective

L.O. Lundqvist^{1,*}, M. Rask², B. David², S. Agneta¹

¹ Örebro university, University Health Care Research Center, Örebro, Sweden

² Linnaeus University, School of Health and Caring Sciences, Växjö, Sweden

* Corresponding author.

Community-based day centers in Sweden are well-established arenas for psychiatric rehabilitation. Little is, however, known of the attendees' perception of the quality of the service provided. Therefore, the aim of the study was to describe and investigate the quality of community-based day center services for people with psychiatric disabilities. A sample of 218 attendees (44% females) between 18 and 71 years old in 14 community-based day center services in Sweden completed the quality in psychiatric care–daily activities (QPC-DA) instrument. The results showed that people with psychiatric disabilities perceived the quality of community-based day center services as high and 87% perceived the overall quality as satisfactory. The highest ratings were found in encounter followed by support, daily activity-specific, secure environment, participation, and the lowest quality was found in secluded environment dimensions of the QPC-DA. Most notably, quality of service was rated higher by those with lower educational level, had waited shorter time to attend the center, and had better mental and physical health. However, particularly aspects of a secluded environment and participation (information) may be areas with potential for improvement. In conclusion, the results adhere to the importance of occupational balance, with periods of rest/privacy during the time at the center.

EV1183

Psycho-education in schizophrenia: Evaluation of a new schizophrenia questionnaire "SCHIWI" and predictors of knowledge gain

S. Lüscher

Klinikum rechts der Isar of the Technical University of Munich, Department of psychiatry and psychotherapy, Munich, Germany

Psycho-education is a well-known therapy within a multi-modal therapy concept for patients with schizophrenia and their relatives, as psycho-education is known to reduce relapse and duration of hospital stays. Here, evaluate a new questionnaire to show the gain of knowledge about schizophrenia, especially in combination with psycho-education during a hospital stay. Furthermore, we aim to find out more about the predictors for knowledge gain after participation in 4 to 8 psycho-educational groups. During 5 years (04/2011 to 08/2015) 517 patients and 223 relatives took part in our psycho-educational groups, 136 participants finished the study. In a test theoretical analysis it was shown that the questionnaire "SCHIWI" with 100 items has similar problems as previous questionnaires, but fulfils the criteria "discriminatory power" and "item-complexity" in a reduced version of 22 (was? Erbsen? Cremants?) and can be considered as a valid questionnaire. We could prove again that psycho-education leads to knowledge gain. Furthermore, we found the predictors "frequency of participation", "basic knowledge" and possibly "relationship to relatives" to be relevant for knowledge gain in patients. Due to the small number of participating relatives we were not able to find secure predictors here,

but we found indications that "previous experience with psycho-education", "subjective knowledge gain" and "education" could be predictors for knowledge gain. This study underlines the importance of psycho-education in the treatment of schizophrenia, but emphasizes the need to find out more about possible predictors in further research.

The possibilities of the improvement language competencies in children with dyslexia. The evaluation of the Tomatis therapy in children aged 6–10 years of age

E. Mojs^{1,*}, A. Sudol¹, W. Samborski²

¹ Poznan University of Medical Sciences, Clinical Psychology, Poznan, Poland

² Poznan University of Medical Sciences, Rheumatology and Rehabilitation, Poznan, Poland

* Corresponding author.

Audio psycho-phonological stimulation training is a method based on listening to various musical sounds by way of a special device called electronic ear. The goal of this therapy is to enhance damaged hearing and consequently facilitate greater stimulation of central nervous system and improve cognitive functions i.e. attention and learning abilities. The second goal was to evaluate the effectiveness of the Tomatis method in the treatment of cognitive functions in children with developmental dyslexia. Data were collected from forty children (age range 6–10 all of whom had various lexical impairments and diagnosed as dyslexia. All children IQ ranged 78–110. All subjects underwent therapy based on the Tomatis method. The relevance group constituted, by healthy ones. Further assessment included reaction time, over sensitivity of hearing sense, verbal fluency, attention, abilities of verbal learning and learning memory–immediate and long term. The effects of the therapy were measured after 9 months of stimulation. Statistically relevant improvement of most evaluated functioning parameters, including shorter time of adequate reaction to presented stimuli was observed. Not only did the patients have lower threshold of sensitivity of hearing sense, ability to localize sources of sound significantly improved ($P < 0.05$) also. Subjects' verbal fluency, attention and immediate verbal memory were enhanced. The phonological abilities improved. Tomatis training significantly improved subjects' cognitive functioning. We could demonstrate its efficiency in relation to such parameters as reaction time, localization of sources of sound and over sensitivity to audio stimuli. The Tomatis method is a useful way of the speech treatment impediments.

Ukraine is the problem of children's mental health. Contemporary one of the most urgent health problems in Ukraine. In recent

years a number of studies confirms the trend of mental pathology of growth with an increase in the number of clinical forms of psychotic register, including behavioral disorders in children. In turn, this is due to the increasing number of emergency situations (antiterrorist operations on the territory of Ukraine) for the last time. Ukraine now is an urgent need to establish a system of psychosocial rehabilitation of children with impaired mental development. International Charity Fund “Alexander Feldman Fund” in the Ecopark established the center for psychosocial rehabilitation of children and adolescents with psychological, emotional and behavioral disorders. The center created the conditions for the restoration of a bio-psycho-social harmony of the child in the conditions of modern urban-deformed medium. The aim of the center is to restore the level of social functioning and quality of life of children with ADHD, children with autism, cerebral palsy, Down syndrome and other neuropsychiatric disorders. The Center based on ecotherapy, also used animal therapy, garden therapy, play therapy, art therapy (studio for painting, sculpting). Individual and group work included various elements of cognitive-behavioral, rational, analytical child, relaxation, and other methods of psychotherapy.

Is social frustration typical of multiple sclerosis patients?

E. Nikolaev^{1,*}, N. Vasil'eva²

¹ Chuvash State University, Department of Social and Clinical Psychology, Cheboksary, Russia

² Chuvash Republic Clinical Hospital, Neurology Unit, Cheboksary, Russia

* Corresponding author.

Introduction Psychological problems of multiple sclerosis patients are often studied in context of distress and depression or quality of life concept. However, analysis of social frustration still has not been an object of research interest. Whereas ignoring patients' feelings of frustration and social worry may worsen the prognosis of treatment.

Objectives and aims To study if the social frustration prevalent among multiple sclerosis patients.

Methods We studied 104 multiple sclerosis patients during in-patient treatment in neurological unit. Male and female patients aged between 19 and 64 years were diagnosed relapsing-remitting multiple sclerosis (RRMS) and secondary progressive multiple sclerosis (SPMS). Psychological indicators of social frustration were assessed by using “The level of social frustration” questionnaire.

Results Lack of social frustration was revealed only in 5% of multiple sclerosis patients. The most frequent area of social frustration in the patients was the sphere of health and labor activity (45%). The second area of social frustration was dissatisfaction with the socio-economic status (37%), the third – the social status (26%). Both male and female patients were equally dissatisfied with their physical condition. Men were more frustrated with their material condition, women – with their inability to work. Some differences were also defined in clinical groups. RRMS patients were more frustrated in need for their status in the society, SPMS patients with their psychological and emotional state.

Conclusions The directions of typical social frustration in multiple sclerosis patients, associations with clinical and gender factors may be considered in system of treatment and rehabilitation.

Building a psychosocial rehabilitation unit: The experience of centro hospitalar entre Douro e Vouga

V. Pais, O. Pinto*, J. Figueiredo, E. Larez, F. Lopes, M. Pereira, M. Fernandez, S. Mariano

Centro Hospitalar de Entre o Douro e o Vouga, Psychiatry, Santa Maria Da Feira, Portugal

* Corresponding author.

Introduction In Portugal, the National Mental Health Plan sought to reform the mental health care system, decentralizing mental health care by promoting community based services. Guidelines point to treatment of Psychotic Disorders with collaborative, person directed and individualized approaches.

Objective The authors propose to describe the development of a new psychosocial rehabilitation unit in a recently created psychiatric department.

Methods The CHEDV's psychiatry department (2009) serves a population of around 340,000. The Psychosocial Rehabilitation Unit (2015) aims to ensure a multidisciplinary and integrated response to users with major psychiatric disorders. The Psychosocial Rehabilitation Unit structures 4 axes of response: detection and initial approach of the disease, intervention in crisis, psychosocial rehabilitation and management of difficult patients.

Results CHEDV's psychosocial rehabilitation unit is responsible for the care of about 25 patients daily. Treatment activities range from specialized consultations, home visits, medication management and crisis telephone to social skills training, psycho-education, neurocognitive rehabilitation, occupational workshops and social intervention/orientation. The unit bases its work on constant communication within the team but also with all other carers of the patient (in or out of hospital).

Conclusions Bringing to the population a set of previously unavailable responses is the most blatant success of this unit that is helping people getting a better and closer care. To improve our work we aim at integrating the quantitative and qualitative psychometric evaluation of the patients. The lack of resources, necessity of further training, insufficient funding, and low political priority remain as the main barriers to community based mental health care.

Early signs of crisis in the perception of users and their family

G. Fucci^{1,*}, N. Ratti², R. Ignarra¹

¹ Ausl Romagna, Mental Health Center of Ravenna, ravenna, Italy

² Ausl Romagna, Mental Health Center of Ravenna, Faenza, Italy

* Corresponding author.

The identification of the early signs of crisis is globally considered one of the fundamental elements in the illness management practice of the psychiatric user. For this reason the mental health center of the city of Ravenna wanted to offer a personalized questionnaire to a 15 random-selected users and their families, with the aim of evaluating and analyzing the alarm signals in the participant's perception. The questionnaire has been created on the basis of other tests in the literature. It is divided in two parts, a “symptomatic”, related to the early signs of crisis, and an “environmental”, focalized on the potentially stressing situations for the individual. The administration took place within the individual and the family talks at the center. This project was implemented not only as a psycho-educational activity for the users and their family's, but also to amplify the knowledge of the staff on these signs. The results have shown how often there are points of difference in the perceptions of the early signs of crisis

of the users and their families and it is believed this could turn out to be an important factor to be worked on within the projects of psycho-education of the mental health center.

Psychological aspects in parents of children with disability and behavior problems

F. Ricci*, C. Levi, E. Nardecchia, A. Antonella, P. Andrea, G. Salvatore

IRCCS San Raffaele Pisana, Pediatric Rehabilitation Center, Roma, Italy

* Corresponding author.

Introduction Parents of children with disabilities are at increased risk of experiencing psychological stress compared to other parents. Children's high levels of internalizing and externalizing problems have been found to contribute to this elevated level of stress. Childhood disability often imposes a social and emotional burden for children and their families.

Objective With this study we evaluated several parents' psychological aspects and the emotional behavioral functioning of their children with disability.

Aim To investigate the possible correlation between parenting stress, level of depression in parents and behavior problems in their children, taking into account the differences between mothers and fathers.

Method Standardized forms (CBCL, PSI, BDI) were completed from 57 (28 mothers) parents of children aged from 6 to 18 years, focusing on psychological well-being includes depression, parenting stress, family resilience and family adjustment.

Results The mean age of our sample was 41.55 ± 5.4 . The level of depression and stress index were higher in mothers than in fathers. Parenting stress was significantly associated with children internalizing and externalizing behavior problems in children.

Conclusion The results of this investigation indicate the importance of examining relations between parenting stress and behavior problems in children with disabilities. Objective of ensuring the rehabilitation process aimed at the welfare of the family. These patterns have implications for both developmental theory and for service provision for individuals with disability and their families.

Predictors of social function and quality of life in patients with traumatic brain injury

S. Ubukata*, G. Sugihara, T. Murai, K. Ueda

Kyoto University, Department of Psychiatry- Graduate School of Medicine, Kyoto, Japan

* Corresponding author.

Cognitive deficits as well as affective and physical symptoms are common after traumatic brain injury (TBI). However, little is known about how these deficits affect functional outcomes. The purpose of this study was to investigate the relationship between neuropsychological, affective and physical sequelae and outcomes such as social function and quality of life in patients with TBI. We studied these relationships in 57 patients with TBI over the course of 6 months post-injury. The patients completed neuropsychological assessments, including the Wechsler Adult Intelligence Scale-III,

the Rivermead Behavioural Memory Test, and verbal fluency test. Affective and physical symptoms were assessed by Beck Depression Inventory-II, Chalder fatigue scale, and Pittsburgh sleep quality index. Functional outcomes were assessed using the World Health Organization (WHO) disability assessment rated by others and the WHO quality of life assessment (WHO/QOL 26). The patients showed impairments in executive function assessed by verbal fluency test. The affective and physical assessments showed mild depressive mood and fatigue problem. Multiple regression analysis revealed that executive function and depressive mood were the best predictors of social function and quality of life, respectively. The findings of this study suggest that executive function and depressive mood are important factors to predict functional outcomes in patients with TBI.

Deinstitutionalization and psychosocial rehabilitation

C. Vidal^{1,*}, L. Melo Vidal^{2,3}

¹ Faculdade de medicina de Barbacena, psiquiatria, Barbacena, Brazil

² Prefeitura Municipal de Barbacena, Saúde Mental, Barbacena, Brazil

³ Barbacena Medicine School, student, Barbacena, Brazil

* Corresponding author.

Introduction Barbacena is a Brazilian city with 140,000 inhabitants, which was known as the "city of madmen" because of the excessive number of patients in psychiatric hospitals. In 2000 it began a deinstitutionalization process, and the patients were transferred to assisted residential services.

Objective Describe the process of deinstitutionalization and social rehabilitation of psychiatric patients.

Methodology The following characteristics were studied: sex, age, medication use, psychiatric diagnosis and the development of social skills.

Results In each therapeutic residence (RT) lives eight patients, supervised by upper and mid-level professionals. Since the implementation of RTs about 400 patients leave the psychiatric hospitals. Most had mental retardation (51.0%), followed by schizophrenia (31.0%). More than half (58.5%) were men. The age ranged from 29 to 97 years, with an average of 64.8 ± 12.4 . A decrease in the average dose of neuroleptics was seen after deinstitutionalization. Direct observation of patients in the RT, and the reporting of caregivers has shown that patients have developed wide range of social performance, such as dating, started at professional courses, attending exercise classes, travelling and learn how to use money.

Conclusion In despite of difficulties in the psychiatric reform process, the community-based treatment and psychosocial rehabilitation approach are the principal models of psychiatric care presently, and the residential services play an important role in this process. The authors emphasize the importance of community support, professional staff and rehabilitation programs as a condition for good outcomes.

Review of physical health care in patients with chronic psychiatric conditions in a rehabilitation unit

A. Yetkil*, S. Wisidagama

Surrey and Sussex NHS Healthcare trust, Psychiatry Liaison, Surrey, United Kingdom

* Corresponding author.

Introduction An important aspect to consider in chronic patients on psychotropic medication is their physical health status. Along with an aging population and the side effects of the medication it is key to identify complexities of their physical health that may be troubling the patient or can potentially effect the patient.

Objectives Using the standards for inpatient mental health rehabilitation services highlighted by AIMS Rehab.

we will assess if the current method used to highlight any physical health concerns are being met for the new patients admitted in to the unit from January 2016 to September 2016.

Aims Evaluate the quality of physical healthcare in Margaret Laurie House (Surrey and Borders NHS trust Rehabilitation unit).

Methods We designed a spreadsheet to capture the standards as outlined in 'physical healthcare' section of the AIMS Rehab document.

We obtained the relevant patient data using the System One electronic patient record. The system contains an embedded template where physical health parameters are entered so we were able to simply copy the data from these sections. We then translated this information into an Excel spreadsheet format.

Results The analysis of the data remains as work in progress at the current time. We anticipate low compliance with the 8 outlined standards (9.1.1–9.2.2). These were all considered type 1 standards; according to the AIMS rehab guidance the expectation is that the service must meet 100% of these standards. Upon re-audit we aim for 100% compliance.

Conclusion Work in progress-to be updated.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1193

Psychometric properties of the Arabic version of adult hope scale

T. Alali

Kuwait University, psychology, Kuwait, Kuwait

Introduction The adult hope scale (AHS) was developed as measure of hope with a 12-item using an 8-point Likert-type scale (Snyder et al., 1991). Although there is an Arabic version of AHS, it is not identical to the original version in terms of the number of items response.

Objectives To evaluate the psychometric properties of the Arabic version of the AHS in undergraduate sample.

Methods The participants were undergraduate Kuwaitis (1000 males and (1000) females. The mean age of the males was (20.25 ± 0.05) years, and for females was (19.96 ± 1.44) with a significant age difference (t = 4.22, P < .000). The Arabic version of the AHS was administered to participants. The internal consistency reliability, factor structure, and convergent validity of the AHS with Life Orientation Test (LOT-R), oxford happiness inventory (OHI), and Satisfaction With Life Scale (SWLS), while the divergent validity of AHS were assessed with Beck Depression Inventory-II (BDI-II) and the beck anxiety inventory (BAI).

Results Internal consistency was satisfactory for the AHS (Cronbach's alpha = 0.83) for males and (Cronbach's alpha = 0.81) for females. The results revealed no significant gender differences on happiness (F = 1.68, P > .05). Principal component analyses (PCA) showed that a three-component solution explains %54.56 of the total variance for males and 51.99% for females. The AHS positively correlates with the following variables: SWLS (r = .43), LOT-R

(r = 0.40) OHI (r = .49) while the AHS correlates negatively with BDI-II (r = -.49) and with BAI (r = -.39).

Conclusions This study provides evidence for the reliability and validity of the Arabic AHS for Kuwaitis.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Measuring affective attitudes towards health among adolescents

M. Iosifyan^{1,*}, G. Arina², A. Korneev², A. Ryabova², V. Nikolaeva²

¹ National Research Center for Preventive Medicine, Laboratory of psychosocial factors, Moscow, Russia

² Lomonosov Moscow State University, Department of psychology, Moscow, Russia

* Corresponding author.

Introduction Affective attitudes play a significant role in health behaviors. However, comparing to cognitive attitudes, affective attitudes are much less investigated.

Objectives To study affective attitudes towards health among adolescents, we measured associations between words related to health and positive/negative emotions.

Aims We used the modified Etkind Color Test (Etkind, 1980) as a new measure of affective attitudes.

Methods Subjects (n = 79, Mage = 14.34 ± 1.21, 35 males) ranked 8 colors from Lüscher's color test (1971) from best to least associated with each of 13 words related to health (e.g. sport, risky behaviors) and 6 words related to positive and negative emotions. To calculate an association between an emotion and a health-related word we used a scoring algorithm, similar to Palmer's and colleagues MCA score (Palmer et al., 2013).

Results Means of associations between words and positive emotions were assessed: my body (0.74 ± 2.02), environment (1.17 ± 1.82), eating (1.23 ± 1.98), health (1.60 ± 1.78), risky behaviors (-1.14 ± 2.14), family (2.13 ± 2.00), sport (2.02 ± 1.86), sleep (0.74 ± 1.85), school stress (-0.95 ± 1.89), hygiene (0.91 ± 1.85), medicine (0.61 ± 1.95), psychological well-being (1.11 ± 2.24), illness (-0.43 ± 1.39). Positive emotions had inverse relation with risk behaviors, illness and school stress and direct relation with the rest 10 factors.

All correlations between negative and positive attitudes towards health related words were significant and negative (-.223 < r < .559), except two (medicine and illness).

Conclusions The modified Etkind Color Test describes semantic space of affective attitudes towards health. It showed that adolescents mostly did not have ambivalent attitudes towards health related factors.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Confirmatory factor analysis of the frost et al multidimensional perfectionism scale-24 (F-MPS 24)

M.J. Soares, J. Azevedo*, A.T. Pereira, A.I. Araújo, J. Castro, B. Chaves, C. Roque, M. Bajouco, A. Macedo

Department of Psychological Medicine, Faculty of Medicine-University of Coimbra, Coimbra, Portugal

* Corresponding author.

Introduction The F-Multidimensional Perfectionism Scale is a widely used instrument to assess perfectionism trait. The original scale comprises 35-items that measure the six dimensions

of Frost et al (1990) conceptualization of perfectionism: personal standards (PS), concern over mistakes (CM), doubts about actions (DA), parental criticism (PC), Parental expectations (PE) and Organization (O).

Objective To examine the factor structure of the 24-items short form of the F-MPS using confirmatory factor analysis (CFA), in a sample of Portuguese university students.

Methods The sample comprises 344 university students (68.4% females), with an average age of 20.69 years (SD = 1.59; range = 17–24). They completed a version of F-MPS with 24 items that results from the selection of the four items with highest loadings in the respective six dimensions of the original Portuguese version (Amaral et al., 2013).

Results After correlated errors, we obtained a good fit for the FMPS with six factors ($X^2/df = 2.125$; CFI = .936; GFI = .891, RMSEA = .057; $P[rmsea \leq .05] = .043$). The 24-item F-MPS short form revealed good internal consistency ($\alpha = .825$). The six dimensions showed acceptable or good internal consistency, as revealed by Cronbach's alpha (α : PS = .80; CM = .76; DA = .82; PC = .84; PE = .89, O = .85).

Conclusions The F-MPS 24 items short form CFA confirmed the six factor model as a reliable and valid measure to assess multidimensional perfectionism in Portuguese university students.

EV1196

The subjective graphic representation as the neural pathway of the information processing: Dyslexia as an example

A. Bernardini

University, filosofia scienze e tecniche psicologiche, Sinalunga Siena, Italy

Introduction The new theory of the cognitive process by A Bernardini.

Objectives to single out and recover deficits of the information processing by a new research method.

Aim to demonstrate dyslexia/language can be considered as an answer to what we are able to perceive. This depends on the way in which the C.N.S. elaborates the two aspect of energy of the internal and external space according to the new theory of the cognitive process by A. Bernardini which underlies her relevant re-educative methodology.

Methods this study was carried out in Italy, in pre-high school education where students with moderate learning abilities and special needs are integrated into mainstream education. The performance of F 81 subjects was examined. They were divided into two groups: the first supported by A. Bernardini's method, the second one supported by a remedial teacher (traditional method) and the control group being the rest of the class. For five months, tailored programs were followed three times a week, for one hour and a half.

Results At the end of the treatment the second group did not show significant results while the first group showed marked improvement. Among the students of the first group, Tobia was the student who best represented dyslexia; for this reason he has been taken as an example.

Conclusion Dyslexia and disturbances in language depend on perceptive deficits and can be singled out and recovered by A. Bernardini method. The last revolutionizes the current research method.

⁴ University of Toronto, Mental health and addiction, Toronto, Canada

⁵ Federal Institute of Pernambuco, Psychology, Recife, Brazil

* Corresponding author.

Introduction Self-efficacy is the belief or personal confidence related to the own ability to perform a specific action necessary to obtain a certain result. Its use refers to the application of validated instruments.

Aims Describe the process of cross-cultural adaptation of the drug-taking confidence Questionnaire (DTCQ-8) drugs' version and to verify its content validity and reliability.

Methods It's a methodological study accomplished by nine experts to the process of adaptation and validation and had a sample of 40 drug users in treatment in the Center of Psycho-Social Attention for alcohol and other drugs, Recife, Pernambuco, Brazil.

Results The mean index semantics' agreement (0.989; 0.989; 1.00), idiomatic (0.967), experiential (0.956), conceptual (0.978) and content validation on the clarity of language (0.972), practical relevance (0.958), the theoretical importance (0.958) and theoretical dimension (1.00) demonstrated a satisfactory process. The clinical validation showed that 57.5% of users were classified as moderate on the self-efficacy item to resist the urge to use drugs in high-risk situations, and the Cronbach's alpha coefficient was 0.889 for the complete instrument, ranging from 0.863 to 0.890 among its items.

Conclusions DTCQ-8 drugs proved to be easy to apply and understand. Its adaptation process was satisfactory for the application in the Brazilian context. The results showed that in this sample, this instrument was suitable to measure the Brazilian user's self-efficacy to resist the urge to consume these substances in high-risk situations.

¹ Azores University, Faculty of Social and Human Sciences, Ponta Delgada, Portugal

² University of Coimbra, Cognitive and Behavioural Center for Research and Intervention, Coimbra, Portugal

³ SUNY Downstate Medical Center, College of Medicine, New York, USA

* Corresponding author.

Introduction The advances and massification of technology have allowed new developments in effective assessment methodologies for the evaluation of cognitive functions and associated functions of several brain systems and structures. Computerized test batteries have become more robust alternatives to paper-and-pencil test

batteries and useful tools for research in several scientific domains, including psychiatry, psychology, genetics and neurosciences.

Aims To validate and disseminate the Portuguese PennCNP battery for clinical and non-clinical studies.

Objectives To translate and provide preliminary psychometric data of the Portuguese PennCNP tests in 9 neurocognitive domains.

Method The PennCNP (Gur et al., 2010) was translated and administered to a sample of 120 Portuguese participants from the general population.

Results Findings on the internal consistency and performance (speed and accuracy) are presented for the 19 tasks included in the PennCNP, in addition to results of correlation analysis within tests on the same domain for criterion validity, and gender sensitivity analysis.

Conclusion Computerized assessment provides efficient and reliable results, based on performance of abstract.

Objective and simple tasks that cover a vast range of cognitive functions The administration requires minimal training and provides a quick and automated scoring procedure, with great utility in several research and clinical fields. The availability of a test battery suitable for a large number of Portuguese native-speakers worldwide is of added value, since the translation of measures to several languages allows creating more extensive normative samples and direct results comparability in future research, including transnational or cross-cultural studies and clinical trials.

Disclosure of interest The authors have not supplied their declaration of competing interest.

“Neurodevelopment in a dish” Elucidates the mechanisms of autism spectrum disorder

M. Ilieva^{1,*}, M. Kamand¹, K. Kolev¹, S.L. Forsberg¹, Å.F. Svenningsen², T. Sheldrick-Michel¹

¹ Odense University Hospital, Psychiatry, Odense, Denmark

² Odense University Hospital, Neurobiology research, Odense, Denmark

* Corresponding author.

Introduction Autism spectrum disorders (ASD) is a group of neurodevelopmental disorders characterized by deficits in social cognition, communication, and behavioral flexibility. Most of the cases appear to be caused by the combination of autism risk genes and environmental factors affecting early embryonal brain development. The current animal and 2D cellular models are not able to recapitulate the complex integrity of the developing brain. Therefore a model of the brain that can cast a light on the pathological processes during brain development is of a high need.

Aim and objectives The aim of our research is to develop a three-dimensional brain organotypic system (brain organoids) for culturing patient's derived induced pluripotent stem cells (iPSC).

Methodology We propose a multidisciplinary approach, involving the generation of patient specific iPSC from somatic cells (fibroblasts) and 3D culturing techniques to build a complex “humanized” in vitro platform for ASD research. Further we will investigate differences in gene expression of potential disease related markers and cellular phenotype between autistic patients and controls.

Results Brain organoids have the ability to recreate the right complexity of the brain. On the cellular and gene expression level, organoids demonstrate a high similarity to the neurodevelopment in vivo and can therefore recapitulate early stages of the neurogenesis.

Conclusion To date organoids are the most relevant cellular in vitro platform for the understanding the mechanisms behind ADS pathology. Organoids are a good modeling system for elu-

cidating the role of epigenetic and environmental factors for development of ASD.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Pictorial representation of illness and self-measure as an instrument for diagnostic of illness representation in youth with ultra-high risk for psychosis

M. Kovyazina^{1,*}, E. Rasskazova², N. Varako¹, S. Enikolopov²

¹ Lomonosov Moscow State University, Department of Psychology, Moscow, Russia

² Lomonosov Moscow State University and Mental Health Research Center laboratory of Medical Psychology, Department of Psychology, Moscow, Russia

* Corresponding author.

Introduction Pictorial representation of illness and self-measure (PRISM) was developed as screening tool assessing implicit reaction to somatic illnesses. Conclusion is based on comparisons of the positions of illness-related (“Illness” and major symptoms) and unrelated (“Me”, “Family”, “Work/study”) objects on the list.

Objectives Due to its easiness and implicitness PRISM could be promising addition to illness representation questionnaires in mental illnesses.

Aim was to reveal validity of the PRISM in youth with ultra-high risk for psychosis.

Methods Eighty-one male patients 16–25 years old meeting criteria of ultra-high risk for psychosis; preliminary diagnoses of mood disorders 34, personality disorders 26, schizotypal disorder 21 patients) filled PRISM, beck cognitive insight scale, symptom checklist 90-r, illness perception questionnaire, quality of life and enjoyment questionnaire and happiness scale.

Results According to hierarchical regression, conditional “Self-Illness” distance (after control for mean distances on the list) was related to less psychopathological complaints, lower subjective illness severity and emotional representations, higher treatment control and better quality of life. “Self-symptoms” distance was related to better cognitive insight, lower emotional representations and consequences and moderated the relationship between “Self-Illness” distance and appraisals of illness length and dynamic. **Conclusions** Conditional “Self-Illness” distance in PRISM could reflect cognitive appraisal of illness based on symptoms and related to life satisfaction while “Self-Symptoms” distance reflects merely emotional reaction based on cognitive insight.

EV1201

Towards a new structure of the interpersonal reactivity index. reliability and validation of the Portuguese version: A comparative analysis

L. Manarte

Faculty of Medicine, Psychiatry, Lisbon, Portugal

Objective Empathy has received a lot of attention with the creation of an Interpersonal Reactivity Index (IRI). IRI is assessed using a 28-item questionnaire with four 7-item scales:

- perspective-taking (PT) scale;
- fantasy (FS) scale;

– empathic concern (EC) scale and iv) personal distress (PD) scale. Such questionnaires have been translated in many languages (see Table 1). This work aims to compare the original model with existing modified, hierarchical, shortened models in the literature and to also translate and validate the IRI for Portuguese.

Methods A convenience sampling was used ($n = 130$) to conduct confirmatory factor analysis (CFA) using AMOS software. The original four-factor model is contrasted with modified, hierarchical and shortened models proposed in the literature, reporting internal consistency statistics and their fit indices.

Results The same structure of factors was found in the sample with reasonably good fit indices $\chi^2/df = 1.57$, CFI = 0.77, AGFI = 0.72 and RMSEA = 0.067. Internal reliability for each scale of the IRI was not excellent (< 0.90), but it is in line with the literature: PT with a Cronbach's alpha of 0.74, FS with 0.79, EC with 0.74 and PD with 0.65. The comparison with other modified versions of the IRI latent factor structure revealed that two models with better fit than the original version, and the potential for a shortened Portuguese version of the IRI.

Conclusion IRI is a valid instrument to measure empathy in the Portuguese Population and is in line with previous findings. Some modifications to the original latent structure provide a better data fit than the original one.

Table 1 Validation studies of the 4-factor model structure of the IRI.

Country	Language	(n)	Reliability measures (Cronbach's alphas)				Fit indices			
			PT	FS	EC	PD	χ^2/df	CFI	AGFI	RMSEA

Development of a new activity measure: Activity perception in healthy population and in people with chronic illness

M. Martin*, I. Alexeeva

University of Oxford, Experimental Psychology, Oxford, United Kingdom

* Corresponding author.

Introduction Self-reports provide rich information about the types of activities people engage in. Reviewing current activity measures two issues become evident. Firstly, they were developed and validated in healthy populations. Secondly, they are diverse in their applications and measured domains. Thus, to assess the construct of activity fully large numbers of measures need to be used.

Objectives The study aimed to explore different dimensions of activity (e.g. work, physical, mental, leisure, sedentary behaviours) using a new scale assessing multiple domains of daily activities.

Methods A new activity scale was used to investigate the types of activity and inactivity in people with chronic illness (asthma, chronic fatigue syndrome (CFS)) and in a healthy group. The types of activities measured included; leisure and sport, home and outside, social activity, work and education, and mental activity. The scale also aimed to measure the construct of inactivity, represented by sedentary behaviours, such as staying in bed during the day.

Results The results showed a pattern of significant correlations between the new activity scale, specifically its two major domains of activity and inactivity, and other measures of functioning and activity in the illness groups, but not in the healthy group.

Conclusions The lack of significant associations between the new activity scale and other measures of activity and functioning within the healthy group indicated the measure may be more suitable for assessing activity in people with chronic illness than in healthy people. Additionally, the results underscore the importance of measuring inactivity as a separate domain.

Outcomes assessment: Reliable change index (RCI) in assessing health outcomes in clinical practice

I. Iraurgi¹, P. Penas^{1,*}, S. Gorbeña¹, M. Montero¹, J. Trujols²

¹ University of Deusto, Department of Psychology, Bilbao, Spain

² Hospital de la Santa Creu i Sant Pau, Psychiatric Unit, Barcelona, Spain

* Corresponding author.

Introduction The assessment of therapeutic outcomes and the evaluation of treatment efficiency and effectiveness is an area of interest for clinicians and researchers. Scientific evidence demands randomized controlled trials and inter-groups comparisons with a minimum number of participants in each treatment modality, a requirement rarely feasible in clinical practice where the assessment of treatment outcomes, with regards to therapeutic goals, is crucial both in terms of statistical significance and clinical relevance.

Objective The aim of this poster is to present an alternative methodology which permits to evaluate the individual's change.

Method The reliable change index methodology allows for the estimation of statistical significance (statistically reliable change) and clinical relevance (calculation of cutoff points and its interpretation criteria). Two examples are presented: a group of patients with asthma in treatment and a female with major depression who underwent electroconvulsive therapy (ECT).

Results/discussion Both cases were analyzed using standardized statistical analyses and the RCI method in order to estimate clinical change. The results illustrated the adequacy of both procedures for decision making in terms of effectiveness. However the RCI offered greater specificity with regards to individual changes. More specifically, RCI provided a more concrete estimation of the proportion of cases of asthma that showed change after the intervention, and also, indicated if such change were not only statistically significant, but also clinically relevant. Besides, when a single case was assessed (ex: ECT case) this methodology proved useful to estimate the efficacy of a continuation and maintenance program.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1204

Confirmatory factor analysis of a Portuguese short version of the cognitive emotional regulation scale

M.J. Martins¹, A.T. Pereira^{1,*}, M.J. Soares¹, A.P. Amaral^{1,2}, N. Madeira¹, A. Araújo¹, A. Macedo¹

¹ Faculty of Medicine, University of Coimbra, Psychological Medicine, Coimbra, Portugal

² Institute Polytechnic of Coimbra, ESTESC-Coimbra Health School Coimbra, Portugal

* Corresponding author.

Introduction The cognitive emotions regulation questionnaire (CERQ) is a 36-item questionnaire to measure specific cognitive emotion regulation strategies used in response to the experience of threatening or stressful life events. The Portuguese version of CERQ proved to be a reliable and valid measure to evaluate eight dimensions: Positive reappraisal and planning, positive refocusing, rumination, blaming others, putting into perspective and self-blame.

Objective To confirm the dimensional structure of a Portuguese short version of the CERQ using Confirmatory Factor Analysis (CFA).

Method Items selection was based on the previous results of the exploratory factor analysis of the 36-items version. Items presenting the highest loading (≥ 70) in their respective factor were selected. A preliminary short version composed of 22 items were answered by a sample of 480 university students (81.9% females), with a mean age of 19.49 years (SD=2.047; range=17–30). CFA (using Mplus software) was used to test if the eight dimensions' model suggested by prior exploratory factor analyses fitted the data.

Results The eight dimensions' model has a good fit ($\chi^2 = 424.015$, $P < .01$; RMSEA=0.056, 90%CI= 0.049–0.063; CFI=0.930; TLI=0.910; SRMR=0.051). Although composed of fewer numbers of items, all subscales presented good reliability (Cronbach alpha $<$ 70).

Conclusions The CERQ-22 is a reliable and valid measure to evaluate cognitive emotion regulation strategies in young adults. Being a shorter version it is particularly useful for multivariate and prospective studies. In the near future we will test this structure in a clinical sample.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Personality traits such as Impulsivity and Sensation seeking are associated with aggressive and/or risky driving behaviour. Understanding the influence of these traits in the driving task is important to perform a more comprehensive study of road trauma, which is an increasing public health and economic concern.

Objective To study the reliability and the construct validity of the Portuguese version of impulsive sensation seeking scale (ImpSS) using exploratory and confirmatory factor analysis (EFA and CFA).

Methods 747 participants [417 (55.8%) women; mean age = 42.13 \pm 12.349 years; mean driving license years = 21.30 \pm 11.338; mean years of regular driving = 20.33 \pm 11.328] answered an online

survey which included this scale, and other socio-demographic information. Inclusion criteria were: driving license and regular driving for at least three years and age lower than 75 years old. The total sample was randomly divided in two sub-samples, with sample A ($n = 373$) being used to perform EFA, and sample B to perform CFA.

Results The most acceptable factor model for ImpSS scale was the two-factor model found with EFA, excluding items 4, 6, 7 and 10 ($\chi^2/df = 2.13$; TLI = .90; CFI = .92; RMSEA = .05, $P = .211$). The internal consistency analysis resulted in: Sensation seeking, $\alpha = .79$; Impulsivity, $\alpha = .76$; total ImpSS score, $\alpha = .82$.

Conclusions These findings suggest that the ImpSS Scale is a valid and reliable measure to assess those personality traits in the Portuguese drivers.

Different subjective criteria for quality of life appraisal in youth with non-psychotic depression, recovering after first psychotic episode and healthy controls

E. Rasskazova^{1,*}, S. Enikolopov², V. Guldán³

¹ Moscow State University, Mental Health Research Center, Clinical Psychology, Moscow, Russia

² Mental Health Research Center, Medical Psychology, Moscow, Russia

³ Moscow region center of social and justice psychiatry, Psychology Laboratory, Moscow, Russia

* Corresponding author.

Introduction Although a plenty of instruments for quality of life in mental illnesses was developed, both general and specific instruments could be biased if the process of well-being appraisal is different in different illnesses.

Objectives We consider personal appraisal of quality of life as a result of the decision making process, which could have different subjective criteria in mental illnesses.

Aims The aim was to compare the contribution of the quality of life domains to the appraisals of general life satisfaction in mental illnesses.

Methods Three groups of males 17–28 years old (74 with non-psychotic depression, 90 developing recovery after the first psychotic episode and 185 healthy controls) filled quality of life and enjoyment questionnaire (version for mental illnesses) and Happiness Scale.

Results Moderation analysis reveals that in non-psychotic depression health, emotional sphere and functioning during the day are more important predictors of general well-being than in the two other groups. Patients developing recovery after psychotic episode are less oriented to the emotional and social domains and financial well-being when appraising their life satisfaction than other participants.

Conclusions Results demonstrate the importance of identifying and working with subjective criteria and process of appraisal of general well-being in patients with mental illnesses. Direct comparisons of quality of life in different clinical groups are biased by different subjective criteria that are important for patients.

Introduction The mental health hospitalization unit of Torrecárdenas Hospital consist of a team of professional psychologists, psychiatrists, nurses and occupational therapists who perform different approaches to look after the hospitalized patient. The therapeutic Objective of this unit is the containment and implementation of intensive interventions in a crisis situation in which it has not been possible to achieve an improvement or control of the patient's symptoms in external resources.

Material and methods We performed a descriptive cross-sectional study with patients hospitalized at the mental health hospitalization unit between September 22 and October 28, taking into account the age, sex, admitted, diagnoses, previous treatments, psychological approach and free hospital stay.

Results (Figures 1–3).

Conclusions The results of this study indicate the most prevalent patient profile has a diagnosis of severe mental disorder. The 66.7% of patients had previous hospital admissions. The 81.5% of hospital admissions are involuntary. The normative psychopharmacological prescription is an atypical antipsychotic as main treatment in our study. We highlight the use of Olanzapine with an 18.52% being consolidated as the first therapeutic option. As adjunctive treatment we have a mood stabilizer such as Valproic Acid with 11.1%; or another antipsychotic such as Paliperidone with the same percentage (11.1%). Regarding hypnotic treatment, it should be pointed out the use of medium-life benzodiazepines (Lormetazepam) with a prevalence of 55.56%.

EV1208

The genetic methods for drug-resistant epilepsy

M. Salohiddinov

Tashkent Medical Academy, Psychiatry and narcology, Boyovut, Uzbekistan

Actuality Mechanisms of underlying pharmacoresistance have been explored insufficiently. Enzymes of a system for biotransformation of xenobiotic and transporters for drugs are the key participants in the systems of metabolism of antiepileptic drugs (AEDs). Among proteins-transporters, glycoprotein P encoded by MDR1 gene plays an essential role in the processes of uptake, distribution and excretion of AEDs.

Objective The work initiated to study gene MDR1 C3435T polymorphism and to assess its association with pharmacoresistance formation in patients with epilepsy receiving antiepileptic drugs (AEDs).

Materials Study involved 89 patients with localization-related epilepsy and 55 unrelated healthy subjects.

Results Distribution of 3435T/C polymorphism in NDR1 gene was analyzed in the patients with the localization-related epilepsy and nominally healthy donors. The distribution of frequencies of gene alleles was found to correspond to the Hardy-Weinberg equilibrium ($P > 0.05$). Incidence of genotypic variants of the polymorphism was as follows, CC was found in 18.6%, CT and TT were observed in 55.9% and 25.4% of cases. In the controls CC was found in 60.0%, CT and TT were observed in 33.3% and 6.6% of cases, respectively. The findings are the evidence for significant effect of functionally weak variants in C3435T polymorphism of MDR1 gene on efficacy of antiepileptic therapy.

Conclusion presence of T-allele of C3435T polymorphism of MDR1 gene increases risk of pharmacoresistance in the patients with epilepsy and is a significant and predicting criterion of efficacy and feasibility of the antiepileptic therapy conducted.

Ambientation/acclaculturation of a psychologist as “methodological internship” for developing qualitative research to study clinical supervisions at a psychiatric outpatient service of Brazilian general hospital

M.E.D.F. Bremlberger, R.A. Bastos, V.L.P. Alves, E.R. Turato*
UNICAMP, State University of Campinas, LPCQ, Laboratory of Clinical-Qualitative Research, Campinas, Brazil

* Corresponding author.

Qualitative research in a psychiatric setting requires methodological updates on its modus operandi for professionals who migrated paradigmatically from other academic areas. The mere adoption of the concept of acculturation, from anthropology to field of health services, may not correspond to specificities of assistance and research in this field.

Objective To discuss results of a certain environment and acculturation strategy for development of humanistic research that took place in a psychiatric outpatient service of a university hospital.

Method Observation of environment of psychiatric supervision for qualitative method in health setting, in period of six months. The first author, doctoral student, psychologist, systematically attended discussions of clinical cases, observing relationship between supervisors and residents. Data were recorded in field diary, followed by free-floating readings and critical analyses. These were also submitted to peer reviewers of the LPCQ-laboratory of clinical-qualitative research.

Results – The experience, similar to an “internship”, has been confirmed as necessary to conduct qualitative research in this field;

– It allowed accurate apprehension of features of environmental functioning and, above all, cultural dimensions of language of participants;

– This proved pertinent for clearing the theme-problem to be researched;

– Postgraduate researchers, in particular those graduates under other paradigms, have strengthened their methodological knowledge on this field, and have been inserted epistemologically for which they will have built new knowledge;

– Finally, this methodological stage improved the so-called active observation and phenomenological listening of the researchers regarding those observed.

Conclusions The experience contributed significantly to establishing and validating the qualitative methodological course.

Disclosure of interest The authors have not supplied their declaration of competing interest.

* Corresponding author.

Introduction Psychosis in patients with epilepsy was known in antiquity and was already described in detail in the nineteenth century.

This kind of psychosis can be categorized in relations to seizures: preictal psychosis (before the seizures), during them (ictal) or after the seizures (postictal psychosis)

Aims Through several cases of patients that were treated in our department with the diagnosis of psychosis, previously or during the treatment diagnosed with epilepsy, we analyse the characteristics and diagnostic criteria of these pathologies.

Methods Systematic literature review in up-to-date and Pubmed, looking for reviews on psychosis and epilepsy, in international scientific journals of neurology and psychiatry.

Conclusions Being able to recognize this several types of psychotic states associated with epilepsy has a clinic and prognosis utility, because made important differences in treatment and in the evolution of the illness.

Family burden in caregivers of schizophrenia patients

H. Ahlem, Y. Zgueb, U. Ouali*, Y. Laajili, S. Ben Alaya, R. Jomli, F. Nacef

Razi hospital, psychiatry A, Manouba, Tunisia

* Corresponding author.

Introduction Schizophrenia is a disabling, chronic psychiatric disorder that has far-reaching consequences for both patients and their relatives. Management of schizophrenia involves family support and care. In this context, burden of care is a concept related to caregivers and family's members of patients assuming responsibility for these patients. This construct can be conceptualized as a syndrome of varying clustering affecting the general and mental health of caregivers.

Objectives This study aims to determine the frequency and clinical correlates of family burden in schizophrenia.

Methods We performed a transversal study in department of psychiatry A at Razi hospital. Thirty principal caregivers of schizophrenia patients were interviewed. Caregiver's burden was assessed using the Zarit scale.

Results The mean age of caregivers was 48.7 ± 7.15 years. In our sample, 63.3% ($n = 19$) were parents, 23.33% ($n = 7$) were brothers

or sisters and 13.33% ($n=4$) were spouses. The mean score of Zarit was 58.75 ± 9.15 . Caregivers had a severe burden in 56.66 of cases ($n=17$). Levels of burden were significantly associated with history of aggressive acting out and poor treatment adherence.

Conclusion Caregivers of schizophrenia patients experience enormous burden which is in part related to clinical features of disease. Further studies are necessary to establish the appropriate interventions in order to reduce and manage general and psychological impact of schizophrenic patients care giving.

Mild depressive symptoms mediate the impact of childhood trauma on long-term functional outcome in early psychosis patients

L. Alameda^{1,*}, G. Philippe², B. Philipp², D. Kim Q.³, C. Philippe²

¹ CHUV, Psychiatry, Psychiatric Liaison Service, Lausanne, Switzerland

² CHUV, Psychiatry, Treatment and Early Intervention in Psychosis Program TIPP, Lausanne, Switzerland

³ CHUV, Psychiatry, Unit for Research in Schizophrenia- Center for Psychiatric Neuroscience, Lausanne, Switzerland

* Corresponding author.

Introduction The mechanism linking childhood trauma (CT) to the functional deficits observed in early psychosis (EP) patients is as yet unknown.

Objectives To examine the potential mediating effect of depressive symptoms in this well-established association.

Methods Two hundred nine EP subjects aged 18–35 were assessed for functioning and psychopathology after 2, 6, 12, 18, 24, 30, and 36 months of treatment. Patients were classified into early-trauma if they had faced at least one experience of abuse (physical, sexual, or emotional) or neglect (physical or emotional) before age 12, and late-trauma if the exposure had occurred between ages 12 and 16. Psychopathology was assessed with the Positive and Negative Syndrome Scale and the Montgomery-Asberg Depression Rating Scale. Functioning was measured with the Global Assessment of Functioning (GAF) and the Social and Occupational Functioning Assessment Scale (SOFAS). Mediation analyses were performed in order to study whether the relationship between CT and functioning was mediated by depressive symptoms.

Results When compared with nonexposed patients, early but not late trauma patients showed lower levels of GAF and SOFAS scores over all the time points, excepting after the first assessment. After 30 and 36 months, the effect of early trauma on functioning was completely mediated by depressive symptoms. No mediating effect of positive or negative symptoms was highlighted at those time points.

Conclusion Mild depressive symptoms mediated the impact of early trauma on long-term functional outcome. Intensifying pharmacologic and/or psychotherapeutic treatment, focused on the depressive dimension, may help traumatized EP patients to improve their functioning.

EV1213

Age at the time of exposure to trauma modulates the psychopathological profile and the level of functioning in early psychosis patients: A prospective study

L. Alameda^{1,*}, G. Philippe², B. Philipp², D. Kim Q.³, C. Philippe²

¹ CHUV, Psychiatry, Psychiatric Liaison Service, Lausanne, Switzerland

² CHUV, Psychiatry, Treatment and Early Intervention in Psychosis Program TIPP, Lausanne, Switzerland

³ CHUV, Psychiatry, Unit for Research in Schizophrenia, Center for Psychiatric Neuroscience, Lausanne, Switzerland

* Corresponding author.

Introduction Evidence suggests a relationship between exposure to trauma and higher levels of symptoms and poorer functional outcomes in early psychotic patients (EPP). However, the impact of the age at the time of exposure to trauma in this association is as yet unknown.

Objectives To examine the potential differential impact of trauma, according to age at the time of exposure, on the level of functioning and on the psychopathological profile of EPP followed-up prospectively.

Methods Two hundred and fifty-five EPP aged 18–35 were followed-up prospectively over 36 months. Patients who had faced at least one experience of abuse or neglect were classified according to age at the time of first exposure (early-trauma: before age 12; late-trauma: between age 12 and 16), and then compared with unexposed patients (non-trauma). The level of symptoms was assessed using the Positive and Negative Syndrome Scale, the Young Mania Rating Scale, and the Montgomery-Asberg Depression Rating Scale. The level of functioning was assessed with the global assessment of functioning.

Results Comparisons over the 3 years of treatment with non-trauma patients revealed that:

- early-trauma patients showed consistently higher levels of positive ($P=0.006$) depressive ($P=0.001$), manic ($P=0.006$) and negative ($P=0.029$) symptoms and showed poorer functional level ($P=0.025$);

- late-trauma patients only showed more negative symptoms ($P=0.029$) as compared to non-trauma patients.

Conclusions The age at the time of exposure to trauma has a modulating effect on its impact on symptoms and functional outcome in EPP and it should be systematically examined in clinical and experimental settings.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Relationship between brain structural abnormalities and early onset psychotic disorder—case presentation

B. Allkoja¹, E. Mitro¹, B. Zenelaj¹, V. Alikaj^{2,*}

¹ University hospital center “Mother Tereza”, Psychiatric service, Neuroscience, Tirana, Albania

² University of Medicine, Faculty of Medicine, Neuroscience, Tirana, Albania

* Corresponding author.

Introduction Contemporary structural models of several psychiatric disorders propose abnormalities in the structure and function of distinct neural networks. Clinical observations of affective and cognitive changes arising from cerebellar lesions and stimulation permit the hypothesis that the cerebellum may not be irrelevant in

some neuropsychiatric states. There is evidence that patients with schizophrenia have altered corticocerebellar connectivity.

Objectives To evidence a case with early onset psychosis accompanied with brain structural abnormalities.

Method Case description.

Results The patient is 15 years old girl with an acute psychotic episode. For more than two months she had demonstrated odd behavior, getting around all the time purposelessly, abandoned school etc. She presented with disorders of perceptions, disorganized speech, insomnia and fluctuations in her mood and behavior. In her brain, MRI was found vermian atrophy, and CT was found hippocampal gliosis and dilatation of temporal corn.

Conclusions Although the structural mapping studies have been equivocal, the weight of evidence supports extending the study of cerebellar activity in schizophrenia. For example, the finding that unaffected first-degree relatives of probands with schizophrenia have reduced cerebellar volumes, along with the observation of reduced cerebellar volumes in neuroleptic-naïve patients with schizophrenia, suggests that cerebellar atrophy may be a hereditary trait rather than a psychotropic associated epiphenomenon.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Traumatic brain injury as psychosis development factor

A. Alonso Sánchez*, A. Álvarez Astorga, H. De la Red Gallego, M. De Lorenzo Calzón, N. De Uribe Viloria, M. Gómez García, C. Noval Canga, E. Mayor Toranzo, J.A. Blanco Garrote
Hospital Clínico Universitario de Valladolid, Psychiatry, Valladolid, Spain

* Corresponding author.

Introduction The pathophysiology of psychosis is not fully discovered yet. However, during the last years many different risk factors are shown to prove to have a strong influence within the development of this pathology. Traumatic brain injury (TBI) is one of them.

Objectives Show TBI as a psychosis development risk factor.

Methods Case report. A clinical vignette is presented followed by the results obtained in a bibliographic review.

Results A young 19-year old immigrant man, who lives with his parents in a social exclusion situation is brought to the hospital after having been observed making estrange religious rituals within a local river. During the anamnesis he declares that God is “getting in touch with him” while he shows to be changed, with suspicion about being pursued. He also reveals to have suffered a mild-severe TBI with 8 years, having right ear audition problems since then. During the hospitalization some medical test were done, such as MRI, showing the lack of the inner right ear, as well as white matter abnormalities in his right hemisphere, which could be consequence of the TBI. Those findings make us think that this pathology might have been influenced, within other factors, by the traumatic brain injury.

Conclusions This bibliographic review shows that traumatic brain injury may increase the risk of developing psychosis up to 65% from healthy controls, with a medium gap of 3.3 years between the TBI and the appearance of psychotic pathology.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Madness and creativity are thought to be related from ancient ages. Nowadays, thanks to new scientific developments and researches we are able to identify common genetic and brain patterns between creativity and psychosis.

Objectives Taking the inspiration of a psychotic patient with some shocking drawings, we want to get deep into the actual knowledge about the relation between creativity and psychosis.

Methods Case report and bibliographic review.

Results A 19-year-old man was brought to the hospital after having been found making strange rituals in the public way. In the anamnesis he showed to have experienced mystic delusions and hallucinations. He made some particularly creative drawings.

We made a review which showed that this patients may have a diminished latent inhibition, which could make them experiencing usual live irrelevant stimuli as something very exciting and creative at the same time. Genome wide association studies show also that people having creative jobs and psychotic patients share some genes, which could be linked to this abnormal latent inhibition.

Conclusions Latent inhibition abnormalities could be related with psychosis and creativity. There are differences within the course of people having this oversensibility, which could be explained due to the presence of protective and risk factors.

EV1217

A fine line between schizophrenia and Hashimoto encephalopathy

I. Amado

Centro Hospitalar Médio Tejo, Psiquiatria, Coimbra, Portugal

Introduction Hashimoto encephalopathy (HE) is an uncommon syndrome associated with Hashimoto thyroiditis. The relationship between these entities is unclear. Even being rare, it appears to be underrecognized.

Objectives Report a case of an atypical presentation of psychosis in a patient with elevated serum levels of antithyroid antibodies and review the literature about similar situations.

Methods Access clinical process, research PubMed, using the mesh terms “Hashimoto encephalopathy” and “psychosis”.

Results A 21-year-old Portuguese female was conducted by authorities to our emergency department after she called for help and was spotted walking barefoot on the streets. Throughout clinical course she presented persecutory ideas, thought blocks, auditory hallucinations, soliloquies, perplexity, total insomnia, bizarre behaviors like coprophagia, trichotillomania and self-injured burns. After some tests, it was found that the patient had high serum levels of antithyroid peroxidase antibody (TPO) and antithyroglobulin antibody (TGO) and reduced folic acid, without other changes. Trials with corticosteroids showed clinical improvement for short periods, as with antipsychotics. No consistent remission was achieved with either approaches.

Conclusion HE is an uncommon syndrome presenting with high titers of antithyroid antibodies that may preconize an acute state of atypical psychosis. Usually, it responds to corticosteroids and so, has a generally good prognosis when treated accordingly. Evidence

suggests that HE is an autoimmune disorder instead of thyroid disease.

Introduction Main schizophrenia symptoms result from abnormalities in brain function, such as hypofrontality and structural deficits on the prefrontal-thalamic-cerebellar circuit, as shown in brain imaging studies in first-episode SCZ patients. Whether metabolic alterations may be underlying these events is being studied thoroughly.

Objectives/aims To assess brain metabolic disturbances in first episode and/or drug-naïve SCZ patients.

Methods We conducted a literature review through Pubmed search for MeSH: schizophrenia, metabolism, glucose, insulin, brain. Controlled studies on first episode and/or drug-naïve SCZ patients were included.

Results Lower metabolic activity in the frontal regions of the brain is associated to an increase in norepinephrine transmission and decrease in dopaminergic transmission with reduced dopamine efflux in the frontal cortex. This seems to lead to cellular changes resulting in resulting lower blood flow and glucose demand. Molecular analysis of postmortem SCZ patients' brains has indicated alterations in glucose metabolism and insulin signalling pathways, showing evidence for prefrontal cortex decreased expression of glucose metabolism, namely glycolytic enzymes such as glyceraldehyde 3-phosphate dehydrogenase, hexokinase, phosphoglycerate mutase, enolase and pyruvate kinase and decreased levels and phosphorylation of the insulin receptor and insulin signalling proteins AKT1 and GSK3 β . Significantly elevated glucose concentrations in cerebrospinal fluid were observed in SCZ patients, but with no serum levels differences. A SCZ brain specific increased glucose could be explained by preferential utilization of lactate, predominantly produced by astrocytes, over glucose as an energy substrate.

Conclusions Abnormalities in brain glucose metabolism and insulin signalling seem to appear in early stages of SCZ, suggesting a role in SCZ onset and pathophysiology.

* Corresponding author.

Introduction Schizophrenia (SCZ) is frequently associated with metabolic symptoms including dyslipidaemia, hyperinsulinemia, type 2 diabetes and obesity. In fact, SCZ patients have been reported to present higher prevalence of these conditions than general population, commonly associated to second generation antipsychotic therapy. Recent studies, however, have demonstrated that peripheral metabolic disturbances can appear at disease onset or drug-naïve patients.

Objectives/aims To assess metabolic disturbances in first episode and/or drug-naïve SCZ patients.

Methods We conducted a literature review through Pubmed search for MeSH: schizophrenia, metabolism, glucose, insulin. Controlled studies on first episode and/or drug-naïve SCZ patients were included.

Results Several studies showed no change in SCZ patients' fasting blood glucose, while others found increased glucose levels and impaired glucose tolerance in SCZ patients compared to healthy controls in several recent studies. Hyperinsulinemia and insulin resistance have also been identified in antipsychotic-naïve SCZ patients and it has been suggested that early onset patients are more likely to present insulin resistance. In addition, there's evidence of increased circulating levels of chromogranin A, pancreatic polypeptide, prolactin, cortisol, progesterone, thus emphasizing that multiple components of the hypothalamic-pituitary-adrenal-gonadal axis may be affected in SCZ. These elevations were associated to normal glycaemia suggesting there may be insulin intolerance during early stages of SCZ, requiring an increased secretion from pancreatic Bcells to maintain normal glucose levels.

Conclusions Recent studies of first onset and/or drug-free schizophrenia patients have shown impaired fasting glucose tolerance, hyperinsulinemia and insulin intolerance, suggesting that metabolic abnormalities may play a role in SCZ onset and pathophysiology.

Systemic review: High dose olanzapine treatment for treatment resistant schizophrenia

Z. Azvee^{1,*}, J. Lally²

¹ Beaumont Hospital, Liaison Psychiatry, Dublin, Ireland

² Royal College of Surgeons Ireland, Psychiatry, Dublin, Ireland

* Corresponding author.

Objectives Schizophrenia is a major mental illness with a progressive course. Thirty percent of cases of patients with schizophrenia do not respond to adequate trials of at least 2 different groups of antipsychotics, are currently classified as having treatment resistant schizophrenia (TRS). Clozapine remains the gold standard, treatment of choice for TRS. However, clozapine does not come without its own challenges. Its risk profile, particularly agranulocytosis, reported in 1% of cases, has led to the necessity of weekly blood counts within the first 18 weeks of treatment and subsequently every month with slow dose titration. Clinically, sedation, weight gain and hypersalivation may further hamper the compliance of patients. Non-compliance has been reported to cause rebound psychosis. Recent studies have raised questions as to which antipsychotic is most efficacious for TRS. Thus, we conducted a systematic review of high dose olanzapine treatment for people with TRS.

Method A systematic review of prospective studies found through search of PubMed, Scopus and hand-searched key papers which included randomized controlled trials and open-label studies which looked at high dose of olanzapine treatment response for TRS.

Results The study is currently ongoing and preliminary results will be presented at the conference in April 2017.

Conclusions The gravity of burden TRS brings to patients extends itself to their families, carers and clinicians. Further evidence on which antipsychotic is more efficacious for patients with TRS would have huge implications in terms of health benefits for the patients, better informed clinical decisions and also health economics in general.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Introduction Schizophrenia is a chronic mental illness associated with several functional impairments. There has been an increasing interest in the impact of schizophrenia on functioning. The development of the Comprehensive International Classification of Functioning, Disability and Health (ICF) Core Set for schizophrenia, a shortlist of 97 ICF categories that are relevant for describing functioning and disability of people living with schizophrenia, has derived from this interest.

Objectives This study aims to explore the content validity of this core set from the perspective of psychiatrists.

Methods In a 3-round Delphi survey, psychiatrists experienced in schizophrenia treatment were asked about patients' problems, resources and environmental factors they treat in patients with schizophrenia.

Results A total of 352 psychiatrists from 65 countries representing all six World Health Organization regions completed the first round questionnaire. The response rate at the third round was 86%. Answers were linked to 422 ICF categories. Of all these, 109 ICF categories reached consensus ($\geq 75\%$ agreement) at the third round. Eighty-seven out of the 97 ICF categories that form the comprehensive ICF core set for schizophrenia were represented in this list. All the comprehensive ICF core set for schizophrenia categories reached consensus except five categories.

Conclusions The content validity of the comprehensive ICF core set for schizophrenia from the perspective of psychiatrists was largely supported. However, further research is needed including other health professionals (e.g., psychologists, nurses and occupational therapists) to further obtain new content validity evidences.

Clinical symptoms, course and outcomes of paranoid schizophrenia are polymorphic. Reliable predictors of severity and activity of schizophrenic process could provide clinicians important prognostic information for adequate and timely implementation of therapeutic and rehabilitative measures. Overall, 206 patients with paranoid schizophrenia were examined. Clinical predictors were collected from hospital records and interviews. *BDNF* gene Val66Met polymorphism (rs6265 G>A), *DRD2* gene C939T polymorphism (rs6275C>T) and *5-HTR2A* gene T102C polymorphism (rs6313 T>C) were studied as potential markers of prognosis for paranoid schizophrenia. Results of research testify that the *DRD2* gene C939T polymorphism and *5-HTR2A* gene T102C polymorphism cannot be used as predictors of the severity and activity of paranoid schizophrenia. The MetMet genotype of *BDNF* gene Val66Met polymorphism can be used as marker of favorable prognosis for paranoid schizophrenia. Schizoid, epileptoid, psychasthenic and conformal accentuation of personality in the premorbid, early onset of psychosis, paranoid and hallucinatory-paranoid variants of onset predicted more expressed severity of paranoid schizophrenia. These prognostic factors can be taken into account in clinical practice.

⁵ Daugavpils Psychoneurological Hospital, Department of differential diagnosis in psychiatry, Daugavpils, Latvia

* Corresponding author.

Introduction Improved insight level among schizophrenia patients is predictive for better illness prognosis.

Objective Explore factors connected to insight.

Aim Evaluate the insight level and clinical characteristics of first time hospitalized schizophrenia spectrum patients.

Methods All consecutive first time hospitalized schizophrenia spectrum patients in a psychiatric hospital from 01.01.2016–26.09.2016. Patients were interviewed upon hospitalization and at the discharge with Scale for the assessment of positive symptoms (SAPS) and negative symptoms (SANS), Schedule of assessment of insight-extended (SAI-E), The Calgary depression scale for schizophrenia (C-sch), sociodemographic and clinical data were collected. All participants signed written informed consent and the study was approved by the Riga Stradins University Ethics committee.

Results From 45 first episode patients, 38 met the inclusion criteria. Mean age was 37.66 years (SD: 11.48 years), the average duration of untreated illness (DUI) was 40.5 months (SD: 57.35 months). Psychopathologic symptoms and insight levels evaluated in scores in the 1st and 2nd interviews were as follows: SAPS 69.11 (SD: 20.78) and 33.61 (SD: 18.04), SANS 63.21 (SD: 25.30) and 40.95 (SD: 24.47), SAI-E 15.50 and 27.24 (SD: 13.24), $P < 0.001$, C-sch 8.50 (SD: 5.31) and 4.27 (SD: 2.86), $P < 0.05$. There was no statistically significant correlation between DUI and insight level. A higher level of insight at hospitalization correlated with higher levels of depression: $r = 0.569$, $P < 0.001$.

Conclusions We noticed a tendency that lower insight levels might correlate with longer periods of untreated illness. We found that higher insight levels correlated with higher symptoms of depression.

A gender approach in prodromes of psychosis

C.M. Calahorra^{1,*}, M. Guerrero Jiménez², B. Giralá Serrano²

¹ Hospital Universitario San Cecilio, Unidad de Salud Mental, Granada, Spain

² Santa Ana Hospital, Psychiatry, Granada, Spain

* Corresponding author.

Background Only 21% of patients included in the South of Granada's First Episodes Program in the year 2014 were women. Studies do not use to focus on sex differences at first-episode samples and it can be masking some relevant variables in this population.

Aims In this exploratory study, we aim to focus on gynaecological consultations during the period of untreated psychosis (DUP) at first episodes of psychosis in women.

Methods A retrospective clinical-cases review of medical histories was made searching for sociodemographic variables, consultations during DUP and psychotic prodromal outcomes.

Results The average age of the sample was 23 years. The average of DUP was one to three months. Sixty percent of referees to mental health services were from primary care and 20% from emergency services. The main symptom was persecutory or prejudice delusions. Thirty-six percent of them were related to sexuality or pregnancy. In most cases, the demands were not bizarre. When a wide history was made and they were properly explored, a delusional theme was appreciated and the reason for consultation was not justified. Eg. Postcoital pill order for not taking precautions, in a telepathic relationship. Forty percent of claims were made in primary care. Half of them were assessed by a gynecologist. Sixty percent were treated in the emergency room.

Conclusions We conclude that these data are relevant for specialists. Both for efficient resource management and for early detection of incipient psychosis. Gynecological abnormal demands are common in consultations to health services for specific malaise during the period of untreated psychosis.

Introduction There are many jobs that offer advantages of treatment with long-acting injectable in psychosis.

Objective To know the changes in the different variables after the start of paliperidone palmitate (PP).

Material and method We performed a descriptive and retrospective study. Were evaluated patients who received maintenance therapy with PP during 48 months.

Results The sample was composed of 29 patients: 72.4% men and 27.6% women. Average age of 46.21 years. In Figures 1, 2 and 3 show data obtained in relation to compliance with treatment, relapse, maintenance dose, number of admissions and visits to emergency departments respectively.

Conclusions The administration of PP is associated with a higher level of compliance with treatment. The patients presented a lower number of relapses, hospitalizations and visits to the emergency room. The maintenance dose more used is 150 mg.

Vitamin B12 deficiency induced psychosis – a case report

A.R. Carvalho*, S. Vacas, C. Klut

Serviço de Psiquiatria- Hospital Beatriz Ângelo, Departamento de Psiquiatria e Saúde Mental, Hospital Beatriz Ângelo, Lisboa, Portugal

* Corresponding author.

Vitamin B12 is one of the most essential vitamins affecting various systems of the body. Cases of neuropsychiatry disorders due to its deficiency are more common in elderly patients with prevalence of 10–20%. The most common psychiatry symptoms reported in the literature associated with vitamin B12 deficiency was depression, mania, psychotic symptoms, cognitive impairment and delirium. Here, we report a case of vitamin B12 deficiency in a 52-year-old male who presented with psychotic features: persecutory

delusions, tactile and auditory hallucinations. Patient had neither recorded psychiatry history nor any drug abuse. Medical history includes hypertension, diabetes mellitus and glaucoma. The patient was not a vegetarian. All relevant laboratory evaluations and head CT were normal except vitamin B12. The patient was treated with antipsychotics (risperidone 3 mg/day) and intramuscular vitamin B12. One week after, there was total remission of psychotic symptoms. In the follow-up during the next four months, psychiatry symptoms did not recur at any time. This case reports a rare case of vitamin B12 deficiency induced psychosis. Although there was concurrent administration of an antipsychotic along with vitamin B12, it underlines the importance of evaluation of vitamin B12 and other potential reversible causes of psychosis.

QTc interval in patients diagnosed with schizophrenia receiving different defined daily dose (DDD) of antipsychotics

T. Christensen^{1,*}, R. Møller Jeppesen²

¹ Aarhus University Hospital Risskov Denmark, Department of Psychiatry, København Ø, Denmark

² Aarhus University Hospital Risskov Denmark, Department of psychiatry, Aarhus, Denmark

* Corresponding author.

Introduction Both 1st and 2nd generation of antipsychotics are associated with prolonged QTc interval. Prolonged QTc can lead to ventricular tachycardia and Torsade's de pointes, ultimately resulting to cardiac arrest and sudden death. Prolonged QTc interval due to increased DDD has not yet been investigated.

Objective To investigate whether increased DDD of antipsychotics, causes further prolonged QTc, by patients diagnosed with schizophrenia.

Aims To learn more about antipsychotics impact on the QTc interval in patients diagnosed with schizophrenia.

Methods An observational study of unselected patients diagnosed with schizophrenia. Enrolled from January 2013 through March 2015 with follow-up until June 2015 in the region of central Denmark. Data was collected from ECG records and patient journals.

Result ECGs were available in 58 patients. We observed no relation between increased DDD of antipsychotics and prolonged QTc. There were no differences in average QTc interval for the whole sample of patients receiving different DDD of antipsychotics.

Conclusion We do not recommend increased attention to patients treated with higher DDD of antipsychotics.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Normalization of mortality rate and life expectancy in schizophrenia: Challenges and options

D. Cohen

Mental Health Care Organization Noord-Holland North, Community Mental Health, Heerhugowaard, Netherlands

Studies of mortality-rates and life expectancy in schizophrenia have consistently shown that the standardized mortality rate (SMR) are raised compared to the general population. In a meta-analysis (2007) of 38 studies with 22,296 deaths, all cause SMR was 2.98. SMR in a French cohort study (2009) in 3470 patients

with schizophrenia, were 3.6 for men and 4.3 for women. A recent epidemiological study (2015) of a US-cohort of 1,138,853 individuals with schizophrenia, 4,807,121 million years of follow-up and 74,003 deaths, all cause SMR was 3.7 for the total population: 3.3 for men and 4.3 for women. Life expectancy, the other side of the coin of increased SMR, in this study was reduced with 28.5 years. Studies in life expectancy, the other side of the coin of increased SMR, show a substantial, if not alarming reduced life expectancy. Israel with 12.5 years and Denmark–15 years for women and 20 years for men – reported the lowest reduction in life expectancy, while Arizona reported the highest reduction of 32 years. Progress in such diverse fields as genetics, neuro-imaging, early diagnosis of (ultra) high-risk populations, CBT and rehabilitation treatment, has not improved schizophrenia SMR or life expectancy. On the contrary, in far a trend is visible, the situation tends to worsen, not to improve. After going through the barriers for optimal somatic care, both patient and health care related, we will discuss options for improvement of the level of somatic health care, at the preventive and therapeutic level.

* Corresponding author.

Purpose Recent evidence points to a critical role of redox dysregulation induced oxidative stress in the pathophysiology of early phases of schizophrenia. An add-on trial with n-acetyl-cysteine (NAC) led to a reduction in negative symptoms in chronic schizophrenia patients. Aim of this study was to explore impact of addition of NAC to standard treatment in early psychosis (EP) patients.

Methods Double-blind, randomized, placebo-controlled trial of addition of NAC, 2700 mg daily, to antipsychotic treatment over 6 months. Monthly assessment of PANSS, GAF, SOFAS and antipsychotics treatment; quantification of brain glutathione levels (GSH_{mPFC}) by ¹H-magnetic-resonance-spectroscopy and of blood cells glutathione (GSH_{BC}) and glutathione peroxidase activity (GPx_{BC}) as marker of oxidation status at the beginning and end of treatment.

Results Overall, 63 patients were included. Spectroscopy data showed that GSH_{mPFC} increased by +23% in the NAC group, while it tended to decrease by –5% in the placebo group ($P=0.005$). No significant difference between NAC and placebo was observed

on global changes in negative symptoms, positive symptoms or functional outcome. However, in patients with high-baseline oxidation status (GPx_{BC}>22.3U/gHb), subgroup explorations revealed an improvement of positive symptoms over time compared to patients with low-baseline GPx ($P=0.02$).

Conclusions While addition of NAC induced an increase of brain GSH, it had no impact on symptomatic and functional outcome in EP patients. However, in patients with high oxidation status, addition of NAC leads to significantly greater improvement in positive symptoms. Future studies on antioxidant interventions in EP should consider biomarker-guided treatment.

* Corresponding author.

Introduction Peripersonal space has been defined as the area immediately surrounding the body in which interactions with a person or an object can occur. Larger peripersonal space may reflect discomfort in close interpersonal situation or cognitive deficit. Individuals with schizophrenia are more sensitive to social stimulation. The capacity to provide accurate judgments of peripersonal space boundaries depend on the capacity to create an organized and structured mental representation that integrates signals from different sensory modalities and brain regions.

Objectives We conducted a study on personal space in patients with schizophrenia using a paradigm that was not affected by emotional and social interference.

Aims We aimed to investigate the characteristics of personal space in patients with schizophrenia.

Methods We recruited 20 schizophrenic patients according to DSM-V criterion and 20 healthy volunteers, matched by gender and age. Schizophrenic symptoms were assessed using the Positive and Negative Syndrome Scale (PANSS). Participants performed the peripersonal space (PPS) task. Collected data underwent statistical analyses.

Results Schizophrenic patients demonstrate a stronger/weaker need for personal space, than the comparison group, depending on the score of negative and positive symptom, as assessed by using the PANSS even without emotional and social interference.

Conclusions Interpersonal interactions between the individual with schizophrenia and people in their immediate environment can lead to increased symptomatology. Social isolation is one of the most primary causes of poor quality of life in mental illnesses. Better understanding of the mechanisms for abnormal interactive behavior could provide significant valid guidelines for innovating intervention programs.

F17464 a new antipsychotic with preferential D3 antagonist, 5-HT_{1A} partial agonist properties. Neurochemical studies

C. Cosi*, V. N'Guyen, N. Consul-Denjean, A. Auclair, P. Heusler, J.C. Martel, L. Leriche, P. Sokoloff, S. Gatti-McArthur

Institut de recherche Pierr-Fabre, centre d'évaluation préclinique, unité innovation SNC, Castres, France

* Corresponding author.

F17464 is a new dopamine receptor antagonist that recently demonstrated antipsychotic activity in a proof of concept study in schizophrenic patients under acute exacerbation. The compound has a unique profile with high affinity for hD₃ receptors (K_i=0.17 nM) and lower affinity for hD_{2L} (K_i=12.1 nM) and hD_{2S} (K_i=6.5 nM). F17464 exhibits also high affinity for h5-HT_{1A} receptors (K_i=0.16 nM). F17464 is a hD₃ antagonist (pK_B=9.13), hD_{2S} very weak partial agonist (pK_B=7.87, emax 8% of DA stimulated in ERK assay) and a 5-HT_{1A} partial agonist (pEC₅₀=7.99). F17464 exhibits consistent affinities for rat striatal D₂ (K_i=4.8 nM) and for rat hippocampal 5-HT_{1A} receptors (K_i=1.14 nM). Neurochemical studies show that F17464 ip (1 h post-dose) produces a significant dose-dependent increase in the levels of DOPAC and HVA in the frontal cortex, caudate-putamen and limbic forebrain and an increase in 3-MT levels in the latter two regions with no changes in total DA content. The effect is significant at the doses of 0.63–2.5 mg/kg ip (PK/PD data will be provided). This pattern of DA metabolite changes is similar to that described for several antipsychotic drugs in rodents and it is indicative of a cortical effect of F17464. F17464 has a very low cataleptogenic activity in rats and mice and does not induce serotonergic signs typical of 5-HT_{1A}. F17464 is therefore a novel a D₃ preferential antipsychotic with a unique mechanism of action and receptor affinity profile and a consistent effect in neurochemistry studies in rodents.

A novel methodology to evaluate the molecular validity of preclinical psychosis models compared to schizophrenia brain pathology

D. Cox*, M. Gottschalk, H. Wesseling, A. Ernst, J. Cooper, S. Bahn

Cambridge Centre for Neuropsychiatric Research, Institute of Biotechnology, Cambridge, United Kingdom

* Corresponding author.

Rodent models of schizophrenia (SCZ) are indispensable when screening for novel treatments, but quantifying their translational relevance with the underlying human pathophysiology has proved difficult. A novel systems methodology (shown in **Figure 1**) was developed integrating and comparing proteomic data of anterior prefrontal cortex tissue from SCZ post-mortem brains and matched controls with data obtained from four established glutamatergic rodent models, with the aim of evaluating which of these models represent SCZ most closely. Liquid chromatography coupled tandem mass spectrometry (LC-MS^E) proteomic profiling was applied comparing healthy and “disease state” in human post-mortem samples and rodent brain tissue samples. Protein-protein interaction networks were constructed from significant abundance changes and enrichment analyses enabled the identification of pathophysiological characteristics of the disorder, which were represented across all four rodent models. Subsequently, these functional domains were used for cross-species comparisons.

Five functional domains such as “development and differentiation” represented across all four rodent models, were identified. It was quantified that the chronic phencyclidine (cPCP) model represented SCZ brain changes most closely for four of these functional domains, by using machine-learning techniques. This is the first study aiming to quantify which rodent model recapitulates the neuropathological features of SCZ most closely. The methodology and findings presented here support recent efforts to overcome translational hurdles of preclinical psychiatric research by associating behavioural endophenotypes with distinct biological processes.

* Corresponding author.

Introduction There is growing evidence about the importance of motor symptoms in psychosis. Motor abnormalities have been observed in naive-drugs, first-episode patients. Clinical assessment of motor abnormalities normally relies upon subjective observer-based ratings. Kinematic analysis of handwriting has proved to be an objective measure of motor symptoms, but it has not been used in clinical settings.

Objectives In the present work, the geometrical analysis of handwriting patterns is proposed as a new tool to evaluate motor symptoms in psychosis.

Method Overall, 35 healthy participants and 43 patients with psychosis from San Agustín Hospital (Linares, Spain) participated in the study. Participants were asked to write with a pen on a white paper (see patterns in the [Figure 1](#)). In order to analyze the heterogeneity of handwriting patterns, we employed lacunarity, a nonlinear measure previously used in the analysis of biomedical images. Lacunarity measures the distribution of gap sizes in a geometrical space. A large value implies large gaps and clumping of points, whereas a small value suggests a uniform distribution with shorter gaps.

Results Lacunarity was significantly higher in handwritten patterns from patients than in controls. In addition, we found a higher heterogeneity in patients with motor symptoms in comparison with patients without motor symptoms.

Conclusions Our results suggest that analysis of handwritten patterns can be a valuable method in the evaluation of motor symptoms.

The predictive role of insight for the evolution of the disease in Romanian patients diagnosed with schizophrenia

C.A. Crisan^{1,*}, S. Pintea², I. Miclutia¹, R. Macrea³¹ UMF "Iuliu Hatiegan" Cluj-Napoca, Department of Neurosciences, Cluj-Napoca, Romania² Babes-Bolyai University, Faculty of Psychology and Educational Sciences, Clinical Psychology and Psychotherapy Department, Cluj-Napoca, Romania³ Psychiatry Clinic II, Adult Psychiatry, Romania

* Corresponding author.

Introduction Schizophrenia is a serious disorder that influences all life aspects of the patients. The most important goals in schizophrenia are remission, recovery, improving psychosocial functioning and quality of life, which can be influenced by different factors, especially insight.

Objectives To evaluate the awareness of illness in Romanian patients diagnosed with schizophrenia and to determine the predictive role of insight.

Aims This study wants to highlight the importance of the evaluation of insight in psychotic patients, taking into account that awareness leads to compliance with treatment, decreased rate of relapses and rehospitalization and a better prognosis.

Material and methods Overall, 80 patients (44 males and 36 females) recruited from first and second psychiatric clinic Cluj-Napoca, diagnosed according to ICD-10 and DSM-V criteria with schizophrenia and acute psychotic disorder participated in this study. A semi-structured interview collected demographical data. Psychotic symptoms were evaluated using PANSS, severity of the disease using CGI and insight using SUMD.

Results Our results showed that the most important predictive factors for the evolution were: level of insight ($r = -0.41$ $P < 0.01$), presence of family history ($r = 0.24$ $P < 0.05$) and belonging to urban areas ($r = 0.23$ $P < 0.05$). The level of insight explained 16% of variance of improving psychotic symptoms during hospitalization.

Conclusions The awareness of illness is one of the predictive factors for long-term schizophrenia and the best predictive model of disease progression is composed of variables SUMD total and PANSS total on admission.

EV1236

Validation of the delusional ideation inventory for the Portuguese population

S. Pimentel^{1,*}, M. Cunha², A. Galhardo², M. Couto¹¹ Miguel Torga Institute, Clinical Psychology, Coimbra, Portugal² Miguel Torga Institute/CINEICC, Clinical Psychology, Coimbra, Portugal

* Corresponding author.

Introduction The dimensional approaches regard delusions as a continuum of the daily beliefs, not being limited to the clinical population and it can also be found in the general population. Due to the multifaceted conceptualization of delusions, the analysis of the dimensions of distress, preoccupation and conviction may be more revealing than the content of the belief itself, whereby an evaluation that incorporates these dimensions is fundamental.

Objective Translation, adaptation and study of the psychometric properties of the Peters et al. delusions inventory (PDI-21) for the Portuguese population.

Aim Assessing the multidimensionality of the delusional ideation in the community.

Methods The sample consists of 249 adults from the general population, aged between 18 to 65. The brief symptom inventory, the social desirability scale of the Eysenck personality questionnaire and the World Health Organization quality of life-bref were used in this study beyond the PDI-21.

Results The Portuguese version of the PDI-21 has shown good psychometric properties regarding its internal consistency and test-retest reliability. It demonstrated significant positive correlations with the psychopathological symptoms and negative associations with social desirability and with the quality of life, confirming its divergent and convergent validity. The analysis of the frequency of delusional ideas for the total of the sample and on the basis of gender has revealed prevalence rates very similar to the ones found in previous studies.

Conclusions The Portuguese version of the PDI-21 has adequate psychometric properties and it can be used to assess the delusional ideation in the general population.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1237

Quetiapine in treatment of first episode schizophrenia

N. Zivkovic*, G. Djokic

Clinic for psychiatric disorders "Dr Laza Lazarevic", Belgrade, Urgent psychiatry, Belgrade, Serbia

* Corresponding author.

Introduction Although there is no cure, schizophrenia is highly treatable disease. Successful first episode schizophrenia (FES) treatment is crucial to minimize personal, vocational and social deterioration. Quetiapine is atypical, second generation antipsychotic, serotonin-dopamine antagonist. Quetiapine is potent blocker of D2, 5HT2A and 5HT1A receptors.

Objective To estimate efficacy of quetiapine in treatment of first episode schizophrenia.

Methods This study included 70 patients with FES diagnosed by ICD-10 criteria, who are divided into haloperidol (H) 35 patients and quetiapine (Q) group 35 patients. Patients were observed for 6 months in hospital and extra hospital conditions, according to protocol which included Positive and Negative Symptom Schedule (PANSS) and the number of withdrawals attributed to adverse event (AE). Control group was treated with haloperidol 5–20 mg/24 h and experimental group was treated with quetiapine 400–800 mg/24 h.

Results Average pretrial PANSS score was 110.1 in quetiapine and 108.5 in haloperidol group. Average PANSS score after 180 days was 50.6 in Q and 60.4 in H group. There is no statistical difference in pretrial scores between groups for PANSS score ($P = 0.647$). There is significant statistical difference in PANSS score reduction after 180 days in both groups ($P < 0.001$). There is significant statistical difference in PANSS score reduction between Q and H group after 180 days ($P < 0.001$). Overall, 8.6% AEs occurred in Q, and 25.8% in H group.

Conclusion Quetiapine has shown better efficacy in treatment of FES comparing to haloperidol, with statistically significant lower adverse effects rate.

Factors of premorbid period indicating the risk of medicated noncompliance in patients with schizophrenia

E. Dmitrieva*, E. Kornetova

Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Endogenous Disorders Department, Tomsk, Russia

* Corresponding author.

Background Methods of assessment of medicated compliance are based upon preceding experience of taking therapy and cannot be applied at the first admission.

Objective To investigate premorbid characteristics in schizophrenic patients and reveal the factors indicating noncompliance.

Methods We used medical record background, interview, Medical Compliance Prediction Scale for Psychiatry for evaluation of the level of compliance, program STATISTICA10 for identification of the average level of compliance in the subgroups of each factor by Kruskal–Wallis test and revealing those subgroups for each factor where the average level of compliance was statistically significantly lower ($P < 0.05$).

Results We examined 120 patients (status corresponded to the ICD-10 diagnostic criteria for schizophrenia, age–18 and older, duration of the disease–5 years and more, patients taking typical or atypical antipsychotics or combined therapy) according to factors of premorbid period such as gender, family history of mental disorders, personality traits, nurture in the family, education level, marital status; substance use, age at the onset of disease.

Conclusions Level of compliance was lower in subgroups of men, patients having several relatives with mental disorders, patients having personality with predominance of irritable and impulsive traits, patients with neglect in parental families, patients with education level lower than high school and with education level higher than bachelor; patients not working or studying to onset of disease; patients who were divorced or widowed; patients living alone; patients using psychoactive substances; patients aged 21 years and older to the onset of disease.

Objectively measurable equilibrium locomotor ataxia in schizophrenia

G. Dzhanupov*, S. Haralanov, P. Terziivanova, E. Haralanova

Medical University, Sofia, Department of Psychiatry and Medical Psychology, Sofia, Bulgaria

* Corresponding author.

Introduction The basic role of cerebellar dysfunctions in schizophrenia pathophysiology is already well-known. Importantly, cerebellar signs such as gait and balance coordination deficits are objectively manifested and measurable. However, both early detection and treatment monitoring of the illness are still-based mainly on subjective psychopathological symptoms.

Aims To introduce an objective and quantitative approach to the cerebellar gait and balance disorders in schizophrenia.

Methods An original (internationally patented) method for objective equilibrium quantification of stepping locomotion (a kind of motion analysis system) was developed and then applied repetitively in 230 schizophrenic patients and 230 well-matched healthy controls.

Results Subclinical but objectively measurable equilibrium locomotor ataxia (ELA) was identified in a large proportion of the investigated patients. Its severity fluctuated along with the

changes in the clinical state. As a rule, the degree of ELA transiently increases during psychotic exacerbation and gradually returns to its prepsychotic level during therapeutic remission. Data analysis revealed that the basic (prepsychotic and postpsychotic) ELA could be viewed as a new schizotaxic biomarker (trait-marker) for schizophrenia, while the degree of its severity could serve as a new objectively measurable state-marker for psychosis. Besides, its dynamics during antipsychotic treatment might be used as an objective measure of the therapeutic response (a kind of surrogate pharmacodynamic biomarker).

Conclusions Objective quantification of the ELA allows for early detection of subclinical signs of cerebellar ataxia (or schizotaxia) in individuals at high-risk for schizophrenia, whereas in psychotic patients it permits their objective antipsychotic-treatment monitoring.

⁴ Vestfold Hospital Trust, University of Oslo, Mental Health and Addiction, Department of psychology, Tønsberg, Oslo, Norway

* Corresponding author.

The mortality of schizophrenia patients is approximately twice that of the general population and there is a 20% reduction in life expectancy in this patient group. Cardiovascular disease (CVD) is responsible for as much as 50% of the excess mortality associated with schizophrenia. One important source of the high CVD prevalence is the cluster of metabolic characteristics defining the metabolic syndrome (MetS: 3 or more of the following features: abdominal obesity, high blood pressure, elevated levels of triglycerides and fasting glucose and low levels of high-density lipoproteins). Patients with schizophrenia seem to be undertreated for these vascular risk factors relative to the general population. More knowledge is needed concerning broadened risk factors of cardiovascular disease in a representative sample of schizophrenia patients. We conducted preliminary cross sectional analyses in a sample of 64 consecutive outpatients with schizophrenia with a mean age of 37 years consisting of 59% men, who were enrolled in a treatment study. All used antipsychotics, and 71% were smokers. We found that (percentage of patients under treatment for the respective somatic condition in parenthesis) 82% were overweight, 49% had hypertonia (17%), 24% hyperglycemia (3%), 48% hypertriglyceridemia and 13% hyperlipidemia (10% triglycerid or cholesterol lowering medication). Forty percent had metabolic syndrome compared to 11% in the normal population (Norway, age corrected). Additionally, estimates of insulin resistance will be conducted. We found that the prevalence of MetS components was high in outpatient schizophrenia. A substantial discrepancy was found between metabolic ill health and medication treatment of such conditions.

EV1241

Victimization and perpetration of crime in patients with schizophrenia and related disorders involuntarily admitted

F. Fortugno

Queen Mary University of London, Unit for Social and Community Psychiatry, London, United Kingdom

Introduction Incidence of crime victimization and perpetration is higher in severely mentally ill people than in general population. In the literature, fewer papers investigate the risk of being a victim than the risk of perpetrating violence in psychiatric patients.

Objectives To study incidence of self-reported crime victimisation or perpetration in 2 multicentric database of patients suffering from schizophrenia or related psychoses who are admitted involuntarily to hospital.

Methods Included involuntarily admitted patients with ICD-10 diagnosis of F20-F29, age 18–65, giving informed consent. Univariable and multivariable logistic regression to estimate odds ratios. Structured interview and BPRS by trained operators.

Results Three hundred and eighty-three and 543 cases for each database. Victims: 37.8% and 28.0%. Accused: 25.6% and 11.6%. Victims had higher BPRS subscale of Mania, were unemployed and had fewer social contacts. Accused had higher mania in one of the 2 sample. Sociodemographic predictors included unemployment and homelessness, younger age and male gender.

Discussion Sociodemographic factors are important predictors of being accused of a crime. Higher symptoms of mania are associated with higher odds of being victim of violence in 2 multicentric samples, after correction for other variables. Rates of both victimisation and perpetration rates are higher than in samples of people from general population or from outpatients settings. Accused and victims have a strong association with consideration on the context of life.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

⁴ Faculty of Biology, University of Barcelona, Department of Biochemistry and Molecular Biomedicine, Barcelona, Spain

* Corresponding author.

Introduction Despite multiple clinical and preclinical studies investigating schizophrenia, the neurobiological basis of this disease is still unknown. The dysregulation of the serotonergic system, in particular the 5-HT2A receptor and the endocannabinoid system have been postulated as possible causes of schizophrenia.

Objectives The aim of this study is to evaluate the expression of CB1-5-HT2A receptor heteromers in primary cultures of pro-neurons from the olfactory epithelium in schizophrenia patients and control subjects.

Methods We recruited a group of 10 healthy volunteers and 10 patients diagnosed with schizophrenia, who were treated with atypical antipsychotics, were clinically stable and had an illness duration range from 1 up to 15 years. The patients were diagnosed with schizophrenia from the medical record and confirmed by the structured clinical interview for DSM disorders. The expression of CB1-5-HT2A receptor heteromers in primary cultures of pro-neurons from the olfactory epithelium was quantified using proximity ligation assays and confocal microscopy.

Results Olfactory epithelium pro-neurons were viable and expressed the neuronal marker, III- β tubulin. We also established the presence and the functionality of CB1-5-HT2A receptor heteromers in these cells using the proximity ligation and cAMP activity assays, respectively. Heteromer expression was significantly increased in schizophrenia patients with respect to controls.

Conclusions This highly innovative methodology will allow the noninvasive, low-cost study of new biomarkers for schizophrenia in a model closely related to the central nervous system.

Disclosure of interest The authors have not supplied their declaration of competing interest. Acknowledgments

¹ Centro Salud Mental Lorca, Adultos, Lorca, Spain

² Hospital Vinalopó, Adultos, Elche, Spain

³ Centro de Salud Mental Cartagena, Adultos, Cartagena, Spain

* Corresponding author.

Introduction Several scientific studies support the relation between pulmonary embolism and antipsychotic treatment (acute or chronic). We present a case of possible association of venous thromboembolism (VTE) and ziprasidone.

Personal antecedents Man, 55-year-old, with mild hypertension. He has neither toxics habits nor allergies. He does exercise every day. He started with behavioral and perception disorders during 9 months before being diagnosed of paranoid schizophrenia in 2002. He began with risperidone 3 mg per day and amisulpride 25 mg per day as hypnotic. It allowed a good development and he keeps stable since then. The treatment produced sedation and weight increase, so it was changed to ziprasidone 60 mg per day and later 40 mg per day. A few months ago, he was hospitalized with breathlessness that started suddenly two days before. After all diagnostic tests, he was diagnosed with pulmonary embolism and right leg VTE. His medical development was very positive and he must begin with acenocumarol (doses-depend) and support stockings.

Conclusion As we know, since last 10 years, antipsychotic exposure significantly increases the risk of pulmonary embolism. Due to the lack of risk related factor in this case, it would point that reason. The increase related is about 50% of developing VTE and this increased risk similarly applies to first and second generation antipsychotics drugs. Despite that, there are more cases in olanzapine, clozapine and haloperidol treatments due to antiaggregatory action and antithrombotic effects. We present this case probably closely related with ziprasidone.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Centro de Salud Mental Cartagena, Infantil, Cartagena, Spain

⁵ Centro de Salud Mental Cartagena, Adultos, Cartagena, Spain

* Corresponding author.

Introduction It is well known about relation between skin and mind, not only due to their mutual origin, but also by their illness expression parallelism. We report a case to show that reciprocity.

Personal antecedents Woman, 42-year-old, single. She only suffers from a skin disease; mild psoriasis guttata placed in both elbows and knees. She treated it with local treatment (cortisone cream) during seasonal pruritus and the lesions did not grow or expand. She was hospitalized due to psychotic symptoms (paranoid delusions with her colleagues) and started antipsychotics treatment (risperidone 12 mg per day and olanzapine 10 mg per night). By the same time, she suffered a psoriasis crisis. Her psoriatic plaques increased their sizes and her chest and both thighs were affected too. She complained about grave pruritus. All her medical test results were normal. After that, the patient improved her psychotics' symptoms, but she started with agoraphobic signs and seclusion at home. Psoriasis were even worse than before and she needed metrotexate to treat it. Being introduced to escitalopram 15 mg per day, anxiety and depression symptoms disappeared and her grave psoriasis became the mild one that she knew.

Conclusion Schizophrenia was associated with a greater variety of autoimmune diseases than was anticipated. Studies found evidence for a shared genetic etiology between schizophrenia and psoriasis. Despite that, we think that the study of psychopathology can amplify our understanding about the etiopathogenesis of psoriasis and associated mental disorders.

EV1245

Frontotemporal dementia misdiagnosed as schizophrenia or other psychotic disorder

A. Giamarelou^{1,2}, P. Polychronopoulos^{1,3}, M. Skokou^{1,2,*}, L. Messinis^{1,2}, P. Gourzis^{1,2}

¹ University Hospital of Patra, Rio, Greece

² Department of Psychiatry, University of Patra, Patra, Greece

³ Department of Neurology, University of Patras, Patra, Greece

* Corresponding author.

Introduction Frontotemporal dementia (FTD) encompasses a group of clinical features that include personality and behavior changes (disinhibition, social isolation, antisocial behavior, compulsion) and executive dysfunction (poor planning, loss of judgment and loss of insight). These features may lead to an incorrect diagnosis of a primary psychiatric disorder.

Objectives To emphasize the difficulties in making a clinical distinction between early frontotemporal dementia and other psychiatric diseases.

Methods We describe 11 patients who suffered from FTD, while initially had diagnosed with primary psychiatric disorders. The cor-

rect diagnosis was achieved by psychiatric and neuropsychological evaluations (WAIS SCALE, ACE-R, MMSE), neuroimaging studies (MRI 7/11, SPECT 8/11) and applying the international consensus criteria for FTD.

Results All patients (5 males and 6 females) were initially diagnosed with psychiatric disorders: schizophrenia (2/11), bipolar disorders (4/11), depression (5/11), schizoaffective disorder (1/11), somatization disorder (1/11), personality disorders (2/11), malingering (1/11), alcohol dependence (1/11), while 5 patients had more than one diagnosis. The age of onset varied from 19 to 53 years old. Final diagnosis of FTD was delayed on average 6,5 years from the onset of symptoms.

Conclusion Clinicians should be familiar with the clinical entity of FTD and its difficult distinction from other psychiatric disorders. A possible hospitalization of a patient with FTD in a psychiatric department and the social impact that it brings may be avoided. On the other hand, the proper care of FTD patients (pharmacological and psychosocial) improves the quality of life of patients and their caregivers.

⁴ Nova Medical School/Faculdade de Ciências Médicas, Universidade Nova de Lisboa, CEDOC, Chronic Diseases Research Center, Lisbon, Portugal

* Corresponding author.

Introduction Tackling stigma and discrimination is a major concern worldwide as demonstrated e.g. in the European Mental Health Action Plan. We need valid and feasible indicators to assess the stigma of mental illness. In Portugal, validated scales focused on mental health consumers' personal experiences of stigma are scarce. The consumer experiences of stigma questionnaire (CESQ) (Wahl, 1999), developed in collaboration with the National Alliance for the Mentally Ill, focuses on users' real life experiences. Although it was validated in different countries, some psychometric properties (e.g. test-retest reliability) are to be tested.

Objectives To further assess CESQ psychometric properties and to validate its Portuguese translation.

Methods The CESQ Portuguese translation was developed in collaboration with the author (Otto Wahl), using standard translation and back-translation procedures. The acceptability of items was assessed in pilot studies and discussed in groups also involving health professionals. The measure was then used in a convenience sample of 122 persons with severe mental illness. Assessments included test-retest reliability ($n=48$). A factor analysis was also conducted.

Results Overall, the CESQ translation proved acceptable and missing items were few, not compromising the analysis. The intraclass correlation coefficient (ICC) for test-retest reliability was 0.83 [95% CI 0.71–0.90] and Cronbach's alpha for internal consistency was 0.80 [95% CI 0.75–0.85]. In the principal component analysis, factor loadings confirmed the two originally reported domains: stigma and discrimination.

Conclusions The CESQ Portuguese version demonstrated good validity and reliability, replicating research using the original version and adding to the documentation of its psychometric properties.

Help-seeking behavior among patients and their relatives presenting to psychiatric unit in southern Sri Lanka

K.D.D.R. Goonawardena*, S.W. Kotalawala, R. Ruban
Teaching Hospital Karapitiya, Psychiatry, Galle, Sri Lanka
* Corresponding author.

Background Early recognition of the signs and symptoms of psychiatric illnesses is important as the delay would predict worse prognosis.

Aims To study the help-seeking behavior and sociodemographic factors of psychiatric patients presenting to Psychiatric Unit Teaching Hospital, Karapitiya.

Methods A descriptive cross sectional study. Sample drawn from patients presenting for the first time to Psychiatric Unit Teaching Hospital, Karapitiya. An interviewer administered questionnaire was used to collect data.

Results Age ranged from 13 to 76 years ($n=50$). Males 34 (68%). Duration from onset of symptoms to first presentation ranged from 2 days to nine years, mean 2 years. Twenty-five (50%) had symptoms for more than one year. Sixteen (32%) stated to have attributed illness to supernatural courses as the reason to delay seeking medical help. None gave difficulty in accessing a psychiatric unit as reason for the delay. Twenty-six (52%) referred by nonpsychiatric medical professionals. Regarding alternative treatment engaged in prior to presentation to a psychiatric unit, eighteen (36%) tried to dispose of evil spirits with the help of yakaduru or kattadi, seven (14%) sought help from indigenous medical practitioners and twenty (40%) engaged in religious rituals. Thirteen (26%) sought nonpsychiatric medical treatment.

Conclusions A substantial number of patients suffering from psychiatric disorders present to psychiatric units delayed. As the majority were referred by nonpsychiatric medical professionals, alerting them regarding importance of early identification of psychiatric illnesses could help in reducing the delay.

* Corresponding author.

Introduction Neurocognitive and social cognitive impairments are central characteristics of schizophrenia and, to a lesser extent, of bipolar disorder. Birth cohorts and familial high risk studies have described cognitive impairments in subjects before onset of diagnosis as well as in children with increased genetic risk for development of the disorders.

Objectives To our knowledge, this is the first study to investigate the correlations between neurocognition and social cognition in parents and offspring simultaneously and with the same methodology. We will divide the parents into subgroups (cognitive impairment and good cognitive functioning) and use these subgroups to describe correlations with their offspring. Identifying associations between parents and offspring can add important clues to risk factors for schizophrenia and bipolar disorder and, on the long-term, help the development of more effective and potentially preventive treatments.

Methods This study is part of the Danish high risk and resilience study-VIA7. The VIA7 cohort consists of 522 children age 7 with zero, 1 or 2 parents diagnosed with schizophrenia or bipolar disorder and both of their biological parents. We assessed neurocognition and social cognition with a comprehensive test battery including: intelligence (RIST), executive functions (WAIS-IV, D-KEFS, CANTAB), verbal memory (TOMAL2), attention, emotion recognition, decision making and response control (CANTAB), theory of mind (animated triangles) and social perception (TASIT). Parental subgroups were based on the 95% CI of the controls (cognitive impairment <95%CI and good cognitive functioning >95% CI).

Results Data analysis is ongoing and results will be presented at the conference.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Gynecological consultations during the period of untreated psychosis

C.M. Carrillo de Albornoz Calahorra¹, M. Guerrero Jiménez^{1,*}, J.E. Muñoz Negro²

¹ Santa Ana Hospital, Mental Health Unit, Motril, Spain

² University Hospital Complex of Granada, Psychiatry, Granada, Spain

* Corresponding author.

Background Twenty-one percent of women with first episode of psychosis in the south Granada between 2008 and 2014 went to hospital emergency during the duration of untreated psychosis (DUP) aiming a gynecological consultation caused by psychotic symptoms. Only one in five was referred to mental health services.

Aims To improve difficulties detecting cases during the prodromal phase, we aim to analyze the patient's profile and reasons for consultation and study whether there are variables that facilitate referral to specialist intervention.

Methods A retrospective clinical-cases review of medical histories was made searching for sociodemographic variables, drug consumption, emergency services consultations and psychotic prodromal outcomes.

Results They were single women between 18–32 years. Sixty percent reported cannabis consumption. All of them live with family. Eighty percent were studying or unemployed. Three types of emergency consultations were reported with a similar incidences: order the emergency-contraception-pill, a pregnancy test or "a scan to check virginity/a nonconsensual relationship". During the initial exploration, about 40% were under the influence of drugs.

Most of them had nonspecific symptoms of anxiety, emotional lability, irritability, etc. In half of the cases were reported weight loss, insomnia and several variations of the usual behavior in recent days.

Discussion The most important variable is to analyze the reason for consultation. Moreover, substance abuse and a combination of prodromal symptoms including positive and other nonspecific are detected. Furthermore, at the profile with possible demands, we believe it is appropriate not to delay mental health assessment after making the appropriate intervention.

First acute psychotic episode: Factors associated with evolution to schizophrenia

N. Halouani*, F. Guermazi, K. Yaich, R. Ennaoui, S. Chouayakh, J. Aloulou, O. Amami

Hédi Chaker University Hospital, psychiatry, Sfax, Tunisia

* Corresponding author.

Introduction The acute psychotic episode have often a dramatic expression. Although it is easily diagnosed, it is not easy to predict the evolution and much less the prognosis that are of concern both for the therapist and the patients' families.

Aims To describe the profile of a population of patients with a first psychotic episode. To identify factors correlated with evolution to schizophrenia.

Methods This is a retrospective study conducted among 55 patients hospitalized for a first acute psychotic episode, in the psychiatry B department during the period extending between January 2010 and December 2015.

Results The average age of patients was 26.5. The majority was single male. The prodromal phase was present with predominantly psychotic symptoms (80%). Schizophrenia was the most frequently encountered scalable diagnosis (38%). Some factors are associated with the evolution to schizophrenia. We can mention male gender ($P=0.004$) and premorbid schizoid personality ($P=0.047$). About correlated clinical factors, we have found an initial symptomatology dominated by loss of interest ($P=0.05$), withdrawal and isolation ($P=0.017$), impulsivity ($P=0.011$), breaking with the usual functioning ($P=0.04$), mental automatism ($P=0.033$), the delusions of persecution ($P=0.025$) and intuitive mechanism ($P=0.023$).

Conclusion When a first acute delusional experience occurs in a young adult, it is always a test of uncertain outcome. However, schizophrenia remains the most feared evolutionary. A better understanding of poor prognosis and early and appropriate management seem paramount to reduce the prevalence of this dreaded evolution.

Combined pharmacotherapy involving aripiprazole and clozapine for controlling the positive symptoms refractory to other antipsychotic treatments in a patient with schizophrenia

G. Hernandez Santillan (Psychiatry resident doctor)*,

K. Lazo-Chávez (Psychiatry resident doctor),

M. Blanco-Prieto (Psychiatry resident doctor)

Mental Health, Madrid, Spain

* Corresponding author.

Introduction Treatment resistance is considered a challenging problem of antipsychotic pharmacotherapy in schizophrenia, especially, when it is associated with other factors, such as cultural aspects, diverse clinical presentation, furthermore functional impact. Then, combination approaches are commonly used, for instance, the add-on of aripiprazole to clozapine; which allows increasing of efficacy and safety.

Objective Assess the response to clozapine–aripiprazole combination treatment in the management of resistant schizophrenia.

Aim Treatment of resistant schizophrenia.

Method Analysis of a clinical case.

Result A 27-year-old male resident in an Iberian country two years ago, is from a Latin American country, lives with his mother, his sister and his nephew. Their parents were separated. Eight years ago, his father died and shortly thereafter, he started impaired behavior, auditory and visual hallucinations, delusions about referentiality, persecution and prejudice, which required a brief hospitalization in their country. Upon arrival, he is included in the network of Mental Health, with positive symptoms, significant behavioral and cognitive disorganization and he needed hospitalization again. Then, treatment is instituted in different lines with risperidone, quetiapine, olanzapine, haloperidol, amisulpride, without results. Then, combined clozapine therapy is initiated up to 400 mg/day, more aripiprazole 20 mg/day, which switch after to pattern injectable depot, with informed consent. Six months after, he presents encapsulated delirium and improvement of disorganization, allowing the patient to retake studies.

Conclusion Clozapine–aripiprazole combination was associated with 22% reduction of clozapine dose. There was improvement in positive and negative symptoms, social functions and amelioration in their metabolic profile.

EV1252

Reducing diabetes type 2 risk in non-selected outpatients with schizophrenia, a thirty-month program

P. Hjorth

University of Southern Denmark, Psychiatry, Kolding/Vejle, Silkeborg, Denmark

Introduction Diabetes type 2 is 2–3 fold more common in patients with schizophrenia compared to the general population. A lifestyle with focus on diet, exercise and medication is required to prevent complications from diabetes type 2.

Objectives Patients may have trouble complying with a well-structured and healthy lifestyle because of factors related to their illness e.g. cognitive disturbances, negative/positive symptoms and treatment with psychotropic medication.

Aims To measure and reduce diabetes type 2 risk factors in patients and examine characteristics associated with a positive outcome.

Methods A naturalistic intervention study through 30 months of clinical work with individual guidance, group sessions and treatment as usual.

Results At index, the newly diagnosed patients had a high consumption of soft drinks and low physical activity. Over time, the newly diagnosed patients worsened their physical profile with increased weight, waist circumference, visceral adiposity index ($P=0.030$) and HbA1c ($P=0.010$). HbA1c increased for newly diagnosed male patients with 0.24 mmol/L ($P=0.007$). The long-term patient's physical activity level was low. After the intervention,

they improved in consumption of soft drinks ($P=0.001$) and fast food meals ($P=0.009$). Furthermore, the long-term patients lowered their weight and waist circumference while becoming more physically active. There were no changes in HbA1c in the intervention period.

Conclusion Our study showed being long-term ill and female gender was associated with positive outcome of lifestyle intervention into improving physical health and reducing diabetes type 2 risk, meanwhile being newly diagnosed and being male showed a negative outcome despite intervention.

EV1253

Doses of antipsychotics in maintenance phase compared to doses in acute phase treatment

J. Ivanušić*, G. Filipović Bilić, O. Koić
University Hospital Center Osijek, Clinic of Psychiatry, Osijek, Croatia
* Corresponding author.

Maintenance phase treatment with antipsychotic medications is recommended for all patients with schizophrenia. From clinical perspective and based on studies, small proportion of patients after first psychotic episode and far smaller proportion of patients with multiple psychotic episodes do not experience relapse. The use of antipsychotic medications as maintenance treatment reduces relapse rates. The optimal doses of antipsychotics in maintenance phase stay unclear although investigators attempted to identify doses sufficiently high to prevent relapses and at the same time sufficiently low to avoid adverse effects. In maintaining remission, it is usually recommended to use doses of antipsychotic medications that were effective in acute phase treatment as long as they are well-tolerated, but few studies and clinical experience show that lower doses than those usual for the acute phase are sufficient for maintenance treatment. The aim is to investigate doses of antipsychotics used in maintenance phase compared to doses used in acute phase treatment.

⁵ University of Kragujevac, Faculty of Philology and Arts, Kragujevac, Serbia

⁶ Universiti of Pristina, Kosovska Mitrovica, Department of Preventive Medicine, Faculty of Medicine, Kosovska Mitrovica, Serbia

* Corresponding author.

Introduction Clinical benefits of antipsychotic treatment depend on the efficacy and on the patients' tolerability and compliance. To reduce patient initiated treatment discontinuation, timely detection of treatment emergent side effects is essential. The Glasgow Antipsychotic Side-effects scale for clozapine (GASS-C) is a recently developed instrument to measure subjectively experienced clozapine side effects.

Objectives Timely detection of unreported clozapine related side-effects.

Aim Documenting the prevalence of side-effects in schizophrenia or chronic psychotic disorder with the Serbian version of the GASS-C.

Methods The sample included 95 in and outpatients with schizophrenia or chronic psychotic disorder. All subjects filled out the Serbian version of the GASS-C and a sociodemographic questionnaire.

Results The median age was 46.1 years; 53.7% of subjects were male. Clozapine doses ranged from 25 to 423 mg. Drowsiness (78%) was the most commonly reported side-effect. Overall, 16.8% of the patients added other complaints, such as headache, pain, hand or leg numbing or nightmares. According to GASS-C total score categorization [2], only 4.2% of subjects were rated with severe side-effects, while 14% of themselves rated their symptoms as severe or distressing. More side effects were reported by female patients and by inpatients. Only a weak positive correlation was found between the severity of the side effects and clozapine dosage.

Conclusions We found the GASS-C to be a useful instrument that elicits both unknown side-effects and patients rating of their severity. Side effects did not clearly relate to the prescribed dose. Future research should include the relation of clozapine plasma levels with side effects assessed with GASS-C.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Effect in antipsychotic-induced hyperprolactinemia after switching to long-acting injectable aripiprazole: A 1-year study

M. Juncal Ruiz^{1,*}, B. Fernández-Abascal Puente¹, O. Porta Olivares¹, M. Gómez Revuelta², R. Landera Rodríguez¹, L. Sánchez Blanco¹, G. Pardo de Santayana Jenaro¹, M. Pérez Herrera¹, J. Mayoral Van Son³

¹ Hospital Universitario Marqués de Valdecilla, Psychiatry, Santander, Spain

² Hospital Universitario de Álava-Sede Santiago, Psychiatry, Vitoria-Gasteiz, Spain

³ Unidad de Salud Mental de Torrelavega. Hospital de Sierrallana, Psychiatry, Torrelavega, Spain

* Corresponding author.

Introduction Antipsychotic-induced hyperprolactinemia is associated with relevant side effects: short-term as hypogonadism, gynecomastia, amenorrhoea, sexual dysfunction and galactorrhoea; long-term as cardiovascular disease, bone demineralization and breast and prostate tumors.

Aims To evaluate the effect of switching to long-acting injectable aripiprazole on long-lasting antipsychotic-induced hyperprolactinemia.

Methods This was a prospective observational 1-year study carried out in 125 outpatients with schizophrenia who were clinically stabilized but a switching to another antipsychotic was indicated. We measured the basal prolactin at the start of the study and 1 year after switching to long acting injectable (LAI) aripiprazole.

Results In basal analytic, 48% had hyperprolactinemia (21.8–306.2 ng/mL) and 66.5% of them described side effects: 78% sexual dysfunction (72% men), 11% galactorrhoea (100% women), 5.5% amenorrhoea and 5.5% bone pain (100% women). In 48% of patients with hyperprolactinemia, the previous antipsychotics comprised: LAI-paliperidone (65.7%), oral-risperidone (7%), oral-olanzapine (6.1%), oral-paliperidone (5.2%), LAI-risperidone (4%) and others (12%). One year after switching to LAI-aripiprazole, prolactin levels were lower in all patients and in 85% prolac-

tine levels were normalized. Overall, 72% described a clinical improvement, especially in terms of sexual dysfunction.

Conclusions Several studies have described an improvement of drug-induced hyperprolactinemia after switching to or adding oral aripiprazole. In our study, we observed that levels of prolactin were normalized in 85% of patients with a clinical improvement in almost all of cases. These findings suggest that switching to LAI aripiprazole may be an effective alternative for managing antipsychotic-induced hyperprolactinemia due to its partial agonism in D2 brain receptors, especially in tuberoinfundibular pathway.

EV1256

The side effects of risperidone depot in patients with psychotic disorders

T. Jupe^{1,*}, F. Elezi², B. Zenelaj², E. Myslimi²

¹ UHC Mother Tereza, Psychiatry, Tirane, Albania

² UHC Mother Thereza, Psychiatry, Tirane, Albania

* Corresponding author.

Background and aim A long-acting form of risperidone is now broadly available for the treatment of schizophrenia and closely related psychiatric conditions. It combines the advantage of previously available depot formulations for first-generation drugs with the favorable characteristics of the modern “atypical” antipsychotics, namely higher efficacy in the treatment of the negative symptoms of schizophrenia and reduced motor disturbances [1].

Methods During this study, we observed side effects that appear in patients that are treated with risperidone depot. Patients were observed for a period of 3 months (October–December 2015) and the side effects were evaluated with Glasgow Antipsychotic Side-effect Scale (GASS). The data obtained were analyzed with SPSS, trying to prove the impact of variables such as: gender, age, diagnosis, dose and duration of treatment on the occurrence of side effects.

Results Through statistical processing, we reached the conclusion that there is a statistically significant correlation between duration of treatment and side effects (P value was 0.0001). Between two variables has a strong positive correlation (Kendall value was 0.766). Has a statistically significant correlation between the drug dose and side effects (P value was 0.026). Between two variables has a moderate positive correlation (Kendall value was 0.504). No statistically significant correlation between these variables: gender-side effects, diagnose-side effects and age-side effects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Mortality in people with psychotic disorders in Finland: A population-based 13-year follow-up study

J. Keinänen^{1,*}, O. Mantere², N. Markkula¹, K. Partti¹, J. Perälä¹, S.I. Saarni¹, T. Härkänen³, J. Suvisaari¹

¹ National Institute for Health and Welfare, Department of Mental Health and Substance Abuse Services, Helsinki, Finland

² McGill University, Department of Psychiatry, Montreal, Canada

³ National Institute for Health and Welfare, Department of Health-Functional Capacity and Welfare, Helsinki, Finland

* Corresponding author.

Introduction People with psychotic disorders have increased mortality compared to the general population. The mortality is mostly due to natural causes and it is disproportionately high compared to the somatic morbidity of people with psychotic disorders.

Objectives We aimed to find predictors of mortality in psychotic disorders and to evaluate the extent to which sociodemographic and health-related factors explain the excess mortality.

Methods In a nationally representative sample of Finns aged 30–70 years ($n=5642$), psychotic disorders were diagnosed in 2000–2001. Information on mortality and causes of death was obtained of those who died by the end of year 2013. Cox proportional hazards models were used to investigate the mortality risk.

Results Adjusting for age and sex, diagnosis of nonaffective psychotic disorder (NAP) ($n=106$) was statistically significantly associated with all-cause mortality (HR 2.99, 95% CI 2.03–4.41) and natural-cause mortality (HR 2.81, 95% CI 1.85–4.28). After adjusting for sociodemographic factors, health status, inflammation and smoking, the HR dropped to 2.11 (95% CI 1.10–4.05) for all-cause and to 1.98 (95% CI 0.94–4.16) for natural-cause mortality. Within the NAP group, antipsychotic use at baseline was associated with reduced HR for natural-cause mortality (HR 0.25, 95% CI 0.07–0.96), and smoking with increased HR (HR 3.54, 95% CI 1.07–11.69).

Conclusions The elevated mortality risk associated with NAP is only partly explained by socioeconomic factors, lifestyle, cardiometabolic comorbidities and inflammation. Smoking cessation should be prioritized in treatment of psychotic disorders. More research is needed on the quality of treatment of somatic conditions in people with psychotic disorders.

Validation of the Czech version of the community assessment of psychic experiences (CAPE)

B. Keřková^{1,*}, Z. Martínková²

¹ Charles University in Prague and General University Hospital in Prague, Department of Psychiatry, First Faculty of Medicine, Prague, Czech Republic

² Charles University in Prague, Film Studies Department, Faculty of Philosophy and Arts, Prague, Czech Republic

* Corresponding author.

Introduction In the Czech Republic, research of the schizophrenia spectrum suffers from a lack of standardized measuring instruments. The community assessment of psychic experiences (CAPE) has been used internationally to quantify positive, negative and affective symptoms associated with the spectrum and to screen individuals who may be in risk of developing a spectrum disorder.

Aims and objectives This study aimed to develop a Czech version of the CAPE and to examine its psychometric properties in a nonclinical population.

Methods An author with an expertise in the field and a subject-naïve author translated the CAPE into the Czech language. After a professional back-translation, the instrument's most suitable version was agreed upon. Lie-scale items were added to allow for an online circulation. The CAPE was administered to a large sample of participants alongside the Beck depression inventory (BDI-II).

Results Internal consistency was assessed using the Cronbach's alpha. Internal structure was evaluated using confirmatory factor analysis and compared to the structure of the original. Criterion validity was examined through correlation analyses of the BDI-II scores and the total and subtotal CAPE scores.

Conclusions It is determined whether the Czech version of the CAPE has sufficient reliability and validity to be recommended for research purposes. It is expected that further study of the CAPE as well as the introduction of additional tools will motivate the standardization of research, diagnosis and prevention of schizophrenia spectrum disorders in the Czech Republic.

¹ Faculty of Medicine, Cairo University, Egypt, Psychiatry, Giza, Egypt

² Faculty of Medicine, Cairo University, Egypt, Clinical

Neurophysiology Department, Giza, Egypt

* Corresponding author.

Background Patients with schizophrenia suffer from cognitive deficits in seven domains in addition to social cognition. P300 latency and amplitude have been linked in these patients to the basic cognitive deficits.

Objectives Comparing patients suffering from schizophrenia with matched healthy subjects as regards auditory event related potential tests as measured by P300.

Subjects and methods Fifty-two subjects were divided into 2 groups: group (A): 27 patients with schizophrenia according to the diagnostic and statistical manual of mental disorders-text revised (DSM-IV TR). Those with current substance use, psychiatric disorders or organic disorders were excluded. Group (B): 25 healthy control subjects with negative history of substance and psychiatric disorders. Patients were assessed using Positive and Negative Symptom Scale (PANSS) for severity of psychotic symptoms, Addenbrook's Cognitive Examination Revised (ACE-R) for basic cognitive, reading the mind in the eye test for social cognition, P300 and electro-encephalography (EEG)

Results The two groups were different significantly in ACE total and its subtests measuring attention-orientation, memory, language, visuospatial and reading the mind in the eye test for social cognition scores with patients showing lower scores ($P=0.000$, 0.012 , 0.000 , 0.038 , 0.041 and 0.001 respectively). Control group had higher amplitude of P300 and shorter latency than patients ($P=0.003$ and 0.005 respectively). P300 amplitude correlated positively with visuospatial memory ($P=0.015$). PANSS general pathology scale correlated positively with duration of untreated psychosis ($P=0.029$) and with fluency ($P=0.047$).

Conclusion Patients with schizophrenia differ from controls in P300.

Influence of clozapine to modified electroconvulsive therapy in the treatment resistant schizophrenia

Y. Kikuchi*, T. Kanbayashi, T. Shimizu

Akita University School of Medicine, Department of Neuropsychiatry,

Akita University Graduate School of Medicine, Akita, Japan

* Corresponding author.

Introduction Clozapine is one of the most effective drugs for the treatment resistant schizophrenia (TRS). It was reported that

modified electroconvulsive therapy (mECT) may be an effective clozapine augmentation strategy in TRS.

Objective The objective of this study was to investigate the influence of clozapine to mECT in the TRS.

Methods Forty-seven patients were recruited in this study, but eight patients were excluded because clozapine was discontinued by reason of side effects. Ultimately, 39 patients were enrolled.

Results Seventeen patients received mECT before clozapine therapy. Two patients continued mECT after starting clozapine therapy. There was a significant difference between before–after clozapine therapy (χ^2 test, $P<0.01$). Intermittent mECT was performed for 3 patients before clozapine and for one patient after starting clozapine.

Discussion This result suggests that clozapine therapy reduces mECT. In Japan, the first-line treatment for TRS is CLO. mECT is recommended for clozapine resistant schizophrenia patients. Prescription of CLO is limited in the part of medical facility because all physicians who prescribe clozapine must be registered with the clozaril patient monitoring service in Japan. It is considered that mECT is more readily selected than clozapine therapy. Therefore, the number of mECT is not reduced generally.

Conclusion Clozapine therapy reduces the necessity of mECT.

Serum 25-OH vitamin D level in patients with schizophrenia spectrum disorders

M. Kopecek*, D. Protopopova, P. Knytl, B. Kohutova, J. Hanka, P. Mohr

National Institute of Mental Health Czech Republic, NIMH Clinical Center, Klecany, Czech Republic

* Corresponding author.

Introduction 25-OH vitamin D level is an immediate precursor metabolite of the active form of vitamin D that leads to expression of more than 200 genes.

Aims The aim of our study was to examine 25-OH vitamin D deficiency ($<50\text{nmol/L}$) and its relationship to demographic factors in recently hospitalised patients with schizophrenia spectrum disorders (SSD).

Methods We assessed 25-OH vitamin D serum level in 41 SSD patients (54% of males, 46% with first episode, 63% during sunny season [May to October]), mean age 30 ± 10.4 years, within first days of hospitalization. The serum 25-OH vitamin D level was analysed with electrochemiluminescence, using immunoanalysators Elecsys Roche.

Results The serum level was significantly higher in sunny season (41.3 ± 27.2 nmol/L) than in November to April (28.4 ± 11.2 nmol/L); t -test, $P<.05$. Sixty-nine percent of patients suffered from 25-OH vitamin D deficiency ($<50\text{nmol/L}$) in May to October and 100% during November to April. The 25-OH vitamin D serum levels were not different between males and females, or between first-episode and multiple-episode patients. No significant correlation between age and 25-OH vitamin D level was found.

Conclusions The high prevalence of 25-OH vitamin D deficiency ($<50\text{nmol/L}$) suggests that some patients with SSD may benefit from vitamin D supplementation.

Funding This study is a result of the research funded by the project Nr. LO1611 with a financial support from the MEYS under the NPU I program.

³ Siberian State Medical University, Faculty of Behavioral Medicine, Department of Clinical Psychology and Psychotherapy, Tomsk, Russia
* Corresponding author.

Introduction Positive-negative dichotomy in course of schizophrenia leads to search for factors which could influence the formation of basic symptoms. The study of patients' body types and morphological peculiarities according clinical feature of schizophrenia could find some influence factors. Body type and regional morphologic dysplasias (RMD) are basically morphophenotypical patterns available for routine examination in usual clinical psychiatric practice.

Aims To reveal associations between body type, morphologic dysplasias and course of schizophrenia.

Methods Anthropometric, somatoscopy examination of patients with schizophrenia with gradually progressive negative disorders: emotional, volition, thought disturbances, increasing autism and social isolation, stable anhedonia with motivation defect were conducted. The accounted morbidity of 168 patients from the whole group of individuals with schizophrenia was about 10% (128 [76%] males, 40 [23.8%] females). Clinical presentations of schizophrenia met the criteria of ICD-10. Anthropometric investigation was conducted with the help of Martin's anthropometer and major thickness compasses for recognition of body type. RMD was registered descriptively.

Results It was shown that in patients with negative course of schizophrenia asthenic body type prevailed (60%) with the accumulation of RMD (94.4%) in comparison with healthy individuals (26.2%, $P < 0.001$). Among patients with positive symptoms of schizophrenia picnic body type prevailed ($P < 0.001$).

Conclusions Asthenic body type, accumulation of multiple RMD is associated with the domination of negative symptoms and continuous course of schizophrenia. Results of the study indicate the need for a deeper study of this issue on constitutional approach.

Introduction The hypothalamus-pituitary-adrenal axis (HPAA) plays a pivotal role in response to a range of external and internal factors often described as "stress". Growing evidence in a literature, suggest various dysregulations of HPAA, in course of numerous mental disorders. Patients with schizophrenia and bipolar disorder seem to have elevated basal cortisol secretion,

what might be caused by the diminution of glucocorticoid receptors' amount. It was of the interest if the cortisol concentration in patients, with diagnosed schizophrenia, differs from healthy individuals.

Materials and methods Two groups of participants were included into the study. First group (study) consisted of 10 patients with diagnosed schizophrenia and control group which included 38 healthy individuals. Study was divided into two stages, first one (pilot) included only control group, and utilized cortisol concentrations measurement from saliva, blood and 24 h urine sample. Second part (main study) involved both groups although focused on a salivary cortisol concentrations.

Results A mean salivary cortisol concentration in patients with schizophrenia who underwent treatment was significantly lower in comparison with healthy individuals.

Conclusions Obtained results indicate that patients who underwent a treatment, and does not present notable clinical signs of schizophrenia, may have moderately lowered levels of salivary cortisol. This may be a reflection of relenting psychotic symptoms as well as a direct effect of atypical antipsychotic drugs on a HPA axis activity.

Objective The aim of this study is to evaluate the association between response to treatment in Moroccan schizophrenic patients and GRM3 gene polymorphisms.

Method We have genotyped three SNPs of GRM3 gene (rs1989796, rs1468412, rs1476455) in 33 Moroccan schizophrenic patients. We assessed the severity of symptoms using Positive and Negative Symptoms Scale (PANSS) and Brief Psychiatric Rating Scale (BPRS) during two months of antipsychotics treatment.

Results The result revealed a positive change in PANSS negative symptoms in patients with rs1468412SNP and a difference in allele frequency of rs1989796SNP between responders and nonresponders to treatment.

Conclusion Our data indicate that rs1468412 and rs1989796 GRM3 gene polymorphisms play a role in response to schizophrenia treatment.

Introduction Remission and recovery rates for people who have had a first episode psychosis (FEP) remain uncertain.

Objectives We conducted a systematic review and meta-analysis to assess pooled prevalence rates of remission and recovery in FEP in longitudinal studies and conducted meta regression analyses to investigate potential moderators.

Methods A systematic literature search of major electronic databases without language restrictions was conducted from database inception until July 1, 2016. Longitudinal studies with follow up greater than 1 year reporting data on remission or recovery rates in FEP were included.

Results Seventy-nine studies were included representing 19,072 FEP patients (mean age = 26.9 years, male = 59.5%). The pooled rate of remission among 12,301 individuals with FEP was 57.9% (95%CI: 52.7–62.9, $Q = 1536.3$, $P < 0.001$, $n = 60$ studies, mean follow up = 5.5 years). Restricting the analysis to studies, which used the remission in schizophrenia working group (RSWG) criteria ($n = 25$ studies, $n = 6909$ patients), the pooled remission rate was 56.9% (95%CI: 48.9–64.5, $Q = 656.9$). Higher remission rates were moderated by studies from more recent years. The pooled prevalence of recovery among 9642 individuals with FEP was 37.9% (95%CI: 30.0–46.5, $Q = 1450.8$, studies = 35, $P = 0.006$, average follow up = 7.2 years). Recovery rates were higher ($P < 0.05$) in North America compared to other regions.

Conclusions Our data suggest that remission and recovery rates in FEP may be more favorable than previously thought. We observed stability of recovery rates after the first two years, suggesting that a progressive deteriorating course of illness is not typical. While remission rates have improved over time, recovery rates have not, raising questions about the effectiveness of specialist early intervention services in achieving improved recovery.

Recent studies in healthy populations have shown a hierarchical network of brain areas to process information over time. Specifically, we revealed that the capacity to accumulate information changes gradually from the early sensory areas toward high-order perceptual and cognitive areas. Previous research in schizophrenia pointed to impairment in comprehension of information. Yet, the neural mechanisms underlying the breakdown of information processing are poorly known. Better understanding of the neural circuits involved in information processing may assist in early identification of predisposition to the disease. Using fMRI, we examined different levels of information comprehension elicited by naturally presented stimuli. Healthy participants, patients with first episode schizophrenia and their undiagnosed siblings listened to a real-life narrated story and scrambled versions of it. To estimate the level of synchronization in response time courses, we calculated inter-subject correlation (inter-SC) across the entire stimuli within each group. The time-scale gradients found in healthy and siblings groups were consistent with our previous findings. Within the schizophrenia group, the reliability patterns obtained for the shortest and intermediate temporal scales were similar to patterns observed in healthy groups. However, the analysis of responses to story condition (long temporal scale) revealed robust and widespread disruption of the inter-SC. In comparison to healthy groups, the response time courses to the story were highly variable within the schizophrenia group, although some significant inter-SCs in the TPJ and precuneus were found. The hierarchical temporal deficit is a fundamental trait that may be a better target for the study of the etiology and pathophysiology of the disease.

Heterogeneous effectiveness patterns of amisulpride in chinese patients with schizophrenia: A cluster analysis of ESCAPE study

Y. Liang^{*}, X. Yu

National Clinical Research Center for Mental Disorders, Peking University Sixth Hospital, Institute of Mental Health, and the Key Laboratory of Mental Health, Ministry of Health, Peking University, Beijing, China

* Corresponding author.

Introduction Rare research was reported about assessing the effectiveness and safety of amisulpride in Chinese patients with schizophrenia before we performed the ESCAPE, a multicenter, single-arm, phase IV study (NCT01795183). This study is a cluster analysis of ESCAPE study.

Objective To identify the effectiveness patterns of amisulpride in Chinese patients with schizophrenia.

Aim To examine baseline characteristics of patients as potential predictors of effectiveness.

Methods Time-series cluster analysis was performed to identify effectiveness trajectories bases on Positive and Negative Syndrome Scale (PANSS) scores in Chinese patients with schizophrenia received amisulpride for 8 weeks. Baseline characteristics of patients were examined.

Results Overall, 295 patients were included for efficacy analysis. Four response trajectories based on positive PANSS were identified (Figure 1): (1) rapid response (cluster 1); (2) gradual response (cluster 2); (3) sustained low level (cluster 3); (4) poor response (cluster 4). Age in cluster 4 was significantly higher than that in cluster 1 and cluster 3 (Table 1, $P = 0.0025$ and 0.0032 , respectively). Similarly, four response trajectories based on negative PANSS were generated (Figure 2): (1) rapid response (cluster 1); (2) gradual response (cluster 2); (3) poor response with moderate PANSS (cluster 3); (4) poor response with high PANSS (cluster 4). Male to female ratio in

cluster 1 was significantly lower than that in cluster 2 and cluster 3 (Table 2, $P=0.0042$ and 0.0208 , respectively).

Conclusion For the first time, we obtained effectiveness patterns of amisulpride-treated Chinese patients. Age and gender may be predictors of effectiveness.

Fig. 1 Time series clustering of PANSS positive score. Four clusters and fitting curves (thick lines) are presented.

Fig. 2 Time series clustering of PANSS negative score. Four clusters and fitting curves (thick lines) are presented.

Treatment of drug-resistant schizoaffective disorder with aripiprazol depot off-label: A case report

L. Niell Galmés*, R.A. Baena Mures, Í. Alberdi Páramo, M.M. Tenorio Guadalupe, G. Montero Hernández, J. Rodríguez Quijano, L. Gallego Deike, A. Carrillo Gómez
Hospital Clínico San Carlos, psychiatry, Madrid, Spain

* Corresponding author.

Introduction We expose a woman diagnosed with schizoaffective disorder 2 years ago, before she received several diagnostics. She was admitted to the psychiatry unit with hyperactivity, pressured speech without taking an appropriate turn, flight-of-ideas,

irritability, expansiveness, emotional lability, ideas of reference and insomnia without diurnal tiredness. In addition, she admitted having abandoned the medication one month ago. She was diagnosed with maniac episode with psychotic symptoms and the medication was reintroduced. After two weeks, no response was observed so we decided to introduce ability depot 600 mg/3 weeks.

Objectives We want to show that it is possible the use of ability depot off-label in patients with a special difficulty in handling. Also, we want to show that higher doses are not dangerous and it's possible to study new treatment guidelines for ability depot.

Methods We use the Positive and Negative Syndrome Scale (PANSS) pre (the day of the introduction) and post (at two weeks) treatment with aripiprazol depot; the Clinical Global Impression rating scale (CGI), also pre and post.

Results We have obtained a punctuation of 180 in PANSS the day of the introduction of the aripiprazol depot and 45 at two weeks. In addition, we obtained 6 in CGI the day of the introduction and 3 at two weeks.

Conclusions In this case, aripiprazol depot has shown good tolerability and efficacy for the acute phase of schizoaffective disorder at higher doses than recommended in clinical guidelines. The efficacy and safety data are consistent with short-term, placebo-controlled studies of aripiprazol depot conducted in similar populations.

⁴ Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Addictive States Department, Tomsk, Russia

* Corresponding author.

Introduction Detection of clinical-biological predictors of the efficiency of antipsychotic therapy in schizophrenic patients, correction and individualization of therapeutic indication of antipsychotics are relevant questions of modern psychiatry. Immune dysfunctions, disturbance of psychoneuroimmunological interaction, metabolic imbalance worsen clinical pattern of disease, contribute to formation of therapeutic resistance and side effects, and decrease efficiency of treatment of patients.

Objective To detect clinical-immunological predictors of the efficiency of therapy of schizophrenic patients with amisulpride.

Methods We examined 19 schizophrenic patients, aged 18–64 years, who received treatment with amisulpride (Solian). The psychometric scale PANSS was used for evaluation of dynamics of psychopathological symptoms. Therapy efficiency was evaluated using CGI scale. The immunological investigation included identification of phenotypes of surface receptors of immunocompetent cells, level of IgM, IgG, IgA, phagocytic activity of leucocytes. Research was carried out in two points: first—at admission, second—by week 6 of treatment. Predictors of efficiency were identified relying on the analysis of interquartile ranges of clinical-immunological parameters.

Results Predictors of high efficiency of amisulpride therapy were identified: clinical–total score according to PANSS less than 70, sum of scores according to subscale of negative disorders is more than 31 and immunological–number of HLADR ± lymphocytes below $0.34 \times 10^9/L$, CD16 ± lymphocytes more than $0.18 \times 10^9/L$.

Conclusion Complex of informative clinical-immunological criteria is proposed, which enables prognosis of the efficiency of psychopharmacotherapy for patients at admission. It enables optimizing the choice of differentiated therapeutic tactics and heightening the quality of specialized medical care for schizophrenic patients.

* Corresponding author.

Impairments in social and cognitive functioning are some of the most disabling features of the schizophrenia. They result in poorer communication with others, difficulties in maintaining employment status and decrease in community involvement. Recently, cognitive remediation therapy (CRT), which relies on computer-based drill and practice exercises, has emerged as a nonpharmacological intervention that aims to target and improve cognitive and social functions. Given the recent success of CRT based approaches, the question arises: can other nonpharmacological interventions which aim to augment and improve socio-cognitive functions be effective? Building upon Vygotsky's (1934) theorizing, we conducted an 8-week long study involving 19 participants. The study uses the methodology of narrative inquiry to examine participants' ability to employ varied socio-cognitive functions (affect, causation, perceptive-taking, logical/hypothetical inference, etc.) when writing about everyday activities and attempting to resolve conflicts in narratives. Prompts employed in this study directed participants to write about three different socio-cultural contexts: (1) inpatient; (2) outpatient and (3) a fictional context. The fictional context aimed to examine participant's ability to imagine and express alternative futures/scenarios. Data show significantly higher frequency of occurrence of linguistic devices tied to cognitive functions in (3) fictional narrative context when compared to either (1) inpatient or (2) outpatient context. Use of affect was the only statistically significant difference between contexts (1) and (2). Findings indicate that individuals diagnosed with schizophrenia are able to vary the use of social and cognitive functions across narrative contexts, suggesting that future socio-cognitive interventions can be anchored in mindfully planned narrative activities.

Antipsychotic polypharmacy among schizophrenia outpatients

H. Maatallah*, H. Ben Ammar, A. Aissa, R. Nefzi, M. Said, Z. El Hechmi

Razi Hospital, Psy F, Tunis, Tunisia

* Corresponding author.

Introduction Since their introduction by Delay and Deniker in the 1950s, neuroleptic drugs have significantly modified the evolutionary prognosis of schizophrenia. Their combination has also become a widespread practice.

Objectives The aim of this study was to analyze the associations of neuroleptic drugs by describing the characteristics of types and doses, understanding the reasons for these associations and studying the relationship existing in such situation regarding adherence to treatment, tolerance and the number of hospitalizations.

Methods Our study was retrospective, descriptive and analytical. It has been conducted from March, 1st to May, 30th 2015 and involved 70 stabilized patients diagnosed with schizophrenia according to DSM 5. Clinical characteristics were collected from patients and their medical records. Evaluations were conducted using PANSS, MARS and GAS.

Results Overall, 70 male patients were recruited. The mean age was 40 years old: 30% received classical monotherapy while 70% were treated only by an atypical antipsychotic. Among patients receiving two drugs, 85% received classical bitherapy while 9% were under both classical and atypical drugs. Only 6% received atypical bitherapy. Chlorpromazine equivalent doses in case of monotherapy was 325.92 mg/day, while it reached 1148.65 mg/day in case of drugs association. Administration of a combined therapy had poor tolerance rate and all patients suffered from adverse effects. Adherence to treatment was better while receiving monotherapy (88% versus 45%) and the number of hospitalizations was lower with an average of 3 against 10.

Conclusion Our study revealed several shortcomings in our current management of patients with schizophrenia and addressed the implication of socioeconomic status on therapeutic outcomes.

Human induced pluripotent stem cells (hiPSCs) in schizophrenia: Modelling the disease and the treatment response

M. Marcatali^{1,*}, F. Marsoner², A. D'Agostino¹, S. Scarone¹, L. Conti²

¹ University of Milan, Department of Health Sciences, Milano, Italy

² University of Trento, Center for Integrative Biology - CIBIO-Laboratory of Stem Cell Biology, Trento, Italy

* Corresponding author.

Response to drug treatment is under the sophisticated control of complex signalling pathways and gene regulatory networks. Indeed, drug-induced modulation of dysregulated gene expression and altered synaptic plasticity are critical steps for the successful treatment of neuropsychiatric disorders. Among the antipsychotic drugs, clozapine (CLZ) is widely considered to be the most effective medication for the treatment of schizophrenia. However, due to its high risk for severe side effects, CLZ use is currently restricted to patients who do not respond to other antipsychotics. Nonetheless, up to 20% of patients are considered nonresponders to CLZ treatment. The mechanism of action underlying CLZ's exceptional clinical efficacy in SCZ is not fully understood. In this context, in vitro molecular and functional assessment of patient-derived glutamatergic and GABAergic neurons' properties are mandatory to reveal the mechanisms underlying CLZ responsiveness and might mirror the clinical response. Here, we will describe the generation of hiPSCs from SCZ patients, classified based on their response to conventional treatments, to CLZ or total resistance to every treatment. These patient-specific hiPSCs have been converted into

enriched cortical glutamatergic neurons and parvalbumin-positive GABAergic interneurons populations that are under inspection to reveal phenotypic and molecular/pharmacological aspects correlating with patient-specific responsivity pattern to CLZ treatment. These results might help to unveil the molecular basis of treatment response profiles that can be exploited to predict response to antipsychotic drugs and that might help to develop personalized treatments, more individually tailored and less hazardous.

³ Hospital Clínic, Psychiatry, Barcelona, Spain

* Corresponding author.

Introduction Most of elderly onset psychosis present as a consequence of one or more organic processes. We present the case of an 81-year-old patient with diagnosis of a posterior fossa meningioma. It emerged with abrupt positive symptoms of psychosis with important family and social disruption. The interest of the case lies in the low frequency of psychiatric symptoms associated to this type of tumor, given its location. Thus, these symptoms may be explained, by normal pressure hydrocephalus (NPH) secondary to the tumor.

Objectives To highlight the importance of performing a complete organic screening in elderly onset psychotic patients.

Material and method From the mentioned case, we performed a literature review of psychopathology associated with NPH.

Results Psychiatric examination demonstrated parasitization delusions and delusional misinterpretations; tactile and visual zoomorphic hallucinations were also present. They were compatible with Ekbom syndrome; anxiety and behavioral disorganization were prominent. We introduced treatment with risperidone 0.5 mg/12 h with important decrease of positive psychotic symptoms. Currently, the patient is waiting for a ventricular-peritoneal shunt.

Conclusions The NPH usually presents with memory failures, psychomotor slowing, problems in calculating and writing. It may progress to a neurological impairment so intense that may be indistinguishable from Alzheimer's disease. From a psychopathological point of view, affective or psychotic symptoms and/or behavioral disorganization may also appear. In few cases, HNT onset shows with prominent psychiatric symptoms instead of neurological impairment. These symptoms may improve with pharmacological and surgical treatment. Thus, it is important to get an accurate diagnosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Reasons to choose a long acting antipsychotic and tolerability

I. Martínez Molina*, N. Gómez-Coronado Suárez de Venegas, P. Blanco Ramón

Hospital Universitario Virgen del Rocío, Salud Mental, Seville, Spain

* Corresponding author.

Introduction Aripiprazole depot is an atypical antipsychotic used to treat positive and negative symptoms of psychosis or acute mania.

Aim Describe the reason why psychiatrists switch the current antipsychotic treatment on to aripiprazole depot, its tolerability and the reasons to stop aripiprazole depot treatment.

Methods Descriptive analysis based on a sample of 37 patients, aged 18–65 years, treated during one year with antipsychotics at two community mental health units.

Results Switching on to aripiprazole depot principal reasons: promote adherence (25%), persistence of symptoms (25%) and high levels of prolactin or sexual dysfunction (16.66%):

– side effects of aripiprazole depot: insomnia (11.11%), inquietude (8.33%), sexual dysfunction (2.77%) and hypertensive crisis during administration (2.77%);

– 83.33% of the patients are still taking it after one year. The most common reasons to stop or change it were the presence of secondaries (11.11%) and clinical exacerbation (5.55%).

Conclusions Aripiprazole depot is well tolerated (even better than other antipsychotics). Common side effects are not severe and appear in a small percent of patients.

Psychological resilience and quality of life amongst people with psychotic illnesses

G. McCarthy*, A. Liston, D. Adamis

NUI Galway and HSE West, Psychiatry Sligo Leitrim Mental Health Services, Sligo, Ireland

* Corresponding author.

Introduction Psychological resilience is defined as an individual's ability to adapt to stress and adversity. People with psychotic illness often experience high levels of distress and difficulties adapting.

Aims To assess the relationship between the resilience of people with psychotic illnesses and their quality of life.

Methodology Outpatients from multiple settings attending Sligo-Leitrim Mental Health Services, aged 18+ years old with a diagnosis of either schizophrenia, bipolar affective disorder or schizoaffective disorder were approached by their treating teams and invited to participate. Other inclusion criteria were having a family member. Drug induced psychoses or no family member were exclusion criteria. The scales used were the Resilience Appraisal Scale and the schizophrenia Quality of Life Scale. This study is part of a larger study looking at family factors and psychosis.

Results The study sample was 58 enrolled but only 49 participants completed the 2 assessments, of these 33 were males (67.3%). Data was analysed using SPSS 21. Pearson's correlation coefficient for resilience and quality of life was 0.503, $P < 0.001$. This shows that higher resilience is associated with better quality of life amongst people with psychotic illnesses. These results could have useful clinical implications. If we can intervene to therapeutically increase resilience, we can eventually improve the quality of life of people with psychoses.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Brain-based psychotherapy for psychosis

L. Mehl-Madrona^{1,*}, B. Mainguy²¹ Eastern Maine Medical Center, Family Medicine, Orono, USA² Coyote Institute, Education, Orono, USA

* Corresponding author.

Introduction Psychotherapy methods are evolving for patients with psychosis.

Methods We present a psychotherapy of psychosis that is brain-based, along with results of working with patients using these methods. Patients with psychosis are known to have decreased connectivity of the elements of the default mode network, also known as the story-making brain. These patients are known to tell narratives that lack coherence, of both excessive elements and inadequate elements. These stories are rigid and either cacophonous or rigidly monologic. The key brain area of the precuneus shows diminished connectivity to other brain areas. We present a narrative approach in which patients are assisted through rehearsal and modeling to tell more coherent stories about their life experiences. We work toward achieving a future orientation in which a sequence of actions leads toward an achievement of a future goal. The protagonist encounters obstacles and learns how to overcome them. Through iterative rehearsals, the story achieves more vivid mental imagery and emotional connectivity. Delusions and voices are accepted and incorporated into those stories in ways that provide the patient with improved capacity to cope with their delusions and voices.

Results We present the results of 59 patients who worked with these techniques and compare them to a matched cohort of patients treated conventionally. The treated patients show statistically significant improvement in positive and negative symptoms and in quality of life.

Discussion Brain-based narrative psychotherapy approaches can improve the quality of life and reduce symptoms.

Conclusion These techniques are worthy of further exploration.

Disclosure of interest The authors have not supplied their declaration of competing interest.

First-episode psychosis intervention – description of our early intervention model

B. Melo*, C. Alves Pereira, R. Cajão, J. Ribeiro Silva, S. Pereira, E. Monteiro

Centro Hospitalar Tondela Viseu, Department of Psychiatry, Viseu, Portugal

* Corresponding author.

Introduction The research about the benefits of early diagnosis and treatment of first-episode psychosis had significantly increased in last decades. There have been several early intervention programs in psychotic disease, implemented worldwide, in order to improve the prognosis of these psychotic patients.

Objectives To present a brief description of the first-episode psychosis intervention team of Tondela-Viseu Hospital Centre–Portugal and its model. We aim to further characterize our population and describe its evolution since 2008.

Aims We aim to clarify the benefits of an early intervention in psychosis.

Methods We conducted a retrospective cohort study of patients being followed by our team from November 2008 to September 2016. Demographic and medical data were collected (such as diagnosis, duration of untreated psychosis, treatments and its clinical effectiveness, relapse rate and hospital admissions) in patient's

clinical records. The intervention model protocol of this team was also described and analyzed.

Results This multidisciplinary team consists of three psychiatrists, one child Psychiatrist, one psychologist and five reference therapists (areas of nursing, social service and occupational therapy). It includes patients diagnosed with first-episode psychosis, aged 16 to 42 years old, followed for five years. The team followed, since its foundation, 123 patients, mostly male. The most prevalent diagnosis are schizophrenia and schizophreniform psychosis. The team is currently following 51 patients.

Conclusions This team's intervention have progressively assumed a more relevant importance in the prognosis of patients with first-episode psychosis, by reducing the duration of untreated psychosis, the relapse rate and by promoting social reintegration.

Rechallenge of clozapine in a low secure setting following pericardial effusion

A. Mohandas^{1,*}, J. McCarthy¹, A. Hartley², E. Fatima³, L. Shearman¹¹ Devon Partnership NHS Trust, Langdon Hospital, Dawlish, United Kingdom² Devon Partnership NHS Trust, Core Trainee CT3, Exeter, United Kingdom³ Devon Partnership NHS Trust, Specialty trainee ST5, Exeter, United Kingdom

* Corresponding author.

Introduction Clozapine is licensed for treatment-resistant schizophrenia and when clozapine is not able to be used, less evidence based practices may be required. Full remission may require combinations or high doses of psychotropic medications having greater potential for interactions and side effects. If this is not successful, symptoms may persist and long-term disability may occur.

Aims To explore safety and efficacy of a rechallenge of clozapine in a patient with treatment resistant schizoaffective disorder, who previously developed pericardial effusion. Collateral history reported best improvement with clozapine compared to other medications.

Objectives To improve level of functioning and reduce need for less evidence based choices of medication.

Methods Initial consultation with clozapine monitoring service over prospects of rechallenge. Full medication history and review. Consultation with a cardiologist regarding validity of local monitoring strategy. Obtain consent from the patient and his family. Titrate clozapine slowly. Once clozapine initiated, measure temperature, blood pressure, pulse rate and monitoring of symptoms of pericarditis including chest pain, cough and dyspnoea daily. ECG and echocardiography at baseline and 2 and 4 weeks after initiation of the rechallenge. ECGs monthly thereafter, with a further echocardiogram at 3 months. Weekly troponin and CRP for three months to monitor developing myocarditis and pericarditis.

Results Successful rechallenge of clozapine with significant reduction in psychopathology, improvement in functioning and no adverse events reported. Reduction of risk enabled transfer to open ward conditions.

Conclusions There is increasing evidence of successful rechallenges of clozapine however, further research is necessary to aid such clinical decisions.

Efficacy of memantine in schizophrenic patients: A systematic review

C. Montemiro*, M.C. Spano, M. Lorusso, G. Baroni, G. Di Iorio, M. diGiannantonio

Department of Neuroscience, chair of Psychiatry, University "G. d'Annunzio", Department of Neuroscience Imaging and Clinical Science, Chieti, Italy

* Corresponding author.

Introduction Several evidences support the hypothesis that glutamatergic dysfunction may be implicated in the pathogenesis of schizophrenia and in the last few year great interest has been focused on the role of the N-methyl-D-aspartate receptor (NMDAR). Memantine is a noncompetitive NMDARs antagonist, binds the same site of NMDARs of Mg²⁺, endogenous blocker of NMDARs, with moderate affinity, rapid unblocking kinetics and strong functional voltage-dependency. Memantine does not affect the physiological activation of NMDARs whereas it blocks the sustained activation under pathological conditions. Preclinical studies have demonstrated that memantine at high concentrations targets many receptors, including serotonin, nicotinic acetylcholine, sigma-1 and serotonin and dopamine receptors.

Objectives Increasing interest in memantine add-on therapy in schizophrenic patients with negative and cognitive symptoms may suggest that memantine could be a new promising treatment in schizophrenia.

Aims The aim of this update was to evaluate clinical data about the memantine effectiveness in schizophrenic patients.

Methods We searched on PubMed to identify original studies about the use of memantine in treatment of schizophrenic patients. The search conducted on June 16th, 2016 yielded 135 records. Neuf papers met our inclusion criteria.

Results Negative symptoms improved in the large majority of patients treated, however there is not a clear evidence on cognitive and positive symptoms (Table 1)

Conclusions Memantine therapy in schizophrenic patients has given unclear results. It seems that memantine improves mainly negative symptoms, while cognitive and positive symptoms did not improve significantly. Further trials with a more numerous sample are required obtain an objective result.

Stressors in patients with schizoaffective disorder

L. Montes Reula*, H. Saiz García, A. Portilla Fernández
 Biomedical Research Center CIB, Psychiatric, Pamplona, Spain
 * Corresponding author.

Patients with schizoaffective disorder have recurrent episodes of a mood disorder with severe psychotic symptoms. In many cases, patients have toxic abuse in some situations that could cause confusion in symptoms and ranking it. It is about a patient diagnosed 5 years ago of schizoaffective disorder with decompensation caused by leaving medication and drug consumption. A year ago, the treatment was changed to intramuscular formulation with abilify maintena to ensure compliance and adherence. The patient continues to consume toxic in weekends, with symptoms of self-referentiality and suspicion towards their environment. Two weeks ago, he was with the girlfriend of a friend and after this event, the friend has been threatening him. The patient has a state of anxiety rising, with interpretations and associations delirious about this friend. He sleeps with a knife in bed if the friend entered his home. It is a very overwhelmed situation, magnifying and causing severe impact on their underlying disorder. When the patient is evaluated, it is decided to add treatment with olanzapine a few days to reduce symptoms and anxiety. Patients with mental disorders have stressors that cause anxiety like a healthy patient. It is true that the impact it has on the patients tend to be older and to overvalue the signs and real situations. In these cases should not be considered a decompensation and attribute symptoms to lack of efficacy of treatment. In many cases, if we associate a more sedating antipsychotic profile, they shall reduce symptoms.

Insight and apathy in patients with paranoid schizophrenia: Rehabilitation approaches

O. Papsuev, L. Movina*, M. Minyaycheva, I. Gurovich
 Moscow Research Institute of Psychiatry, Outpatient Psychiatry and Organization of Psychiatric Care, Moscow, Russia
 * Corresponding author.

Introduction For many decades, clinicians were very well aware of lack of insight in patients with paranoid form of schizophrenia. This group of patients is not only less compliant with pharmacotherapy, but also is hard to manage in the rehabilitation setting. This dictates the necessity to develop special approaches to this group of patients, based on clinical data.

Method Fifty patients with schizophrenia spectrum disorder were randomly recruited to be assessed by PANSS scale and Apathy Evaluation Scale (AES), which was introduced both by trained clinicians (C) and as a self-assessment measure (S). Demographic data was collected along with clinical description on prevailing symptoms during acute phase.

Results While AES-C scores were very well correlated with PANSS motivation subscale, AES-S scores showed prominent discrepancies both with PANSS items and AES-C version. Lower scores on AES-S were also associated with paranoid schizophrenia and prevailing delusional symptoms in acute phase. As well AES-C/AES-S ratio also correlated with paranoid form and delusional symptoms in manifest psychoses.

Discussion Patients with paranoid schizophrenia not only lack insight into positive symptoms, but tend to underestimate their negative symptoms such as motivation and apathy. Clinically, this can be described by overestimated strengths, overstated expectations, exaggerated hopes, mistakenly overrated beliefs. But when

faced with reality, these patients are unable to adjust themselves and frequently are negativistic to offered help and therapies.

Conclusion We assume that paranoid patients should be treated not with straightforward strategies, such as psychoeducation, but with less stigmatizing methods that work on metacognitive and motivational levels.

² Andalusian Health Service, CIBERSAM, University of Granada, Mental Health Unit, University Hospital Complex of Granada, Granada, Spain

* Corresponding author.

Introduction Pharmacological treatment is the gold standard in delusional disorder (DD), moreover the second generation antipsychotics (SGA) are widely used in the treatment of DD, in spite of this, none SGA is authorized for the treatment of DD.

Objectives To evaluate the evidence available for pharmacological treatment in adults with DD. Especially, that concerning SGA.

Methods A systematic review on pharmacological treatment of DD was conducted. We selected the best evidence available. Then, we analysed them critically, assessing its biases and quality, finally performed a narrative and quantitative synthesis.

Results The quality of the evidence was very low. There were not randomized clinical trials. $n=385$, 177 SGA. Antipsychotics achieved a good response in a 33.6% of the patients. First generation antipsychotics (FGA) did show superiority compared to SGA (39% good response vs. 28%, respectively. $P \leq 0.02$). We could not find data about superiority of any drug over other. Pimozide, traditionally considered the most effective drug, did not confirm to be a superior treatment compared to others. Reasons for superiority of FGA were analyzed. The role of another treatments were testimonial, but antidepressants can be a promising treatment.

Conclusions There is no evidence to make strong recommendations, although antipsychotics in general appear to be an effective treatment for DD. Superiority of FGA against SGA was shown. We need to develop clinical trials in DD and SGA, since their better tolerance profile might be the best candidates to do.

Keywords Delusional disorder; Pharmacological treatment; FGA; SGA

* Corresponding author.

Introduction Toxoplasma gondii infection has been recently associated with schizophrenia and other psychiatric disorders.

Aim The aim of the present study was to evaluate the prevalence of T. gondii antibodies among acute psychiatric patients from Western Romania.

Methods This study included 214 consecutive patients admitted at the psychiatric clinic, County Clinical Emergency Hospital in Timisoara, Romania, between 30.06.2011 and 12.01.2012. Clinical and laboratory investigations were performed in these hospitalized patients, including serologic tests for T. gondii IgG and IgM antibodies.

Results The 214 patients aged 19 to 71 years (mean = 42.5), 64.9% were females. T. gondii antibodies were detected in 117 (54.7%) of 214 psychiatric patients. When the data were analyzed by diagnostic groups, T. gondii antibodies were demonstrated in 30 (50.84%) of 59 patients with schizophrenia, in 28 (59.57%) of 47 with persistent delusional disorder, 10 (31.25%) of 32 with acute and transient psychotic disorder, 13 (54.16%) of 24 with schizoaffective disorder and 35 (70%) of 50 with bipolar disorder. A high prevalence of T. gondii antibodies was found among patients with bipolar disorder compared to those with schizophrenia ($P=0.043$) acute and transient psychotic disorder ($P<0.0001$) and healthy controls ($P<0.0001$). Of the 18 patients with schizophrenia and a BPRS score <51 , T. gondii antibodies were detected in 13 (72.2%) compared to 17 (41.4%) of 41 in whom BPRS score was >51 ($P=0.03$).

Conclusion These findings suggest that T. gondii infection may be associated with several psychiatric disorders. A high seroprevalence of T. gondii was demonstrated in patients with bipolar disorder.

Aims The approach to mental illness and specifically in serious mood disorders, long-term treatments that improve adherence as continuous treatments ensure compliance are needed, they minimize the risk of relapse and readmission and therefore increase the chances to have a good fit and social, relational and even occupational functioning.

Method We analysed a sample of 42 male diagnosed with schizophrenia, schizoaffective disorder, chronic delusional disorder that starts treatment with Paliperidone Palmitate in outpatients. It is analysed the dose of paliperidone palmitate employed for stabilization and family satisfaction at the time of stabilization is analysed in the study.

Results The mean dose of Paliperidone Palmitate is 138 mg. The patient diagnosed with schizophrenia are 47.6% and the average dose is 132.5 mg. Chronic delusional disorder is 2.3% and the mean dose 50 mg. Other comorbidity mood disorders are 21.4% and the mean dose is 183 mg. Other disorders (F70, F72...) are 28.5% and mean dose 133 mg. The average family satisfaction (minimum 1 up to 5) is 4, with the highest score among patients diagnosed with F20 Schizophrenia.

Conclusions Long lasting injectable medications achieve important adherence and a high percentage of antipsychotic monother-

apy, thus reducing the side effects, although in our sample 8% which has occurred was removed therefrom.

⁴ Hospital Nuestra Señora del Prado, family and community medicine, 45600, Spain

* Corresponding author.

Introduction We report the successful management of a 49-year-old woman with an initial diagnosis of schizoaffective disorder transitioned to resistant schizophrenia. First contact with our psychiatrist service in 2000; referring problems with treatment adherence and occasional toxic abuse, she underwent 15 admissions in acute adult psychiatric hospitalisation units since then (last discharge March, 2015), and a one-year stay (2012–2013) in an adult mid-term mental health unit. She is currently followed-up throughout the major mental-health outpatient visits program.

Aims The patient was prescribed paliperidone 6 mg 2-0-0, oxcarbazepine 600 mg 1-0-1 and clonazepam 0.5 mg 1-0-1 during the last 2 months.

Methods Due to lack of treatment adherence and toxic abuse she suffered a psychotic decompensation in May 2015. She was then prescribed clozapine 200 mg 1-0-2, boosted with aripiprazole 400 mg once monthly. The adjunction of aripiprazole once monthly (AOM) was intended to improve treatment adherence, and to supplement the psychotic control of clozapine without entailing a worsening of therapy tolerability. The patient was monitored during 5 months in our unit.

Results We observed a positive psychopathological evolution of the patient, which allowed us to re-evaluate the initial diagnostic, ascribing the previous mood fluctuations to toxic consumption.

Conclusion Previous works have been published about the combination of clozapine and oral aripiprazole for the treatment of resistant schizophrenia, but, as far as we know, this is the first report of the combined use of clozapine and AOM. Based on our results, this antipsychotic combination resulted in a psychopathological improvement of the patient, with good tolerability.

Treatment patterns in schizophrenia: Clinical case of successful management with a series of long acting injectable antipsychotics

M. Palomo Monge^{1,*}, J.F. Calvo Mauri¹, M.F. Tascon Guerra², A. Duque Domínguez³, S. Díaz Conde⁴, P. Padilla Romero¹, M.F. Alcocer Lanza⁵, R. Ochoa Blanco¹, B. Lara de Lucas¹

¹ Hospital Nuestra Señora del Prado, Psychiatry, 45600, Spain

² Hospital Nuestra Señora del Prado, Psychiatry, Spain

³ Hospital Provincial de Ávila, Psychiatry, Ávila, Spain

⁴ Centro de Rehabilitación Psicosocial y Laboral, psychologist, 45600, Spain

⁵ Hospital Nuestra Señora del Prado, family and community medicine, 45600, Spain

* Corresponding author.

Introduction We report the successful management of a 57-year-old woman with a 20 year diagnostic of paranoid schizophrenia (first visit November, 1995). She presented several comorbidities (arterial hypertension, diabetes mellitus and morbid obesity), with a history of five previous hospitalizations (1995, 2012, January and May 2014, and April 2016).

Aims/methods The patient was always prescribed depot antipsychotics: she was treated for 14 years with Zuclopentixol depot (discontinued due to dermic adverse reactions and weight gain). After a period with oral paliperidone (from 2012 until 2013) and due to lack of adherence to oral therapy, in August 2013 she was prescribed paliperidone palmitate. The treatment was discontinued after nine months (May 2014) due to weight gain, a significant increase of serum prolactin levels and two psychotic relapses that led to hospital admissions.

Results She was then prescribed Fluphenazine decanoate depot for one year and 4 months, but she was switched to Aripiprazole once monthly (AOM) in September 2015 to avoid metabolic syndrome.

Conclusions Non-personalized antipsychotic treatment in a patient with a complicated comorbidity history can result in lack of compliance and a risk of relapse, and in a worsening of her medical conditions, with the consequential negative impact in her functioning and quality of life. Based on our results, the treatment with AOM resulted in a positive evolution of the patient, with a good tolerability profile, in an improvement of treatment-caused adverse events (weight loss, and prolactin serum levels normalization); all factors that enable treatment adherence and good clinical response.

Disclosure of interest The authors have not supplied their declaration of competing interest.

² University of Bari "Aldo Moro", Department of Educational Sciences, Psychology and Communication Sciences, Bari, Italy

³ Bari University Hospital, Psychiatry Unit, Bari, Italy

* Corresponding author.

Introduction The genetic architecture of schizophrenia is based on polygenic trajectories. Indeed, genes converge on molecular co-expression pathways, which may be associated with heritable characteristics of patients and their siblings, called intermediate phenotypes, such as prefrontal anomalies and thalamic dysconnectivity during attentional control [2].

Objectives Here, we investigated in healthy humans association between co-expression of genes with coordinated thalamo-prefrontal (THA-PFC) expression and functional connectivity during attentional control.

Methods We used Brainspan dataset to characterize a coordinated THA-PFC expression gene list by correlating post-mortem gene expression in both areas (Kendall's Tau > .76, Bonferroni $P < .05$). Then, we identified a PFC co-expression network¹ and tested all gene sets for THA-PFC and PGC loci [3] enrichments

($P < .05$). SNPs associated with the first principal component of the resulting enriched gene set were combined in a Polygenic Co-Expression Index (PCI) [1]. We conducted Independent Component Analysis (ICA) on attentional control fMRI data ($n = 265$) and selected Independent Components (ICs) including the thalamus and being highly correlated with an attentional control network². Multiple regressions were conducted (predictor: PCI) using a thalamic cluster previously associated with familial risk for schizophrenia [2] as ROI (FWE $P < .05$).

Results In one of the 8 ICs of interest there was a positive effect of PCI on thalamic connectivity strength in a cluster overlapping with our ROI ($Z = 4.3$).

Conclusion Decreased co-expression of genes included in PCI predicts thalamic dysconnectivity during attentional control, suggesting a novel co-regulated molecular pathway potentially implicated in genetic risk for schizophrenia.

Erotomania: A psychodynamic overview

E. Pereira*, F. Coutinho, A.S. Machado, C. Reis
 Centro Hospitalar de São João, Clinic of Psychiatry and Mental Health, Porto, Portugal

* Corresponding author.

Introduction Erotomania is a delusional disorder in which one believes to be loved by someone else. Even though its etiology is not known, psychodynamic factors have been proposed as a possible explanation.

Objectives To review the psychodynamic etiology of erotomania.
Methods A search of the Medline/Pubmed database was conducted using the terms “erotomania” and “psychodynamic”.

Results Several authors wrote about the psychodynamic etiology of erotomania. Kraepelin describes it as a “compensation for the disappointments of life”. De Clérambault highlights the idea of “sexual pride”: stimulated by the absence of affective and sexual approval, erotomania flourishes as a way of satisfying the individual’s pride. Hollender and Callahan explain the disorder as a result of an ego deficit of not feeling attractive enough. According to Segal, the erotomaniac delusion meets the patient’s need for love and it is related to the idea of it as the ultimate way of approval. Taylor highlights the patients’ isolation, loneliness and extreme dependence on others.

Conclusions About every author agrees with the idea that the erotomaniac delusion acts as a gratification to the individual’s narcissistic needs, when personal experience has failed to do so. Wanting to be loved is the core of human motivation and the delusion most commonly appears in people who feel rejected by society; facing that perceived rejection, it emerges as the fantasy that other human being is in love with them. This is a relevant overview of this disorder with implications in patients’ treatment, since psychotherapy could be important along with drug treatment.

The association between first-episode psychosis and abnormal glycaemic control: Systematic review and meta-analysis of clinical studies

B. Perry^{1,*}, G. McIntosh², S. Weich¹, S. Singh¹, K. Rees¹

¹ University of Warwick, Department of Mental Health and Wellbeing, Warwick, United Kingdom

² North West School of Anaesthesia, Anaesthetics, Manchester, United Kingdom

* Corresponding author.

Background Schizophrenia, which is linked to a range of physical health conditions, might share intrinsic inflammatory disease pathways with type-two diabetes mellitus (T2DM). Psychotropic medication has presented a major confounder in examining this association. First-episode psychosis (FEP) patients present an interesting cohort to study this potential association, being generally younger with less comorbidity, and with limited exposure to antipsychotic medication.

Aims To assess whether FEP, which could be described as ‘developing schizophrenia’, is associated with prediabetes, or ‘developing diabetes’, to determine whether intrinsic disease links could cause the conditions to develop in unison.

Methods Using PRISMA criteria, we searched Embase, Medline, PsychInfo, Web of Science, and Google Scholar to 6th January 2016. We assessed case-control studies with biochemical assessment of prediabetic states in FEP patients alongside matched controls.

Results Twelve studies were included, involving 1137 participants. Several measurements examined prediabetes, including fasting plasma glucose, impaired glucose tolerance, and insulin resistance. Pooled analysis found FEP to be related to impaired glucose tolerance (mean difference 1.31 [0.37, 2.25]), insulin resistance (mean difference 0.30 [0.18, 0.42]), and the number of patients with impaired glucose tolerance (odds ratio 5.44 [2.63–11.27]).

Conclusion Our findings suggest a potential link between prediabetic markers, in particular impaired glucose tolerance and insulin resistance, and FEP. However, we cannot establish causality, and the studies contributing to this review were at some risk of bias. Nevertheless, the findings might help to explain the increased prevalence of T2DM in patients with schizophrenia and could have implications for the management of schizophrenia patients.

Patients with schizophrenia assessing psychiatrists’ communication skills

A. Pestana Santos^{1,*}, V. Santos¹, I. Carvalho²

¹ Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

² Faculty of Medicine of Oporto University, Psychology, Oporto, Portugal

* Corresponding author.

The doctor-patient relationship constitutes the matrix of the entire medical practice. One way in which doctors develop a positive rapport with their patients is through appropriate communication. Evidence suggests that doctors do not communicate with their patients as they should. Important gaps are observed in doctors’ communication with patients with schizophrenia.

Aim Examine psychiatrists’ communication skills as assessed by their patients with schizophrenia and through external observation, considering patients’ socio-demographic and clinical variables and analyse the importance that aspects of communication have for patients.

Methodology This cross-sectional study involved a sample of 30 patients and 11 doctors. An adapted and culturally validated version of the Communication Assessment Tool was used for data collection. Data were analysed in IBM SPSS Statistics®, version 24.

Results Male patients constituted 86.7% of the sample and mean age was 46.7 ± 13.3 . The overall mean percentage of items rated as excellent by patients was 57.4%. On the other hand, external observer percentage of excellent scores was much lower when compared with patients' scores. Single, divorced or widower/widow patients, patients with higher educational level and patients with shorter number of years in medical treatment gave significantly higher scores to psychiatrists' communication. Patients' sex, age, occupation residence and family type did not yield statistically significant effects on patients' ratings.

Conclusions Communication is at the heart of psychiatrists' daily practice. Many communication styles might be needed, depending on the nature of clinical encounters and patient expectations. Specific training is required to optimise psychiatrists' communication skills on everyday practice.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁴ Azienda Ospedaliera Universitaria Integrata Verona, Section of Radiology, Verona, Italy

* Corresponding author.

Introduction Anatomical alterations in the Superior Temporal Gyrus (STG) have been reported in schizophrenia. The STG is one of the most asymmetric and lateralized structure of the brain, and the process of lateralization seems to vary according to gender. Although it has been suggested that patients with schizophrenia do not show normal brain lateralization, only few studies investigated it in the STG considering the effects of sex.

Objectives The objective of this study is to evaluate sexual dimorphism in STG volumes in a sample of patients with schizophrenia compared to age- and sex-matched healthy controls.

Methods Seventy-two right-hander males (40 schizophrenia patients and 32 controls) and 45 right-hander females (18 schizophrenia patients and 27 controls) underwent clinical evaluation and a 1.5T MRI scan. Gray and white matter volumes of regions of interests within the STG were detected, including the Heschl's Gyrus (HG) and the planum temporale (PT).

Results Female patients with schizophrenia presented a reduction in left PT gray matter volumes ($F=4.58$, $P=0.03$) and a lack of the normal PT asymmetry index ($t=0.27$; $P=0.79$) compared to female controls ($t=5.47$; $P<0.001$). No differences were found between males for volumes or laterality. Also, in patients with schizophrenia STG gray and white volumes negatively correlated with positive symptoms ($r=-0.33$, $P=0.02$ and $r=-0.29$, $P=0.03$ respectively), whereas left PT gray matter volumes were negatively associated to duration of illness ($r=-0.27$, $P=0.04$).

Conclusions Sexual dimorphism plays a key role on PT in schizophrenia, underlying the importance of gender as a modulator of brain morphology and lateralization of schizophrenia.

Introduction Functioning of patients with delusional disorder may be impaired, particularly if the delusional thinking is chronic rather than episodic. They refuse to characterize their beliefs as false and view opposing views with surprise, if not hostility and disdain, dismissing or ignoring them, and continuing their struggle to find resolution or restitution for the wrongs they have endured or the illnesses from which they suffer. They typically reject and often resent the suggestion that they are mentally compromised. They are a difficult group to engage clinically, often refusing to meet with a clinician about their delusions and/or to take medication. The first-line treatment of delusional disorder is antipsychotic medication rather than other clinical interventions. Patients with the disorder often reject psychiatric treatment, it is particularly important that medication be prescribed in the context of a therapeutic relationship that includes support, education, encouragement of healthier pursuits, and discouragement of damaging, delusion-inspired actions.

Methods We describe a case of a 55-year-old woman with a delusional disorder that was diagnosed 4 years before. The supervision of the right take of the treatment was not possible and the intensity of behavioral disturbances increased. Then we started the treatment with long-acting injectable aripiprazole.

Results Within the 4 months following the start of treatment, her mental state improved by attenuation of psychotic symptoms.

Conclusions Long-acting aripiprazole could be an effective tool for treatment of psychotic symptoms in patients with no insight and difficulties to check the proper treatment take.

* Corresponding author.

Introduction More than 60% of patients receiving intensive treatment with first generation antipsychotic manifest some type of clinically significant extrapyramidal side effects. Parkinsonian syndrome is the most common and is characterized by rigidity, tremors, akinesia and bradykinesia and usually improves with discontinuation of antipsychotic drug or anticholinergic association.

Methods It is a 60-year-old man, married with two children. Initiates contact with mental health in 2013 with a diagnosis of adjustment disorder. In February 2014 he requires hospitalisation, establishing the diagnosis of delusional disorder and starting treatment with long-acting injectable paliperidone palmitate (100 mg/month) with remission of psychotic symptoms in a few days. When we receive the patient in our clinic, he presents parkinsonian extrapyramidal symptoms (UKU subscale: 18), with significant functional limitation. We decrease the dose to 75 mg/month and an anticholinergic was added without improvement of Parkinsonian clinic, so we decided to switch to long-acting injectable aripiprazole 400 mg/month, objectifying complete remission of extrapyramidal syndrome (UKU subscale: 0).

Conclusions The mechanism of action of aripiprazole m LAI (partial agonist of D2 receptors in the brain) without decreases in the nigrostriatal dopamine pathway, of improving extrapyramidal effects associated one other antipsychotics.

This is a case report of a 63-year-old patient with no previous attentions in mental health. He is referred by his general practitioner because he presents wounds all over his body. He reports that there is a plague of bugs at his place that bite him everywhere. Therefore, he scratches continuously, trying to remove the stingers, and injuring himself all over. The family ensures there are no bugs at all, but the patient threatens to set fire to the house in order to extinguish the plague or even kill himself. An OCD with cleaning compulsive behavior was also present since many years, as well as an alcohol abuse. The patient required hospitalization in the psychiatry service. Organic cause for the disorder was discarded. Long-acting injectable aripiprazol was introduced and the patient stopped drinking. Progressively, the delusional symptoms began to subside. Now he maintains no awareness of illness but he says the bugs are disappearing and, at least, they do not bite him anymore.

Introduction Approximately a third of patients with schizophrenia show limited response to antipsychotic medication. As several studies have been suggesting new classifications to schizophrenia, our aim is to review different hypothesis and seek a new way of approaching patient's treatment in day-to-day practice.

Methods The methods we used consisted on reviewing several papers that have recently been published on the area of classification and treatment of schizophrenia, considering an approach to the findings that enables a practical and clinical advantage in the area.

Discussion New studies suggest that neuroimaging measures of dopamine and glutamate function might provide a means of stratifying patients with psychosis according to their response to treatment. Some of those studies associate treatment response with the anterior cingulate level of glutamate and striatal dopamine synthesis capacity. Other study identified three biotypes with different outcomes to psychosis, reaching a stronger association between biotypes as predictors of illness severity than the DSM-V classification. If a correlation between these studies was found, we would be able, in theory, to predict the response to treatment using simple and affordable neurobiological measures.

Conclusion Associating the anterior cingulate glutamate levels, the striatal dopamine synthesis capacity and biotypes hypothesis in schizophrenia, one can expect to be possible to predict the degree of response to treatment, based on more affordable methods to day-to-day clinicians than the measure of neurotransmitter levels, enabling the regular clinicians to narrow their pharmacological options for patients, achieving better results in the approach to schizophrenia.

Hyperthermia and neuroleptic malignant syndrome-Case report

K. Puljić^{1,*}, M. Herceg¹, V. Jukić²

¹ University Psychiatric Hospital Vrapce, Department of Biological Psychiatry, Zagreb, Croatia

² University Psychiatric Hospital Vrapce, Department of Forensic Psychiatry, Zagreb, Croatia

* Corresponding author.

Neuroleptic malignant syndrome (NMS) is a rare, but life-threatening, idiosyncratic reaction to neuroleptic medications that is characterized by fever, muscular rigidity, altered mental status, and autonomic dysfunction. NMS often occurs shortly after the initiation of neuroleptic treatment, or after dose increases. Malignant hyperthermia (MH) or malignant hyperpyrexia is a rare life-threatening condition that is usually triggered by exposure to certain drugs. The 46-years-old female patient was diagnosed schizophrenia at the age of 22. Currently, she is hospitalized due to psychotic decompensation. The patient was admitted with following daily dose therapy of: haloperidol 15 mg, biperiden 4 mg and diazepam 15 mg. During this hospitalization she develops muscle rigidity, tremor, hyperthermia, and laboratory results showed increase of enzymes CPK and LDH, so we started treatment of suspected malignant neuroleptic syndrome. After a treatment and

recovery with complete withdrawal of all presented symptoms, our patient developed a malignant hyperthermia that was resistant to all applied medications. Our dilemma is whether presented symptoms of malignant hyperthermia are related to malignant neuroleptic syndrome or not?

* Corresponding author.

Introduction The prevalence of acute and transient psychotic disorder (ATPD) varies from 3.9–9.6 per 100,000 population [1]. Even if it has clinical course with psychosis, there is no evidence that ATPD is similar with schizophrenia [2].

Objectives Since in Bosnia and Herzegovina (BH) are not established specialized services for early interventions (EI), community mental health centers (CMHC) are basic services for fast and most efficient interventions in the cases of ATPD among other psychiatric disorders. The mental health reform has planned to establish EI services in the future [3].

Aims and method To show CMHC as efficient service in the treatment of ATPD without using hospitalisation of young woman with two years follow up (case study)

Results Full recovery of young female with ATPD using team approach and model of case management. After follow up of two years was any indications that psychotic disorders will develop.

Conclusions Even we have not EI specialized services in our country, CMHC have capacities to manage ATPD in community settings avoiding hospitalisation of young people.

When the term “schizophrenia” is enough to modify the way you interact with others: Evidence for a motor synchrony task

N. Rainteau*, R. Salesse, S. Raffard, D. Capdevielle
Hôpital La Colombière, Service Universitaire de Psychiatrie Adulte, Montpellier, France

* Corresponding author.

Introduction Most individuals with schizophrenia will be confronted with some forms of stigmatization. In recent years, the term “schizophrenia” has been increasingly contested by clinicians and family members and many of them argue for a change of name. Surprisingly, most of the research has been explored through self-reports but behavioural research is still lacking. The aim of our study was to assess through an experimental design if the term “schizophrenia” was enough to modify social behaviours.

Methods Eleven participants from the community were asked to engage in three coordination tasks with a simple dot displayed on a screen and moved by another person. Participants had to synchronize their movements with either a schizophrenia patient, a patient with neuro-emotional integration disorder (NEID) or a healthy subject, situated in different rooms. Each condition was counterbalanced between participants. In reality, the movements of the dot were pre-recorded (five trajectories) and were therefore identical for all three conditions.

Results Measuring the error between the displayed and performed trajectories, participants coordinate worse when they thought interacting with a schizophrenia or NEID patient in comparison to the “healthy” ($F(2,20) = 4.02; P = .034; n2P = 0.29$) condition. Post-hoc analysis revealed an even higher difference between “schizophrenia” and “healthy” conditions ($P = 0.01$).

Conclusion Our study is the first to demonstrate that the label “schizophrenia” directly impacts our behaviour, with negative consequences on social interactions. However, our results cannot confirm yet a positive effect induced by changing the name.

Comparison of hospitalization rates in schizophrenic patients on first generation versus second generation antipsychotic depots

S. Rasool*, B. Roy

South Essex Partnership Trust, psychiatry, Basildon, United Kingdom

* Corresponding author.

Introduction There is limited data on the efficacy rates between first and second generation antipsychotic depots. One good indicator of efficacy is the rates of hospitalization. Some studies have shown that second generation depot antipsychotics significantly reduce hospitalizations rates as compared to conventional depots.

Objectives Comparison of hospitalization rates for patients with schizophrenia on first and second generation antipsychotic depots.

Methods A retrospective observational study was done by reviewing the records of an antipsychotic depot clinic in Essex, United Kingdom. A list of 47 patients enrolled and receiving depot antipsychotics was obtained. Their records were studied and hospital admission rates calculated.

Results Of the 47 patients 11 were excluded as they were on depot antipsychotics for non-schizophrenic diagnoses. Of the 36 patients with schizophrenia, 12 were on second generation and 24 were on first generation depots.

Amongst the 24 patients on first generation depots, 19 were male, 5 female and mean age was 52 years.

Of the 12 patients on second generation depots, 10 were male and 2 female and mean age was 46 years.

When comparing hospital admission rates between the 2 groups, the following data was noted (Table 1).

Conclusions There is no difference in hospitalization rates between patients on first generation antipsychotic depots as compared to second generation antipsychotic depots.

Table 1

	Admission	No admission	Marginal row totals	P value
First generation antipsychotic	7 (6) [0.17]	17 (18) [0.06]	24	0.414216
Second generation antipsychotic	2 (3) [0.33]	10 (9) [0.11]	12

* Corresponding author.

Introduction In a perspective of personalized care for smoking cessation, a better clinical characterization of smokers with schizophrenia (SZ) is needed. The objective of this study was to determine the clinical characteristics of SZ smokers with severe nicotine (NIC) dependence.

Methods Two hundred and forty stabilized community-dwelling SZ smokers (mean age = 31.9 years, 80.4% male gender) were consecutively included in the network of the FondaMental Expert Centers for schizophrenia and assessed with validated scales. Severe NIC dependence was defined by a Fagerstrom questionnaire score ≥ 7 . Major depression was defined by a Calgary score ≥ 6 . Childhood trauma was self-reported by the Childhood Trauma Questionnaire score (CTQ). Ongoing psychotropic treatment was recorded.

Results Severe NIC dependence was identified in 83 subjects (34.6%), major depression in 60 (26.3%). 44 (22.3%) subjects were treated by antidepressants. In a multivariate model, severe NIC dependence remained associated with major depression ($OR = 3.155, P = 0.006$), male gender ($OR = 4.479, P = 0.009$) and more slightly with childhood trauma ($OR = 1.032, P = 0.044$), independently of socio-demographic characteristics, psychotic symptoms severity, psychotropic treatments and alcohol disorder.

Conclusion NIC dependence was independently and strongly associated with respectively major depression and male gender in schizophrenia, and only slightly with history of childhood trauma. Based on these results, the care of both nicotine dependence and depression should be evaluated for an effective smoking cessation intervention in schizophrenia. Bupropion, an antidepressant that has been found as the potential most effective strategy for tobacco cessation in schizophrenia to date, may be particularly relevant in male SZ smokers with comorbid major depression.

Schizoaffective disorder and schizophrenia: Clinical differences

F. Romosan*, L.M. Ienciu, A.M. Romosan, R.S. Romosan

"Victor Babes" University of Medicine and Pharmacy, Neuroscience, Timisoara, Romania

* Corresponding author.

Introduction Schizoaffective disorder (SAD) and schizophrenia (SZ) are important causes of disability and morbidity. Finding clinical features that can help in their early differentiation may lead to a better understanding of these two nosologic entities.

Objectives The purpose of this study was to find clinical differences between SAD and SZ.

Methods We selected for this study 83 inpatients from the Timisoara Psychiatric Clinic, diagnosed with either SAD ($n = 35$) or SZ ($n = 48$), according to ICD-10 criteria. The research was conducted between 2014 and 2016. Socio-demographic (age, sex, education, marital status) and clinical data were analysed. The Brief Psychiatric Rating Scale (BPRS) was used to assess symptom severity.

Results Delusions of grandiosity were found significantly more frequent in SAD patients ($P = 0.001$). By contrast, bizarre delusions ($P = 0.025$), derealization phenomena ($P = 0.03$) and negative symptoms ($P = 0.003$) appeared more frequent in schizophrenic patients. We found no significant differences between the two samples regarding onset age, number of episodes, duration of episode, duration of remission and suicidal thoughts/attempts. Although the SZ sample had higher BPRS total scores than SAD patients, the differences were not statistically significant.

Conclusions Even though SAD and SZ are very similar in respect to their clinical presentation, this study also revealed certain differences that may enhance specific knowledge regarding these two disorders.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Urban Spaces and psychic disease: A case series from Florence

E. Rondini*, M. Bertelli

Fondazione San Sebastiano, CREA Centro di Ricerca e Ambulatori, Florence, Italy

* Corresponding author.

People with schizophrenia or other psychoses present alterations of multi-sensory processing and impairments in cognitive functions. They seem to be more sensitive to external stimuli than the general population, which can negatively impact on their emotional state. The purpose of the study was to assess how elements of urban milieu combine with spatial experiences of people with these disorders, affecting their spatial perceptions and social interactions. The group of participants consisted of 10 patients aged between 20 and 40 years, with schizophrenia or other psychoses. We used qualitative methods to assess behaviours in different urban routes, including a period of participant observation and a series of semi-structured interviews. Pathways within the city were recorded using a Global Position System (GPS), in order to link perceptual and behavioural data to specific urban spaces. The data analysis has revealed positive interactions between most of participants and the city. Different places have been differently perceived in terms of stress and comfort. The wide squares and the art-rich sites of the city center, as well as public parks and gardens, have been connected with positive feelings and senses of pleasure. Conversely, the presence of a high number of people and the movement experiences through public transport services have emerged to be associated with negative emotions. A deeper understanding of

mechanisms and processes that interest the link between urban space and psychological disease can contribute to show new directions for the improvement of urban life quality and to progress both in psychiatry and in urban planning.

The awareness of social inference task (TASIT) updated: Signal detection theory (SDT) in emotion recognition and its link to psychotic symptoms

R. Rossi^{1,*}, V. Santarelli¹, M. Carmela¹, D. Gianfelice², R. Ciccirelli¹, F. Pacitti¹, A. Rossi¹

¹ University of L'Aquila, Applied Clinical Sciences and Biotechnologies DISCAB, L'aquila, Italy

² SPDC Ospedale San Salvatore, DSM, L'aquila, Italy

* Corresponding author.

Introduction Social cognition (SC) is an impaired domain in schizophrenia. However, little is known on the Signal Detection properties of SC deficits.

We analyzed the relationship between emotion perception and psychotic symptoms in a sample of schizophrenic patients. For this scope, we extended the scoring system of the awareness of social inference task-emotion recognition (TASIT-ER) according to signal detection theory (SDT).

Methods Sample:

– one hundred and nineteen inpatients from L'Aquila Inpatient unit diagnosed with schizophrenia.

Dependent variable:

– Positive and Negative Syndrome Scale (PANSS)'s Positive, Negative, Disorganized, Excited and Depressed dimensions, and total score.

Independent variable:

– a modified version of TASIT-ER. The original scoring system, including only "HITS", was extended with "False Alarm" (FA), defined as a detection of an emotion when not present.

Statistical analysis:

– multivariable linear regression models for each sub-group of emotions to assess the effect of FAs on psychotic symptoms compared to HITS.

Results FAs on positive emotions were associated with disorganized ($b=31.95$), excited dimensions ($b=41.84$) and PANSS Total ($b=152.46$); FAs on negative emotions were associated with Excited dimension ($b=-57.97$) and PANSS Total ($b=-243.70$). HITS on Negative emotions were associated with Negative ($b=-13.37$), Disorganized ($b=-8.64$) Excited ($b=-8.74$) dimensions and with PANSS total ($b=-45.30$).

Discussion FA rates were more strongly associated with total PANSS score than HIT rate, suggesting a prominent role of false recognition in defining psychotic symptoms, especially disorganized and excited ones, consistently with computational models of psychosis that rationalize false recognition as failures of active inference systems in updating their predictive model of sensory information.

Can the 'mediation' approach help to understand the role of lack of insight in the relationship between symptoms and functioning in schizophrenia?

R. Rossi^{*}, V. Santarelli, C. Marucci, G. Pizziconi, F. Pacitti

University of L'aquila, DISCAB, L'aquila, Italy

* Corresponding author.

Introduction The relationship between Lack of insight (LoI) and other symptoms in schizophrenia is complex. LoI could be associated with severity of symptoms at one side and global functioning at the other. For this nature LoI is a candidate 'mediator' for the relationship between psychotic symptoms and global functioning.

Objectives The aim of this study is to explore the possible role of LoI as a mediator between psychotic symptoms and global functioning in a sample of people with schizophrenia.

Methods Seventy-three patients with a diagnosis of schizophrenia were included. The five-factor model of the PANSS by Wall work was used to assess psychopathology and G12 item as an estimate of LoI. Global assessment of functioning (GAF) was used to measure global disability. Pearson's r correlations and linear regressions for Sobel test for mediation were performed. PANSS factors were modeled as predictors of global functioning and LoI as the mediator.

Results Correlations revealed the prerequisite relationships between LoI, positive, negative and disorganized PANSS factors and global functioning. Mediation analyses show that LoI partially mediates the relationship between positive and disorganized factor scores and global functioning. No mediation for negative factor score was observed.

Conclusions Lack of insight mediates the relationships between positive and disorganized factors and global functioning. The partial mediation we report suggests that LoI on the one hand is an independent contributor to global function, but further shows an indirect effect of PANSS positive and disorganized factors to GAF total score.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁵ Sheba Medical Center, Division of Psychiatry, Ramat Gan, Israel

* Corresponding author.

Background Previous research has shown that people with psychotic disorders have impaired functioning prior to the onset of the illness. The main goal of the proposed study was to deepen understanding of the characteristics of pre-morbid impairment in persons later diagnosed with psychotic disorders.

Methods We examined unique pre-morbid data from IDF archives, including narrative summaries of pre-induction interviews of 17-year old adolescents (168 male adolescents who were later hospitalized for psychotic disorders, and 168 matched control subjects). The data were analyzed using mixed-method analysis, combining qualitative and quantitative research methods.

Results Between group comparisons revealed more adaptation difficulties, family problems and dealing with medical conditions in the group of future psychotic disorder patients, while suicidal thoughts and loss of a close person showed trends towards significance. Two factors characterized classification of outcome: adaptation difficulties and family problems. A "high-functioning" factor was significantly higher within the control group, while a

“strange” factor was higher among the future psychosis patients. A “high-functioning” factor was identified as a protective factor.

Discussion This study used narrative analysis of interview summaries of adolescents who underwent pre-induction assessments. The current study replicated previously published findings that were obtained as a result of retrospective investigations and comparing numeric scores, using unique pre-morbid data and in-depth qualitative analyses, combined with a quantitative one. The main strengths of the current study are the fact that the subjects were interviewed before the onset of psychosis, as well as the fact that the analyses of the data were performed blinded to outcome.

Disclosure of interest The authors have not supplied their declaration of competing interest.

A scale of autonomy for patients with schizophrenia – new instrument for clinical assessment of the level of independency: Description and validation

G. Rupchev*, M. Morozova

Federal State Budgetary Scientific Institution “Mental Health Research Center”, Laboratory of Psychopharmacology, Moscow, Russia

* Corresponding author.

Introduction Today the scales for measurement of functional status and life satisfaction (GAF, PSP, EQ-5D, SQLS) gain more importance in assessing schizophrenic patients. Autonomy of living is to the great extent the basis of patient well-being. Each of these scales has the criteria, testing ability for independent life, but none of it tests autonomy as a separate object.

Objective Development of a new scale.

Aims Description and validation of a scale for evaluation of autonomy of living in schizophrenic patients.

Methods Forty patients diagnosed with schizophrenia according to ICD–10 (F 20.xx), 13 males and 27 females, aged 49.8 ± 9 , disease duration is 22 ± 8.6 years. New scale and PANSS, CGI-S, NSA, BACS, GAF, PSP was administered.

Results The scale comprises five points (activity, intentional behavior, range of social interaction, specificity of interaction with the doctor (medical conventionality) and autonomy), and total score. The internal consistency of the scale was high – cronbach’s alpha 0.83. The construct validity with GAF and PSP was moderate (R varied from 0.36 to 0.55). The total score of the new scale correlated with the PANSS negative subscale score ($R = -0.51$), with CGI-S score ($R = -0.57$), and with the BACS total score ($R = -0.57$).

Conclusion The scale of autonomy corresponds to the major psycho-diagnostic requirements: internal consistency, construct and discriminative validities. It can be considered a new instrument for assessing the integrative target of treatment and rehabilitation of patients with schizophrenia.

Introduction Schizophrenia is associated with increased physical morbidity and mortality. In particular, cardio-metabolic diseases are more frequent. Several underlying reasons have been discussed, including adverse lifestyle behaviors, or adverse effects of neuroleptic treatment. However, little is known about changes of cardiac and intra-abdominal adipose tissue, both are risk factors for the development of cardio-metabolic diseases.

Objectives/aims To compare, cardiac and intra-abdominal adipose tissue between patients with schizophrenia and healthy controls.

Methods Ten physically healthy patients with schizophrenia according to DSM-V were included, and compared to healthy control subjects. Cardiac and intra-abdominal adipose tissue was quantified using magnetic resonance tomography. Further factors assessed comprise the metabolic syndrome, physical activity, smoking behavior, and scores for the assessment of cardio-metabolic diseases (FINDRISK score and modified ESC score).

Results Cardiac adipose tissue and intra-abdominal adipose tissue was increased in patients with schizophrenia. Further findings were higher diastolic blood pressure, more smoking, less physical activity, and an increase for diabetes and cardiovascular disease risk according to the modified ESC and FINDRISK score.

Conclusions The new finding in our study is an increase of cardiac adipose tissue, a risk factor for the development of cardiovascular disorders, in physically healthy patients with schizophrenia. Furthermore, the risk for the development of type-2 diabetes mellitus is increased, indicated by higher amount of intra-abdominal adipose tissue, and the results of the FINDRISK score. We conclude that lifestyle alterations, particularly exercise training that has been shown to reduce cardiac and intra-abdominal adipose tissue, should be recommended in patients with schizophrenia.

Not the same old madness: Evaluating the clinical profile of the “schizophrenia spectrum” disorders

A. Russo^{1,*}, N. Verdolini^{1,2}, G. Menculini¹, P. Moretti¹, R. Quartesan¹, A. Tortorella¹

¹ Division of Psychiatry, Clinical Psychology and Rehabilitation, Department of Medicine, Santa Maria Della Misericordia Hospital, University of Perugia, Perugia, Italy

² Bipolar Disorders Unit, Institute of Neuroscience, IDIBAPS CIBERSAM, Hospital Clínic, Barcelona, Spain

* Corresponding author.

Introduction The “schizophrenia spectrum” concept allowed better identifying the psychopathology underpinning disorders including schizophrenia, schizoaffective disorder (SZA) and cluster A personality disorders (PD).

Aims To compare the clinical portrait of the schizophrenia spectrum disorders, focusing on the impact of the affective dimension.

Methods Inpatients at the acute psychiatric ward of Perugia (Umbria-Italy) were evaluated with the structured clinical interview for DSM-IV Axis I and Axis II disorders and diagnosed with a “schizophrenia spectrum” disorder according to DSM-IV-TR. The clinical evaluation was conducted using the positive and negative syndrome scale (PANSS). Pearson correlations of the different subscales in the three groups and between the negative scales with the affective symptom “depression” were conducted.

Results The sample consisted of 72 inpatients (schizophrenia 55.6%, SZA 20% and cluster A PD 19.4%). The negative and the general psychopathology scales directly correlated at different degrees in the three groups (schizophrenia: $r=0.750$, $P<0.001$; SZA: $r=0.625$, $P=0.006$; cluster A PD: $r=0.541$, $P=0.046$). The symptom “depression” directly correlated with 5 out of 7 negative symptoms: blunted affect ($r=0.616$, $P<0.001$), emotional withdrawal ($r=0.643$, $P<0.001$), poor rapport ($r=0.389$, $P=0.001$), passive/apathetic social withdrawal ($r=0.538$, $P<0.001$), lack of spontaneity & flow of conversation ($r=0.399$, $P=0.001$).

Conclusions Our study confirmed the existence of the “schizophrenia spectrum” with combined different disorders lying on a continuum in which negative symptoms mainly correlated with the psychopathological functioning. Noteworthy, the symptoms of the negative scale strongly correlated with the “depression” symptom, underlying the impact of the affective symptoms on the severity of the “schizophrenia spectrum” disorders.

Ultra-resistant schizophrenia and potentiation strategies

S. Khouadja*, R. Ben Soussia, S. Younes, A. Bouallagui, I. Marrag, M. Nasr

University Hospital, Psychiatry, Mahdia, Tunisia

* Corresponding author.

Introduction Treatment resistance to clozapine is estimated at 40–70% of the treated population. Several clozapine potentiation strategies have come into clinical practice although often without evidence-based support.

Objective The aim of our work was to identify the potentiation strategies in ultra-resistant schizophrenia depending on the subtype of schizophrenia.

Methodology This is a prospective study conducted on patients with the diagnosis of schizophrenia, based on DSM-IV-TR criteria, and hospitalized in the psychiatric department of the university hospital in Mahdia, Tunisia. The study sample consisted of patients meeting the resistant schizophrenia criteria as defined by national institute for clinical excellence (NICE), and the prescription of clozapine for 6 to 8 weeks was shown without significant improvement.

Results we have collected 10 patients. The mean serum level of clozapine was 462.25 mg/L. The potentiation strategies were different depending on the subtype of schizophrenia. For the undifferentiated schizophrenia, we have chosen ECT sessions. For the disorganized schizophrenia, we opted for amisulpiride and aripiprazole. For the paranoid forms, we have chosen the association of risperidone and ECT. A psychometric improvement was noted in BPRS ranging from 34 to 40%.

Conclusion Every potentiation strategy entails a cost, whether it is an additional monetary cost, adverse effects or greater stress to caregivers. The cost/benefit equation should be thoroughly evaluated and discussed before commencing a strategy.

⁷ School of Medicine, University of Zagreb, Psychiatry, Zagreb, Croatia

* Corresponding author.

Introduction Previous studies suggested that patients with schizophrenia had an increased prevalence of antibodies against toxoplasma gondii (TG) and that those seropositive patients had higher symptom severity. However, there is no data on the relationship between treatment-resistant schizophrenia (TRS) and TG seroprevalence.

Objectives To determine the association between TRS and TG seropositivity, and to further investigate the relationship between TG seropositivity and different clinical features of schizophrenia.

Methods In this cross-sectional study, we included 210 male inpatients with schizophrenia. TG seropositivity was determined by ELFA assay. Treatment-resistance was defined as a failure of at least 2 adequate anti-psychotic trials. Data were analyzed using χ^2 test or Mann–Whitney test.

Results The rate of TG seropositivity in the entire sample was 52.3%, whereas 47.6% of patients met the definition for treatment-resistance. Seropositive patients had twice the rate of treatment-resistance compared to seronegative patients (63.6% vs. 30.0%, $P<0.0001$). Moreover, in the seropositive group, the patients were older (47.6 ± 12.2 vs. 39.81 ± 12.01 years, $P<0.0001$), had higher number of previous hospitalizations (13.9 ± 11.7 vs. 9.6 ± 8.5 , $P=0.0073$), and increased Calgary depression scale for schizophrenia (CDSS) total score (7.8 ± 4.5 vs. 6.3 ± 3.8 , $P=0.012$). There were no differences between the groups in the age of disease onset, smoking, positive and negative syndrome scale (PANSS) total, positive and negative scores, and the life-time history of suicide attempts.

Conclusions Our results support the hypothesis that TG seropositivity might contribute to treatment-resistance in schizophrenia, at least in male patients.

The aim of the present poster is to describe an initial complex case of schizoaffective disorder with other clinical adverse conditions (metabolic disorders) in a young adult male, which gradually went into a positive treatment way from polypharmacy to monotherapy. His psychiatric history started when he was 25-year-old, he was diagnosed of heroine dependence, hypercholesterolemia and hypertriglyceridemia. In 2000 he had a suicide attempt in a context of depressive mood and delusions. He needed a psychiatric hospitalization for the first time in his life and he received anti-psychotics

for the first time too. Drug abuse was detected in that hospitalization (cannabis and alcohol). In 2001 was diagnosed of paranoid schizophrenia. In 2007 the diagnosis was modified to schizoaffective disorder and also was detected high blood pressure, Diabetes Mellitus II and overweight. From 2007 to the present he passed from a scheme treatment composed by four or more psychotropic drugs to monotherapy (only one psychotropic drug, an anti-psychotic), he stayed clinically stable and all his metabolic parameters remained equal or improved.

Enjoying expression: Exploring the benefits of music therapy on patients diagnosed with schizophrenia and using metaphor games/improvisations for increasing emotional awareness level

Ö. Salur^{1,*}, E. Ala-Ruona², S. Uçar³, N. Eren³

¹ University of Jyväskylä, Music Psychology/Music Therapy, Istanbul, Turkey

² University of Jyväskylä, Music Psychology/Music Therapy, Jyväskylä, Finland

³ Istanbul University, Psychiatry Department, Istanbul, Turkey

* Corresponding author.

Although music therapy is an evidence-based and effective therapy method in clinical psychiatric settings all around the world, the literature on music therapy's effect specifically on emotional awareness is very limited. This study, which has been conducted as a part of presenter's music therapy master's thesis aims to examine the clinical benefits of music therapy in a Turkish university hospital, to enable further research and promote the recognition of music therapy as a valid clinical method in psychiatry in this country. A study was conducted in Istanbul university psychiatry clinic with 6 patients currently under standard care due to diagnoses of schizophrenia or schizophrenia-like disorders by the hospital staff. The participants attended 20 music therapy sessions with pre-post clinical psychological tests applied around the sessions. The results reveal that group music therapy supports the well being of outpatients diagnosed with schizophrenia. Significant changes on general functionality, personal and social performance, depression levels, increase in the level of ways of coping with stress and decrease in difficulties in emotion regulation concerning emotional awareness and are reported. Music therapy games/improvisations using animals as metaphors were played to reach emotional content of patients that normally have very limited verbal sharing in sessions, which possibly effected the change on emotional awareness. Session notes consisting of the therapy crew's observations support the statistical analysis of these benefits. These findings show that music therapy can be beneficial on multiple dimensions, including emotional awareness, in a Turkish university hospital; and therefore, more implication opportunities are suggested.

EV1313

Pre-morbid personality trait and cognitive function impact on schizophrenia course and social maladaptation

D. Samburskis

Riga Center of Psychiatry and Narcology, Psychiatry, Riga, Latvia

Background Certain personality traits are found in persons with high risk for schizophrenia onset and therefore it could be used as diagnostic marker.

Objectives To analyze correlations between personality traits and cognitive functions on schizophrenia onset and its course and social adaptation.

Methods This was a retrospective cohort study conducted in Riga center of psychiatry and narcology, Latvia. Study consisted of two parts. In the first part, data on first presentation schizophrenia patients hospitalized in 2006 was collected from medical records. Patients without completed MMPI, Schulte table; visual memory and 10 words recall tests were excluded from study group. The Second part of the study consisted of participant interviews that were held in early 2016 acquiring demographic data and each participant completed a Sheehan disability scale (SDS). Microsoft Excel 2016 and SPSSv22 were used for data operation.

Results Study group consisted of 11 males and 20 females (35.5%/64.5%). Mean age of participants was 37 years (IQR = 48–33), but mean age at onset of first schizophrenia symptoms was 27 years (IQR = 37–21). 68% ($n=21$) of participants had schizoid personality traits as per MMPI and they had higher results on all SDS subscales. There was a negative correlation between the SDS score in the first section with the occupational level in 2006 ($P=0.065$) and 2016 ($P=0.040$) and marital status in 2016 ($P=0.040$) in those with psychopathy scale.

Conclusion The hypothesis that schizoid personality traits are a leading factor in the onset of schizophrenia, have not been proven. Schizophrenia patients with psychopathic personality traits are likely to have better social adaptation.

Is there a “critical age” for first use of marijuana? Analysis of cannabis induced experiences by age at first use in a large internet-based sample

M. Sami*, S. Bhattacharyya

Institute of Psychiatry, Psychology and Neuroscience, Department of Psychosis Studies, London, United Kingdom

* Corresponding author.

Introduction Increased psychotomimetic response to cannabis is demonstrated in psychosis-prone individuals. Early use of cannabis has poorer prognostic outcomes. However, as yet no cut-off age for early use has been established.

Aims and objectives To determine, if age at first use affects later cannabis experiences and to determine if a “critical age” of first use exists for psychotomimetic cannabis experiences.

Methods The cannabis experiences questionnaire (CEQ) (EUGEI version) was administered to a large internet-based non-clinical sample. Regression analysis was conducted of age at first use against CEQ scores controlling for gender, age frequency of use and duration of use. To determine cut-off age: independent ‘t’ tests (parametric) and Mann–Whitney-U tests (non-parametric) were used to determine significance of differences in CEQ scores at cut-off ages from 12–25.

Results We obtained data for 1115 participants. Younger age at first use was significantly associated with increased psychotomimetic experiences (adjusted $P<0.001$). All cannabis experiences were increased in those commencing at younger age at every cut off age from 17 to 22 ($P<0.001$) with maximal difference at 22. Psychotic experiences significantly varied from age of first use of 19 to 22 with maximal difference at cut-off ages 20, 21 and 22 ($P<0.001$). Pleasurable experiences were significantly reduced in those commencing later at every cut-off age from age of

use 17 to 22 ($P < 0.001$) with maximal difference between groups at age 20.

Conclusions Later onset of use is associated with reduced cannabis experiences till the early 1920s. This may have public health implications.

³ Centro de investigación Biomédica en Red de Salud Mental CIBERSAM, psychiatry, Barcelona, Spain

* Corresponding author.

Introduction Although physical restraint (PR) is a non-rarely practice on psychiatry there are few studies that focus the attention on the risk factors for this intervention. PR is a legitimacy practice when is needed and well applied but is not free from side effects. Knowing risk factors might be useful to improve the application of PR.

Objectives Study the risk factors involved with the use of PR at patient's home in individuals with schizophrenia before the involuntary transport (IT) to a psychiatric facility.

Methods Is a descriptive and observational study of 267 psychotic patients that were assisted by a psychiatric home care unit (EMSE) in Barcelona during their IT. The sample was divided in two groups, depending on the need of PR. Socio-demographic data were collected as well as positive and negative syndrome scale (PANSS), WHO disability assessment schedule (WHO/DAS), global assessment of functioning scale (GAF), Scale to assess unawareness of mental disorder (SUMD). Aggressiveness was assessed by PANSS-EC consisting of 5 items: excitement, tension, hostility, uncooperativeness and poor impulse.

Results From the 267 psychotic patients 109 required PR. 154 were male and the average of age was 47. The results were significant in the PR group versus no PR for PANSS-EC ($P = 0.000$), as well as WHO/DAS ($P = 0.017$), GAF ($P = 0.042$), Positive PANSS ($P = 0.000$), age ($P = 0.001$) and substance use ($P = 0.012$). Were no significant for gender, insight or Negative PANSS.

Conclusions Aggressiveness and violence were the most important PR related factors followed by positive symptoms, age, substance use and global functioning.

Effectiveness in controlling symptoms with long-acting injectable aripiprazole

L. Sánchez Blanco^{1,*}, M. Juncal Ruíz¹, G. Pardo de Santayana Jenaro¹, R. Landera Rodríguez¹, M. Gómez Revuelta², O. Porta Olivares¹, M. Pérez Herrera¹, N.I. Nuñez Moral²

¹ Hospital Universitario Marqués de Valdecilla, Psychiatry, Santander, Spain

² Hospital Universitario de Álava-Sede Santiago, Psychiatry, Vitoria-Gasteiz, Spain

* Corresponding author.

Introduction Depot antipsychotic treatment has been a radical change in the evolution and prognosis of patients with schizophrenia. Long-acting injectable aripiprazole is an antipsychotic dopamine partial agonist. It has a good tolerance in terms of metabolism and prolactine level.

Objetives Studying the causes of readmission at the acute unit of Marqués de Valdecilla university hospital (HUMV) in patients treated with Long-acting injectable aripiprazole LAI 400 mg.

Methodology This is a descriptive study which pretends to assess the causes of readmission in a sample of 30 patients (12 women, 18 men) with non-affective psychosis, which had entered the acute unit of HUMV from 1st January to 30th September 2016 because of psychotic decompensations and had been treated with long-acting injectable aripiprazole 400 mg.

Results Out of the 30 patients there were five readmissions during the observation time. Two of them for psychotic decompensation, two because of premature abandonments, with oral aripiprazole supplementation and the last one because of desertion of injectable drug. No gender differences were observed.

Conclusions It is necessary 15 days of oral supplementation before and after the first dose of long-acting injectable aripiprazole to ensure that adequate therapeutic levels are achieved and to avoid readmissions by misuse of the drug. One of the limitations encountered in this work would be the small sample size and limited observation time. A longer-term research may allow to find more scientific evidence to clarify the clinical safety and efficacy of long-acting injectable aripiprazole in patients with non-affective psychosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Psychotic disorder of organic etiology, in the context of sarcoidosis. A case report

L. Sánchez Blanco^{1,*}, M. Juncal Ruíz¹, G. Pardo de Santayana Jenaro¹, M. Gómez Revuelta², R. Landera Rodríguez¹, O. Porta Olivares¹, E. López García¹, M. Pérez Herrera¹, N.I. Nuñez Morales²

¹ Hospital Universitario Marqués de Valdecilla, Psychiatry, Santander, Spain

² Hospital Universitario de Álava-sede Santiago, Psychiatry, Vitoria-Gasteiz, Spain

* Corresponding author.

Introduction Neurosarcoidosis is an uncommon cause of psychosis. It courses with an affection of the brain, the spinal cord and other areas of the nervous system. It associates both neurological and psychiatric symptoms: cranial mononeuropathy, myelopathy or radiculopathy meningitis, neuroendocrine dysfunction, dementia, delusions, hallucinations.

Objectives To review in Pub-Med about neuropsychiatric manifestations of neurosarcoidosis.

Methods We describe the case of 60-year-old woman diagnosed with long evolution schizoaffective disorder with a recent decompensation in the context of a stressful situation. As somatic background to highlight: cognitive impairment (encephalic bilateral and symmetrical frontal atrophy in cranial magnetic resonance) and a probable sarcoidosis with hilar and mediastinal lymph nodes without histologic confirmation. She was hospitalized at the acute care unit because of a decompensation of her schizoaffective disorder. The patient was distressed, with delirious speech, sensoriperceptive hallucinations, hypothyria and weight loss.

Results Firstly we evaluate the lack of clinical improvement with an anti-psychotic drug in previous hospitalizations. For that reason, we thought in organic mental disorder as an alternative diagno-

sis. We started treatment with corticosteroids in spite of we did not observe a decompensation of sarcoidosis. In a few days it was remarked a clinical improvement and remission of the delusional and affective clinic.

Conclusions It is needed to complete the study and continue the monitoring of the patient to see the evolution and drug response. The diagnosis of neurosarcoidosis should be kept in mind for patients with both neurologic and psychiatric symptoms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Can drug interaction be useful? Case report of a schizophrenic patient treated with paliperidone long-acting injection

M. Sarpe^{1,*}, M. Bran², L. Maria³

¹ Senior MD, Psychiatrist, CMI Marcel Sarpe, Private Practice, Focsani, Romania

² Assistant Professor, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania

³ Associate Professor, University of Medicine and Pharmacy “Carol Davila”, Bucharest, Romania

* Corresponding author.

Introduction Intramuscular paliperidone palmitate (PLAI) is a long-acting atypical anti-psychotic approved in Romania for the maintenance treatment of adults with schizophrenia.

Objectives To determine the efficacy and tolerability of PLAI in a non-compliant patient with previously very low tolerability to oral anti-psychotics. The patient had been on risperidone long acting injection (RLAI) and had significant adverse events (i.e. tremor, akathisia) which persisted even when treated with the lowest dose of PLAI: 50 mg.

Aims Since the efficacy of PLAI was good, and since a lower dose (than 50 mg of PLAI) is not available in Romania, we tried different ways to lower plasma concentration (PC) of the anti-psychotic because the patient presented clinically significant adverse effects (AE).

Methods Initially the time between the injections was extended at maximum recommended (35 days), with a slight effect, then an off label treatment was associated in order to lower the PC of PLAI. We used 300 mg of carbamazepine long acting, that may lower the PC of PLAI up to 30%. For the evaluation of the efficacy and tolerability, we applied: the clinical evaluation, the positive and negative syndrome scale, the Barnes Akathisia rating scale, the Simpson-Angus Scale and the abnormal involuntary movement scale.

Results After using the above mentioned, strategies, the one that had indeed good results on reducing AE, with no alteration of the psychic status of the patient, was the association of carbamazepine.

Conclusions In clinical practice, some off label medication associations may be salutary!

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1319

Tracking referrals to early intervention in psychosis team: An audit

J. Sharma

Black Country Partnership Foundation NHS Trust, Early Intervention Services, West Bromwich, United Kingdom

Aims To monitor if the early intervention services (EIS) in Sandwell meet the standard of assessing all patients referred to

the team within the set target. To monitor factors that affects the outcome including the source of referral, whether the patients, are known to another team, and the demographic features of the patient.

Background Providing timely, appropriate and coordinated care for patients presenting with a first episode of psychosis has been a focus for EIS teams to improve outcomes, experiences and in reducing costs. In April 2016, new target times of 5–10 days for referral-to-assessment and 14 days for referral-to-treatment were introduced by the government.

Method All the referrals that were made since 01/04/2016 were followed up. A comparison was made with the referral-to-assessment and referral-to-treatment target for referrals made before the 01/04/16.

Results There has been an increase in referrals. Preliminary evidence gathered suggests that there has been a marked improvement in the referral-to-assessment pathway and referral-to-management pathway. Patients referred to the EIS are offered an earlier assessment. Majority of the referrals made are however not appropriate to receive care from the EIS, and are not taken on by the team. All the patients that are accepted by the team are offered a NICE treatment package. Most of the referrals that come from other EIS teams or wards, are accepted by the team, at least for an extended assessment. Referrals from Children services are usually at the point when they are due to turn 18, for a second opinion.

EV1320

Antipsychotics in first-episode psychosis: Patterns of prescription in an inpatient unit

F. Monteiro*, P. Azevedo, L. Monteiro, C. Machado, G. França, A. Norton, A. Reis

Hospital de Magalhães Lemos, Inpatient Unit C, Porto, Portugal

* Corresponding author.

Introduction The treatment of first-episode psychosis patients is different from those with multiple-episode schizophrenia: the response to antipsychotics is better, the required doses are lower and the sensitivity to side-effects is higher. As such, current guidelines recommend a “start slow, go slow” strategy and an active avoidance of side-effects.

Objectives/aims To know the patterns of antipsychotic prescription in first-episode psychosis patients of our inpatient unit.

Methods We retrospectively reviewed the clinical data of all non-affective first-episode psychosis patients admitted to the Inpatient Unit C of Hospital de Magalhães Lemos during 2015. The antipsychotics prescribed at admission and discharge were recorded, as well as the doses.

Results A total of 29 patients were identified. The mean age was 36.6 and 65.5% were man. At admission, all patients were medicated with second-generation antipsychotics: 62.1% with risperidone, 27.6% with olanzapine, 6.9% with paliperidone and 3.4% with aripiprazol. The mean dose of risperidone was 3.5 mg/day. By the time of discharge, 34.5% of patients were prescribed a depot antipsychotic, half of them risperidone. Among those with oral medication only, 55.5% were prescribed risperidone, 22.2% paliperidone and the remainder 22.3% other antipsychotics (aripiprazol, olanzapine or quetiapine). The mean dose of risperidone was 3.7 mg/day.

Conclusions Second-generation antipsychotics are clearly preferred. The mean dose by the time of discharge is similar to that used in clinical trials. However, antipsychotics are initiated at doses above the minimum effective dose. On discharge, an important proportion of patients are prescribed depot antipsychotics, which are known to improve medication adherence.

Predictors of transition to psychosis in individuals at clinical high-risk for psychosis

M. Skuhareuskaya^{1,*}, O. Skugarevsky²

¹ Republican Mental Health Research Center, Psychiatry department N° 27, Minsk, Belarus

² Belarusian State Medical University, Psychiatry and Medical Psychology, Minsk, Belarus

* Corresponding author.

Objective Clinical high risk (CHR) for psychosis state is characterized by presence of potentially prodromal for schizophrenia symptoms. The aim of this study was to assess the predictors of transition to first psychotic episode.

Methods The study included 123 CHR subjects. All the subjects were characterized by the presence of one of the group of criteria: (1) UHR criteria, (2) basic symptoms criteria and (3) negative symptoms and formal thought disorders (FTD). The presence of FTD in clinical high-risk individuals was assessed with methods of experimental pathopsychology. The mean length of follow-up was 26 months (SD 18). All subjects were males, mean age = 20.2 (SD: 2.1). We examined the subjects' performance using the Cambridge automated neuropsychological test battery. We applied survival analyses to determine associations between a transition to psychosis and sociodemographic, clinical and neurocognitive parameters. To determine which items are the best predictors, Cox regression analyses were applied.

Results The psychosis developed in 39 subjects (31.7%). Global assessment of functioning, positive symptoms, blunted affect, social isolation, impaired role function, disorganizing/stigmatizing behavior, basic symptoms (thought pressure, unstable ideas of reference), neurocognitive parameters (visual memory and new learning, decision making, executive function) significantly influenced the transition to psychosis. A prediction model was developed and included unusual thought content (Wald = 12.386, $P < 0.0001$, HR = 2.996), perceptual abnormalities (Wald = 4.777, $P = 0.029$, HR = 1.43) and impaired role function (Wald = 1.425, $P < 0.028$, HR = 4.157).

Conclusion Clinical measures are important predictors for transition to psychosis in high-risk individuals.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1322

Diogene syndrome: About two clinical cases

H. Snene

EPS Ville Evrard, psychiatry, France

Introduction Diogenes syndrome was first described in 1975 by Clark to characterize the behavioral disorder in the elderly involving neglect of personal and domestic hygiene and a hoarding disorder or hoarding. He is regarded as a psychiatric disorder in its own right in the DSM V and declines criteria compulsive hoarding disorder ("Hoarding Disorder"). The condition is under diagnosed or its prevalence is important from 3.3 to 4, 6%.

Objective Study through two clinical, etiologic and psychopathological diogenes syndrome (DS) and the main diagnostic and therapeutic difficulties.

Case n° 1 Mrs. L. is 57 years old, without children and with a degree in political science. She was taken back by his partner for behavioral disorder type of pathological accumulation of objects.

His home has become inaccessible due to the accumulation of multiple stacks of magazines and other items. The meeting allowed to objectify an incurique presentation, delusional and hallucinatory syndrome.

Case n° 2 Mrs. BH aged 67, retired, widowed for 17 years. She lives alone after the suicide of his daughter. This would be followed by breast cancer. The patient was admitted following a report of neighbors who discovered that Mrs. BH, isolated for months, sleeping in the garden of her home saw the unhealthy state of the place and the accumulation of waste.

Conclusion Diogenes syndrome is heterogeneous, covering multiple medical, psychiatric and social situations. Its pathogenesis remains poorly understood and its management refers to any clinician can examine ethical questions the legitimacy of its actions.

Moment-to-moment associations between emotional disturbances, aberrant salience and persecutory delusions

S.H. So^{1,*}, A.K.C. Chau¹, E. Peters², J. Swendsen³, P. Garety², S. Kapur⁴

* Corresponding author.

Introduction Experiences of depression and anxiety are common among patients with persecutory delusions. It has been theorized that emotional disturbances affect the formation and appraisal of persecutory delusions directly and possibly via increasing the sense of aberrant salience.

Objectives Using a time-lagged analysis of experience sampling data, this study modelled the role of momentary levels of negative emotions and aberrant salience in maintaining persecutory delusions in patients with active delusions.

Methods Clinically acute participants with at least a mild level of persecutory delusions were assessed using experience sampling method (ESM; 7 entries per day for 14 days) and clinical rating scales. ESM data of participants who completed at least 30 ESM entries were analysed by using multilevel regression modelling.

Results The final sample consisted of 14 participants, with a total of 1161 momentary observations. Time-lagged analysis revealed that both negative emotions ($B = 0.125$, $P = .009$) and aberrant salience ($B = 0.267$, $P < .001$) predicted an increase in persecutory delusions in the next moment. Conversely, persecutory delusions did not predict change in negative emotions or change in aberrant salience in the next moment ($ps > .05$). Negative emotions also predicted an increase in aberrant salience in the next moment ($B = 0.087$, $P = .009$).

Conclusions Our results supported the hypothesis that both negative emotions and aberrant salience exacerbate persecutory delusions, rather than being merely the sequelae of the symptoms. Our results suggested both direct and indirect (via aberrant salience) pathways from negative emotions to persecutory delusions.

Delayed post-hypoxic leukoencephalopathy: Case report

M. Solderdelcoll Arimany^{1,*}, M. Garriga², E. Parellada³¹ Institute of Neuroscience- Hospital Clínic de Barcelona- Barcelona- Spain, Department of Psychiatry and Psychology, Manlleu, Spain² Institute of Neuroscience, Hospital Clínic Barcelona, IDIBAPS, CIBERSAM, University of Barcelona, Barcelona, Catalonia, Spain, Bipolar Disorders Unit, Barcelona, Spain³ Institute of Neuroscience, Hospital Clínic Barcelona, IDIBAPS, CIBERSAM, University of Barcelona, Barcelona, Catalonia, Spain, Barcelona Clinic Schizophrenia Unit BCSU, Barcelona, Spain

* Corresponding author.

Introduction Delayed post-hypoxic leukoencephalopathy (DPHL) is an underrecognized syndrome of delayed demyelination, where patients manifest neuropsychiatric symptoms after a period of 2–40 days of apparent recovery from a cerebral hypo-oxygenation episode.

Objectives We report a case of a patient who successfully recovered from an overdose of heroin, but then suffered a delayed abrupt neurological deterioration.

Aims To improve assessment and recognition of DPHL.

Methods An adequate retrospective collection of clinical data and nonsystematic review of the literature was performed.

Results A 43-year-old male with schizoaffective disorder who attempted suicide with an overdose of heroin, was successfully revived and return to his previously mental status, but 3 weeks after, he abruptly developed progressive cognitive impairment with akinetic mutism and ataxia. He was admitted to our acute psychiatric unit after brain CT and chemistry analyses were unremarkable. Brain MRI showed diffusely symmetric hyperintensity in the white matter (WM), pronominally the periventricular WM, on FLAIR and T2 weighted sequences. At 16 weeks postoverdose, he presented improvement both cognitive and motor symptoms, lasting deficits in frontal-executive functions.

Discussion DPHL is characterized by similar clinical and neuroimaging features regardless of the initial insult. The mean lucid interval coincides with the replacement half-life for myelin related lipids and proteins. Prolonged mild-to-moderate hypo-oxygenation of WM is thought to disrupt myelin turnover. It appears probable that these were responsible for DPHL in our patient rather than a direct toxicity.

Conclusion DPHL can be diagnosed when clinical history, laboratory assessments and MRI findings are concordant. DPHL requires extensive support care and carries a relatively good prognosis.

EV1325

When schizophrenia leads to terrorism: A case report

N. Staali

Razi hospital, psychiatry ward G, Tunis, Tunisia

Background Some have suggested that terrorists are mentally ill and have used labels such as psychopathic or sociopathic, narcissistic, paranoid, are schizophrenic types, or passive-aggressive. Others have argued that although terrorist actions may seem irrational or delusional to society in general, terrorists in fact, act rationally, and there is no evidence to indicate that they are mentally ill/disordered, psychopathic or otherwise psychologically abnormal.

Objective and method Here we present the case of Mr. A, a 32 year old man diagnosed with schizophrenia, who travelled to Egypt and Syria in attempt to join the ISIS terrorist organization, and discuss

the clinical features, treatment processes and two years follow-up of this particular case.

Conclusion As described in some studies, most terrorists do not demonstrate serious psychopathology and there is no single personality type. Thus, the relationship between terrorism and mental illness mostly refers to the question about pathological travel as part of a religious and messianic delirium.

Keywords Schizophrenia; Terrorism; Pathological travel; Religion

Impairment of visual working memory among patients with paranoid schizophrenia

M. Stoimenova-Popova^{1,*}, I. Veleva¹, P. Chumpalova¹, L. Tumbev¹, A. Todorov¹, M. Valkova², V. Valtchev³¹ Medical University-Pleven, Faculty of Public Health-Psychiatry and Medical psychology, Pleven, Bulgaria² Medical University-Pleven, Neurology and Neurosurgery, Pleven, Bulgaria³ National Sports Academy, Biochemistry and Physiology, Sofia, Bulgaria

* Corresponding author.

Introduction Schizophrenia is associated with working memory (WM), executive dysfunction and access visual WM dysfunctions among patients with paranoid schizophrenia (PSz).

Material and methods We examined 89 patients (41.35 ± 11.52 years old, 65 males, 24 females, 15 with basic, 52 with middle and 22 with high formal education) with PSz (65% with prevalence of positive and 31 of negative syndromes) by Benton visual retention test (BVRT, var.A and E).

Results The average number of correct performed items was 3.12 ± 1.183 , the average errors, 13.04 ± 3.70 (6.51 ± 3.05 at left and 5.35 ± 2.30 at right visual field (VF)). Females had more corrects ($P=0.0256$). Education is associated with less errors and more corrects. Patients with prevalence of negative syndromes showed more errors at left VF than those with positive, although the total number of errors and corrects were similar. Ageing was not directly associated with total number of corrects and errors. Twenty-three percent of our patients had addictions, 52% had omissions, 96% distortions (average 4.12 ± 2.31), 78% perseverations, 79% rotations, 83% misplacements and 61% size errors. Horizontal displacements were obtained from 42%.

Conclusions Visual WM dysfunction is frequent among patients with PSz. Female sex and high education are associated with better test performances. Negative syndromes are related with high number of errors at left VF, but not with total numbers of corrects and errors. We suggest horizontal displacement as specific error among patients with PSz.

Introduction Hypothyroidism psychocognitive key features may include melancholia, memory impairment, depression and dementia which could be misdiagnosed as a psychiatric disorder.

Objective To study the incidence of hypothyroidism in psychiatric patients.

Methods This retrospective study included 232 psychiatric patients with mean age of 43.39 ± 10 years old weight mean of 79.81 ± 19.07 kg, BIM of 29.55 ± 6.83 , enrolled in a public mental health service.

Results Twenty point twenty-one percent (39) patients presented hypothyroidism with thyroid-stimulating hormone (TSH) levels above 5 mIU/L and Free T4 levels below 0.7 ng/dl.

Comparing the incidence of hypothyroidism in Brazilian population estimated rate of until 10% [1] with this psychiatric patients population we observed a significant difference with p value of $2.28 \text{ E-}6$. Neuroleptics 92%(36), biperiden 62%(24) and benzodiazepines 38% (15) were the most frequent prescribed drugs for these hypothyroidism patients.

Conclusion Significant difference in the incidence of hypothyroidism between general Brazilian population and the studied psychiatric patients was observed [2,3].

Introduction The average length of stay in Japan at psychiatric hospital is 292 days. In recent years, measures to shorten the hospitalisation period are being promoted.

Objective To understand patients who were discharged from emergency ward/acute psychiatric care units the needs post-discharge, in order to improve the quality of psychiatric nursing care at the psychiatric out patient care.

Methods Sixty-two patients who have been hospitalised in emergency ward/acute psychiatric care units, with a diagnosis of

schizophrenia and mood disorders, and currently visiting the out-patient department of psychiatric care were selected as the subject. Semi-structured interviews were conducted.

Results The issues that patients faced post-discharged were;

– daily life issues: how to support themselves, how to cook, what to eat, and how to sleep;

– relationship with families and supporters;

– concerns of their conditions such as anxiety, restlessness, dissatisfaction, loneliness, isolated feeling, drowsiness. Patients consulted their family members, their doctors, or professionals other than doctors.

Conclusion The needs for the support for patients who recently discharged from an acute psychiatric ward were high, with the instability of the patient as well as the possibility of worsening their symptoms. There was a high demand for professionals other than a doctor as a consultant, given the limited consulting resources the patients have. The patients' concerns post-discharge varied widely, focusing mainly on their daily lives. Support system, including monitoring, is necessary during early stages of discharge.

Corticosteroid-induced psychosis: Case report and review of the literature

M. Tenorio Guadalupe*, I. Alberdi Páramo
H.C.U. San Carlos, Psychiatry, Madrid, Spain

* Corresponding author.

Introduction Steroid psychosis still presents many unsettled clinical aspects. Despite several reviews and case reports are available, modes of onset and recovery need a more accurate description. We will focus on a 53-year-old woman who was hospitalized against her will because of her agitated psychotic state. Her symptoms were indicative of an acute psychotic disorder resulting from the use of corticosteroids. We considered it important to report this case because corticosteroids have been widely prescribed since about 1950 to treat a broad spectrum of somatic illnesses and to emphasize the relevance of the dose of steroids in this case.

Objectives We describe a case of substance-induced psychotic disorder resulting from corticosteroids administration and we review the scientific literature about this topic.

Aims To obtain more information about the incidence of steroid-induced psychotic symptoms, the relation between the type of steroids, its dose and the clinical presentation, the most important risk factors and how to prevent psychotic episodes during steroids-treatment.

Methods After discussing the case, we studied the literature systematically using official medical browsers.

Results Very little reliable evidence has been available relating to steroid-induced psychosis.

Conclusions There is much to learn about adverse psychiatric reactions to corticosteroid treatment. It should be improved awareness of the limited available knowledge and to stimulate research aimed at improved methods of prevention, recognition and treatment.

“Pseudoneurotic Schizophrenia” Revisited: The role of obsessive-compulsive symptoms in low-level disorganization psychosis

M. Tonna*, R. Ottoni, F. Paglia, C. De Panfilis, C. Marchesi
University of Parma, Neuroscience, Parma, Italy

* Corresponding author.

Objective Recent research has suggested a dual impact of obsessive-compulsive dimension on functioning in schizophrenia with a gradual transition from an improving to a worsening effect depending on obsessive-compulsive symptom (OCS) severity (from mild to moderate-severe). Aim of the present study was to investigate whether this varying effect of OCS on functioning might be mediated or moderated by schizophrenia symptom dimensions or occur independently.

Method Seventy-five patients affected by schizophrenia were administered the SCID-IV, the PANSS, the YBOCS and the SOFAS. The sample was divided into two groups according to the severity of OCS (absent/mild and moderate/high).

Results In both groups, a significant interaction between OCS and disorganization dimension was found: the dual effect of OCS on functioning occurred only among patients with low disorganization symptoms while it was no more apparent at higher levels of disorganization (Figure 1).

Conclusion Data suggest that in patients with schizophrenia, functioning at least in part depends on the interaction between disorganization and OCS. Particularly, mild OCS contributes to higher levels of functioning in patients with psychosis at low levels of disorganization. In keeping with the historical concept of “pseudoneurotic schizophrenia”, we speculate that obsessive dimension might have a pathoplastic influence in milder forms of schizophrenia spectrum disorders, balancing the effect of underlying low disorganization symptoms.

Antipsychotics in chronic schizoaffective disorder: A naturalistic study

B. Tsygankov*, A. Ryzhukhinskaya, K. Evgeny, A. Pavlichenko
 Moscow State Medical Dental University, Department of psychiatry,
 narcology and psychotherapy, Moscow, Russia

* Corresponding author.

In spite of the beneficial effects of antipsychotics (AP) on the course of schizoaffective disorder (SAD) in general, there is an evidence for some negative aspects of their application. The objective of the study was to investigate the clinical manifestations and the course of resistant SAD while treated by the different AP. At present, the research includes 63 patients with SAD and duration of psychotic and/or affective symptoms more than six months. The research was naturalistic follow-up. The first group of patients ($n=18$) were treated with SGA. An average duration of hospitalization was 61.2 days. After a reduction of acute psychotic condition, subthreshold psychotic and anxiety symptoms were still remaining. The total PANSS score was 71 ± 8 . The second group ($n=24$) was treated with a combination of FGA and SGA. An average duration of hospitalization was 53.8 days, the total PANSS score was 79 ± 6 . It has been prevailed subthreshold bipolar symptoms. The third group of patients ($n=21$) were treated with FGA. An average duration of hospitalization was 45.5 days; the total PANSS score was 63 ± 10 . The negative symptoms and subthreshold depressions have been prevailed among the patients.

To conclude, the treatment of SAD by the SGA and combination of SGA and FGA are more likely associated with persistence of subthreshold psychotic and/or bipolar disorder and the longer duration of hospitalizations. On the other hand, application of FGA in SAD is more likely associated with negative symptoms and depressions after a reduction of acute psychotic condition.

EV1332

The emergence of psychosis in a patient with severe hypothyroidism: A case report and literature review

M.L. Turk*, J. Rosen
 University of Virginia Health System, Psychiatry, Charlottesville, USA
 * Corresponding author.

Hypothyroidism is associated with changes in mental state that can range from mild cognitive impairment to depression to florid myxedema coma. A few cases have linked the occurrence of psychotic symptoms in the context of severe hypothyroidism, an event referred in the literature as "myxedema madness". We describe the case of a 48-year-old male with no past psychiatric history and a past medical history of hypertension and hypothyroidism who presented to the psychiatric unit for management of new-onset psychosis, particularly paranoid delusions. On basic medical screening, the patient was found to have severe hypothyroidism manifested by a TSH level of 51.85 and a free T4 level less than 0.4. The patient was treated with both an antipsychotic and thyroid hormone replacement, after which his hypothyroid symptoms and his psychosis improved. Liothyronine was also prescribed to speed up the recovery course, as his delusions were thought to be due to his hypothyroidism. The aim of this poster is to shed light on the possibility of development of psychosis concomitantly with severe hypothyroidism, given the rarity of such events, as well as to illustrate the importance of treating the underlying medical cause rather than only focusing on the treatment of the psychiatric symptoms. The use of Liothyronine proved to be beneficial in this case, as the patient's symptoms drastically improved after its adminis-

tration. This could potentially illustrate the importance of using Liothyronine particularly in the treatment of delusional disorder in severe hypothyroidism.

Adjunctive minocycline in clozapine and amisulpride treated schizophrenia patients with persistent symptoms

E. Tzavellas*, D. Karaiskos, J. Konstantinou, E. Oikonomou, R. Soldatos, T. Paparrigopoulos

Eginition Hospital Of Athens, Psychiatry, Athens, Greece

* Corresponding author.

Objective Clozapine and amisulpride are two effective antipsychotic and their combination often is used for treatment refractory people with schizophrenia, yet many patients partially respond. Clinical data and the recent literature suggest benefits with minocycline. In our study we adjunct minocycline in five schizophrenic patients and we observed them for a period of 6 months.

Methods Our patients received adjunct minocycline (100 mg oral capsule twice daily).

Results Using the PANSS, we identified a statistically significant ($P<0.05$) clinical improvement from the fourth week of treatment for positive mainly, and less for negative symptoms in all our patients. Global cognitive function did not differ, although there was a significant improvement in working memory favoring minocycline. Moreover there was a marked reduction of anxiety and depressive symptoms.

Minocycline was well tolerated and no patient presented side effects.

Conclusion Minocycline seems to help significantly schizophrenic patients who do not respond fully to their medication consisted of clozapine and amisulpride. Larger studies are needed to validate these findings.

Major psychotrauma and social stress–risk factors for the unfavorable course of paranoid schizophrenia

T. Udristoiu^{1,*}, I. Udristoiu¹, F. Militaru¹, S. Ristea², A.G. Vilcea¹, M.C. Pirlog¹

¹ University of Medicine and Pharmacy of Craiova, Psychiatry, Craiova, Romania

² University Clinic of Psychiatry Craiova, Psychiatry, Craiova, Romania

* Corresponding author.

Introduction Recent studies in the neurobiology of schizophrenia highlighted the role of neuropsychoenocrine activations as a consequence of psychostress followed by the activation of the HPA axis with an excess of endogenous cortisol. The relation endogenous cortisol–glutamatergic hyperactivation enhances the excitotoxic mechanisms and the cortical-subcortical alterations in schizophrenia.

Method We conducted a retrospective study on 40 patients, with ages between 25 and 55 years, admitted in the university clinic of Craiova between January 1, 2015 and December 31, 2015 for paranoid schizophrenia according to ICD-10 criteria and with positive history of psychotrauma and physical abuse in childhood and adolescence.

Results The frequency of psychotraumas, social stress and physical abuse in our group was significantly higher in women (63.33%), in patients with urban residence (80.00%) and age group 36–45 years (46.67). There was a pattern of residual defectuality reflected by positive symptoms (83.33%), alcohol abuse (80.00%), aggressive behavior (66.67%) and suicide attempts (30.00%). The poor course with minimal social functioning (GAFS < 40; 36.67%) was correlated with a high number of relapses and hospitalizations (> 9 hospitalizations; 43.33%), cognitive deficit (MMSE < 23; 76.67%). The psychosocial factors involved in the pathogenesis and course of schizophrenia were social stress (60.00%), physical abuse in childhood and adolescence (20.00%) and psychotraumas (20.00%).

Conclusions. Psychotrauma and physical abuse in childhood and adolescence and during the course of paranoid schizophrenia constitute a risk factor for a poor outcome with cognitive deterioration, aggressive and suicidal behavior that call for prophylactic measures and qualified psycho-social interventions associated to the pharmacological treatments.

Differential diagnosis and therapy of cycloid psychoses: A case report

A.M. Uminska-Albert*, G. Eikmeier

Klinikum Bremerhaven, Klinik für Psychiatrie- Psychotherapie und Psychosomatik, Bremerhaven, Germany

* Corresponding author.

Kraepelin already challenged his dichotomy of psychoses, because in clinical practice too many cases were not in line with his pattern. Different terms for these disorders were coined. Leonhard separated cycloid psychoses from other forms of endogenous psychoses. The idealized subtypes (anxiety-beatific, hyperkinetic-akinetic-motility and confusional exited-inhibited) are characterized by a bipolar course with complete recovery. Operationalised criteria were developed by Perris. We report on a 60 year old woman diagnosed as schizophrenic in 1984/1985 and 2006. In August 2015 she was admitted with stupor and mutism and therefore was treated with fluphenazine and lorazepam. Six days later the clinical picture changed, she became confused and very agitated. After change of treatment to benperidole her clinical condition improved within 12 days. After 3 further days she became confused, agitated and euphoric again. The symptoms persisted in spite of a change of treatment to haloperidole. After diagnostic revision therapy was augmented with lithiumcarbonate. Six days later the psychotic symptoms began to improve and were completely remitted after 10 further days. The case report points out that a differential-diagnostic revision of an apparently therapy-resistant schizophrenia should not only be carried out according to ICD 10 criteria but a cycloid psychosis should be taken into account, too. Perris-criteria are contrasted with ICD 10-criteria for schizophrenia and mania with psychotic symptoms. Symptomatology and clinical course in our patient fulfilled exactly the Perris-criteria. We recommend an augmentation trial with lithium in acute phases of cycloid psychoses by all means before ECT.

Attitude of person living with psychosis towards MH professionals: A qualitative study

K. Vaiphei^{1,*}, P. Sreedaran², V. Sathyanarayanan²

¹ St. John's Medical College Hospital, Psychiatry, Bangalore, India

² St. Johns Medical College Hospital, Psychiatry, Bengaluru, India

* Corresponding author.

Aims Studies investigating attitudes of people with mental illness are scarce. The aim of the present study was to investigate person living with psychosis on their attitudes and perception towards the mental health professionals in contact with mental health services.

Methods An in-depth interview was used to explore their lived experiences and attitude towards mental health professionals.

Results Both negative and positive attitudes were prevalent among the patients. Most negative attitudes concerned on not giving time, the MHPs are most interested in financial gains. They felt attitude changes according to diagnosis, psychosis perceived as diagnosis with violence; they are more interested in protecting themselves, perception that treating symptoms and not cause of illness. On the contrary, they felt positive on the relationship and time given to them.

Discussion and conclusions The PLWI's attitude to MHPs could be a product of the type of admission (forced upon), symptoms related or on the type of service settings. The present study is purely qualitative, single settings, could not be generalised. However it points on the need for sensitization of MHPs and relationship building oriented intervention.

Parkinson's disease and psychosis: Report of a case

M. Valverde Barea^{1,*}, A. España Osuna¹, F. Cartas Moreno²

¹ Complejo Hospitalario de Jaén, Psiquiatria, Jaen, Spain

² USMC-Úbeda, Psiquiatria, Jaen, Spain

* Corresponding author.

Introduction Jealous delusional ideation appears in 7-14% of cases of Parkinson's disease. Treatment with dopaminomimetics drugs is a significant risk factor for psychosis. However, the most likely etiology of psychosis in these patients is a loss of central cholinergic function associated with age since described psychosis even before the introduction of the L-Dopamine. Cognitive impairment and sleep disorders are predictors of development of psychosis.

Objective Present a clinical case of psychosis in Parkinson's disease and its treatment.

Method Reason for consultation. Patient diagnosed with Parkinson's disease with behavioral disorder and delusional.

Current illness The patient after antiparkinsonian medication has increased suspicion, self-referentiality, delusional jealousy ideation to her husband, delusional interpretations regarding somatic symptoms, insomnia and behavioral disorders with aggression.

Family background Mother with Alzheimer's.

Personal history No contact with mental health.

Psychopathological examination Conscious, repetitive language, dysphoric mood with delusions of prejudice and jealousy.

Mixed insomnia.

Diagnosis Psychosis in Parkinson's disease.

Treatment Quetiapine 300 mg/day. Carbidopa 25 mg/L-dopa 100 mg: 1-0-1. On subsequent visits quetiapine was suspended and replaced by clozapine 200 mg/day.

Results The treatment of psychosis was effective with the use of quetiapine and subsequently clozapine with good tolerance and effectiveness. He also said lower antiparkinsonian medication.

Conclusions Psychotic symptoms are the most common psychiatric clinic in Parkinson's disease. Often not enough antiparkinsonian dopaminomimetics reduced to control psychotic symptoms and use of antipsychotics is required. The use of antipsychotics in

Parkinson's disease should be careful for the likely increase in motor clinical and increased mortality. The most useful, are especially quetiapine and clozapine atypical antipsychotics.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1338

Muscarinic mechanisms in psychosis: A multimodal imaging study

T. Van Amelsvoort

Maastricht University, Department of Psychiatry and Psychology, Maastricht, The Netherlands

Background The majority of people with psychosis suffer from cognitive problems. These cognitive problems are among the most disabling features of the illness and have a negative effect on clinical outcome. Research has demonstrated that acetylcholine including muscarinic receptors play an important role in cognitive function. A post-mortem study in chronic patients with schizophrenia demonstrated a decrease of 75% of muscarinic M1 receptors.

Aim The aim of this study was to investigate the role of M1 receptors in-vivo in brain and cognitive function in psychosis.

Methods Thirty medication free patients with psychosis and 30 healthy controls matched for age, gender and IQ were included for 1) 1x IDEX Spect scan to determine M1 binding potential; 2) 2x fMRI scan using a visual memory task; 3) 2x MRS to determine choline concentrations; 2x CANTAB cognitive battery. Except for SPECT all subjects were tested twice, once with placebo and once with biperiden M1 antagonist.

Resultaten Patients demonstrated a significant negative correlation between M1 binding potential and cognitive impairments and negative symptom scores on PANSS. Following biperiden challenge, performance on verbal learning and memory was worse. Hippocampal activity was larger during a visual memory task in patients.

Conclusie These results support a role for the M1 receptor in cognitive function in psychosis.

Schizophrenia and obsessive compulsive disorder

K. Vrbova*, J. Prasko, A. Cinculova, B. Krnacova, B. Talova, A. Tichackova, K. Latalova

Faculty of Medicine and Dentistry, Palacky University and University Hospital Olomouc, Department of Psychiatry, Olomouc, Czech Republic

* Corresponding author.

Introduction A recent reviews of published researchers suggest, that up to 25% of schizophrenia patients suffer from obsessive-compulsive symptoms (OCs) and about 12% fulfill the diagnostic criteria for obsessive-compulsive disorder (OCD). Recently, the interest in this issue has significantly increased, probably due to the finding, that second generation antipsychotics, especially clozapine, might induce or aggravate OCs.

Objective The aim of our study was to investigate and clarify the literature data about the extent to which comorbid OCs affects the severity and course of schizophrenia.

Methods The articles were identified by the keywords "schizophrenia comorbidity" and "obsessive compulsive disorder", using the medline and web of science search. Additional information was obtained by studying the references of summaries of relevant articles.

Results Obsessive-compulsive symptoms or fully expressed obsessive-compulsive disorder leads to more severe overall psychopathology and poorer treatment outcomes in patients with schizophrenia. This comorbidity is accompanied by increased neurocognitive impairment, high levels of anxiety, depression, and suicidality, less favorable levels of social and vocational functioning, and greater social and health service utilization.

Conclusions In clinical practice, schizophrenia patients should be carefully monitored for OCs, which may occur at any time during the schizophrenia disease. Early recognition and targeted treatment of this comorbidity reduce patient's distress; positively influence the course of illness and overall treatment outcome.

Comorbidity of schizophrenia and social phobia

K. Vrbova^{1,*}, J. Prasko¹, K. Latalova¹, D. Kamaradova¹, M. Ociskova¹, Z. Sedlackova²

¹ Faculty of Medicine and Dentistry- Palacky University and University Hospital Olomouc, Department of Psychiatry, Olomouc, Czech Republic

² Faculty of Arts- Palacky University Olomouc, Department of Psychology, Olomouc, Czech Republic

* Corresponding author.

Introduction The most common comorbid disorder in schizophrenic patients is a social phobia. It is usually an unrecognized problem that may be associated with a high distortion in managing claims of life.

Objectives The aim of our study was to determine the extent to which comorbid social phobia affects the severity and course of schizophrenia.

Methods The publications were identified in the database medline and web of science using the keywords "schizophrenia comorbidity" in combination with the terms "social phobia" or "social anxiety disorder". Other relevant sources of information were obtained from the cited works by important articles.

Results The current state of research shows that the incidence of comorbid social phobia in psychotic disease states in the range from 11% to 36%. Social phobia in psychotic patients remains largely unrecognized. An untreated social phobia is associated with more severe psychotic symptoms, worse quality of life and lower self-esteem. It also increases the tendency to social isolation and overall worsens social adaptation. Patients with comorbid social phobia and schizophrenia have a higher amount of lifetime suicide attempts and often abuse alcohol or addictive substance.

Conclusions Patients who have both schizophrenia and social phobia have a lower quality of life, impaired functioning in life, a higher incidence of suicide attempts and increased risk of relapse of psychosis. It is, therefore, necessary that physicians treating the patients with schizophrenia had in mind the possibility of the presence of comorbid social phobia, and in the case of its occurrence, they also treat it.

EV1341

Schizoaffective disorder and life quality

W. Bouali*, I. Marrag, F. Ellouze, A. Dekhil, M. Nasr Hospital, psychiatrie, Mahdia, Tunisia

* Corresponding author.

Introduction schizoaffective disorder is a nosographic entity characterized by a combination of symptoms of schizophrenia with mood episodes. The fact that its diagnosis is difficult, and often oscillates between schizophrenia and bipolar disorder raises the problem of its care and the outcome of patients who suffers from it.

Objective To evaluate the quality of life of treated patients with schizoaffective disorder.

Materials and methods This is a cross-sectional study realized at the psychiatric consultation of Mahdia hospital during a 6month period. Data were collected from patients and from their medical records using a predefined questionnaire.

Results A total of 52 patients were included, the average age was 38 years. The majority of patients (63.5%) were unemployed. The use of psychoactive substances was noted in 63.5% of patients. Multiple linear regression analysis allowed us to find that 12 factors were more significantly associated with impaired quality of life which were, in descending order of importance: the EAS score > 39, the EGF score ≤ 70, the null or partial adherence, the presence of side effects seriously affecting daily activity, the depressive subtype, the lack of employment, the socio-economic level, the lack of stable budgetary resources, an age > 60years, the widowed and divorced marital status, the PANSS score (≥ 45) and negative symptomatology (PANSS).

Conclusion The diagnosis of schizoaffective disorder has a triple relevance: clinical, prognostic and therapeutic. Identifying a schizoaffective disorder and the risk factors that may affect the quality of life provides a significant practical impact for the patient's benefit.

EV1342

Schizoaffective disorder and life events

B. walid*, I. Marrag, F. Ellouze, A. Dekhil, M. Nasr
Hospital, psychiatrie, mahdia, Tunisia

* Corresponding author.

Introduction The schizoaffective disorder is multifactorial. Several factors almost unquestioned, even indisputable, participate in the episodes' decompensation and affect various fields: biological, pharmacological or neurobiochemical.

Objectives Draw up the sociodemographic and clinical profile of patients treated for schizoaffective disorder and determine the role of life events in the onset of the disorder.

Methods This is a retrospective study of 52 patients hospitalized in the psychiatric department of Mahdia diagnosed with schizoaffective disorder according to DSM-IV-TR during the period from January 2014 until June 2014. The information was collected using a preset sheet with 35 items.

Results A total of 52 records was gathered. The average age was 38 years. The sample was predominantly male, of rural origin in 61.5% of cases. The level of education was low in 59.6% of cases. More than half were without profession and single in 46.2% of cases. The mean age at onset of the disorder was 25.2 years. The presence of life events preceding the onset of the disorder was noted in 22 patients, that to say, 42.3% of the sample. Family and emotional events were most frequently encountered with respective rates of 48.2 and 24.7%, followed by the professional events (20%) and social ones (6%).

Conclusion Life events are due to chance but also to the environment. The complexity of the "event" concept was again underlined in a new perspective, breaking social rhythms.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EEG spectral power changes in solving spatial logical task in schizophrenia patients in the first episode and in remission

Y. Zaytseva^{1,2,*}, Z. Garakh³, A. Morozova⁴

¹ National Institute of Mental Health, National IT System of Mental Health and Brain Monitoring, Klecany/Prague, Czech Republic

² Charles University in Prague, Prague, Czech Republic

³ Institute of Higher Nervous Activity and Neurophysiology of RAS, Psychophysiology, Moscow, Russia

⁴ Charles University in Prague, 3rd Faculty of Medicine, Prague, Czech Republic

* Corresponding author.

Introduction Despite the assumption that the EEG parameters in schizophrenia may be predictive for the treatment outcome, there are only a small number of such studies present. We hypothesised that the characteristics of the changes in EEG rhythms during cognitive load might differ in the first episode of psychosis and remission being dependent on the stage of the illness.

Methods The EEG rhythms spectral power (SP) in the resting state and their changes during the performance of spatial logical task in 25 first-episode psychosis patients (FEP) and same patients in remission (REM) after 6–18 months were analysed. Control group included healthy subjects matched with patient group by gender, age and years of education.

Results The resting state SP values did not differ in FEP and REM. When performing a task, FEP theta SP was decreased compared to the resting state values in F7, F8, P3, T6 sites ($P < 0.05$), while gamma2 SP was increased in Fz ($P < 0.001$) and Pz ($P < 0.01$). REM theta, alpha, and beta1 SP was decreased in the same way as in norm in all sites ($P < 0.05$). Gamma2 SP increase was found in sites Fp1, F8, Fz ($P < 0.05$). FEP theta and beta1 SP changes during cognitive load positively correlated with the PANSS scales (delusions, thought disorders, hallucinations). REM did not have significant correlations between SP and PANSS parameters.

Conclusions The analysed REM EEG characteristics differ less from the norm than the FEP. Based on the results, the performance of the task is related to the stage of the illness.

Serum testosterone level and its relation to aggressive behavior in schizophrenia

M. Zholob^{1,*}, S. Godinova¹, M. Zelman²

¹ Psychiatricka nemocnica Hronovce, Acute male department, Hronovce, Slovak Republic

² Psychiatricka nemocnica Hronovce, Acute female department, Hronovce, Slovak Republic

* Corresponding author.

This work is presenting partial preliminary outcomes of our study focused on evaluating the levels of testosterone in psychotic patients and its relationship to aggressive behavior.

Our study group included 10 male patients (from planned 20), with history of aggressive behavior at baseline and 24 male patients (from planned 40), without history of aggressive behavior. Non-aggressive patients were considered as control group. All included patients were hospitalized in psychiatric hospital Hronovce with diagnose of psychotic disorder. Levels of testosterone were measured by laboratory evaluation. Aggressive behavior was assessed by HCR scale, which was linked with every TSH evaluation. The level of testosterone was measured in all subjects at the baseline and in

the group of aggressive patients was realized next measurement after 14 days of hospitalization.

According to our preliminary findings, the average level of TSH in our whole study group was 478.66 ng/dl (range from 158.06 to 767.81). The control group showed average value of TSH 486.84 ng/dl (range from 158.06 to 767.81). The group of patients with history of aggressive behavior showed average value of TSH 459.04 ng/dl (range from 191.81 to 638.02) and after 14 days of cure the levels were of average value 452.55 ng/dl (range from 253.53 to 657.92).

These preliminary findings don't show significant intergroup differences, but there are some clear casuistic declines in TSH. After collecting the envisaged group of patients we plan to correlate values of testosterone level with the score of HCR, intergroup comparison and detailed analysis (including demography, pharmacology).

Belief inflexibility and dimensions of delusional beliefs in non-affective psychosis: Comparison with non-clinical meaningful beliefs

C. Zhu*, S.H. So

The Chinese University of Hong Kong, Psychology, Shatin, Hong Kong Special Administrative Region

* Corresponding author.

Introduction Belief inflexibility (BI) has been considered as a crucial factor for delusional conviction, but less is known about other dimensions of delusional beliefs. Question has been raised

regarding the extent to which BI distinguishes delusions from strongly held (non-deluded) personally meaningful beliefs.

Objectives We examined the association between BI and major dimensions of delusional beliefs/non-clinical personally meaningful beliefs, and compared results from two BI measures (Maudsley assessment of delusions schedule [MADS] and bias against disconfirmatory evidence [BADE] task).

Methods Idiosyncratic delusional beliefs from 40 outpatients with non-affective psychosis and personally meaningful beliefs from 30 healthy controls were assessed in an interview. Belief dimensions (conviction, preoccupation, and distress) and BI were measured.

Results Compared with controls, patients reported higher levels of distress and preoccupation but a comparable level of conviction (3.30/4 vs. 3.00/4, $t(66.967) = 1.928$, $P = n.s.$). Patients exhibited lower belief flexibility than controls on MADS but not on BADE. In patients, delusional conviction was associated with lower flexibility on a MADS item ("possibility of being mistaken": $t(38) = 4.808$, $P < 0.01$) and the BADE evidence integration index ($r = 0.463$, $P = 0.01$). In healthy controls, belief conviction was associated with lower flexibility on a MADS item ("reaction to hypothetical contradiction": $t(27) = 3.345$, $P = 0.002$). Two-way ANOVA revealed that the association between possibility of being mistaken and conviction was stronger in patients than controls ($F(1) = 6.718$, $P = 0.012$). In both groups, BI on either measure did not correlate with distress or preoccupation.

Conclusions BI was specifically associated with belief conviction. The association was significant for both groups, and was stronger in patients than controls.

Sexual satisfaction among women with breast cancer

S. Abdollahifard^{1,*}, M. Maddahfard²

¹ Jahrom University of Medical Sciences, Jahrom, Iran

² BHOWCO Trading GmbH, Frankfurt am Main, Germany

* Corresponding author.

Background Despite the outstanding breakthroughs in medical sciences, breast cancer is still regarded as one of the most important diseases, worldwide. This condition is also the most common cancer among women and the second leading cause of death.

Aim This study aimed to investigate on sexual satisfaction among breast cancer patients

Methods This review article has written by more than 32 published papers in websites during 2008 until 2016.

Result Esfandiari et al. (2015) have done a study about a comparison of marital satisfaction, public health and body image among normal subjects and breast cancer patients with breast evacuation and conservation in Tehran, Iran. The result of this study showed that women with breast cancer were significantly different from normal subjects in terms of marital satisfaction, mental health and body image.

Rezaipour et al. (2004) has done a study about relationship between women's experience of orgasm and marital relation satisfaction in health care centers of Arak. This result showed there was a relationship between women's orgasm experience and the amount of satisfaction from marital relation.

Nekouefard and Jahangiry (2014) have done a study about sexual function among patients with breast cancer in Tehran. In their study, there was a meaningful and direct relationship between type of surgery and sexual satisfaction. The results of that study show that disease and treatment have a considerable influence on marital relationship.

Conclusion It seems that dealing with marital satisfaction of women during the early stages of breast cancer diagnosis and treatment is a necessary for mental health.

Persistent genital arousal: Differential diagnosis and management in the emergency room of psychiatry

C.M. Calahorro^{1,*}, M. Guerrero Jiménez², B.M. Girela Serrano²

¹ Hospital Universitario San Cecilio, Unidad de Salud Mental, Granada, Spain

² Santa Ana Hospital, Psychiatry, Motril, Granada, Spain

* Corresponding author.

Background We describe the case of a 50 years old woman who attended the emergency room for complaints that involves continuous orgasms in the last two months that she describes "as waves". The woman is a widow and claims not to have had sexual relationships since her husband died four years ago.

Main objective Persistent genital arousal disorder (PGAD) is a relatively unknown clinical condition affecting several women. Moral standards, as well as conservative beliefs regarding sexuality, are believed to be involved in the etiology and maintenance of this syndrome. Nevertheless, there are no consistent data on the content of the beliefs system presented by these women.

PGAD It has been identified as a condition of often unprovoked genital arousal associated with a significant level of distress.

PGAD is not well understood, and no definitive cause has been determined.

Our main objective was to review the literature on PGAD, identify possible causes of the disorder, and provide approaches to the assessment and treatment of the disorder based on the authors' experience and recent literature.

Comments PGAD is a potentially debilitating disorder of unwanted genital sensation and arousal that is generally spontaneous and unrelenting. Since its first description in 2001, many potential etiologies and management strategies have been suggested. PGAD likely represents a range of conditions manifesting in unwanted genital sensations. Successful treatment requires a multidisciplinary approach and consideration of all reversible causes as well as cognitive therapy.

Multidisciplinary approach about contraception in a day hospital of mental health

C.M. Calahorra^{1,*}, M. Guerrero Jiménez², B.M. Girela Serrano²

¹ Hospital Universitario San Cecilio, Unidad de Salud Mental, Granada, Spain

² Santa Ana Hospital, Psychiatry, Granada, Spain

* Corresponding author.

Background Women with mental illness are a disadvantaged group both in terms of their gender and because of their mental disorders, and they experience serious problems related to reproductive health.

The high rates of unplanned and unwanted pregnancies among women with schizophrenia underscore the importance of understanding their attitudes and practices related to family planning. Different studies reveal that even though many sexually active women with serious mental illnesses do not want to become pregnant, they do not use birth control.

Objectives Release last data about contraception methods among patients with severe mental illness after doing a bibliographical review. Also reflect present setup in Motril day hospital women patients and their relationship with sexuality and contraception. At the same time we intend to clarify and unify the proceedings on ethical problems respecting subject's autonomy, beneficence, qualification and minors' protection.

Methods Data were collected through face-to-face interviews and a questionnaire based on the literature and prepared by the researchers which was designed to determine the kinds of reproductive health issues the patients were experiencing.

Results It was found that female patients with psychiatric disorders had more negative attributes with regard to contraception approach and sexuality compared with a corresponding healthy population.

Conclusions We reached an agreement about future contraception approaches in Motril day hospital users as part of the global treatment offered in our section.

Motril Hospital gynaecology service has facilitated the proceedings for contraceptive subcutaneous implants insertion in those indicated women.

Day hospital patients were instructed individually and through group work about healthy sexuality.

¹ Instituto Superior Miguel Torga, Psychology, Coimbra, Portugal

² Instituto Superior Miguel Torga, CINEICC, Faculty of Psychology and Education Science of University of Coimbra, Psychology, Coimbra, Portugal

³ CINEICC, Faculty of Psychology and Education Science of the University of Coimbra, Psychology, Coimbra, Portugal

* Corresponding author.

Introduction Societal changes in the last decades led to the arise of new paradigms on gender equity. Studies addressing fertility/infertility issues have been conducted mainly in women and in this research area, male partners have deserved less attention. More recently there has been a major focus on the idea that fertility/infertility aspects have to be conceptualized from a couples' perspective.

Goals The current study sought to explore attitudes towards gamete donation and surrogacy in a sample of young men in reproductive age.

Methods A total of 111 males with ages ranging from 18 to 40 years old and without children completed an online questionnaire addressing attitudes towards gamete donation and surrogacy.

Results The majority of participants (77.3%) would be willing to donate their sperm, and their main motivation for doing that would be to feel "happy to help a couple struggling to have a child". Participants stated that the likelihood of donating would increase if they were able to attend counseling, to complete the procedure in an IVF center located in their residence area, and being provided with more information about infertility. Regarding surrogacy 82% are in favor of this procedure legalization and 49.5% would be willing to use it if they needed.

Conclusion Men showed a positive attitude towards sperm donation and surrogacy, emphasizing the importance of counseling and information availability on these topics. This may suggest that they are willing to get involved when fertility issues are addressed.

Sexual minorities: The terminology

M.C. Cochat Costa Rodrigues*, F. Leite, M. Queirós Magalhães Lemos Hospital, Psychiatry, Porto, Portugal

* Corresponding author.

Introduction The term "sexual minority" includes a variety of gender and sexual identities and expressions that differ from cultural norms. Usually, sexual minorities are comprised of lesbian, gay, bisexual and transgender individuals.

Objectives/aims Definition of the correct terminology for sexual orientation, sexual behaviors, gender identity, gender expression and gender dysphoria.

Methods Literature review concerning researched articles published in Pubmed/Medline as well as related bibliography.

Results Human sexuality is a broad concept that embodies interaction among anatomy, hormones, physiology, psychology, interpersonal relationships and sociocultural influences.

Healthcare providers can support sexual minorities by normalizing sexuality throughout childhood, early identification of gender or sexual orientation nonconformity and associated psychosocial and health concerns, helping parents support their child, assisting with decisions about disclosure and providing educational resources to the community.

Conclusions This work focuses on providing more awareness about this topic and reducing stigma associated with sexual minorities.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Sexual functioning in male patients suffering from depression and anxiety disorders

G. Ciocca, G. Di Lorenzo*, G. Comite, E. Limoncin, D. Mollaioli, E. Bianciardi, C. Niolu, E.A. Jannini, A. Siracusano University of Rome, Tor Vergata, Systems Medicine, Rome, Italy

* Corresponding author.

Introduction Sexual dysfunctions are frequent in patients with mental illnesses. In particular, anxious and depressive symptomatology often impacts on sexual functioning.

Objectives The aim of this study was to evaluate the relationship between sexual function and psychological symptoms in a group of male patients with depression and anxiety disorders.

Methods From outpatients program, we consecutively recruited a group of 46 males: 28 patients had major depression and 18 anxiety disorders. Then, we administered two self-report psychometric tools to assess male sexuality, depression and anxiety, i.e., international index of erectile function (IIEF-15), and Depression Anxiety Stress Scales (DASS-21). *t*-tests and Pearson correlations were performed.

Results We found significantly higher score in terms of desire and general sexual wellness in people with anxiety disorder compared to people with depression. However, we found more significant correlations among depressive/anxious symptomatology and sexual impairment in males with anxiety disorders compared to males with depression.

Conclusions Our results revealed that males diagnosed with depression show a decrease of sexual desire, as a vast part of literature previously affirmed. On the contrary, the relationship between psychological symptomatology and sexual dysfunction, as the reduction of erectile function, was higher in males with anxiety disorders. This difference is probably due to a major iatrogenic effect of antidepressive treatments in depressed patients, while in anxious patients could be the psychological state, per se, the main cause of sexual dysfunctions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Sexual dysfunction and mood stabilizers in bipolar disorder: A review

C. Gómez Sánchez-Lafuente*, R. Reina Gonzalez, M. Hernandez Abellán

Hospital Universitario Virgen de la Victoria, Psychiatry, Málaga, Spain

* Corresponding author.

Introduction Mood stabilizers can cause many side effects. Although many of these are well known, like thyroid and renal failure after taking lithium, sexual dysfunction side effects remains unclear.

Methods We made a systematic computerized literature search of clinical studies using MEDLINE, The Cochrane Library and Trip for clinical studies of sexual dysfunction published up to December 2015.

Results Only eight relevant papers were identified. All of them studied lithium sexual dysfunction in bipolar disorder patients. Valproic acid, carbamazepine and lamotrigine were not studied in patients with bipolar disorder. Nevertheless, the three were studied in epilepsy. Clinical reports usually used Arizona Sexual Experience Scale or Psychotropic Related Sexual Dysfunction Questionnaire to measure sexual dysfunction and Brief Adherence Rating Scale to measure medication adherence. They suggest lithium could decrease desire and sexual thoughts, worse arousal and cause orgasm dysfunction. In overall, those patients with sexual dysfunction had lower level of functioning and poor compliance. Taking benzodiazepines during lithium treatment may increase the risk of sexual dysfunction even more.

Conclusion There are few studies that focus on mood stabilizers sexual dysfunction. This inevitably entails a number of limitations. First, the small sample size and, in some studies, the relative short period of follow-up may underestimate the results. Besides, practical management was not treated in any study. Actually, handling this side effect have not been well established.

To conclude, this revision suggest that approximately 30% patients receiving lithium experience this side effect, and it is associated with poor medication adherence.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Sexuality of Tunisian women with polycystic ovary syndrome

N. Halouani*, S. Ellouze, R. Naoui, J. Aloulou, O. Amami Hédi Chaker University Hospital, psychiatry, Sfax, Tunisia

* Corresponding author.

Introduction The polycystic ovary syndrome (PCOS) is a heterogeneous disease with multiple facets. In a few decades, this syndrome has gone from a purely gynaecological domain to sexology one; PCOS is thus considered a systemic disease. However, the domain of sexuality continues to be neglected. The aim of our study was: assessing women's sexuality with PCOS by comparing them to a sample correlated with the age of control subjects. We performed a cross-sectional study of case-control, conducted between October and November 2015.

Data was collected by oral questionnaire proposed to women whose anonymity was respected. To assess the sexuality we used the "female sexual function index" (FSFI) developed by Rosen et al.

Results The average BMI of the patients was 30.2 ± 6.3 kg/m², with a range of 17.2 to 43.5 kg/m². The average frequency of sexual intercourse per week was 1.6 ± 0.5 for patients and 2.1 ± 0.9 for the controls. The scores used in this study show that 90% of sexual dysfunction exists in women with PCOS. For controls, a sexual dysfunction was found in 40% of cases.

All aspects of sexuality were affected (desire, arousal, orgasm and satisfaction). The lowest scores were found in the following areas: arousal, lubrication and orgasm.

Conclusion The therapist during a consultation for a patient with PCOS should check her psychological state. Also, asking the patient about her sex life should be part of the monitoring of the disease.

EV1354

Methylation of the HPA axis related genes in men with hypersexual disorder

J. Jokinen

Umeå University, Clinical Sciences, Umeå, Sweden

Introduction Hypersexual disorder (HD) defined as non-paraphilic sexual desire disorder with components of impulsivity, compulsivity and behavioral addiction, was proposed as a diagnosis in the DSM-5. Recent research shows some overlapping features between HD and substance use disorder including common neurotransmitter systems and dysregulated hypothalamic-pituitary-adrenal (HPA) axis function. We have reported that HD was significantly associated to DST non-suppression and higher plasma DST-ACTH levels indicating HPA axis dysregulation in male patients with HD.

In this cohort, comprising 54 male patients diagnosed with HD and 33 healthy male volunteers, we aimed to identify HPA-axis coupled CpG-sites, in which modifications of the epigenetic profile are associated with hypersexuality.

Methods We performed multiple linear regression models of methylation M-values to a categorical variable of hypersexuality in 87 male subjects, adjusting for depression, DST non-suppression status, CTQ total score, and plasma levels of TNF-alpha and IL-6.

Results Seventy-six individual CpG sites were tested, and four of these were nominally significant ($P < 0.05$), associated with the genes CRH, CRHR2 and NR3C1. Cg23409074-located 48 bp

upstream of the TSS of the CRH gene—was significantly hypomethylated in hypersexual patients after corrections were made for multiple testing using the FDR-method. Methylation levels of cg23409074 were positively correlated with gene expression of the CRH gene in an independent cohort of 11 healthy male subjects. CRH is an important integrator of neuroendocrine stress responses in the brain, modulating behavior and the autonomic nervous system; our results show epigenetic changes in CRH gene related to hypersexual disorder in men.

⁴ Institute of Psychiatry and Neurology, 3rd Psychiatric Clinic, Warszawa, Poland

* Corresponding author.

Introduction Dual Control Model (DCM) is one of the contemporary concepts of mechanisms rooted in the central nervous system that control human sexual behaviors. The DCM holds promise for application both in scientific settings and, although at the moment limited, clinical practice. A number of psychometric tools, i.e. the SIS/SES, SES II-W and SES II-W/M questionnaires based on the DCM theoretical assumptions have been developed.

Methods A total of 309 women aged 18–45 were eligible for the study. Inclusion criteria were met by 214 individuals who were included in the further analysis. Sexual excitation/sexual inhibition inventory for women (SESII-W) was used to evaluate sexual inhibition and sexual excitation. Semi-structure interview was used to evaluate sexual function in investigated individuals. Correlation between risky sexual behaviors, FSD and SE/SE was measured.

Results Among the women, 28.5% were diagnosed with FSD, with orgasmic dysfunction being the most common, 11.2%. Engaging in risky sexual behavior (having multiple sexual partners and one-night-stand sexual relationships, sexual intercourse with persons known to be HIV-positive, drug users or prostitutes, unprotected vaginal, oral and anal sex, sex for money or drugs and sexual activity while using alcohol and/or psychoactive substances) was associated with higher sexual excitation scores and lower sexual excitation scores of SESII-W. In contrast, the presence of FSD were negatively correlated with SE and positively with SI.

Conclusions Dual control model might be a good model describing different sexual behaviors in the population of women.

Sexual excitation, sexual inhibition and a prevalence of sexual disorders among msm and heterosexual men

R. Kowalczyk^{1,*}, M. Kaluga¹, K. Jacek², K. Nowosielski³

¹ Andrzej Frycz Modrzewski Krakow University, Department of Sexology, Kraków, Poland

² Pomeranian Medical University in Szczecin, Department of Psychiatry, Szczecin, Poland

³ Medical College in Sosnowiec, Department of Sexology and Family Planning, Sosnowiec, Poland

* Corresponding author.

Introduction Dual control model of the sexual response (DCM) indicates, that there are two separate, but cooperating systems of sexual excitation and inhibition. Previous studies using DCM concept have shown, that MSM (men having sex with men) had higher excitation (SES) and one of the types of inhibition (SIS1) levels, in comparison to the exclusively heterosexual men. MSM also reported more frequent occurrence of sexual disorders (erectile disorders, premature ejaculation and decreased sexual desire).

Objectives Comparison of the MSM and heterosexual men groups in order to verify erenow observed differences in sexual excitation/inhibition propensity and prevalence of sexual problems.

Methods The sample consisted of two groups: 47 heterosexual men and 60 MSM. The participants have anonymously filled up questionnaires (Polish version of the Sexual Inhibition/Sexual Excitation Scales SIS/SES and the author's survey) via internet. Then statistical analysis was executed.

Results Our findings have shown, that both groups were similar in their propensities for sexual excitation (SES) and inhibition due to the risks of failure in sexual performance (SIS1), while MSM scored higher on the inhibition scale, related to the threat of negative consequences of sexual response (SIS2). Heterosexual men more frequently suffered from premature ejaculation and less commonly reported decreased desire. There were no differences in the erectile disorders report between MSM and heterosexual men.

Conclusions Our findings are mostly in conflict with previous DCM studies results. Several issues, just like method of sexual orientation assessment or cultural differences may had its impact on such results. More detailed studies on these issues are required.

The under-diagnosed green-eyed monster: Otello syndrome and how to manage it

B. Latecki

Llfe Empangeni Private Hospital, Private psychiatric practice, Empangeni, South Africa

Otello syndrome derives its name from Shakespeare's drama (character) and, clinically, describes a person with delusions of the partner's infidelity. A variety of other psychopathology may present: obsessive-compulsive features, alcohol dependency, voyeurism, sadism, possessiveness and domineering, hypersexuality, paranoid attitude, abuse of different nature, violent behaviour, including, occasionally, homicide. Yet, in the author's opinion, the syndrome, unless it presents itself as obviously absurd, is frequently missed.

Management is rather difficult and does not always result in recovery but, if not treated with neuroleptics, it would render any other means of treatment useless. The condition could pose a diagnostic challenge. Moreover, it also poses an ethical dilemma whether to warn the spouse of the psychotic condition of the partner, the poor prognosis and possible implications of its existence. Moreover, the long-term partners of such patients frequently present with the symptoms of dependency, submissiveness or even masochism. The paper discusses the abovementioned issues, including the likely psychodynamics, biological background, historical and social elements and possible effective management.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

EV1358

The importance of psychosexual variables in the sexual functioning in sexually active adults

H. Pereira

University of Beira Interior, Psychology and Education, Covilhã, Portugal

Introduction Sexuality is a very important human dimension which contributes to psychosocial well-being and psychosexual variables, such as sexual self-esteem, sexual anxiety and sexual depression, can affect sexual functioning; however, there are few studies that demonstrate this relationship.

Objectives To assess the psychosexual variables and sexual performance levels in a sample of adults, and verify and determine the degree of association between sexual functioning and self-esteem, anxiety and sexual depression.

Methods The study included 422 adults that were sexually active (who had sex in the previous month); 265 (62.8%) were women and 149 (35.3%) were men, who filled out a sociodemographic questionnaire and scales related to sexuality and sexual functioning, Sexuality Scale and Sexual Functioning Questionnaire Short Form (CSFQ 14), broadcast over the internet.

Results The results obtained allowed to know the relationships between the variables and psychosexual sexual functioning, and was statistically significant correlation between the two dimensions and significant differences between the correlation when comparing gender and sexual orientation.

Discussion and conclusions This study allows us to highlight the importance of psychosexual variables in sexual functionality expression, in the sense that those working in the area of sexuality should be aware of how the human psyche interferes with sexual manifestation.

Sexual dysfunction in obese women

R. Sellami¹, M. Moalla¹, L. Affes², I. Feki¹, F. Mnif², M. Abid², J. Masmoudi^{1,*}

¹ Hedi chaker Hospital, psychiatry A, Sfax, Tunisia

² Hedi chaker Hospital, endocrinology, Sfax, Tunisia

* Corresponding author.

Introduction The increasing prevalence of obesity represents a major public health problem, with can effect on physical and emotional well-being and psychosocial function. Somatic and psychological dysfunctions, such as infertility, osteoarthritis, social disabilities caused by stigmatization, sleeping problems or apnea, are also known to follow obesity. Sexual dysfunction (SD) may also be related to obesity, but is rarely mentioned, and may cause concern for the affected individual and partner, constituting a great problem.

Objectives The aim of this study was to identify the frequency of SD among obese women.

Methods Our study concerned 42 obese married women consulting in endocrinology department. Obesity was defined by body mass index (BMI) ≥ 30 . All participants assessed a sociodemographic data and the "Female Sexual Function Index" (FSFI). FSFI is a 19-item multidimensional self-reporting measure that quantifies six domains of female sexual dysfunction (FSD), including desire, arousal, lubrication, orgasm, satisfaction, and pain. Score ≤ 26 indicate the presence of FSD.

Results The mean age was 33.6 years (20 \rightarrow 47 years). The mean total score of FSFI was 22.5 (3.2 \rightarrow 32.6). The percentage of SD among obese women was 68.2%. FSFI score was correlated to ancient obesity ($P=0.026$; $r=0.347$) and waist circumference

($P=0.007$; $r=0.412$). High socio-economic level was correlated to desire and satisfaction ($P=0.021$ and $P=0.048$ respectively). Women with high educational level have better blurbification ($P=0.005$). FSFI score was not correlated to BMI or obesity class.

Conclusion Almost two-thirds of obese women have sexual dysfunctions. Women with ancient obesity and higher waist circumference seemed to have better sexual functions.

Rethinking classification of zoophilia

D. Sendler^{1,*}, M. Lew-Starowicz²

¹ University of Lublin Medical School, Department of Psychiatry and Sexual Consultation Clinic, Lublin, Poland

² Institute of Psychiatry and Neurology, III Department of Psychiatry, Warsaw, Poland

* Corresponding author.

Introduction In 2011, Anil Aggrawal proposed ten-point classification system of zoophilia, based on forensic literature review.

Objectives (1) Allow for conceptualization and improved management of zoophilic patients in clinical practice or forensic examinations, (2) describe identity of modern-day zoophiles, including demographics and psycho-social profile, and (3) determine normative and pathologic traits and behaviours.

Methods A qualitative observational study of user activity ($n=958$) on discussion forums, combined with brief demographic survey. Data were analyzed according to principles of grounded theory. Surveys of own design (demographic, discreet + open ended questions) were answered by 350 participants. Presented data show aggregate conclusions from mixed methods qualitative and quantitative analysis.

Results Proposed classification system categorizes zoos as either classic, sexual, romantic, or platonic. Relationship goals of classic and romantic zoos are reminiscent of those typical of human partnership, differentiated by the commitment and psychological distress level (romantic zoos, affectionate relationship goals outweigh sexual pursuit; classic zoos, romantic and sexual urges cause distress rather than pleasure). Sexual zoos show high prevalence of hypersexuality traits. Platonic zoos are typically confused about the roots of their sexuality. Contrary to common perceptions, prevalence of sexual sadism is extremely low ($<1\%$ in our study). Sociopathic traits determine propensity for animal cruelty, which is not synonymous with typical zoophilia. Half of respondents were in committed relationship with human partner, whom they frequently attempted to "convert" into practicing zoophile.

Conclusions We can categorize zoophiles into four sub-types. Emotional attachment and sexual urges play equal role in bonding with animal partner.

Digital communities of people with paraphilia: A study of zoophiles

D. Sendler^{1,*}, M. Lew-Starowicz²

¹ University of Lublin Medical School, Department of Psychiatry and Sexual Consultation Clinic, Lublin, Poland

² Institute of Psychiatry and Neurology, III Department of Psychiatry, Warsaw, Poland

* Corresponding author.

Introduction Accessibility of the Internet allows people to connect anonymously and without boundaries – features particularly

important for people with relatively rare sexual preference such as paraphilia.

Objectives To (1) allow for conceptualization and improved management of zoophilic patients in clinical practice or forensic examinations, (2) analyze how zoophiles network using online discussion forums, and (3) describe main goals of digital networking.

Methods A qualitative observational study of user activity ($n=958$) on discussion forums, combined with brief demographic survey. Data were analyzed according to principles of grounded theory. Next, surveys of own design (demographic, discreet + open ended questions) were answered by 350 participants. Presented data show aggregate conclusions from mixed methods qualitative and quantitative analysis.

Results Zoophiles (or, zoos) use Internet to connect with other zoophiles (26.6% to have casual sex, 17.7% for dating, and 17% to exchange pornography). Connections are easiest to be established in countryside, where zoophilia clusters. In fact, there are village communities of zoos where explicit sharing of animal sexual partner(s) (28%) and/or voyeurism (30%) serve as bonding ritual. Over 40% of zoophiles are reluctant to meet other zoos in person, since they view them as “weird”, pointing to phenomenon of internalized stigmatization due to having non-normative sexuality. Online forums are also used by zoophiles to exchange information about which districts are at risk of becoming a target of social ostracism.

Conclusions People with zoophilia use digital communities to network, meet for sex, find dating partners and for own safety reasons.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Motivation of sexual relationship with animal—Study of a multinational group of 345 zoophiles

D. Sendler^{1,*}, M. Lew-Starowicz²

¹ University of Lublin Medical School, Department of Psychiatry and Sexual Consultation Clinic, Lublin, Poland

² Institute of Psychiatry and Neurology, III Department of Psychiatry, Warsaw, Poland

* Corresponding author.

Introduction We explore relationship-seeking behaviour of zoophiles (zoos), using Francoeur's (1991) definition of sexual orientation (as consisting of affection orientation, sexual fantasy orientation, and erotic orientation).

Objectives This study intends to be the largest in recent decades' comprehensive analysis of self-identified zoophiles, living on all five continents. It describes similarities and differences between normative sexual orientations (hetero- and homo-) and zoophilic sexuality, using Francoeur's (1991) framework.

Method A qualitative observational study of user activity ($n=958$) on discussion forums, combined with brief demographic survey. Data were analyzed according to principles of grounded theory. Next, surveys of own design (demographic, discreet + open ended questions) were received by $n=350$ participants. Presented data show aggregate conclusions from mixed methods qualitative and quantitative analysis.

Results Trend analysis yielded four main discussions among zoophiles – worldview, personal space, sex life, and online space. Within worldview category, zoos overwhelmingly discuss bad press (55%), as well as social (41%) and legal (22%) ostracism. In personal space, the primary concern is coming at easy with own sexuality (>60%) and forming lasting relationship with either human, animal, or both partners simultaneously. In terms of sex life, zoos are concerned with improving sex play (>40%) and figuring out legality of sexual encounters with animals (22%). Concerning online

space, the biggest concern here is networking (40%) and meeting other zoos for dating (15%).

Conclusions Modern zoophiles have a wide array of personal, social, legal, and sex life challenges that can be approximated using qualitative studies.

Sexual and mental health of patients with cardiovascular disease: A review

A.R. Szczegielniak*, M. Krzystanek

Medical University of Silesia, Department of Psychiatry and Psychotherapy, Katowice, Poland

* Corresponding author.

More than 4,000,000 people die from cardiovascular diseases in Europe every year. Even though a significant reduction in mortality of patients suffering from heart and blood vessels disorders can be observed across the continent, a number of hospitalizations in this group constantly increase. Large disparities in the assessment of population's health awareness, prevention activities and the availability of specialized treatment between different regions of Europe are still recognized with the highest incidence rates in Central Europe, Eastern Europe and the countries of the former Soviet Union. Both researchers and clinicians pay increasingly more attention to the cardiac patients' quality of life. It determines not only the daily physical, mental and social functioning, but also a general response to the further treatment conducted in outpatients clinic. Sexuality is an integral part of the human personality. Disorders appearing in the area make it difficult to fully achieve the comprehensive well-being from the individual, interpersonal and social dimension. Reduction of satisfaction and decrease in sexual activity are commonly observed in cardiac patients and frequently associated with depression and anxiety disorders. Older age, pharmacological treatment, and variety of cardiovascular risk factors (diabetes, hypertension, dyslipidemia, physical inactivity, smoking) also negatively influence sexual functioning. Thus, cardiac rehabilitation programs must be designed in a way to include recommendations regarding clinical management of sexual dysfunction, improving functional capacity, quality of life, morbidity and mortality of the patients with cardiovascular disease across Europe. Psychiatric assessment and general psychological well-being appraisal seem to be inseparable in these regards.

Evaluation of self-esteem and childhood trauma in patients with sexual disorders

G. Teksin Unal^{1,*}, O. Sahmelikoglu Onur¹, C. Karsidag¹, M.G. Teksin Bakir²

¹ Psychiatry, Prof. Dr. Mazhar Osman Psychiatric and Neurological Diseases Training and Research Hospital 3, Clinic, İstanbul, Turkey

² Psychiatry, Gazi University Faculty of Medicine, Department of Psychiatry, Ankara, Turkey

* Corresponding author.

Introduction Sexual dysfunction (SD) is defined as the deterioration of sexual response cycles caused by anatomic, physiologic or psychological reasons.

Objectives We believe that SD is closely related to self-esteem and childhood trauma (CT).

Aim In this study, the level of self-esteem and CT in patients diagnosed with SD vs. controls are aimed to be compared. In addition, relationship between complaints of SD self-esteem and CT variable subgroups are planned to be investigated.

Method Twenty-four patients visited Prof. Dr. Mazhar Osman Psychiatric Hospital with matching defined criteria and 24 control counterparts statistically matching were taken sociodemographic data form, Rosenberg Self-esteem Scale (RSS) and Childhood Trauma Questionnaire (CTQ-28) was applied.

Results CTQ-28 averages and RSS variables which are sensitivity to criticism, depressive mood, psychosomatic symptoms, feeling threatened in interpersonal relationships, degree to participate in discussions, relationship with father were higher in patients with SD ($P < 0.05$). Considering the relationship between complaints of SD and CTQ-28 subscales, physical abuse, emotional abuse, physical neglect, emotional neglect averages of patients were observed significantly different rooted by genitopelvic pain/penetration disorder and premature ejaculation and in emotional neglect by premature ejaculation and low libido combination ($P < 0.05$).

Conclusions In literature, there are many studies that show CT leads to SD and several studies state that self-esteem is affected in patients with SD [1]. CT must be considered and determined in the goal of treatment of SD.

Evaluation of depression and anxiety, and their relationship with insomnia, nightmare and demographic variables in medical students

S.A. Haji Seyed Javadi

Qazvin University of Medical Sciences, Psychiatry, Qazvin, Iran

Introduction Researches showed comorbidity of sleep disorders and mental disorders.

Objectives and aims The current study aimed to evaluate depression and anxiety and their relationship with insomnia, nightmare and demographic variables in the medical students of Qazvin University of Medical Sciences in 2015.

Method The study population included 253 medical students with the age range of 18–35 years. Data were gathered using Beck depression inventory, Kettle anxiety, and insomnia and nightmare questionnaires and were analyzed by proper statistical methods.

Results Among the participants, 126 (49.6%) subjects had depression and 108 (42.5%) anxiety. The prevalence of depression and anxiety among the subjects with lower family income was significantly higher ($\chi^2 = 6.75$, $P = 0.03$ for depression and $\chi^2 = 27.99$, $P < 0.05$ for anxiety). There was a close relationship between depression with sleep-onset difficulty, difficulty in awakening and daily sleep attacks, and also between anxiety with sleep-onset difficulty and daily tiredness ($P < 0.05$). In addition, there was a close relationship between depression and anxiety with nightmare; 16.2% of the subjects with depression and 26.5% of the ones with anxiety experienced nightmares.

Conclusion Results showed a relationship between nightmare, insomnia and level of family income with increasing depression and anxiety in the medical students; hence, due to the importance of medicine in human life, it is necessary to evaluate the mental health of medical students, identify and solve the relative problems such as anxiety, depression and related symptoms such as insomnia and nightmare in them.

Insomnia and sleep state misperception: Clinical features, diagnosis, management and implications

J. Isaac^{1,*}, C. Santos², A. Matos Pires²

¹ ULSBA, Psychiatry and Mental Health Department, Beja, Portugal

² Unidade Local de Saúde do Baixo Alentejo, Hospital de Beja, Psychiatry, Beja, Portugal

* Corresponding author.

Background Insomnia is a highly prevalent complaint, largely associated with mental disease. Clinical evidence classifies insomnia in 2 subtypes: with sleep misperception (WSM) and without sleep misperception (wSM). That presents distinctive pathophysiologic pathways and different public health implications.

Objectives Describe the main differences between primary insomnia WSM and wSM regarding:

- clinical features;
- diagnosis;
- management;
- implications.

Methods We conducted a systematic review. PubMed, Embase and PsycInfo were searched from 2000–2016. The reference lists of systematic reviews, narrative synthesis and some important articles were included. Following the inclusion criteria, we selected 25 studies from 59 articles.

Results The prevalence of sleep-state misperception in primary insomniacs (total sleep time > 6.5 h and sleep efficiency $> 85\%$) is around 26%. Insomniacs with normal sleep duration showed a profile of high depression and anxiety and low ego strength, whereas insomniacs with short sleep duration showed a profile of a medical disorder.

Cortical hyperarousal is higher in insomniacs and could be related to an alteration in sleep protection mechanisms. The sleep architecture was relatively normal for the WSM comparing with the group wSM. Risk of cardiometabolic, neurocognitive morbidity and mortality, and responses to treatment are different between these two insomnia phenotypes. Patients with short sleep duration may respond better to biological treatments, whereas insomnia with normal sleep duration may respond primarily to psychological therapies.

Conclusions The clinical characteristics of patients with sleep-state misperception differed from those without this condition. Available research related to these conditions is expanding rapidly, but many questions remain unanswered.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Sleep environment of preschool children effects on children's sleep disorder and parents' mental health

S. Lee^{1,*}, H. Ji-Hye², M. Duk-Soo³, Y. Soyoun¹, P. Boram¹, C. Seockhoon¹

¹ Asan medical center, Psychiatry, Seoul, Republic of Korea

² Purme Foundation Nexon Children's Rehabilitation Hospital, Psychiatry, Seoul, Republic of Korea

³ Seoul Metropolitan Children's Hospital, Psychiatry, Republic of Korea

* Corresponding author.

Introduction In Korean culture, co-sleeping of parents and children are quite common, which is different from the Western culture where solitary sleeping of children is preferred. In this study, we evaluate the sleep environment factors that effect on children sleep disorder, and parent's parenting stress and mental health.

Methods Surveys were conducted to 115 participating parents of preschool children sleeping behaviour lecture. Seventy-one completed surveys were analyzed for the study. The mean age of target children was 53 ± 23 months. Parents' mental health was evaluated by using several forms such as Insomnia Severity Index, Korean-Parenting Stress Index short form, and The Patient Health Questionnaire-9. Children's sleeping environment and quality were assessed by Child Sleep Habit Questionnaire and Sleep environment survey.

Results Pearson correlation analysis ($P < 0.05$) was conducted to evaluate the relationship between the sleep disorder of children, and the parent's parenting stress and mental health. Analyzing the data through the partial least square path modeling, co-sharing would have negative effect; bed-sharing could have negative effect on the depressing emotion of parents ($P = 0.065$). Solitary sleeping of children could have positive effect on parent's mental health ($P < 0.01$).

Conclusion Preschool children's sleeping disorder occurs more often in co-sleeping children with parents than solitary sleeping children. Parents' parenting stress is related to the parent's age and depression, further related to the children sleeping disorder and their sleep environment. Although, it is difficult to generalize the exact cause, evaluation and improvement of children's sleep environment would help to reduce the parent's parenting stress.

Trazodone a good start key for normal sleep in two cases of somnambulism

G.C. Marinescu^{1,*}, S. Popa², I.C. Zarioiu²

¹ Spitalul Judetean de Urgenta Pitesti and Psychiatry Private Care, Sectia de Psihiatrie, Pitesti, Romania

² Psychiatry Private Care, Psychiatry, Pitesti, Romania

* Corresponding author.

Introduction In our current practice, we do not see many cases of somnambulism in adults. We do not have much information about their treatment and outcome. In difficult cases, some clinicians try to use benzodiazepines, which decrease slow-wave sleep. More recent reports suggest the use of zolpidem.

Objectives Sleepwalking disorder consists of a sequence of complex behaviours that are initiated in the first third of the night during deep NREM (stage III and IV) sleep. The architecture of normal sleep is impaired. In important cases - with dangerous behaviour - we need treatment.

Aims Trazodone is an antidepressant with sedative effect due to H_1 and α_1 receptors blockade. Trazodone can rewrite the bad sleep architecture of depressive patients with insomnia and improve

sleep in such cases. For these reasons, we try to use trazodone in somnambulism.

Method We had two case studies (males, 24 and 22 old), diagnosed with NREM arousal disorder, sleepwalking type, according to DSM-5. Both patients were treated with trazodone 50 mg/day, up-titrated with 50 mg/day every three days. The target used dose was 150 mg/day because this is the most sedative.

Results Somnambulism disappeared in both cases after the first dose of trazodone. We treated three month both patients and then down-titrated and stopped the treatment. After one year from stopping the treatment, the patients had not new episodes of somnambulism.

Conclusions Trazodone has the power to rewrite, in those cases, the sleep architecture of somnambulism. This action is due to blockade the brain's arousal histamine and adrenaline systems.

Sleep duration and suicidal behavior: A systematic review

T. Pereira¹, S. Martins^{1,2,*}, L. Fernandes^{1,2,3}

¹ Faculty of Medicine, University of Porto, Porto, Portugal

² CINTESIS, Center for Health Technology and Services Research, UP, Porto, Portugal

³ Clinic of Psychiatry and Mental Health, CHSJ, Porto, Portugal

* Corresponding author.

Introduction Suicide is a serious public health problem, being the second leading cause of death among 15–29-year-olds. Many risk factors have been associated with suicidal behavior, such as psychiatric disorders, family history of suicide, loss of a close friend/relative, physical/sexual abuse, lack of support network, or sleep disturbances where nightmares and insomnia have been consistently reported to increase the risk of suicidal behaviors.

Objective To conduct a systematic review to examine the association between short sleep duration and suicidal behaviour (suicide ideation/attempt/suicide).

Methods This is a systematic review of published research articles in the electronic database PubMed in the last 10 years. The query "sleep" or "sleep disorders" and "suicide" was used. Studies that assessed the relation between sleep duration and suicidal behaviour, with a well-defined index for sleep disorders and with an outcome measure of suicidal behavior were included.

Results Of the 522 references founded, 33 articles met the inclusion criteria (1 review, 1 qualitative and 31 quantitative studies). An association between short sleep duration and suicidal behaviour was found in most of the studies with children/adolescents and adult samples. However, this relation was not verified in the research into the elderly.

Conclusion The results point to a significant association between short sleep time and the presence of suicidal behaviours, for both adults and children/adolescents. The effect of short sleep duration seems to be more consistent with suicidal ideation, but not for attempts, needing further studies to highlight the importance of this link between sleep duration and suicide.

Personality and insomnia: The role of genderA.P. Amaral^{1,2}, M.J. Soares², A.T. Pereira^{2,*}, S. Bos², C. Roque², A. Macedo²¹ Institute Polytechnic of Coimbra, ESTESC, Coimbra Health School, Coimbra, Portugal² Faculty of Medicine, University of Coimbra, Psychological Medicine, Coimbra, Portugal

* Corresponding author.

Introduction Several epidemiological studies have been conducted to document the prevalence and correlates of insomnia. Most of them confirm their high prevalence in the general population, and a gender difference in the risk for insomnia.

Aims To study the role of gender in the relationship between personality (perfectionism and neuroticism) and insomnia ([IG] insomnia group, [ISG] insomnia symptoms group, and [GSG] good sleepers group).

Methods A total of 549 college students (80.1% females) filled in the MPS (Frost et al., 1990; Hewitt and Flett, 1991), EPI (Barton et al., 1992, 1995), and a self-reported questionnaire to assess insomnia symptoms.

Results No differences were found between female and male samples, concerning the dimension of perfectionism – doubts about actions. The IG and the ISG showed higher levels of doubts about actions than the GSG. However, only in female sample the IG and the ISG showed higher levels of concern over mistakes in comparison with the GSG. In males, no significant differences between the sleep groups were found, in which respects concern over mistakes. The level of extroversion was higher in the GSG, but only in male sample. In females, there were no significant differences between the sleep groups in relation to extroversion.

Conclusions No gender differences were found for the role of doubts about actions in insomnia. Only in females, the dimension – concern over mistakes is important in insomnia, and only in males the dimension – extroversion is important to have a good sleep. These results warrant further research.

Use of buspirone in selective serotonin reuptake inhibitor-induced sleep bruxismV. Prisco^{1,*}, T. Iannaccone¹, G. Di Grezia²¹ University of Naples SUN, Department of Psychiatry, Naples, Italy² University of Naples SUN, Department of Radiology, Naples, Italy

* Corresponding author.

Sleep bruxism is characterized by the involuntary clenching or grinding of the teeth during sleep and can cause severe health problems, including the destruction of tooth structure, temporo-mandibular joint dysfunction, myofascial pain, and severe sleep disturbances. Iatrogenic sleep bruxism may be common during treatment with psychotropic medications, such as anti-psychotics and antidepressants, especially selective serotonin reuptake inhibitors (SSRIs). Bruxism is a common movement disorder that affects 8–21% of the population. The majority of bruxism symptoms are mild or moderate, although rare but severe cases may lead to serious periodontal damage, temporo-mandibular dysfunction, sleep disturbances, jaw pain, and stiffness. As a result, such cases must be treated with medication. It has been hypothesized that the mechanism of SSRI-induced bruxism may involve excessive serotonergic action on the meso-cortical neurons arising from the ventral tegmental area. It has been argued that, the addition of buspirone, was necessitated by the high level of resid-

ual anxiety. As a result, these symptoms may have been prevented through the use of buspirone alone. Buspirone, is an agonist of the 5-HT1A receptor that increases dopaminergic neuron, firing in the ventral tegmental area and increases the synaptic release of dopamine in the prefrontal cortex. These effects ameliorate drug-induced bruxism. Buspirone can also ameliorate extrapyramidal side effects, such as akathisia and tardive dyskinesia, and this property may be an additional explanation for the bruxism-related effects of the drug. Furthermore, buspirone may be an effective treatment for the bruxism associated with the use of these medications.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Background Multiple sclerosis (MS) is the commonest chronic autoimmune demyelinating and inflammatory disease of the CNS, afflicting both body and mind. Typical symptoms are fatigue, paraesthesia and depression, along with cognitive impairments. Whereas there is extant research on fatigue, depression, and cognitive impairment of patients with MS during the clinical course, no research focused on sleep, psychological functioning, and physical activity (PA) at the moment of the diagnose. The aims of the present study were therefore to assess possible state markers of mental toughness (MT) as a dimension of psychological functioning, sleep disturbances (SD), PA among patients at the moment of the diagnose, and to compare these data with those of healthy adolescents and healthy young adults.

Methods A total of 23 patients with recently diagnosed MS (M = 32.31 years), 23 healthy adolescents (M = 17.43 years), and 25 healthy young adults (M = 20.72 years) took part in the study. They completed questionnaires covering socio-demographic data, MT, SD, and PA.

Results Patients with MS reported similar MT traits as adolescents, and an equal amount of moderate PA and SD as young adults. Further, patients reported a lower level of vigorous PA, compared to healthy adolescents and young adults.

Conclusions Compared to healthy adolescents and young adults, patients at the moment of the diagnose of MS reported similar MT traits, SD and moderate PA. The pattern of results suggests that at the moment of the diagnose MS is not predictable by poor MT, poor sleep, and decreased level of moderate PA.

Introduction Nowadays, 30% of the Spanish population suffers from some form of sleep disorder, occupying much of the visits to a psychiatrist. Sleep disorders are not a serious condition by itself, but have serious implications in daily life: physical exhaustion, poor performance, daytime sleepiness. Insomnia is a most common sleep disorder, however, hypersomnia must also be considered due to the limitations that it causes.

Objective By the description of case report, we will carry out a review of the syndrome Kleine Levine.

Methods Case report.

Results A case of Kleine–Levin syndrome in a 23-year-old male is described. The episodic disorder was characterized by excessive sleep, voracious appetite, hyper-sexuality, irritability and memory loss. Among its history, he included a psychotic episode in childhood and an episode of behavioral disorder caused by a stressful situation. His partner refers a similar episode of hypersomnia last year that was self-limiting in 15 days and he did not go to the doctor. Patients often act normal between episodes. Remission was spontaneous. Prospects, for organic aetiology, differential diagnosis. However, arises additional tests (analytical, brain CT, EEG. . .) resulted no pathological. Patient fulfilled the criteria for KLS, but due to the rarity of the disorder he was previously diagnosed as psychosis not otherwise specified.

Conclusions This case report aim to highlight that KLS though considered a rare disorder but not uncommon and lack of enough available research data is likely to be responsible for missed or erroneous diagnosis; thus we require more systematic studies regarding etiologies and treatment.

Evaluation of insomnia management in the elderly by general practitioners

M. Turki*, J. Aloulou, N. Halouani, R. Ennaoui, O. Amami
Hedi Chaker University Hospital, Psychiatry “B” Department, Sfax, Tunisia

* Corresponding author.

Introduction Insomnia is the most common sleep disorder in the elderly. Its management must take into account the physiological changes associated with age, a higher frequency of co-morbidities and polypharmacy.

Aim To evaluate the management of insomnia in the elderly patients by general practitioners and to compare it with international recommendations.

Methods We conducted a cross-sectional and descriptive study among general practitioners in Sfax over a period of two months (January and February 2016). We proposed to these doctors to participate in our study by sending to them a questionnaire in their emails, which they fill anonymously.

Results A total of 32 doctors responded to the questionnaire. Among them, 62.5% reported that they often or very often receive elderly consulting for insomnia. Before prescribing hypnotic drugs, 65.6% of practitioners reported that they often advise lifestyle and dietary rules. The most prescribed hypnotic classes were: benzodiazepines (BZD) 59.37%; antihistamines 59.37% and homeopathic treatments 56.25%. In the last prescription, the treatment period exceeded 30 days in 18.75%. As for the prescription of BZD, molecules with long half-life were used in 37.48% of cases, and the dosage was identical to adult in 34.4% of cases.

Conclusion The prescription of hypnotic treatment in the elderly meets a logical approach to care, after an accurate diagnosis, taking into account psychiatric and somatic co-morbidities, the precautions and contraindications. In this context, we have identified several shortcomings in the management of insomnia in the elderly in general practice. A multiplication of training on this subject is needed.

A comparison and contrast of cannabis and amphetamine-type stimulant induced psychoses

F. Alharbi
King Abdulaziz Medical City, Mental Health, Riyadh, Saudi Arabia

Background The term “psychosis” is very broad. Substance users represent one group with particularly high rates of psychotic symptoms.

Objective This review will present an update on cannabis and amphetamine-type Stimulant (ATS) and will try to differentiate and compare their associated psychotic features.

Method A systematic literature search was conducted from 1980 to date in the following databases: MEDLINE, PsycINFO and PubMed. Articles were included if they were highlighting substances induced psychoses, with particular emphasis on stimulants/amphetamine/methamphetamine and cannabis/marijuana induced psychoses, schizophrenia-spectrum disorder or schizophrenia.

Results There are many differences between these two substances regarding source, neurobiological processes, average latency periods before developing psychosis, clinical features as compared to schizophrenia, risk of using drugs and developing psychosis and drugs use and development of schizophrenia and urine screening test. With the recent proposals to regulate cannabis use, a further investigation of the association of this use with psychosis is required.

Conclusions Our search elicited many studies of one substance and its association with psychosis but few comparative studies across substances. Yet in our opinion, these comparisons could shed further insight on the development of psychotic features.

* Corresponding author.

Introduction The care to the alcohol and/or other drugs' user focuses on the logic of care for extended clinical and harm reduction, under the focus of the user and his family co-responsibility towards treatment.

Aim This study aimed to understand the concept of self-care developed by drug users.

Methods It is about a descriptive exploratory study with a qualitative approach. It was conducted in a center of psychosocial attention (CPSA), in Recife, Pernambuco, Brazil. The study participants were alcohol and/or other drugs users, over the age of 18 years, both sexes and were in treatment in the mentioned service in morning, afternoon and evening shifts. Data collection occurred in consultation records and individual interviews for the sample characterization, and three operating group sessions, one per shift, guided by the question: "what is self-care for you?" The interviews and sessions were audio-recorded, transcribed and submitted to analysis by ALCESTE software.

Results It was noted that self-care was conceptualized by the drug users from different points of view. For some, self-care is to self-protect, for others it means taking medications. The family, religion and CPSA were identified as a support network for the self-care maintenance. Furthermore, the self-care was related to the desire to recover losses.

Conclusion This study provided the understanding improvement of the self-care concept, supporting the care practice for the interventions planning, targeting the co-responsibility of the alcohol and/or other drugs users.

Regional features of prevalence of cannabinoid dependence in children in Siberia

I. Artemyev^{1,*}, S. Vladimirova²

¹ Mental Health Research Institute, Tomsk National Research Medical Center of RAS, Addictive States Department, Tomsk, Russia

² Mental Health Research Institute, Tomsk National Research Medical Center of RAS, Department of Coordination of Scientific

Investigations, Tomsk, Russia

* Corresponding author.

Aim To distinguish socio-cultural predictors of cannabinoid dependence of child population in Siberia.

Methods Clinical verification of dependence, due to cannabinoid use in the age group "0–14 years" across 22 administrative territories of Siberia and the far east. Review, of statistical materials of regional narcological institutions.

Results Cannabinoid dependency in children has been revealed in 8 of 22 territories—intensive indices per 10,000 of the population of the matched age were in two territories—0.2, one territory—0.4, in two—0.7, and in three—2.1, 3.2, 14.0, respectively. In the related territories, the specific weight of cannabinoid dependence in total structure of substance dependence for population as a whole

(children, adolescents, and adults) was as follows: 0.7%, 0.8%, 2.7%, 3.5%, 27.2%, 67.6% and 76.9%. Therefore, for those territories where ill children are under observation their number per 10,000 of the population is closely associated with structural size of addictions: high level of cannabinoid dependence, formed in the territory, is interrelated with greater number of children, dependent on cannabinoids in this territory. With account for made corrections it should be recognized that "saturation level" of the territories, in particular, with cannabinoids results in higher indices of substance dependence among child population.

Conclusions It should be considered that calculation of intensive indices is conducted for the age group "0–14 years" while diagnosed age range includes children aged 9–14 years, therefore, real indices of dependence, with account for this hypothetical correction, are three times higher as a minimum.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1378

Selincro use in a patient diagnosed with dependence to stimulants, alcohol abuse and hyper-sexuality

A. Ballesteros*, Á.S. Rosero, F. Inchausti, E. Manrique, H. Sáiz, C. Carrión

Red de Salud Mental de Navarra, Psychiatry, Pamplona, Spain

* Corresponding author.

Introduction Hyper-sexuality is an increased sexual activity that causes stress the individual at social levels. There are studies that support the theory that neurophysiological abnormalities of individuals appear in this disorder and do not overlap with the alterations found in substance addictions. However, it is doubtful whether addiction to other substances can trigger behavior in the sexual sphere.

Objective To report a case of abuse of alcohol as a trigger relapse in terms of sexual alterations in a patient diagnosed with alcohol abuse, stimulants dependence and hyper-sexuality.

Case description Here we report a married gentleman in the fourth decade of his life that presents behavior and sexual activity level compatible with a case of hyper-sexuality. After conducting motivational interviews with the psychologist to aim a sustained abstinence of amphetamines and a lack of alterations on the sexual sphere, the patient achieved clinical stability over several years. However, it is referred for psychiatric consultation as he presented recently abusive alcohol consumption associated with Speed. He relapsed in the sexual sphere by increasing sexual desire and impulsiveness. It was decided to prescribe oral nalmefene (1 tablet daily) for two months and then stop treatment regularly (taken PRN in case of high risk situations). As a result, he has had sustained remission for over 6 months.

Conclusion Although, there are studies suggesting that neurobiological changes among the pathologies described are different, the treatment of alcohol abuse can be beneficial in other diseases such as hyper-sexuality as disinhibition associated with alcohol intoxication.

EV1379

Example of alert and reporting system of scopolamine poisoning among Parisian cocaine users at regional, national and European levels

A. Batisse^{1,*}, C. Chevallier¹, J. Azevedo Correia², M. Martinez³, G. Hoizey⁴, M. Chèze⁴, S. Buscaïl², M. Deveaux⁴, S. Djezzar¹, B. Sandrine², D. Samira¹

¹ Groupe hospitalier Lariboisière/Fernand-Widal/Saint-Louis, CEIP, Addictovigilance, Paris, France

² Health regional agency ARS, Île-de-France, direction de la santé publique, Paris, France

³ French Monitoring Centre for Drugs and Drug Addiction OFDT, Unit emerging trends and new drugs, Paris, France

⁴ Laboratoire Toxlab, Paris, France

* Corresponding author.

Introduction In the literature, few intoxications are related to scopolamine due to its presence in cocaine, heroin or even in counterfeit rohypnol tablets. Nonetheless, during summer 2016, several cases of non-fatal intoxication appeared in the region of Paris.

Objectives Demonstrate how clinical detection of rare toxic events are fostered by exchanges in close collaboration with different territorial level.

Aims Improve the detection of short toxic epidemic.

Methods Suspected cases of scopolamine poisoning notified to Parisian Addictovigilance centre were reported. Information shared through different levels of the alert process contributed to strengthen their assessment.

Results Seventeen cases of probable scopolamine poisoning among cocaine users were registered between the 6 and 24 of July. In the first 4 cases, toxicological analysis, of blood samples were scopolamine positive, with high concentration between 7 ng/mL and 25 ng/mL (usual therapeutic range: 0.1 to 1.1 ng/mL). A collected sample of this cocaine powder had a purity of 23.2%, with 15.2% of scopolamine. Half time of scopolamine is longer than half time of cocaine (3–8 hours versus 1–2 hours): this could explain why the observed effects lasted over 24 hours (8/17). Main clinical features were mydriasis (15/17), high blood pressure (12/17), tachycardia (13/17), behavioural disorder with agitation (13/17), hallucinations (5/17), and coma (8/17). Practitioner's responsiveness and the extensive information sharing [MM1] between regional and European level were congruent.

Conclusions Adulterated street drugs can lead to short toxic epidemic which could be unnoticed. Emerging event should require careful assessment with linkage between risk assessors and risk managers.

⁵ Yüzüncü Yıl University, Faculty of Medicine Hospital, Van, Turkey

* Corresponding author.

Objective This study was performed with the aims of determining the perceptions of nursing staff in psychiatric hospitals regarding the causes and treatment of substance addiction as well as their attitudes towards people with substance abuse problems.

Method This study was carried out with 389 nurses working at 5 state psychiatry hospitals in Turkey. In this study, demographic questionnaire, the causes of drug abuse scale (CADAS), drug abuse scale (CUDAS), attitudes scale (AS), and a demographic questionnaire were used. Independent sample *t*-test, variance, correlation, and linear regression analyses were used.

Results In this study, 82.8% of the nurses were female, and the mean age was 33.79 ± 7.58 . We found that the demographic characteristics of the nurses did not affect their perception regarding the causes of addiction and treatment ($P > 0.05$); but it did have an effect upon their attitude towards people with substance use problem ($P < 0.05$). Also, it was established that there was a negative relationship between their perception regarding causes of substance misuse and their attitude towards a person with substance use problem; and a positive relationship between their perception regarding substance misuse treatment and their attitude towards the person with substance use problem ($P < 0.05$).

Conclusion Nursing staff working in psychiatric hospitals in Turkey have the perception that a person takes substances in order to “cope with problems” and for reasons pertaining to his/her “social environment”. Nursing staff tends to indicate a negative attitude towards persons with substance abuse problems, such distancing themselves socially from the patients.

Evaluation of dynamics of neurocognitive indicators and pathological craving in patients with dependence on synthetic cannabinoids during use of microwave resonance therapy

N. Bokhan^{1,*}, A.F. Abolonin², I.I. Belokrylov²

¹ Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Administration, Tomsk, Russia

² Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Addictive States Department, Tomsk, Russia

* Corresponding author.

Background There is no unequivocal estimation of influence of synthetic cannabinoids on health of the users, their influence on neurocognitive functions and their correction with use of microwave resonance therapy (MRT).

Objective To evaluate dynamics of pathological craving and neurocognitive functions in patients with dependence on synthetic cannabinoids during use of MRT.

Materials and methods Thirty-two patients (main group with dependence on synthetic cannabinoids with MRT) and 38 patients (control group with medication and without MRT) were examined. Craving was evaluated with “Drug Craving Scale”; efficiency with CGI. For evaluation of psychophysiological functions we used methods: “number square”, “balance-tranquility”, “verbal memory”, “linear visual estimation”, “exclusion of the word”.

Results and discussion After therapy, stopping of symptoms of pathological craving was observed in the main group as 29.6% as more than in control group, improvement according to CGI as 37.1% as more than in control one. The evaluation of neurocognitive indicators was conducted. Attention: in the main group improved by

11 ± 1.3 points; in control one by 7 ± 3.1 points. Level of activation: in the main group decreased by 16 ± 2.9 points; in control one by 9 ± 3.5 points. Memory in the main group improved by 3 ± 0.21; in control one by 2 ± 0.3 points. Perception: in the main group improved by 1.5 ± 0.2; in control one by 0.8 ± 0.12 points. Thought: in the main group improved by 14.0 ± 1.6; in control one by 6.4 ± 1.1 points. Thus, it was shown that during use of MRT both perception and processing of information, improve in complicated conditions, reduction of pathological craving accelerates.

² Psychiatric Clinics of the University of Basel, Center for Affective, Stress and Sleep Disorders, Basel, Switzerland

³ Psychiatric University Hospital, Center for Affective, Stress and Sleep Disorders, Basel, Switzerland

* Corresponding author.

Introduction Amphetamine abuse has become a serious health concern worldwide, and this holds also true for Iran.

Aims Investigating psychological and socio-demographic dimensions to predict amphetamine-abuse.

Methods Hundred amphetamine abusers and 100 healthy controls took part in this cross-sectional study. Participants completed questionnaires covering socio-demographic and psychological dimensions.

Results Compared to healthy controls, amphetamine abusers reported more insecure and ambivalent attachment styles, higher novelty-seeking and risky behaviour, less current social support and stable relationships, and lower emotional competencies. No differences were found for socio-demographic dimensions.

Conclusions Results from this cross-sectional study underscore that amphetamine abuse was related to poor social relationships, poor emotional competencies and higher risky behaviour. The cross-sectional nature of the study, however, does preclude any conclusions about the causal direction of amphetamine abuse and poor interactional behavior.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Treatment of alcoholism – New targets?

L. Carvalhão Gil^{1,*}, M. Lázaro², A. Ponte¹, J. Teixeira¹, H. Prata Ribeiro¹, T. Mota¹

¹ Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisboa, Portugal

² Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal

* Corresponding author.

Introduction Alcohol use disorders (AUD) is a preventable cause of significant morbidity and mortality worldwide. AUD is a heterogeneous disorder stemming from a complex interaction of neurobiological, genetic, and environmental factors. To achieve

treatment effectiveness this heterogeneity should be considered, as well as safety.

Objectives Review mechanisms underlying alcohol addiction in order to work out new, more effective treatment strategies.

Aim To update on treatment for alcoholism.

Methods A literature search was performed on PubMed database.

Results Alcohol dependence is a chronic, relapsing condition in which there is evidence of significant change in the motivation and control systems in the brain. Increasingly drug therapy is focused not just on the treatment of the acute withdrawal syndrome, but on modifying these other dysregulated brain systems. Of the numerous neurotransmitter systems that have been identified for the development of new medicines, the most promising compounds appear to be those that modulate the function of opioids, glutamate with or without gamma-aminobutyric acid, and serotonin. Other putative therapeutic medications including direct modulators of dopamine function and enzyme inhibitors also shall be discussed. At present, only four medications are approved for the treatment of alcohol dependence in Europe, that is naltrexone, acamprosate, disulfiram and the most recent nalmefene. Among other promising strategies the following drugs are mentioned: baclofen, topiramate, ondansetron, aripiprazole, rimonabant and varenicline.

Conclusions Pharmacological development remains a high priority in the alcoholism field. Drugs have different safety profiles that need to be balanced with the treatment objective, individual patient preferences and comorbid conditions.

Disclosure of interest The authors have not supplied their declaration of competing interest.

² Federal University of Paraíba UFPB, Center for Studies in Public Health, João Pessoa, Brazil

³ Federal University of Paraíba UFPB, Nursing, Recife, Brazil

* Corresponding author.

Introduction Among the psychosocial care network services and devices, highlights the Center of Psycho-Social Attention (CPSAad) aimed at building a comprehensive, regionalized care, based on the extended clinic and from Singular Therapeutic Project (STP).

Aims Report a successful experience of building a Singular Therapeutic Project in Center of Psycho-Social Attention.

Methods This is a descriptive/reflective study type experience report, held in CPSAad from experiences of Mental Health's Multidisciplinary Residency members linked to the Center for Studies in Public Health, João Pessoa, Paraíba, Brazil.

Results It was noted that the STP assists practitioners in the planning of interventions from the needs highlighted by the user and it promotes the knowledge exchange and the co-responsibility of those involved in the care. Therefore, was built a STP of a homeless alcoholic user who initially attended the service as its basic needs refuge (food, hygiene and rest) without showing any interest in participating of activities, little interaction with professionals and other users, difficulties in expressing himself, besides often arriving at the service under alcohol influence. The residents planned the STP from the user's admission through the qualified hearing and construction of bonds.

Conclusions The Singular Therapeutic Project operationalization allowed the user to feel cared, attended in his needs and recognized by the staff; favoured its treatment co-responsibility, leading him to participate in the proposed activities, medical appointments and

examinations, and consequently the improvement of his interpersonal relationships.

Ethylone: A synthetic cathinone emerging in Barcelona

M. de Dios^{1,*}, E. Monteagudo¹, A. Trabsa¹, M. Grifell¹, L. Galindo², P. Quintana³, A. Palma², M. Ventura⁴, D. Sanagustin², S. Pérez¹, M. Torrens¹

¹ Institut de Neuropsiquiatria i Addiccions, Psychiatry, Barcelona, Spain

² Institut de Neuropsiquiatria i Addiccions, Psiquiatria, Barcelona, Spain

³ Energy Control, Asociación Bienestar y Desarrollo, Psiquiatria, Barcelona, Spain

⁴ Energy Control, Asociación Bienestar y Desarrollo, Energy Control, Asociación Bienestar y Desarrollo, Barcelona, Spain

* Corresponding author.

Introduction Synthetic cathinones, the active component in “bath salts”, have surfaced as a popular alternative to other illicit drugs of abuse, such as cocaine, MDMA (ecstasy), and methamphetamine, due to their potent psychostimulant and empathogenic effects.

Objectives To describe the presence of Ethylone in samples delivered to energy control from 2014 to 2015 in Spain.

Methods The total number of samples analyzed from 2014 to 2015 was 8324. Only those samples containing ethylone were studied. They were analyzed by energy control, a Spanish harm reduction NGO that offers the possibility of analysing the substances that users report. Analysis was done by gas chromatography-mass spectrometry.

Results From June 2014 to December 2015, 8324 samples were delivered to EC. From this samples 28 (0.336%) contained ethylone. Twelve (0.144%) were delivered as MDMA, representing a 0.783% of the samples delivered as such, and only one sample (0.012%) delivered as MDMA presented ethylene as an adulterant along with MDMA. Other 6 samples (0.072%) were delivered as ethylone and 10 samples (0.120%) were delivered as unknown pills.

Discussion Ethylone consumption is found to be an emerging issue according to the results of our samples, an increase of such is found during 2015. This might be traduced as an increase of ethylone in the drug market, but a sample selection bias should be considered as samples were voluntary delivered by consumers. An alarming phenomenon is that in some occasions ethylone is sold as MDMA, but effects take longer to occur and last longer, which may lead to an overdose if used as MDMA.

Psychometric evaluation of the Slovenian translation of the Circumstances, Motivation and Readiness Scales

M. Delic^{1,*}, K. Kajdiz¹, P. Pregelj²

¹ University Psychiatric Hospital Ljubljana, Center for Treatment of Drug Addiction, Ljubljana, Slovenia

² University of Ljubljana, Faculty of Medicine, Department of Psychiatry, Ljubljana, Slovenia

* Corresponding author.

Introduction According to the available data, treatment motivation and readiness are closely linked to retention. There are

instruments for measuring the stages of motivation and readiness, and predicting treatment retention and outcome.

Aim This study describes psychometric properties, while focusing on the reliability of the Slovenian version of the Circumstances, Motivation and Readiness (CMR) scales.

Methods We included 109 male and female patients with opioid addiction at the Centre for Treatment of Drug Addiction, Ljubljana. The CMR was translated into Slovenian by using the “forward-backward” procedure by our team and its author. Data analysis addressed psychometric properties of the CMR. Internal consistency was examined by applying exploratory and confirmatory factor analysis, while reliability was examined with Cronbach's coefficient alpha.

Results Cronbach alpha coefficients of reliability were calculated for each of the three CMR subscales and for the total score. The total alpha was 0.842. Alpha for Motivation was 0.860, for Circumstances 0.372 and for Readiness 0.818. Exploratory factor analysis extracted a 3-factor solution with 56% explained total variance. The factors do not provide an exact match with the dimensions C, M and R.

Conclusion On the basis of these results we can conclude that the Slovenian translation of the CMR is a valid instrument for evaluating patients' motivation and readiness for treatment.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Czech gamblers view on luck as the cause of uncontrollable events

T. Dlhosova^{1,*}, R. Kundt²

¹ Masaryk University, Department of Psychology, Brno, Czech Republic

² Masaryk University, Department for the Study of Religion, Brno, Czech Republic

* Corresponding author.

The belief in deterministic luck is considered to be one of the factors contributing to maintenance of gambling behavior. This belief was found to be stronger during the gamble situation in problematic gamblers than non-problematic. The present study deals with the difference in luck attribution between the Czech gamblers and the control group. The main goal was to find out whether the difference between belief in luck is also present in non-gamble situation. A questionnaire containing the Belief in luck and luckiness scale and 14 stories of uncontrollable events was administered to 30 pathological gamblers and 30 matched participant (by age, education, gender and nationality), who did not play any hazard games regularly. In uncontrollable events participants chose from non-material causes (luck, chance, god, destiny) one they believed to be the best fit. Results have shown a statistically significant difference between gamblers and control group in the way of attributing the causes. Control group has chosen significantly more “chance” option meanwhile gamblers opted for luck, God and destiny. There was no statistically significant difference in explicitly formulated belief in luck. It seems that the stronger casual attribution of luck, god and destiny in pathological gamblers compared to non-gamblers are not restricted only to gaming situations. Rather we can find it in other uncontrollable events as well. The absence of the difference between patients and control group in explicit belief in luck measured by questionnaire could be pointing to the stronger effect of the treatment for explicit belief than for more subtle causal attributing.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Efficacy of rational emotive therapy among substance users

T. Dutta

Department of Psychology, Asutosh College, University of Calcutta, Psychology, Kolkata, India

Introduction Rational emotive behavior therapy refers to a realistic time bound therapeutic approach, starting with activated concern model of emotional disturbance and change.

Objective To set short-term goal and long-term goal for substance users by rational emotive behavior therapy.

Aims The present study aims at ameliorating emotional disturbance among addicts.

Methods A purposive sampling method was adopted. Therapy was administered on 50 substance users admitted in recovery hospital running by pioneer organization Human Development and Research Institute. Each day morning meeting was organized consisting of creed, narration from day by day; personal and interpersonal pull up, acknowledgement, newspaper reading, recreational activities, and serenity prayer. Quantitative and qualitative analysis was recorded.

Results Inferential statistics have shown that statistically significant differences were found among them those who have undergone counselling processes. They have found a proper orientation and significant qualities of life. Such therapy enabled them to find sobriety.

Conclusion In conclusion, it could be stated that Rational Emotive Behaviour therapy was found to be effective among substance users. We can utter with Walen et al. that rational emotive behaviour therapy is 'not merely working to dispel misery, but actively promoting happiness'.

Reasoning, critical thinking and attitudes toward substance abuse in adolescence: Explaining the mediator role of emotional intelligence

H. Rezaei^{1,*}, A. Shafiabady², Y. Ghaedi³, A. Delavar¹, M. Esmaeili¹, L. Fattah Moghaddam⁴

¹ Allameh Tabatabaeei University Tehran, Counselling Department, Tehran, Iran

² Allameh Tabatabaeei University Tehran, Psychology and Education Sciences, Tehran, Iran

³ Tehran Kharazmi University, Educational Philosophy Department, Tehran, Iran

⁴ Tehran Medical Sciences Branch, Islamic Azad University, Department of Psychiatric Nursing, Tehran, Iran

* Corresponding author.

Introduction Adolescence is frequently described as a golden time for prevention of substance abuse.

Aims This study is aimed at determining the fit of structural equation modeling for change of attitude toward substance abuse based on the components of emotional intelligence (intrapersonal awareness, interpersonal awareness, adaptation, stress management, and general mood) and reasoning, critical thinking in female adolescents.

Objectives and methods The data were collected in random multistage sampling from 800 senior high school students at 4 different regions of Tehran by using the Bar-on Emotional Intelligence Inventory, the adolescent-special revised inventory, Ricketts Critical Thinking Questionnaire, New Jersey Test of Reasoning Skills and Nazari's Questionnaire for Attitude toward Substance Abuse. In the 618 valid questionnaires were statistically analyzed.

Results Path analysis and path coefficients in the structural equation model suggested that the strongest relation belongs to the reasoning skill, directly predicting attitude with a 61% level and also, has indirect, significant impacts on attitude through intrapersonal awareness, adaptation and stress management. The weakest relation belongs to general mood which, with a 21% level, predicts attitude toward substance abuse. Results of the fit indices in the final model also indicate that all indices are at a desirable level and the model has good fit to the data, implying that there is a linear relation between independent variables and between the moderating variables and a dependent variable.

Conclusions It is reasonable to show the importance of attitude toward substance abuse in prevention programs for students.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1390

Efficacy of vortioxetine for patients with dual pathology

L. Fernández Mayo*, E. Barbero García, D. Baño Rodrigo, M. Agujetas Rodríguez, A. García Sanchez, V. De Antonio Pérez
CAID Majadahonda, Drug Addiction Attention Center, Majadahonda, Madrid, Spain

* Corresponding author.

Introduction Patients with dual pathology have worse clinical evolution and worse therapeutic response. Drugs modify the functioning of certain neurocerebral transmission systems, producing cognitive, emotional and behavioral changes. Vortioxetine (Brintellix[®]) is used as a treatment for major depressive disorder (MDD) and it is considered a new multimodal antidepressant. Preclinical data suggest that the effects on numerous serotonin receptors result in regional increases in noradrenaline and dopamine as well as glutamatergic transmission.

Objectives This analysis assessed the efficacy of vortioxetine (Brintellix[®]) in patients with affective disorders and abuse drugs (dual pathology).

Methods Efficacy was assessed with a study of patients who were recruited in a qualitative and observational study. They were treated with vortioxetine (Brintellix[®]). Outcome measures included changes from baseline to endpoint in Hamilton Depression Rating Scale (HDRS). They were also interviewed weekly about craving and substance use. Urine test controls were done to corroborate results.

Results A total of 11 vortioxetine-treated patients improved their depressive and anxiety symptomatology. Seven of them (64%) were males and four of them (36%) were women. Cocaine was the main drug of abuse ($n=9$, 82%). The doses were between 5 and 20 mg/day. After the clinical evaluation and 12 weeks of treatment, they achieved to reduce significantly the drug use and verbalized a decrease in craving. Two patients dropped out of the study.

Conclusions Vortioxetine (Brintellix[®]) was shown as efficacious in reducing depressive and anxiety symptoms in patients with dual pathology.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Alcoholic hallucinosis after chronic alcohol abuse: A case report

J.J. Fernandez Miranda^{1,*}, D.F. Frías Ortiz¹, F.C. Maria Francina², P. Rossi², O.W. Muquebil Ali Al Shaban Rodríguez³

¹ AGC SM-V-SESPA Asturias Mental Health Service, Psychiatry and Mental Health, Gijón, Spain

² Parc de Salud MAR, “Hospital del Mar”, Addiction and Drug Rehab, Barcelona, Spain

³ AGC SM-III-SESPA Asturian Mental Health Service, Psychiatry and Mental Health, Luarca, Spain

* Corresponding author.

Introduction Alcoholic hallucinosis is a rare complication of chronic alcohol abuse and a prevalence of 0.6–0.7% in alcoholics has been reported.

Case report A 54-year-old Indian immigrant in Barcelona was referred for psychiatric evaluation in April 2016 by due of his behavioral alterations. Evaluation revealed that he was apparently asymptomatic when he came to Spain, 18 years ago. He had been consuming alcohol since 1974 and gradually the frequency and quantity increased to 600 mL of rum daily by 1996. He complained of hearing voices of family members, being irritable even when he was alone and in catatonic phases. He was found to be gloomy, reclusive, not sleeping and talking to oneself. He used to have sleep disturbances; irritability and tremors when temporarily stopped alcohol consumption. He presented a clinical abstinence syndrome, with pharmacological resistance to benzodiazepine perfusion: it was necessary to use dexmedetomidine an Alpha2-agonist with sedative and analgesic properties. After 12 days of medical treatment on UCI, he recovered from abstinence syndrome and was transferred to psychiatry ward. Blood analysis showed raised aspartate amino transferase and alanine amino transferase. Computed tomography and magnetic resonance imaging brain revealed bilateral lateral ventricle enlargement with narrowing of lower end of Aqueduct of Sylvius. He was treated with oral paliperidone. The dose was gradually increased to 18 mg/day and he responded quickly. In the follow-up, he was abstinent from alcohol, compliant with treatment and free from all kinds of hallucinations after medication adherence and psychotherapy.

Alexithymia and alcohol use disorders: A critical review

F. Ghali*, F. Fekih Romdhane, M. Mezghanni, M. Zghal, G. Jmii, A. Belkhiria, I. Khemiri, I. Ghazeli, R. Ridha, L. Jouini
Razi Hospital, Psychiatry, Mammouba, Tunisia

* Corresponding author.

Introduction Alexithymia is a multifaceted construct that was first described by Sifneos as difficulty identifying and communicating feelings, differentiating feelings and somatic sensations of emotional arousal, a diminution of fantasy and imagination and an externally oriented cognitive style. Between 45–67% of alcohol dependent individuals have been identified as alexithymic.

Aims and methodology The aim of this study is to review the published research on alexithymia and alcohol use, to present a critical update on the relationship between alexithymia and alcohol use disorders.

Results Research studies have shown high prevalence rates of alexithymia in alcohol dependent populations, yet there is only preliminary evidence to indicate relationships between alexithymia, alcohol consumption and severity of alcohol problems, and limited evidence examining the different dimensions of alexithymia in relation to alcohol dependence. Hence, the notion that alexithymia is a vulnerability factor in the development and maintenance of alcohol use disorders is premature. Despite limited support for a relationship between alexithymia and alcohol dependence, several studies have examined alexithymia in association with other risk factors for alcohol use including attachment, depression, personality disorder traits, emotional and perceptual dependency and suicidal ideation.

Conclusion A number of key issues need to be addressed in examining the veracity of the link between alexithymia and alcohol dependence. Although, alexithymia is often considered a risk factor for the development of alcohol use disorders, there is little evidence to support this notion. Given that alexithymia may have the potential to interfere with treatment outcomes, a better understanding of the role of alexithymia in alcohol use is needed.

EV1393

Addictive behaviors among psychiatric outpatients

L. Ghanmi^{1,*}, K. Zitoun¹, I. Hachaichi¹, S. Hamrouni¹, O. Salem¹, L. Zouari², M. Maalej²

¹ Regional Hospital of Gabes, Psychiatry, Gabes, Tunisia

² University Hospital Hedi Chaker, Psychiatry “C”, Sfax, Tunisia

* Corresponding author.

Introduction Little is known about the epidemiology of smoking and substance use disorders (SUD) among psychiatric outpatients in south of Tunisia.

Objective Examine the prevalence of smoking and SUD among adult psychiatric outpatients at the regional hospital of Gabes.

Method A survey was conducted to assess the extent of alcohol abuse, drug abuse and smoking among adult psychiatric outpatients ($n=115$), with different psychiatric diagnoses (DSM-5), aged over 18 years, following the psychiatric department of the regional hospital of Gabes. Data collection was done through a semi-structured interview with the patient and a family member + review of medical records. SUD was defined as an abuse or dependence to alcohol or drug.

Results Smokers account for 29.6% of the patients. Smoking was significantly higher in male patients (97.1% vs. 43.2%, $P<10^{-3}$). Compared to nonsmokers, smokers patients had significantly more the diagnosis of schizophrenia (64.7% vs. 35.3%, $P=0.004$), a higher level of education (52.9% vs. 32.1%, $P=0.03$), a higher rate of alcohol (14.7% vs. 1.2%, $P=0.008$) and drug use disorders (8.8% vs. 0%, $P=0.02$), and a higher rate of relapses (3.5 vs. 2, $P=0.004$). Alcohol use was noted in 6% of patients and cannabis in 4%. Patients with a SUD had significantly more the diagnosis of schizophrenia (100% vs. 36.2%, $P=0.05$), a higher rate of smoking (100% vs. 27.7%, $P=0.02$). Financial situation, education, marital status and age of onset of the disease were not associated with SUD.

Conclusion Addictive behaviors are prevalent among psychiatric outpatients. This has implications in treatment and management of these patients.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1394

Impact of hepatitis B (HBV)/C (HCV) virus co-infection on the survival of schizophrenic patients with co-occurring substance use disorders followed for 12 years

Y. Gimelfarb^{1,*}, A. D'r Wolf², M. Ben Tzarfati¹

¹ AMHC, Administration, Bat Yam, Israel

² NZMHC, Community Clinic, NZ, Israel

* Corresponding author.

Introduction There is no evidence on influence of HBV/HCV co-infection on survival characteristics in population with dual disorders.

Objective To determine the impact of HBV/HCV co-infection on the long-term survival of schizophrenic patients with co-occurring substance use disorders.

Methods Charts of 223 subjects admitted from January 1, 2002 to May 31, 2006 were assessed. The Kaplan–Meier survival analysis was used to estimate the cumulative survival rates. The association between HBV/HCV and mortality was estimated using the Cox proportional-hazard regression models, with adjustments for potential confounders. The main outcome was all-cause mortality. Median observation time was 10.3 years.

Results Total all-cause 11 year, unadjusted mortality was 18.0% in population with no viral hepatitis (VH) infection ($n=185$; 83.0%), 66.7% in population with HBV mono-infection ($n=3$; 1.3%), 50.0% in population with HCV mono-infection ($n=28$; 12.6%), and 64.3% in population with HBV/HCV co-infection ($n=7$; 3.1%), $P<0.00001$. In Cox regression, the adjusted hazard ratio was 4.22 (95% CI: 1.00–18.63; $P<0.05$) for the HBV, 4.24 (95% CI: 2.13–8.47; $P<0.00001$) for the HCV, 6.18 (95% CI: 2.01–19.01; $P<0.0015$) for the HBV/HCV, all vs. no VH-infection.

Conclusions The high mortality of schizophrenic dual disorders patients with HBV/HCV necessitates new approaches to secondary and tertiary prevention to reduce the burden of chronic liver disease and to improve survival. The strong adverse effect of HBV/HCV on survival should encourage clinical trials including schizophrenic dual disorders patients on whether patients benefit from treatment choices. It is essential that adequate resources and strategies are targeted to the schizophrenic dual disorders patients with HBV/HCV.

Increased intake of monosaccharides and disaccharides in opioid-addicts

E.J. Gorzelańczyk^{1,*}, A. Szponar², P. Walecki²

¹ Nicolaus Copernicus University, Medical College, Department of Theoretical Biomedical Sciences and Medical Informatics, Bydgoszcz, Poland

² Jagiellonian University Medical College, Faculty of Medicine, Krakow, Poland

* Corresponding author.

Introduction Persons dependent on opioids often characterized by the coexistence of a whole range of dysfunctional behaviors, which may also lead to eating disorders.

Objectives Impulsive and risky behavior, conducive to the formation of polysubstance dependence, including food addiction, which manifests itself in the uncontrollable craving substances, that are quickly metabolized and turned into sugar in the bloodstream.

Aims Aim of the study was to assess the nutritional status and carbohydrates consumption in opioid-dependent individuals treated with methadone substitution therapy.

Methods Fourteen opioid addicts during methadone maintenance treatment were examined. Eighteen healthy individuals matched for age and gender were included to the control group. The 24 hour diet recalls interview was used. After the dietary recall, a special questionnaire was administered to ascertain frequency of refined carbohydrates consumptions during the past 30 days.

Results It was found the nutritional deficiencies in the diet and poor nutritional status in opioid-addicts compared to healthy ones. Opioid-dependent individuals significantly more often snack between meals. It was found increased consumption monosaccharides and disaccharides in foods and beverages in opioid-addicts compared to healthy ones ($P<0.05$).

Conclusions Investigation of dietary behaviors may facilitate understanding of dynamics of addiction, so that we can use more effective methods of treatment.

The cat and the mouse game: Is there a shift towards more dangerous substances in the cathinone illicit market?

M. Grifell^{1,*}, L. Galindo¹, M. Ventura², E. Ribera¹, P. Quintana², A. Palma¹, X. Carbón², L. Gonzalez¹, L. San-Emeterio¹, C. Diez-Aja¹, F. Caudevilla², M. Torrens¹

¹ Parc de Salut Mar, Institut de Neuropsiquiatria i Addiccions, Barcelona, Spain

² ABD, Energy Control, Barcelona, Spain

* Corresponding author.

Introduction After mephedrone's ban in March 2010 new cathinones proliferated widely, even a new branch of atypical derivatives was launched into the market, represented by MDPV. The cardiovascular and central nervous system toxicity draws attention to this new family of cathinones, also known as pyrovalerones. MDPV was scheduled in 2011, leading to the apparition of Alpha-PVP from which there is little information.

Objectives The aim of the present study is to describe the evolution of different cathinones in the samples delivered for analysis to the harm reduction NGO energy control from March 2009 to March 2016 in Spain.

Methods Energy control is a Spanish harm reduction NGO that offers to drug users the possibility of analyzing the substances they intend to consume. From March 2009 to March 2016 a total of 24,528 samples were analyzed by the NGO from which 760 contained cathinones. Substance analysis was done by gas chromatography–mass spectrometry.

Results From 2009 to 2016, cathinones represented a 2.82% from all analyzed samples. From March 2009 to March 2010, only 5 different cathinones were detected, in this same period methylone ($n=16$; 37.20%) and mephedrone ($n=17$; 39.53%) represented 76% of analyzed cathinones ($n=43$). From March 2015 to March 2016, 132 cathinones were detected: methylone and mephedrone represented only 19.69%, giving prominence to clephedrone ($n=25$; 18.93%) and Alpha-PVP ($n=24$; 18.18%).

Conclusions The evolution of synthetic cathinones detected by energy control is consistent with the evolution described in the literature. From 2009 to 2016, the cathinones detected diversify and new substances with higher toxicity potential appear.

Is cloninger type 1 and type 2 alcoholism differ in terms of emotion regulation?

D. Gulec Oyekcin*, A. Gurgun
Canakkale Onsekiz Mart University Medical Faculty, Psychiatry,
Canakkale, Turkey

* Corresponding author.

Introduction Emotional disturbances are a central characteristic of many mental disorders, including alcohol addiction.

Objectives In this study we aimed to investigate the emotion dysregulation among alcohol use disorders and to compare the emotion regulation difficulties with type 1 and type 2 alcoholism.

Methods Thirty-three treatment-seeking AUD individuals were recruited from addiction division of psychiatry department of Çanakkale Onsekiz Mart University. Patients who agreed to participate in the study and completed detoxification treatment were enrolled to the study. After describing the study and obtaining informed consent, participants were assessed with demographic questionnaires (including questions such as age, gender, income status, duration of alcohol use, amount of alcohol use, duration of abstinence were given to participants) followed by the semi-structured interview. Emotion regulation was assessed with the difficulties in emotion regulation scale.

Result Of the patients, 93.9% were male. The average age of participants was 41.21 ± 12.8 years. Of the participants, 60.6% were type 1 and 39.4% of type 2. There was statistically significant difference between type 1 and type 2 alcoholism in terms of emotion regulation. Type 2 alcoholism has more emotional regulation difficulties than type 1 alcoholism. This finding may be consistent with earlier onset of having more impulsive drinking pattern in type 2.

Conclusions In conclusion alcohol use disorders are thought to be associated with emotion dysregulation. Emotion regulation difficulties, was higher in type 2 than type 1. Emotional regulation strategies should be considered in the interventions and may be evaluated as a new prognostic criteria.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1398

Impact of childhood trauma on co-morbidity among alcohol dependent patients: Controlled study

D. Gulec Oyekcin*, A. Gurgun

Canakkale Onsekiz Mart University Medical Faculty, Psychiatry, Canakkale, Turkey

* Corresponding author.

Introduction Childhood trauma has been found to be prevalent in treatment-seeking alcoholics.

Objectives We aimed to investigate the childhood trauma prevalence among alcohol dependent patients and the prevalence of psychiatric co-morbidity.

Methods A total of 61 participants were assessed; 35 treatment-seeking alcohol dependent patients and 26 age-gender matched controls in the addiction division of psychiatry department of Çanakkale Onsekiz Mart University. After describing the study and obtaining informed consent, participants were assessed with demographic questionnaires, followed by the structured clinical interview for the DSM-IV-TR and childhood trauma questionnaire (CTQ-28).

Result The 91.4% of the patients were male, mean age was 42.03 ± 12.9 . The overall prevalence of CTE of the alcohol dependent patients was (88.6%) higher than the control (42.3%) group. Respectively the prevalence of physical neglect was 80%, emotional neglect 74.3%, emotional abuse was 51.4%, physical abuse 40% and sexual abuse 28.6%. For psychiatric disorders 96.8% of the alcohol dependent patients with childhood trauma reported any of the psychiatric disorders, 64.5% ever having a mood disorder with 25.8% ever having any anxiety disorders, and 16.1% ever having attention and hyperactivity disorder. The most common psychiatric co-morbidity was found to be as depression (58.1%).

Conclusions In conclusion alcohol use disorders are thought to be associated with childhood trauma. Patients with alcohol use disorders are exposed to have more childhood trauma. Childhood trauma is associated with psychiatric co-morbidity especially depression. We have to ask for childhood trauma in alcohol dependent patients with psychiatric co-morbidity.

Tobacco cessation failure: Predictive value of BDI score

H. El kefi^{1,*}, Y. Guetary², I. Bouzouita¹, C. Bechikh Brahim¹, W. Krir¹, S. Eddif¹, A. Oumaya¹

¹ Hôpital militaire principal d'instruction de Tunis, Psychiatry, Tunis, Tunisia

² Hôpital militaire principal d'instruction de Tunis, Emergency Unit, Tunis, Tunisia

* Corresponding author.

Background Smoking is a major healthcare issue. Evidence shows considerable comorbidity between nicotine dependence and depressive disorders.

Objectives We are interested in the correlation between Beck's depression inventory (BDI) scores and smoking cessation outcomes.

Methods Retrospective, transversal and analytical study. Data were collected from 95 patients followed in the smoking cessation consultation of The military hospital of Tunis. The BDI was used to assess depressive symptoms and nicotine dependence evaluated by Fagerstrom test for nicotine dependence (FTND).

Results Population was composed of men (92%), married in 65% of cases, with a mean age of 45 ± 13 years. The mean age of smoking initiation was 18 ± 4.5 years. Regular smoking average was 37 ± 20 Packs/Year. The mean cigarette consumption was 30 ± 15 per day. Forty-two percent patients reported at least one attempt to quit smoking, with an average of 37.26 days of abstinence. The mean score of FTND test was 7 ± 2.31 . The BDI score was higher than 3 in 86% of cases. Patients with severe depression (BDI > 15) had never attempted a withdrawal in 71% of cases ($P=0.009$), had a high or very high dependence in 85.7% of cases ($P=0.016$). The average of cigarettes per day was 40 ($P=0.035$) and they had failed withdrawal in 79% of cases ($P=0.53$).

Conclusion There was a fairly consistent association between presence of depression and smoking severity. This suggests that for individuals with nicotine dependence who are interested in quitting smoking, assessment and treatment of depressive symptoms may improve smoking cessation outcomes.

EV1400

Does a state of alcohol hangover impair event based prospective memory?

T. Heffernan

Northumbria University, Psychology, Newcastle upon Tyne, United Kingdom

Introduction The alcohol hangover state (AHS) is characterized by range of symptoms (e.g., drowsiness, fatigue, gastro-intestinal problems, dry mouth, nausea, sweating) that remain after ones blood-alcohol level returns to zero following a recent bout of excessive drinking. Recent findings have revealed a range of cognitive deficits associated with an AHS, including memory deficits. It is less clear what impact the AHS has upon everyday remembering; of which prospective memory is an excellent example (PM: memory for future plans/actions; such as remembering to perform a task at a specific time).

Aims The present study explored whether the AHS impairs everyday PM.

Methods Twenty-one AHS participants were compared with 28 non-AHS controls using a between-groups design. All completed a prospective remembering video procedure (prvp), which measured event-based pm. the prvp required the participant first to memorise a series of specific action-locations combinations and then to recall these combinations whilst viewing a CD clip of a busy shopping high street. Drug use (alcohol, smoking, etc.) and mood (anxiety and depression) were also measured, as these have been shown to have a deleterious impact upon PM.

Results The AHS group recalled significantly fewer event-based PM combinations on the PRVP compared with the non-AHS control group ($P < 0.05$). There were no significant differences between the groups on age, smoking, alcohol use or mood.

Conclusion These results confirm that a state of alcohol hangover impedes everyday prospective memory. The wider implications will be discussed at conference.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

EV1401

Audit of near-fatal overdoses (NFOs) in patients on treatment via substance misuse services (SMS)

U. Javed*, R. Moore, C. McIntosh

Forth Valley Royal Hospital, Psychiatry, Larbert, United Kingdom

* Corresponding author.

Introduction In the NHS Forth Valley (Central Scotland) substance misuse service (SMS), there is an arrangement whereby the details of individuals administered naloxone for overdose via the ambulance service are passed to the SMS. Each patient has an allocated keyworker (nurse). It is accepted that near fatal overdoses (NFOs) are possible precursors to fatal overdose and drug-related deaths.

Objectives To assess:

- if the information is being disseminated appropriately;
- service response and follow-up for individuals;
- patterns which might influence prescribing practice.

Methods A list of NFOs of known patients for the previous two years was acquired from the ambulance service. There was a retrospective review of the SMS prescribing database and clinical casenotes.

Results Patterns:

- 81% male;
- 53% aged < 40;
- 14% of NFO's involved those in titration phase;
- 86% were prescribed methadone. Methadone average dose 57 mg (20–80 mg) and 54% were prescribed > 60 mg/day.

Receipts of information:

- sixty-one percent of keyworkers were notified.

Service response:

- in most cases when the keyworkers was informed, there was prompt action to contact and review patients (0–21 days). However, only 21% had a timely review (within 1 month) by a doctor following NFO.

Conclusion There needs to be an improvement in the dissemination of information between the ambulance service, administrative staff and keyworkers. Most NFO patients were prescribed > 60 mg of methadone. There needs to better identification of “harm-reduction” prescribing whereby methadone doses should be reduced at times of ongoing drug use. Fourteen percent of NFO's involved those in titration phase (twice weekly reviews) which provides an opportunity to screen and intervene for potential NFOs.

Sexual dysfunctions in injectable drug users in Tunisia

J. Jihene*, M. olfa, Z. Haifa

Razi Hospital, the Outpatient Service of the Hospital Razi, Mannouba, Tunisia

* Corresponding author.

Introduction The drug addiction in the buprenorphin with high dosage (BHD) by injectable way, represents a real plague in Tunisia, consequently, we are confronted with diverse complications including the sexual dysfunctions.

Objectives Identify and determine prevalence of the sexual dysfunctions among this population.

Methods It is a transverse, descriptive study. We looked for sexual dysfunctions by using the international index of the erectile function (IIEF 15), among a population of 52 male users of BHD by injectable way.

Results The average score in the IIEF-15 was 36.65 with a standard deviation of 20.87, a negative correlation with duration and the quantity of consumption was noted.

The average erectile function (EF) was 15.63 ± 9.26 , which corresponds to a mild to moderate erectile dysfunction, whereas 31% had a severe dysfunction.

The average score of the orgasmic function (OF) was 6.35 ± 3.52 .

The average score of the sexual desire (SD) was 4.27 ± 2.90 .

The average score of the satisfaction with sexual intercourses (IS) was 5.77 ± 4.54 , an alteration was noted in 96% of the cases, which was correlated with the severity of the consumption.

The average score of the global satisfaction (OS) was altered at 92% of the subjects.

The majority of the subjects brought back the chronology of their disorders in after the consumption of BHD. No patient consulted in sexology.

Conclusion It is thus important to educate stakeholders, on the frequency of sexual dysfunctions and the importance of their screening to improve the management of this problem.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Addictology consultations: Experience of the outpatient department of the Razi hospital

J. Jihene*, M. Olfa, Z. Haifa

Razi Hospital, the Outpatient Service of the Hospital Razi, Mannouba, Tunisia

* Corresponding author.

Introduction The addiction is a social and universal phenomenon. Its coverage is quite recent in Tunisia. It requires a facilitation of the access to healthcare, with broadcasting of the policy of reduction of risks.

Objectives Raise a current situation of the addicting conducts of our patients.

Methods Retrospective descriptive study, concerned the patients having an addiction in psychoactive substances followed in the external consultation of the hospital Razi between November 2014 and September 2016.

Results The average age was 34 ± 10.23 years.

Among the patients, 93.7% was of sex male.

Almost half immigrated in secret in Europe.

Seventy-five percent had criminal record.

The most used product was tobacco followed by alcohol, cannabis, benzodiazepines, Trihexyphenidyl and the opiates.

The buprenorphin is the most consummate opiate in misuse.

Target substances of the request of weaning are respectively: the buprenorphin (58.87%), benzodiazepines (12.63%), the trihexyphenidyl (7.71%), the alcohol (5.61%), the cannabis (5.26%).

A pathological personality was raised in 17.5%.

A psychiatric comorbidity was found to 8% of the patients.

The coverage is made on 3 shutters: biological by the symptomatic treatment of the weaning and the comorbidities, psychological and social by the social and occupational reintegration thanks to non-governmental organizations.

Conclusion Addictology is a stigmatized speciality in Tunisia, by the peculiarity of the patients and the slowness of the results. Nevertheless the number of consultants does not stop increasing where from the interest to create more specialized services and structures of rehabilitation.

Nalmefene against alcohol use disorder: A report of one case

M. Juncal Ruiz^{1,*}, O. Porta Olivares¹, L. Sánchez Blanco¹, R. Landera Rodríguez¹, M. Gómez Revuelta², G. Pardo de Santayana Jenaro¹, R. Martín Gutiérrez¹, E. López García¹, R. Medina Blanco¹, L. García Ayala²

² Hospital Universitario de Álava-Sede Santiago, Psychiatry, Vitoria-Gasteiz, Spain

* Corresponding author.

Introduction Alcohol consumption represents a significant factor for mortality in the world: 6.3% in men and 1.1% in women. Alcohol use disorder is also very common: 5.4% in men and 1.5% in women. Despite its high frequency and the seriousness of this disorder, only 8% of all alcohol-dependents are ever treated. One potentially interesting treatment option is oriented toward reducing alcohol intake.

Aims To describe one case who has improved his alcohol consumption after starting treatment with nalmefene, an opioid receptor antagonist related to naltrexone.

Methods A 35-year-old male with alcohol use disorder since 2001 came to our consult in November 2015. He was in trouble with his family and he had a liver failure. We offer a new treatment option with nalmefene 18 mg to reduce alcohol consumption.

Results Before to start nalmefene he drank 21 drinks/week. Six-month later, he decreased alcohol intake until 5 drinks/week with better family relationship and liver function. After starting nalmefene he complained of nausea, so we recommend to take the middle of the pill for next 7 days. After this time he returned to take one pill with good tolerance and no more side effects or withdrawal syndrome.

Conclusions Nalmefene appears to be effective and safe in reducing heavy drinking and in preventing alcohol withdrawal syndrome due to its opioid receptor antagonism. This case suggests nalmefene is a potential option to help patients, who do not want or cannot get the abstinence, in reducing their alcohol consumption.

The royal road to the obesity: A case report of food addiction

A. Kandeger^{1,*}, H. Bozkurt²

¹ Selcuk University, Department of Psychiatry, Konya, Turkey

² Gaziosmanpasa University, Department of Child and Adolescent Psychiatry, Tokat, Turkey

* Corresponding author.

Increasing prevalence of obesity in the world and increasing role of processed foods in daily life has led to become the focal point of food addiction. In recent years, the animal studies and human brain imaging studies demonstrated the neurobiological and behavioral similarities between drug addiction and food addiction. Here, we aim to present a 13-year-old, female, adolescent who applied with complaints of anger and irritability and shows serious addictive behaviors of chocolate. Our patient with increasing chocolate consumption in the last two years was using atomoxetine 60 mg/day with attention deficit hyperactivity disorder (ADHD). She gradually needs more chocolate to be satisfied. She has complained of nervousness, irritability and serious chocolate-seeking behavior during chocolate deprivation. She gained weight in proportion to the increase in chocolate consumption. Her daily diet was increasingly deteriorated. We used behavioral approach and sertraline in her treatment and were observed that partially benefit from treatment. Combined data from retrospective accounts of adults and prospective observations of youth indicates that juveniles with ADHD are at increased risk for cigarette smoking and substance abuse and behavioral addiction such as Internet addiction, gambling and sex addiction during adolescence. Recognition of the food addiction is important to fight against obesity, strengthening the treatment of choice in the food addiction and take political measures against food addiction are becoming inevitable.

Chronic methiopropamine modifies preference of choice in rat gambling task

H.S. Yoon, W.Y. Kim, M.J. Ku, B.R. Cho, M.J. Kwak, J.H. Kim*
Yonsei University College of Medicine, Physiology, Seoul, Republic of Korea

* Corresponding author.

Introduction and aims Rat gambling task (rGT) is a recently developed animal model making translational research possible in psychiatric disorders related to decision-making deficits. Methiopropamine (MPA) is a structural analog to methamphetamine and a temporary controlled substance. Although increasing concerns have been raised regarding MPA's abuse, few sources of information exist regarding its psychopharmacology. Thus, we investigated whether MPA produces any changes in the choice of preference in rGT.

Methods Rats were trained in a touch screen chamber to learn the relationships between 4 different light signals on the screen and accompanied reward outcomes and punishments set up with different schedules, for one session of 30 min each day. Once animals showed a stabilized pattern of preference, they were given a total of 5 IP injections (a single injection per day, every other day) with saline or MPA followed by 2 weeks of withdrawal. Upon MPA challenge injection, their preference of choice was re-tested in rGT chambers.

Results Depending upon their preference of choice, rats were separated as risk-averse or risk-seeking groups. When they were pre-exposed to and challenged with MPA, rats in the risk-averse group significantly changed their preference toward more disadvantageous choices. These effects were not shown when they were pre-exposed to saline and challenged with MPA.

Conclusions These results indicate that MPA badly influences decision-making behavior as in gambling task, implying that it may aggravate pathological symptoms of bad choices, resulting in

negative consequences, observed in the patients with behavioral addictions.

Identifying the relationship between marital adjustment and, sex roles and burnout rather than dependence features of the patient in wives of the patients with AUD

A. Kokurcan^{1,*}, K. Nazan², İ.Ö. İlhan²

¹ Diskapı Yıldırım Beyazıt Education and Research Hospital, Psychiatry, Ankara, Turkey

² Ankara University, Psychiatry, Ankara, Turkey

* Corresponding author.

Objective To identify the relationship between marital adjustment and, sex roles and burnout rather than dependence features of the patient in wives of the patients with AUD.

Method The study sample consisted of 33 wives of AUD patients (according to DSM-IV-TR criteria) who were applied to a University Hospital Alcohol Dependence Clinic to leave alcohol use. Sociodemographic questionnaire, Marital Adjustment Scale (MAS), Maslach Burnout Inventory (MBI), Bem Sex Role Inventory-Short Form (BSRI) and, Beck Depression Inventory (BDI) were applied to the wives of ADD patients.

Results Mean MAS score was under cut-off score (29.63 ± 10.33) and it shows that marital adjustment is lower in wives of ADD patients. It was shown that marriages longer than ten years, and higher emotional exhaustion scores were associated with lower marital adjustment in our study. Masculinity scores were higher in wives who perceived their income status higher. In contrast to previous studies, which examined marital adjustment, masculinity role was found to be associated with higher marital adjustment in our study.

Discussion Emotional exhaustion and depression are common in spouses of the patients with ADD in our study. There may be a distortion in expected roles of the spouses which cause a disequilibrium on the family relationship. Lower income status, having increased number of children was associated with severe depression in wives which found to reduce marital adjustment scores. Finally, most of the wives of ADD patients will need psychotherapeutic treatments during addiction period. So incorporating spouses into treatment of ADD patients is a necessity to improve marital adjustment and burnout.

Interventions to improve lifestyle and quality of life in patients with concurrent mental illness and substance use

A. Juel¹, C.B. Kristiansen^{2,*}, P. Munk-Jørgensen², P. Hjorth³

¹ Aarhus University Hospital, Department of Affective Disorders, Randers NO, Denmark

² Southern University of Denmark, Department of Psychiatry, Odense, Denmark

³ Psychiatric Hospital Randers, Mental Health Center, Randers, Denmark

* Corresponding author.

Background Patients with co-existence of psychiatric disorders and substance use have an increased risk of premature death. This

is attributable to a higher prevalence of physical comorbidities and the lifestyle related to substance use. Furthermore, they experience low quality of life (QoL). Studies addressing lifestyle interventions for these patients are warranted.

Aims To investigate the physical health and QoL in patients with co-existence of psychiatric disorders and substance use, and to analyse for changes in their (a) health, (b) substance use and (c) QoL after a 24-month health-promotion programme. Further aims were to investigate associations between (a) QoL and number of interventions, (b) QoL and patient characteristics and (c) QoL and length of participation in the intervention.

Methods In this naturalistic cohort study, 64 non-selected patients were engaged in health-promoting interventions added to contemporary treatments. QoL and clinical variables were measured at the beginning of and continuously during the programme by means of the WHOQoL-Bref questionnaire.

Results At enrolment, the patients' intake of cannabis and alcohol was high. During follow-up, patients consumed significantly fewer caffeinated beverages ($P=0.038$) and fast-food meals ($P=0.018$), and slept significantly less ($P=0.032$). The average dose of antipsychotic medication increased significantly ($P=0.015$). QoL was low at enrolment but improved significantly overall ($P=0.009$) and in the psychological ($P=0.020$) and environmental domains ($P=0.012$) at follow-up. The difference in total QoL was positively associated with the number of interventions attended.

Conclusion This programme shows promise in addressing health promotion for these patients and can easily be integrated into contemporary treatments.

Clock genes SNP array identifies a key role of the PER1/HES7 gene in the risk of cannabis addiction and psychiatric comorbidities

G. Lafaye*, A. Benyamina

Hôpital Paul-Brousse, Addictologie, Villejuif, France

* Corresponding author.

The existence of biological rhythms disruption in addicted subjects has been described including disturbances in their sleep-wake pattern, rest-activity rhythms, and feeding schedules. Circadian rhythms have also been related to psychiatric diseases, including mood and anxiety disorders and the regulation of dopaminergic transmission, especially in reward circuitry in substance abusers. The relationship between them remained enigmatic and no data on the role of clock genes variants on cannabis dependence have been documented. We aimed at exploring the role of clock gene genotypes as potential predisposing factor to cannabis addiction, using a high throughput mass spectrometry methodology that enables the large-scale analysis of all the known clinically-relevant polymorphisms of the core human clock genes. We have conducted a case-control study on 177 Caucasians categorizing between cannabis-addicted subjects ($n=83$) and casual cannabis consumers ($n=94$). We report here a strong association between the TT* genotype RS1442849 in *PER1/HES7* gene and a significantly higher risk of vulnerability to be dependent to cannabis. Moreover, this SNP was overrepresented in the subsets of cannabis users with more severe characteristics like personal psychiatric history, unemployed status, and beginning of cannabis use early in lifetime as well as large weekly consumption. *HES7* gene is a newly described gene with a circadian expression regulated by reactive oxygen species in many cell types including neural stem cells. The *HES7* TT* genotype RS1442849 gene could intervene on the dopamine reward systems. This genotype thus represents the first potential biomarker for

stratification of cannabis consumers for the risk to develop a true dependence.

Do not forget alcohol damage – Cognitive impairments related to alcohol

M. Lázaro*, L. Carvalhão Gil, A. Ponte, T. Mota
Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal
* Corresponding author.

Introduction Chronic excessive alcohol consumption may lead to structural and functional damage of the brain. Alcohol-related cognitive impairments are well-established and confirmed by neuropsychological and neuroimaging studies. However, the influence of each neuropathological mechanisms is still under discussion. This topic is increasingly becoming focus of attention in psychiatry.

Objectives Review the neuropathology, clinical features, neuropsychology and management of alcohol-related cognitive impairments.

Aims Evaluate clinical impact, management and prognosis of alcohol-related cognitive impairments.

Methods A literature search was performed on PubMed and Medscape database.

Results According to our literature research, there is a debate concerning the relative contributions of the direct toxic effect of alcohol and the impact of thiamine deficiency on the alcohol-related cognitive impairments. Research about this issue is challenging, considering the multiple patterns of alcohol abuse, the personal and lifestyle factors, and the vulnerability of specific brain regions. The cognitive decline is linked to neuroanatomical alterations and primarily affects executive functions, episodic memory, and visuospatial capacities. These deficits may range from mild to severe but usually remain undiagnosed, unless they are specifically investigated. Maintenance of lasting abstinence is associated with cognitive recovery, but some impairments may persist and interfere with the prognosis.

Conclusion Recognizing and screening for alcohol-related cognitive impairments is crucial to offer significant benefits to patients by optimising management strategies.

⁵ National Center for Mental Health, Department of General Psychiatry, Seoul, Republic of Korea

* Corresponding author.

Introduction The Internet is commonly used in modern society; however, Internet use may become a problematic behaviour. There

is an increasing need for research on problematic Internet use (PIU) and its associated risk factors.

Objectives This study aims to explore the prevalence and health correlates of problematic Internet use among South Korean adults.

Methods We recruited the participants aged between 18 and 84 years old among the online panel of an online research service. The sample size of the survey was 500. Of these 500 participants, 51.4% ($n=257$) were men and 48.6% ($n=243$) were women. A participant was classified as a problematic Internet use (PIU) if his/her total score of Young's Internet Addiction Scale (YIA) was above 50. Stress Response Index (SRI), Fagerstrom test for nicotine dependence, lifetime average caffeine consumption, and sociodemographic query form were used in the collection of data. The t test and chi-square test were used for data analysis.

Results One hundred ninety-seven (39.4%) of the participants was classified into the PIU group. There was no difference of gender and education between PIU and normal users. However, PIU group was younger (mean 39.5 years) than normal users (mean 45.8 years). PIU group was more likely to have high levels of perceived stress, nicotine dependence, and drink more often caffeinated beverages ($P < 0.05$).

Conclusions These data indicate that problematic Internet use is associated with perceived stress level, nicotine and caffeine use in South Korean Internet users. More research is needed to better understand the relationship between Internet use and mental health issues.

⁴ Mental Health Services in the Region of Southern Denmark, Centre for Telepsychiatry, Odense, Denmark

⁵ Odense University Hospital, Centre for Eating Disorders, Odense, Denmark

* Corresponding author.

Introduction Exercise addiction is a condition described by a craving for physical training resulting in excessive exercise behaviour and withdrawal symptoms. It has not been accepted as a mental disorder and further research is needed to examine the pathology of the condition.

Objectives Exercise addiction is suggested to have links to other mental disorders and risks in terms of negative consequences such as injuries. Treatment for exercise addiction faces several challenges as the condition is associated with ambivalence, and studies based on controlled interventions are missing.

Aims The aim of this study was to examine and interpret the existing research on links, risks and challenges faced in treatment interventions.

Methods A literature review was conducted in the databases PubMed, PsycINFO and Scopus with the terms: "exercise addiction, excessive exercise" and/or "comorbidity, eating disorder, depression, anxiety, personality, pain, injury, illness, social isolation, stress, intervention, treatment".

Results Exercise addiction seems to be associated with eating disorder pathology, obsessive-compulsive behaviour and personality

traits characterized by perfectionism, narcissism and neuroticism. Overload injuries (e.g. stress fractures) and impaired interpersonal relations are reported. In a treatment context, low compliance is described as a challenge. Thus, motivational interviewing is recommended, and also cognitive behavioural therapy is suggested for treatment. None of these interventions have yet been scientifically evaluated in addicted exercisers.

Conclusion This review concludes that exercise addiction has links to psychopathology and increases the risk of injuries. More research is needed to estimate the level of psychosocial and physiological distress in these athletes. Controlled treatment interventions have to be conducted.

Introduction The psychoactive substances consumption modifies the users' sense-perception.

Objectives Discuss the therapeutic workshop as a stimulation strategy of the sense organs.

Methodology The activities were developed at a Center of Psycho-Social Attention for alcohol and other drugs – CPSAad, located in north-eastern Brazil. The therapeutic workshop was divided into six sessions; being worked a sense organ in each meeting. Initially, the sessions were explained and they entered the room in silence. At first, vision and lastly, taste. The taste dynamic session was initiated by the pool where users experienced different flavours and made distinctions between them, including a food without flavour, experiencing feelings of pleasure and displeasure. This dynamic was finalized in the institute's kitchen with different ice cream flavours. The participants freely served themselves, being led to reflections on their choices of pleasure. The sixth session was constituted by listening about all Therapy Workshop Experience of the Senses, on which participants reported emotions and feelings experienced during the sessions, such as: fear, anxiety, craving, denial, pleasure and displeasure.

Results It was identified a universe of sensations that can be translated into a sense-perception reframing about themselves and their surroundings.

Conclusion The participants presented a sensory dullness, relating the experienced stimuli to the consumption of psychoactive substances, demonstrating a strong equivalence between the proposed activity and substance dependence. This activity enabled an interdisciplinary approach, through knowledge and interventions exchange.

Prescription opioid abuse, addiction and psychopathology in a pain clinic

A.I. López Lazcano^{*}, L. Ortega, A. Fauli, C. Busquets, A. Lligoña
Hospital Clínic de Barcelona, IDIBAPS, Psychiatry, Barcelona, Spain
* Corresponding author.

Introduction There has been an escalation of therapeutic use and abuse of opioids. Aberrant drug related behaviors (ADRB) have prevalence between 2.8% and 62.2% in chronic pain patients treated with opioids and dependence is estimated around 3.27%.

Objectives To estimate the prevalence of dependence, ADRB, risk of opioid abuse, and co-occurring disorders in patients with chronic pain in our environment.

Methods A total of 115 ($n = 115$) patients attending our pain clinic were screened to evaluate the risk of opioid abuse and presence of dependence including a clinical interview, hamilton depression scale (HAD), opioid risk tool (ORT), diagnostic criteria for substance abuse and dependence (DSM IV-TR) and a checklist of ADRB.

Results Among the patients, 78.26% were taking opioids, aberrant opioid related behaviors were detected in 20% and 8.9% met criteria for abuse or dependence; 11.3% had high risk and 20% moderate risk of opioid abuse (ORT). The most prevalent substance use disorders were sedative (11.3%) and alcohol (5.2%). There was a significant difference in means ($t = -3.20$ $P < 0.005$) in ORT scores between patients with current opioid dependence ($x = 7.70$ [$s.d. = 3.07$]) and without it ($x = 2.88$ [$s.d. = 3.58$]); 30.4% had anxiety, 20% depression and 3.5% adjustment disorders; 57.5% and 48.3% had a score > 10 on anxiety and depression respectively on the HAD.

Conclusions A systematic screening of risk of opioid abuse and of dependence as well as psychotherapy to treat comorbid psychopathology should be part of the treatment protocol.

Cannabinoid hyperemesis syndrome: A Parisian case series

M. Marillier^{1,*}, A. Batisse¹, C. Chevallier¹, L. Laviale², S. Djezzar¹

¹ Groupe hospitalier Lariboisière–Fernand-Widal, CEIP-Addictovigilance, Paris, France

² Santé publique France, Addictions drogues alcool info service ADALIS, Paris, France

* Corresponding author.

Introduction Currently, cannabis remains the most widely used illicit psychoactive substance in the world. Its main pharmacological properties are known and its use for therapeutic purpose is still expanding. Also, its acute and chronic toxicity become more described, even if some mechanisms of pharmacotoxicology still remain to clarify as the cannabinoid hyperemesis syndrome (CHS). **Objectives** To describe cases of CHS, to highlight the clinical presentation and all the complexity of the medical exploration for making an accurate diagnosis.

Method We present a case series of CHS related to cannabis use and notified to the Parisian addictovigilance center.

Results Eight cases were collected between 2011 and 2016. The users are almost exclusively men (7/8), with a median age of 31 years and some of them present a history of psychiatric disorder. All of them report important daily cannabis consumption (up to 15 joints by day) with duration of consumption averaged at 10 years. All patients present recurrences of clinical signs of the syndrome including vomiting (8/8) and abdominal pains (8/8) leading to repeated hospitalizations. Despite the presence of compulsive taking hot showers notion (7/8), specific sign of the CHS, its diagnosis were made by a physician in 5 cases. Carried out medical

examinations are often complete, invasive, even going to an explorative laparotomy for one patient.

Conclusion The CHS remains not well known. A better understanding of this syndrome will enable better patient care while avoiding costly spending unnecessary investigations.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Drug safety related to agents used for opioid maintenance therapy

M. Gahr^{1,*}, J. Eller¹, C. Hiemke², R.W. Freudenmann¹, B.J. Connemann¹, D. Lang³, C. Schönfeldt-Lecuona¹

¹ University Hospital of Ulm, Psychiatry and Psychotherapy III, Ulm, Germany

² University of Mainz, Psychiatry and Psychotherapy, Mainz, Germany

³ University Hospital of Ulm, Psychosomatic Medicine and Psychotherapy, Ulm, Germany

* Corresponding author.

Introduction There is only little data regarding drug safety related to agents used for opioid maintenance therapy (OMT).

Objectives/aims To study drug safety and the reporting behaviour of adverse drug reactions (ADR) related to OMT.

Methods A cross-sectional questionnaire-based telephone survey among physicians providing outpatient OMT in a federal state of Germany ($n = 176$; response rate = 55.7%) was conducted.

Results Most of the respondents ($n = 97/55.1\%$) reported that they observe ADR related to buprenorphine, [dihydro]codein and [levo]methadone rarely ($n = 38/21.6\%$), very rarely ($n = 39/22.2\%$) or never ($n = 20/11.4\%$). Methadone was reported to be most frequently associated with the occurrence of ADR ($n = 82/46.6\%$), followed by levomethadone ($n = 33/18.8\%$), buprenorphine ($n = 6/3.4\%$), and dihydrocodeine ($n = 3/1.7\%$). Frequently observed ADR related to these agents were gastrointestinal, nervous system and psychiatric disorders, and hyperhidrosis. Methadone and levomethadone (not buprenorphine) were reported to be frequently associated with fatigue, weight gain, and sexual dysfunction. Only buprenorphine was reported to be frequently associated with withdrawal and rebound effects, and drug intolerance. Hundred twenty-nine participants (73.3%) stated that they never report ADR related to OMT, whereas $n = 19$ (10.8%) did so when referring to ADR related to their complete medical practice ($\text{Chi}^2 = 141.070$; $\text{df} = 1$; $P < 0.001$).

Conclusions Our data revealed similar patterns of ADR related to outpatient OMT as those reported in the product information or in pain therapy. Motivation to report ADR related to agents used for OMT may be reduced compared to ADR related to the general medical practice.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Absent substance use disorder and survival of extraordinarily high blood alcohol concentration

M. Gahr*, H. Graf, K. Malejko

University Hospital of Ulm, Psychiatry and Psychotherapy III, Ulm, Germany

* Corresponding author.

Introduction Intoxications with alcohol are very frequent in clinical psychiatry and may lead to death depending on (maximum) blood alcohol concentration (BAC) and accompanying factors as

liver function, tolerance, comedication, etc. Death may occur due to ethanol-induced respiratory depression and/or aspiration of gastric content (due to an impaired gag reflex); thus, securing of the airway and ventilation are occasionally necessary.

Objectives/aims To illustrate the broad range of clinical outcomes of alcohol intoxications and their adequate therapy.

Methods We present the case of a 58-year female patient with depression who demonstrated a very high BAC of 8.68 g/L (representing the highest survived BAC in literature) due to ingestion of large amounts of alcohol with suicidal intent.

Results Intubation and ventilation were lifesaving and the patient did not develop any physical or mental consequential damage. As the patient had not regularly used alcohol or any other psychotropic agent tolerance could be ruled out.

Conclusions This case emphasizes the necessity of rapid securing of the airway in patients with alcohol intoxication and respiratory depression and, furthermore, illustrates the large inter-individual differences regarding ethanol susceptibility.

The neural basis of cognitive control in gambling disorder: A systematic review of fMRI studies

L. Moccia^{1,*}, M. Pettorruso¹, L. De Risio¹, F. De Crescenzo¹, L. Di Nuzzo¹, E. Conte¹, B. Leone¹, V.R. Ferri¹, G. Martinotti², M. Di Nicola¹, L. Janiri¹

¹ University Hospital "A. Gemelli", Catholic University of the Sacred Heart, Psychiatry and Psychology, Rome, Italy

² "G. D'Annunzio" University, Department of Neuroscience and Imaging, Institute of Psychiatry, Chieti, Italy

* Corresponding author.

Introduction Decreased cognitive control over the urge to be involved in gambling activities is a core feature of gambling disorder (GD). Cognitive control can be conceptualized as the sum of high-order cognitive faculties interacting in the achievement of goal-oriented behaviors. As such, cognitive control can be differentiated into several cognitive sub-processes, such as response inhibition, conflict monitoring, decision-making and cognitive flexibility, all of which prove to be pivotal in GD clinical phenomenology.

Objectives Over the past few years, several studies and reviews have indicated a lack of cognitive control in GD through self-report questionnaires and neurocognitive tasks. Conversely, there are only a limited number of neuroimaging studies, which investigate the neural mechanisms underlying diminished cognitive control in GD.

Aims This research aims to systematically review functional magnetic resonance imaging (fMRI) studies that target cognitive control in GD.

Methods A literature search was conducted in order to find appropriate published articles on fMRI studies in GD.

Results Fourteen fMRI studies were included. Depending on which neurocognitive task was employed, the studies were divided into five different sections: conflict monitoring, response inhibition, delay discounting, cognitive flexibility and decision-making.

Conclusions Impaired activity in prefrontal cortex may account for decreased cognitive control in GD, contributing to the progressive loss of control over gambling behaviors. However, the way in which cognitive control interacts with affective and motivational processes in GD is still matter of investigation. Among prefrontal areas, orbitofrontal cortex has been indicated as a possible nexus for sensory integration, value-based decision-making and emotional processing, thus contributing to both motivational and affective aspects of cognitive control.

Introduction Due to the continuous search for new, legal, less expensive, and more powerful highs by drug users, the synthesis of novel cathinone derivatives has become a fruitful industry, leading to a fast emergence of new alternative substances every year. Methylone (3,4-methylenedioxy-N-methylcathinone) is one of the substances that rapidly emerged as the main ingredient of “bath salts”, becoming readily accessible on the Internet. This fact has raised concerns about its potential harmfulness.

Objectives The aim of the present study is to analyze the presence of methylone in samples delivered to energy control from 2014 to 2015 in Spain.

Methods A total of 8324 samples were assessed from June 2014 to May 2015. Only those samples acquired as methylone were studied. They were analyzed by energy control, a Spanish harm reduction NGO that offers the possibility of analyzing the substances that users report. Analysis was done by gas chromatography-mass spectrometry.

Results Ten users reported to have acquired methylone (0.12%). The most used source for acquiring it was the Internet (60%). Other sources included a friend or relative (10%), home-delivered (10%) or undetermined (20%). There was no peak of consume as 50% were acquired in 2014 and 50% in 2015.

Discussion According to the results, the presence of methylone in our samples is extremely low. Therefore, despite the fact that methylone monitorization is ought to be carried out, this substance is not expected to be an emerging issue concerning Public Health and no further clinical research should be done.

Substance use among youth psychiatric outpatients

S. Morais^{1,2,*}, J. Silva Ribeiro¹, P. Oliveira¹, E. Mendes¹, A. Botelho¹, H. Godinho¹, L. Vale¹, A. Bessa¹, P. Renca¹, V. Santos¹, N. Madeira^{1,2}

¹ Coimbra Hospital and University Centre (CHUC), Psychiatry Department, Coimbra, Portugal

² University of Coimbra, Faculty of Medicine, Coimbra, Portugal

* Corresponding author.

Introduction Portuguese young adults (15–34 years old) were more frequent engaged in substance abuse (1.2%) than the general population, according to the Portuguese substance use annual report (2014). Alcohol was the most frequent substance use on youth adults. Cannabis was the most frequent illicit substance used (23.9% of users were considered dependent), with higher prevalence than previously reported. LSD (0.4%) use was also higher among young adults than in previous studies. Cocaine (0.4%), heroine/opiates (0.4%), ecstasy (0.3%), and hallucinogenic mushrooms (1.1%) had their consumption lowered among young adults.

Objectives/aims To characterize a population of young adult psychiatric outpatients, regarding substance use and associated risk.

Methods Socio-demographic characterization of our young adult unit outpatient users between 1st January 2015–31st July 2016. Substance use was assessed with the Portuguese version of Alcohol, Smoking and Substance Involvement Screening Test (ASSIST).

Results A total of 255 outpatients were observed during the timeframe; 58 outpatients were assessed with ASSIST: 44 females (75.9%) and 14 males (24.1%), aged between 16–33 years old (average: 20.95; median: 19.50). For tobacco, 3.5% had high risk, 37.9% moderate risk and 58.6% low risk; 22.4% had moderate risk of alcohol, 13.8% moderate risk of cannabis, and 20.7% moderate risk of tranquilizers. For others substances (cocaine, stimulants, inhalants, hallucinogens, and opiates) the risk was low.

Conclusions In our sample, alcohol and cannabis use had the highest risk, as reported in the National Annual Report; however, we observed a moderate risk for tranquilizers use. In future care planning, youth mental health should address tobacco and alcohol abstinence, and preventive measures regarding anxiolytics should be undertaken, such as banning sale without medical prescription.

EV1421

Comparative examination of the differences between cannabis psychosis and methamphetamine psychosis in a psychological state

A. Oda

National Hospital Organization, Simofusa Psychiatric Center, Psychiatry, Chiba, Japan

Background With the rapid and intensive spread of marijuana abuse among youth, Japanese society is focusing on law enforcement against drug abusers. In 2016, a mass killing allegedly committed by a marijuana abuser was reported in Japan.

Objectives To consider that common recognition of the diverse process and potential risks of cannabis psychosis should be shared among psychiatrists.

Aims Elicit differences between cannabis psychosis and methamphetamine psychosis, and determine whether specific guidelines for treatment of cannabis psychosis are required.

Method Intensive retrospective review of distinctive methamphetamine and cannabis psychosis through case studies in our hospital.

Result Major symptoms of methamphetamine psychosis include auditory hallucination and paranoia, however recovery is achieved soon after undertaking treatment. In cannabis psychosis, distinctive features are megalomania and by a pseud-enlightenment experience of supernatural existence, abusers stick to an unrealistic self-estimate of omnipotent, which leads them to refuse the fading away of this feeling and repeat abuse.

Conclusion Psychological substances have strong suggestibility so abusers' symptoms are easily modified by their mental state. Involvement of syndicate or perception of illegality reflects abusers' drastic symptoms, but after dehospitalisation, recurrences are relatively fewer. Cannabis, however, grows wild and is admitted legally in some countries, so abusers lack awareness of guilt by mistaken perception of omnipotence and unrealistic optimism. Due to addiction and depersonalization, they rather enjoy gaining contact with supernatural power and fall into social withdrawal and are implicated to social problems. Considering the difficulty of rehabilitating and returning abusers to the community, we should not disregard the risks of cannabis abuse.

Amy Winehouse Foundation young persons' substance use survey–pilot findings

G. Ofori-Attah^{1,*}, N. Knights², T. Mazhari²

¹ Camden & Islington NHS Foundation Trust, UCL, Amy Winehouse Foundation, General Adult Psychiatry, London, United Kingdom

² Amy Winehouse Foundation, Substance Misuse, London, United Kingdom

* Corresponding author.

Introduction Government-funded research indicates the prevalence of substance use in this age group is decreasing. However, anecdotal evidence suggests otherwise.

Previous surveys have been limited by:

- difficulty recruiting schools;
- the range of substances included;
- paper surveys.

Objectives To determine whether a secure online survey method improves substance use prevalence data collection in school age adolescents.

Method An online survey was created following literature review, and assessment of the reliability and validity of existing surveys. A comprehensive range of substances were included. A total of 750 students (11–16 yrs) from a mainstream school in Lancashire completed the survey during a supervised classroom session. Focus groups were conducted with students and teachers.

Results No technical problems were encountered and survey data was securely transferred to Excel allowing instant analysis.

Teachers felt the survey would be unproblematic to administer independently and found the inclusion of substances such as legal highs, and energy drinks, especially relevant.

Most students completed the survey within the session and reported a positive experience, although some difficulties understanding wording were mentioned. They felt an online survey improved confidentiality (and therefore honesty) and was easier to fill in. However, there was concern about teachers reading their responses.

Conclusions A secure online survey may be acceptable to both teachers and students, and enables the collection of hundreds of surveys in a short time period. It also improves analysis techniques. Further analysis of whether there is a teacher-versus-researcher supervision effect on the honesty of student responses is required.

EV1423

Population characteristics of methamphetamine shabu users

L. Oviedo Peñuela^{1,*}, M. Torrens^{1,2,3}, F. Fonseca^{1,2,3}, P. Rossi^{1,3}

¹ Institut de Neuropsiquiatria i Addiccions, Hospital del mar, Psychiatry and Addiction Department, Barcelona, Spain

² Universitat Autònoma de Barcelona, Psychiatry Department, Barcelona, Spain

³ IMIM Institute Hospital del Mar d'Investigacions Mèdiques, Psychiatry and Addiction Department, Barcelona, Spain

* Corresponding author.

Introduction Shabu is a crystal methamphetamine whose consumption is common among the community of Philippine immigrants in Spain.

Objectives To describe the sociodemographic, healthcare and clinical characteristics of patients using shabu who have been treated by the psychiatry and addiction department of a tertiary hospital.

Methods We describe the cases of patients treated in the psychiatry and addiction department of the hospital del Mar in Barcelona, Spain with methamphetamine use disorder. We collected sociodemographic variables, monitoring features and psychiatric comorbidity from the review of medical records.

Results Ten cases of patients with severe use disorder of shabu were identified. Eight patients are from the Philippines. Nine are men (90%). At the beginning of the medical follow-up the average age was 30 years (21–41 years). All of them reported being unemployed. Four patients were referred urgently to the hospital from an ambulatory care center, two belonged to a specific program for children and adolescents, two were treated at the emergency department and two were assessed during their admissions in other departments. Regarding clinical characteristics, six had associated psychiatric disorders: two have paranoid schizophrenia, two had induced psychotic episode, one had unspecified psychosis and other had conduct disorder.

Conclusions Shabu is a drug that the Philippine community in Spain consumes in their daily life in a social context. However, consumption of this drug could be linked to the onset of psychotic symptoms. Registration is necessary to standardize the consumption pattern in order to establish a relationship between consumption and the appearance of psychotic and organic symptoms.

Elevated neutrophil lymphocyte ratio in patients with substance use disorders

N. Ozkan*, M.B. Sonmez, P. Tas Durmus, Y. Gorgulu, R. Kose Cinar, M.E. Vardar

Trakya University School of Medicine, Psychiatry, Edirne, Turkey

* Corresponding author.

Introduction Disturbances in inflammatory processes may play a role in the pathophysiology of psychiatric disorders. The neutrophil lymphocyte ratio (NLR) and C-reactive protein (CRP) are indicators of the systemic inflammatory response.

Objectives The current study was prepared based on the assumption that dysregulated immune function and elevated inflammation markers may be seen in substance use disorders.

Aims Our aim was to investigate whether NLR and CRP are higher in patients diagnosed with substance use disorders than in healthy subjects.

Methods The participants in the study included 115 male inpatients diagnosed with alcohol ($n=41$), heroin ($n=46$), or synthetic cannabinoid ($n=28$) dependence according to the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV-TR), and 32 healthy male volunteers. We used NLR and CRP as measures of systemic inflammation. Blood samples were taken on the next morning of admission for detoxification. Addiction severity was assessed using the Addiction Profile Index (API).

Results The difference between the groups with respect to NLR was statistically significant ($P=0.014$). Patients diagnosed with alcohol, heroin or synthetic cannabinoid dependence had similar NLR. Patients with alcohol or synthetic cannabinoid dependence had significantly higher NLR than healthy controls ($P=0.001$ and $P=0.029$, respectively). Patients with heroin dependence trended towards statistically significantly higher NLR compared to healthy controls ($P=0.067$). CRP levels did not differ significantly between

the patient and control groups. NLR and CRP were not significantly correlated with API scores.

Conclusions Our findings suggest that NLR is elevated in patients with substance use disorders in comparison to healthy controls.

EV1425

Retrospective analysis of a novel community opiate detoxification programme within Bristol specialist drug & alcohol service (BSDAS)

L. Paklet*, I. Radu, B. Watson
Avon & Wiltshire Mental Health Partnership NHS Trust, BSDAS,
Bristol, United Kingdom

* Corresponding author.

Introduction Until recently community opiate detoxification strategies have largely been limited to gradual dose reductions in opiate substitute treatment (OST). These detoxes are often lengthy leading to “windows of opportunities” in patients’ motivation to detox being missed. Furthermore, many patients remain on sub-optimal OST doses for long periods of time, during which they are more vulnerable to relapse to illicit opiate use.

Within our community service, we adapted and implemented a novel two-week community opiate detoxification programme using buprenorphine front-loading and lofexidine. We worked in partnership with Bristol drugs project (BDP) to offer an 8-week psychosocial intervention alongside the medically assisted detoxification.

Objectives Assessing the completion rates and clinical safety of this intervention.

Methods Data collection was performed through retrospective review of patients’ case notes over a 9-month period.

Results Seventy-five percent of the patients starting an opiate detox successfully completed the intervention.

Lofexidine improved the mean opiate withdrawal scores by 28% at 45 min after the first dose and this was a sustained effect throughout the detox. Mean systolic blood pressure dropped by 6.2 mmHg at 45 min after the first dose of lofexidine and by 16.5 mmHg two days later however this was asymptomatic in all patients. There was no significant change in the heart rate and no adverse events.

Conclusion Our team innovatively adapted and tailored a cost-effective community opiate detoxification programme using a multi-agency strategy in a climate of limited funding and staff resources. Our data clearly indicates positive outcomes in terms of completion rates and clinical safety.

EV1426

Nalmefene effectiveness in reducing alcohol consumption and prevention of craving: A case report

G. Pardo de Santayana^{1,*}, R. Landera¹, M. Juncal¹, O. Porta¹,
L. Sánchez¹, M. Gómez², N. Nuria²

¹ Hospital Universitario Marqués de Valdecilla, Psychiatry,
Santander, Spain

² Hospital Universitario Alava-Sede Santiago, Psychiatry,
Vitoria-Gasteiz, Spain

* Corresponding author.

Introduction Alcohol use disorder is a pressing problem in our society. However, only a small percentage of patients with alcohol use disorder are ever treated. Nalmefene acts as an antagonist

of mu opioid receptors preventing the pleasurable sensation that often accompanies alcohol consumption, while its modulation of kappa opioid receptors can decrease the dysphoria associated with alcohol withdrawal.

Aim Studying the effect of nalmefene on patients with alcohol use disorder who are trying to reduce their daily alcohol consumption.

Methods This is a descriptive study that pretends to assess the effect of nalmefene 18 mg/day on alcohol intake in a sample of five patients (3 men and 2 women) that came to our psychiatric consultation from March to September 2016. They all had tried in the past to stop or reduce their alcohol consumption but were unable to do so. We initiate follow-up with the patients in psychiatric consultation for the next three months with a monthly frequency.

Results Out of the 5 patients, 4 reported to have reduced their alcohol consumption over the observation time, going from 32 drinks per week to 18 drinks per week on average. The fifth patient abandoned prematurely the treatment due to the appearance of side effects (nausea). No other relevant side effects were detected.

Conclusions Nalmefene appears to be effective and safe reducing abusive alcohol intake and avoiding alcohol withdrawal syndrome. Therefore, nalmefene can be considered a good therapeutic option helping reduce alcohol consumption in patients with alcohol use disorder.

The effectiveness of case management interventions for patients suffering from substance use disorders

L. Penzenstadler^{1,*}, A. Machado¹, Y. Khazaal^{1,2}

¹ Geneva University Hospitals, Addictology, Geneva, Switzerland

² Geneva University, Medicine, Geneva, Switzerland

* Corresponding author.

Introduction Substance use disorder (SUD) is a growing health problem which needs a very complex range of care due to the chronic and relapsing nature of the disorder and the multiple psychosocial problems involved. There are often difficulties in current outpatient programs to deliver and coordinate ongoing care and access to different health care providers. To improve treatment outcomes various case management (CM) models have been developed, at first in other psychiatric domains but also for patients with SUD.

Aims The aim was to assess the effectiveness of CM for patients with SUD using existing studies.

Methods Systematic review of CM interventions for patients with SUD by analyzing randomized controlled studies on this matter found on the electronic database PubMed published between 1996 and 2016.

Results and conclusions Most of the analyzed studies showed improvement on the chosen outcome measures, although, these varied in the different studies. Mainly the treatment adherence improved, but substance use only reduced in a third of the studies. Overall functioning improved in about half of the studies. Further, studies are necessary to determine inclusion criteria for CM treatment for patients suffering from SUD in order to orientate patients most likely to benefit from this approach to the specific CM programs. There are still only few studies on this intervention and SUD. Further, studies are needed to examine the effect of treatment intensity of the CM intervention. Also longitudinal studies are needed to ensure the effectiveness of these treatments.

New designer benzodiazepines use in Barcelona

S. Pérez González*, M. De Dios Felis, E. Monteagudo Gimeno, D. Sanagustín Bosqued, A. Trabsa Biskri, M. Grifell Guàrdia, L. Galindo Guarín, P. Quintana Mathe, M. Torrens Melich
Institut de Neuropsiquiatria i Addiccions, Parc de Salut Mar, Psychiatry, Barcelona, Spain

* Corresponding author.

Introduction New designer benzodiazepines such as phenazepam, etizolam, diclazepam, clonazolam and flubromazolam have appeared in the recreational drug market due to that they provide an attractive alternative to prescription-only benzodiazepines as they are readily available over the Internet.

Objective To describe the presence of new designer benzodiazepines in samples delivered to energy control since 2010 to 2016 in Barcelona.

Methods From 2010 to 2016, 24,551 samples were delivered to energy control. Among this samples 43 (0.175%) were analysed as benzodiazepines. They were analyzed by energy control, a Spanish harm reduction NGO that offers the possibility of analyzing the substances that users report. Analysis was done by gas chromatography-mass spectrometry.

Results From the 43 samples analyzed as benzodiazepines, 1 (2.32%) was delivered in 2010, none in 2011, 2 (4.65%) in 2012, 2 (4.65%) in 2013, 1 (2.32%) in 2014, 15 (34.88%) in 2015 and 21 (48.83%) in 2016.

Discussion The data shows that new designer benzodiazepines use is increasing in Barcelona, especially in the last two years. Abuse an addiction to these drugs may be a new public health problem in Barcelona. Unknown side effects may appear due to lack of information about pharmacokinetic profile of these drugs.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1429

Cognitive status and addiction denial in the early stages of alcohol addiction

P. Ponizovskiy*, A. Gofman

Moscow Research Institute of Psychiatry, Department of mental disorders complicated by substance abuse, Moscow, Russia

* Corresponding author.

Introduction Denial is a common feature of alcohol addiction that is apparent in the early and late stages of the disease. Defensive psychological mechanisms and cognitive failure have been reported as reasons for addiction denial. Effective therapeutic approaches should consider the reasons for anosognosic denial.

Aims and objectives The study investigates the correlations between the degree of denial of alcohol addiction and cognitive status of people in the early stages of alcohol dependence.

Method Subjects were identified using clinical interview the AUDIT questionnaire investigating compulsive drinking, impaired control of drinking, alcohol tolerance, and symptoms of withdrawal.

Results Forty-nine alcoholic patients at early stage of alcohol dependence were identified. At assessment, all had been abstinent for at least 7 days. They reported compulsive drinking, impaired control over it, increased alcohol tolerance, but no withdrawal symptoms followed by relief drinking. The level of denial was defined by summing up the quantitative ratings of awareness of alcohol addiction and its harmful effects. Three groups emerged of non/mild, moderate, and severe levels of addiction denial. Neuropsychological evaluation of verbal memory, logical memory, visual-motor coordination, and motor and mental speed was conducted.

Conclusion The identified cognitive deficiencies in the 3 groups were mild. Correlation between the poorer test performance and higher levels of denial was not significant. In the early stages of alcohol addiction, the anosognosic denial appears to be an unconscious ego defense mechanism leading to rejection of all the addiction-related problems.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Seasonal variation and alcohol consumption: A retrospective observational study

R.A. Colombo, M. Preve*, E. Bolla, R. Traber

Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

* Corresponding author.

Introduction Seasonal and geographic variations in light exposure influence human mood and behavior, including alcohol consumption. In literature alcohol consumption have a clear seasonal rhythm, with specific differences during the year [1]. Seasonal changes in mood and behavior (seasonality) may be closely related to alcoholism [2]. The aim of our study is to evaluate the relationship between alcohol consumption and seasonal variation.

Method One hundred and nine inpatient are assessed with: the SCID-P for axis I diagnosis. Inclusion criteria are: (1) acute alcohol intoxication at the admission. All the socio-demographic characteristics are explained.

Results The peak period of alcohol admission is in the autumn, the lowest period is in spring in April and May. There is any significant difference related to gender. The 76% of the admission are coerced admission. The rates of co-morbidity are: personality disorders (30.3%), affective disorders (22.9%) and psychotic disorders (12.8%).

Discussion and conclusion Some patients with alcoholism have a seasonal pattern to their alcohol misuse. Several lines of evidence suggest that changes in the circadian system are also involved in the development of non-seasonal mood disorders, such as major depression and bipolar disorder. Thus, developmental alcohol exposure produces subtle abnormalities in circadian rhythms that may contribute to the development of seasonal and non-seasonal mood disorders [3]. Further research is warranted to replicate our clinical and qualitative observations and, in general, quantitative studies in large samples followed up over time are needed. Methodological limitations, clinical implications and suggestions for future research directions are considered.

Disclosure of interest The authors have not supplied their declaration of competing interest.

25c-nbome: Case report and literature review

M. Preve*, S. Casigliani, L. Tognola, R. Traber, R.A. Colombo

Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

* Corresponding author.

Introduction Novel psychoactive drugs (NPS) have rapidly increase in the last years in the drug market as a recreational use. A new group of toxic phenethylamine derivates named NBOMe of 2 C

class present have emerged recently, are frequently bought using the internet and have similar effects to other hallucinogenic drugs; however, they may pose larger risks, due to the limited knowledge about them, their relatively low price and availability via the internet [1–3]. The purpose of this report is to review the clinical evidence for the potential of abuse of NBOMe compounds. We propose a case report and literature review.

Method We conducted a systematic review of the literature with the principal database (PubMed, Enbase, PsychInfo) and we present a case report.

Results The effects of 25C-NBOMe is characterized by hallucination, violent agitation, rhabdomyolysis and kidney injury.

Discussion and conclusion Effects from 25C-NBOMe in our case report were similar to previous individual case reports in literature [2,3]. The clinical features were also similar to effects from other analogues in the class (25I-NBOMe, 25B-NBOMe). In our case, violent agitation (signs of serotonergic stimulation), rhabdomyolysis and kidney injury were observed [2,3]. Further research is warranted to replicate our clinical and qualitative observations and, in general, quantitative studies in large samples followed up over time are needed. Methodological limitations, clinical implications and suggestions for future research directions are considered.

Paramethoxymethamphetamine (Mitsubishi turbo) abuse: Case report and literature review

M. Preve*, N.E. Suardi, M. Godio, R. Traber, R.A. Colombo
Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

* Corresponding author.

Introduction Paramethoxymethamphetamine and paramethoxyamphetamine (PMMA and PMA) are two so-called designer amphetamines, which appear from time to time on the illegal narcotics market in many countries. They are frequently sold as ecstasy or amphetamine, often mixed with amphetamine or methamphetamine [1,2]. Paramethoxyamphetamine (PMA) is a hallucinogenic synthetic substituted amphetamine with capable of development of dependence [3]. The purpose of this report is to review the clinical evidence for the potential of abuse of paramethoxyamphetamine. We propose a case report and literature review.

Method We conducted a systematic review of the literature with the principal database (PubMed, Enbase, PsychInfo) and we present a case report.

Results The effects of paramethoxyamphetamine is characterized at the beginning with symptoms like euphoria, derealization, psychomotor activation, feeling in tune with surroundings and in love for friends, who come to visual and auditory illusions and hallucinations, paranoid delusion, and violent agitation.

Discussion and conclusion The use of these recreational drugs is especially common among young people participating in rave parties. Occasionally paramethoxymethamphetamine (PMMA) or paramethoxyamphetamine (PMA) are found in street drugs offered as ecstasy. Further research is warranted to replicate our clinical and qualitative observations and, in general, quantitative studies in large samples followed up over time are needed. Methodological limitations, clinical implications and suggestions for future research directions are considered.

EV1433

Screening for alcohol use disorder, in mentally healthy military personnel

K. Rantis^{1,*}, K. Gougoulas²

¹ 424 Military Hospital, Psychiatric Clinic, Thessaloniki, Greece

² Aristotle University Thessaloniki, 3rd Psychiatric Department, Thessaloniki, Greece

* Corresponding author.

Introduction AUD, with a prevalence of 7.5% in Europe, is a common disorder among general population. Reports show higher incidence in military personnel.

Purpose To detect possible AUD in mentally healthy military personnel, and estimate the need for a more regular screening.

Methods Using the AUDIT questionnaire, we assessed personnel ($n = 248$) visiting our outpatient department, from January to June 2016, diagnosed as having “no major psychopathology”, by gender, age, marital status, rank and education. The results were processed using the SPSS Mann–Whitney-U and Kruskal Wallis tests.

Results We tested $n = 215$ men and $n = 33$ women, most aged over 35, married, $n = 97$ officers and $n = 151$ NCOs (non-commissioned officers), of medium or higher education; 59.7%, scored very low (0–2), $n = 11$ had a borderline score of 6–7, 6 scored > 8, with one scoring 16, all men and NCOs. Women had very low scores (72.7% $P = 0.009$). Older personnel concentrated on lower scores, while the younger (18–24) have higher odds of AUD (12.6% scored 6+). Married personnel scored lower ($P < 0.001$). No significant correlation between AUDIT scores and education ($P = 0.705$), however, lower education personnel seem to concentrate on very low scores (82.6%).

Conclusions Female gender, age, marriage, and rank may have a positive effect on alcohol use. Lower educated personnel possibly drink less due to their more physical duties. The fact that 17 diagnosed as mentally healthy personnel had a score implying borderline to problematic alcohol use, could underline the need for a more regular screening for alcohol use disorder in the armed forces.

EV1434

Alcoholism and alcoholic psychoses in Russia: An analysis of the trends

Y. Razvodovsky

Grodno State Medical University, Pathological Physiology, Grodno, Belarus

Introduction Russia has one of the highest alcoholism (alcohol dependence) and alcoholic psychoses incidence/prevalence rates in Europe, which may be explained by high overall population drinking and prevalence of irregular heavy drinking of vodka. The role of binge drinking in modifying the effect of alcohol on the risk of alcoholic psychoses in Russia has been emphasized in clinical and aggregate-level studies.

Aims The present study aims to examine the phenomenon of dramatic fluctuations in alcoholism and alcoholic psychoses rates in Russia during the late Soviet (1970–1991) to post-Soviet period (1992–2015).

Method To examine the relation between changes in the sales of alcohol and alcoholism/alcoholic psychoses incidence/prevalence rates across the study period a time-series analysis was performed.

Results According to the results, alcohol sales is a statistically significant associated with alcoholic psychoses incidence/prevalence rates, implying that a 1 litre increase in per capita alcohol sales is associated with an increase in the alcoholic psychoses incidence/prevalence rates of 17.6% and 14.0% correspondingly. The association between alcohol sales per capita and alcoholism incidence/prevalence rates was also positive, but statistically not significant.

Conclusion These findings suggest that the alcoholic psychoses incidence/prevalence rates are the reliable indicators of alcohol-related problems at the population level. The outcomes of this study also provide indirect support for the hypothesis that the dramatic fluctuations in the alcoholic psychoses incidence/prevalence rates in Russia during the last decades were related to the availability/affordability of alcohol.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Introduction Substance use disorder is a growing phenomenon among old adults. It is usually significantly undervalued, misidentified, under diagnosed and poorly treated. It has been related to cognitive impairment but there are few studies focused on the elderly.

Aim To evaluate the relationship between drug use and cognitive impairment in old adults.

Methods We conducted a prospective study (basal and 6 month follow up) in 67 patients over 65 years old seeking for treatment for drug misuse (alcohol and prescription drugs, mainly benzodiazepines) in addiction and dual diagnosis unit in Barcelona. A specific protocol was performed to evaluate attention, executive function, working memory, learning capacity, fonetic and visual fluency, decision-making, visual construction and cognitive flexibility (FCT, CPT-II, N-BACK, COWAT FAS, TAP, SDMT, IGT, CVLT, TOL, RFFT, STROOP). Patients were compared with a control group (healthy non drug users) with same characteristics (gender, age range and education status). The protocol consisted in two separated sessions of 90 minutes each one performed by a neuropsychologist.

Results Results obtained suggested that patients under drug misuse had worse scores in fluency, visual construction, memory and attention compared with controls. After 6 month treatment and achieving abstinence patients improve in cognitive skills as verbal learning, short-term memory and free recall of verbal information.

Cognitive impairment profile changes depending on the substance abused (alcohol or benzodiazepines).

Conclusions Drug use can produce deleterious effects in old adults. However, those who achieve abstinence may improve some cognitive functioning as verbal learning, short-term memory and free recall of verbal information.

⁴ Parc Taulí Hospital, Psychiatry Service, Sabadell, Spain

⁵ Vall Hebron University Hospital, Headache Outpatient Unit, Department of Neurology, Barcelona, Spain

* Corresponding author.

Introduction Pain medication misuse is commonly found in patients under headache treatment and may produce co-morbid anxiety and depressive symptomatology. Management of this issue requires a comprehensive and integrative treatment including psychotherapy. Group interventions have been scarcely studied in addictive disorders, those interventions aims to decrease drug misuse and improve related psychiatric symptoms.

Aim To study the efficacy of group interventions base on cognitive-behavior approach in patients with pain medication misuse.

Method Patients with pain medication misuse were included and were evaluated with BDI, STAI, SF36 and HIT scales (basal and at the end of treatment sessions). Patients were recruited from headache outpatient unit. Twelve sessions of one hour were performed with a cognitive-behavior approach (weekly).

Results We present preliminary results about the efficacy of group interventions in patients with pain medication misuse. Descriptive results pre- and post- treatment were analyzed in depressive symptoms (M = 20.14, SD = 12.25; M = 14.67, SD = 19.50) and in areas of quality of life: physical functioning (M = 48.75, SD = 31.13; M = 60.50, SD = 41.68), bodily pain (M = 12, SD = 9.25; M = 42.75, SD = 34.09), general health perceptions (M = 25.75, SD = 16.96; M = 44.25, SD = 22.33), vitality (M = 33.75, SD = 13.82; M = 48, SD = 34.82).

Conclusions Pain medication misuse is commonly found in chronic headache patients, consequently worst outcomes for both pathologies. Group interventions may be useful in management of pain, anxiety and other co-morbidities. Furthermore, it may favor drug use decrease and even abstinence.

Alcohol-related cue-reactivity predicts abstinence duration in individuals with severe alcohol-use disorders

S. Karthik^{1,*}, B. Holla¹, R.D. Bharath², G. Venkatasubramanian¹, V. Benegal¹

¹ National Institute of Mental Health and Neurosciences, Psychiatry, Bangalore, Karnataka, India

² National Institute of Mental Health and Neurosciences, Neuro Imaging and Interventional Radiology, Bangalore, Karnataka, India
* Corresponding author.

Introduction Alcohol use disorder (AUD) is an important global public health problem with complex aetiology and relapsing remitting course. Clinical measures of alcohol dependence severity and alcohol-craving, are largely unreliable in identifying individuals at high-risk for relapse. Functional human neuroimaging methods that employ symptom provocation paradigms have shown promise in identifying critical brain regions with cue-elicited alcohol-craving response.

Objective The present study aimed at examining the utility of fMRI cue-reactivity (CR) in predicting relapse risk.

Methods The study was conducted on inpatients of a tertiary care neuropsychiatric hospital. Thirty-two treatment-seeking right-handed men were recruited for the study after informed consent. Following detoxification and 3-day drug-washout period, they underwent a task-based fMRI while viewing images of alcohol-related and control cues presented to them using a previously validated fMRI paradigm. All patients received anti-craving medications (baclofen: 60–80 mg/d, $n = 16$; naltrexone: 50–100 mg/d, $n = 16$) and were prospectively followed-up till their first alcohol lapse.

Results Random-effect analysis using one-sample test revealed significant CR to alcohol-related cues (relative to implicit baseline) with activation in salience-reward related regions [insula, cingulate, dorsal striatum (DS)], visual-attention regions [occipito-temporal] and deactivation of default-mode regions [posterior cingulate (PCC)] (all significant at $P_{FWE} < 0.05$, whole-brain corrected). Cox-proportional hazard regressions revealed that greater CR in Insula ($\text{Chi}^2 = 10.33$; $P = 0.001$; HR = 3.1; 95% CI = 1.5–6.3) and DS ($\text{Chi}^2 = 10.87$; $P = 0.001$; HR = 2.8; 95% CI = 1.5–5.2) predicts faster subsequent time to first drink after accounting for the role of clinical measures.

Conclusion These findings indicate that CR can serve as potential marker to identify individuals at high-risk for relapse. Further examination of intervention-related CR change may aid in personalizing treatment of AUD.

Modafinil: A smart drug with psychiatric implications

H. Saiz Garcia^{1,*}, L. Montes Reula¹, A. Portilla Fernández¹, V. Pereira Sanchez², N. Olmo Lopez³, E. Mancha Heredero¹, A.S. Rosero Enriquez¹, M.E. Martinez Parreño¹

¹ Complejo Hospitalario Navarra, Psychiatry, Pamplona, Spain

² Clínica Universidad de Navarra, Psychiatry, Pamplona, Spain

³ CSM Salburua, Psychiatry, Vitoria, Spain

* Corresponding author.

Introduction Modafinil is approved to treat excessive somnolence but it is also off-spec used as a treatment for ADHD and as a cognitive enhancer. Research on the effects of modafinil on cognitive function have yielded mixed results. Modafinil interact with dopamine, noradrenaline, serotonin, glutamate, orexin, histamine and GABA levels. The regulation of these neurotransmitters

is widely known to be implicated in most of the neuropsychiatric disorders.

Methodology A review was conducted aiming to clarify the biological mechanisms of action of modafinil; its effects on attention, learning, executive functions and creative thinking; as well as possible neuropsychiatric disorders associated to its intake. The literature search was conducted in PubMed data reviewing articles dating between 2015 and 2016.

Results (1) Empirical evidence for cognitive enhancing effects of one of the most frequently used substances, modafinil, is sparse. Studies suggest that with more protracted and complex testing, more benefits are associated to modafinil use.

(2) Modafinil may be implicated in alterations of reward-related behaviour. Compared to placebo, modafinil leads to an enhanced tendency to make previously rewarded choices compared to the avoidance of previously punished choices. This pattern of altered choice behaviour is probably induced by an increase of the dopamine level and a potential contribution of elevated noradrenaline.

Conclusions Some people share information about this drug in social network. Off-label use of this drug may be implicated in alterations of reward-related behaviour and patients with previous psychiatric disorders should be aware of its possible adverse effects.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Nootropics: Emergents drugs associated with new clinical challenges

H. Saiz Garcia^{1,*}, L. Montes Reula¹, A. Portilla Fernandez¹, V. Pereira Sanchez², N. Olmo Lopez³, E. Mancha Heredero¹, A.S. Rosero Enriquez¹, M.E. Martinez Parreño¹

¹ Complejo Hospitalario Navarra, Psychiatry, Pamplona, Spain

² Clínica Universidad de Navarra, Psychiatry, Pamplona, Spain

³ CSM Salburua, Psychiatry, Vitoria, Spain

* Corresponding author.

Introduction The “nootropic” or simplified as a “smart drug”, is a common term that will tag along with the compound responsible for the enhancement of mental performance. Certain individuals with a history of mental or substance use disorders might be particularly vulnerable to its adverse effects.

Methodology A review was conducted aiming to clarify the mechanisms associated of how these drugs increase mental functions including memory, motivation, concentration, and attention; and which kind of individuals are at risk of developing adverse effects when taking these drugs. The literature search was conducted in PubMed data reviewing articles dating between 2015 and 2016.

Results – Glutaminergic Signalling, Cholinergic System, Amyloid Precursor Protein and Secondary Messenger may be related to the cognitive enhancement achieved by Nootropics. Others, like insulin and angiotensin receptor may involved too.

– Some of them, like Ginkgo biloba, seem to have neuroprotective effects observed in human and animal models, acting as antioxidant and antiapoptotic, also inducing inhibition effects against caspase-3 activation and amyloid-aggregation toward Alzheimer's disease.

– Synthetic nootropics, a lab created compound such as piracetam, especially in people with history of drug abuse, may be associated with psychiatric exacerbations of some patients.

Conclusions Young adults all over Europe, especially university students, are starting to use nootropic drugs to improve their academic results. Some of them seem to have beneficial effects over mental health but others are sometimes related with sudden and unexplained exacerbations in stable psychiatric patients. It is important to early identify symptoms and to treat them properly.

³ Bakirkoy Mental Health and Neurological Diseases Education ve Treatment Hospital, Department of Psychiatry, Istanbul, Turkey

⁴ Kackar State Hospital, Department of Neurology, Rize, Turkey

* Corresponding author.

Smoking is the most important avoidable cause of morbidity and premature mortality in the European Union and other countries. Identification of individual characteristics that predict success in smoking cessation is highly desirable. Psychological determinants of smoking cessation, especially depression and anxiety disorders are associated with a higher prevalence of smoking, a higher rate of nicotine dependence, and elevated withdrawal symptoms. In this study, we aimed to identify the determinants that effect the smoking cessation program success. We scanned 232 patient files, who attended between February 2016–June 2016 in Smoking Cessation Program in a State Hospital. The patients who have applied at least two times to unit were included to study. Phone calls were done 6 months after first admission to check the status of smoking. Then we compared sociodemographic characteristics, nicotine dependence levels and psychological symptoms of patients. Sociodemographic Data Form, Fagerstrom Nicotine Dependence Scale and Symptom Check List-90 were done with every patient. It is important to determine the predictors to quit smoking for smoking cessation program. In many studies, the level of nicotine dependence has been identified as the main predictor of successful smoking cessation. It is known that the psychiatric co-morbidity is related with low success in this program. Determining psychiatric co-morbidity and treating this will be effective for success of smoking cessation.

EV1441

Alexithymia in patients with substance use disorders

R. Sellami, M. Moalla, I. Feki, S. Hentati, J. Masmoudi*, A. Zahaf Hedi Chaker Hospital, Psychiatry A, Sfax, Tunisia

* Corresponding author.

Introduction Alexithymia is considered as a deficit in emotion processing. It includes difficulty to identify and describe feelings as well as discriminate between feelings and physical sensations. Alexithymia may be a risk factor for substance use (SUD).

Objectives The objective of this work is to identify the prevalence and correlates of alexithymia among patients with SUD.

Methods This study concerns 40 subjects who were hospitalized in a rehabilitation center in Sfax. The subjects completed a form investigating sociodemographic and drug use characteristics. Alexithymia was assessed using the Toronto Alexithymia Scale TAS-20 a. The TAS-20 have three factors: difficulty in identifying feelings (F1), difficulty in describing feelings (F2), and externally oriented thinking (F3).

Results The mean age of 30.86 ± 8.07 years. The mean score of alexithymia was 65.39 ± 9.65 (42–83). The scores of its dimensions were 25.3 ± 6.10 for F1, 17.16 ± 3.3 for F2 and 23.16 ± 3.18

for F3. The prevalence of alexithymia was 62.8% among addicts. High alexithymic patients did not differ from low or moderate alexithymic patients in terms of, employment, education or the type of substance. TAS-20 was correlated to socio-economic status ($P=0.002$). No correlation was observed between age and alexithymia (total TAS-20) when measured as a continuous variable ($P=0.802$). High alexithymic patients exhibited a higher preference for poly-substance use compared with no alexithymic patients ($P=0.05$).

Conclusion Findings suggest that alexithymia is frequent in SUD patients. It should be noted in clinical practice that many patients with SUD may have a reduced capacity to identify and describe feelings during detoxification.

An unusual case of 'laughing gas' addiction in Singapore

A. Selvaraj*, K.E. Wong

Institute of Mental Health, National Addictions Management Service, Singapore

* Corresponding author.

Objective Recreational use of nitrous oxide (N₂O) or 'laughing gas' inhalation is a common phenomenon in countries like UK and US where it is associated with music festivals and parties. However, as far as we know, recreational N₂O use in Singapore has hitherto not been reported in the press or scientific journals. We report the first case of N₂O use and addiction in a young Singaporean male who was introduced to it by a friend from a Western country where its use is prevalent.

Methods A 20-year-old Singaporean male with an existing psychiatric diagnosis of major depression, presented with a 3 year history of solitary regular N₂O inhalation that escalated from infrequent low dose use to the current daily high-dose use which he was unable to control. He exhibited symptoms of dependence – including preoccupation, tolerance, withdrawal and difficulty in cutting down. No major adverse medical complications were noted so far.

Results The patient was assessed to have Nitrous Oxide Dependence; and is currently undergoing regular counselling sessions in an attempt to motivate him to cut down or stop his N₂O use.

Conclusion This case is unique for 2 reasons:

– extant literature suggests that only anecdotal evidence exists for psychological dependence of N₂O in Singapore; yet our patient clearly demonstrates psychological dependence;

– this is the first reported case of N₂O use disorder in Singapore; and perhaps ASEAN, with the unusual presentation in a young male whose use is solitary and private.

* Corresponding author.

Introduction Alcohol dependence is a serious problem in Central Europe and the treatment effect depends on level of patient's motivation. The theory of change assumes that therapeutic approaches should be adapted to the motivation stage.

Objectives To examine the state of readiness to change at the beginning and the end of inpatient 6-week and 12-week therapeutic program in Slovakia, Poland, and Czechia.

Aim To compare readiness to change with insight and motivation. To find out, whether patients change during the therapeutic program and how this change leads to advances in treatment.

Methods A total of 380 inpatients were examined using Alcohol Use Disorders Identification Test (AUDIT), the Stages of Change Readiness and Treatment Eagerness Scale (SOCRATES), Readiness to Change Questionnaire (RCQ), and Demographic Questionnaire.

Results Measured by AUDIT, single patients declared higher severity of alcohol dependence than married or divorced patients. A majority of patients were at the stage of action (68.5%) or preparation (26.3%) according to RCQ at the beginning of the treatment. Readiness to change was higher at the end of both programs in terms of taking steps in married patients and in terms of Decreasing of Ambivalence in single patients. The results of the 6-week program appear to be slightly better than 12-week treatment.

Conclusions The intention and motivation to treatment changed during therapy. Marital status may increase the active component for readiness to change, while passive component (decreasing the ambivalence) is observed in single patients. Duration of the program does not seem to be crucial for readiness to change.

Disclosure of interest The authors have not supplied their declaration of competing interest.

The prevalence of psychiatric co-morbidities and relapses in males treated for alcohol dependence syndrome – Prospective study from tertiary de-addiction care unit in Kerala, India

S. Soman*, A. Vr

Mental Health Centre, Psychiatry, Thiruvananthapuram, India

* Corresponding author.

Kerala has high percapita consumption of alcohol among the other Indian states.

Objectives Prevalence of psychiatric co-morbidities in alcohol dependence syndrome and association of severity of alcohol dependence, personality dimensions, motivation and short delay relapses.

Methods A prospective study in 91 male alcoholic patients for 2 months.

Results Two groups not relapsed (NR=48) and Relapsed (R=43) were comparable in age, SADQ severity score, average units of alcohol consumption and years of alcohol use. Average consumption was 17 units/day (500 mL spirits), age of onset before 25 years 87%, mean age 40 and severe alcohol dependence was in 57% of study population. Co-morbid nicotine use was 80.2% and in equal numbers in the relapsers and non-relapsers group.

Conclusions Bipolar disorder was the most prevalent (19.8%) in the study population. About 53.8% had alcohol dependence as the primary diagnosis with no associated psychiatric co-morbidities. Anxiety disorders (12%) and personality disorders (19.7%) were found more in the relapsers group. Anxiety symptoms seemed to be a risk factor for relapsing compared to other co-morbidities in bivariate analysis (Pearson χ^2 5.998, $P=0.014$). Psychoticism among relapsers were high (Pearson χ^2 4.901, P value 0.027, OR: 3.782, 95% CI: 1.103–12.958). Co-morbidities were not statistically significant in multivariate (Pearson χ^2 1.765, $P=0.184$, OR: 1.755, 95% CI: 0.763–4.037). Severity of alcohol dependence in relapsers was not significant (Pearson χ^2 0.650, $P=0.722$). Motivation levels of 62.8% of relapsers were low, 32.6% medium and only 4.7% reported high motivation (Pearson χ^2 11.846, $P=0.003$). Poor motivation proved to be a risk factor for future relapse ($P=0.008$, 95% CI: 1.266–4.648, SE.332).

Anti-craving biofeedback program in clinical course of pathological addictions

I. Sosin^{1,*}, Y. Chuev², A. Volkov², O. Goncharova²

¹ Kharkov Medical Academy of Postgraduate Education, Narcology, Kharkov, Ukraine

² Kharkiv Medical Academy of Postgraduate Education, Narcology, Kharkiv, Ukraine

* Corresponding author.

Introduction Modern clinical narcology searches for anti-craving programs to overcome psychoactive substances (PAS) pathological addiction with bio-adaptive regulation of systems (BARS).

Aims and objectives To develop computer modified biofeedback program integrated with Luscher test.

Method Twenty-two PAS addicts who were undergoing biofeedback modified psycho-training were examined. Computer rheoencephalogram (REG) was used as an external monitoring module.

Results Technologically novel biofeedback computer modification was developed with preceding Luscher computer testing for determination of the individual preference colour and the colour producing individual unpleasant associations in respondents. Consequently, biofeedback program was corrected differentially by changing standard colour templates for those personified on monitor. Cerebral hemodynamics condition transferred to individually designed for a particular respondent colour registers is used as a homeostatic parameter reflecting alcohol craving presence/absence: in case of the disordered REG parameters the signal reflects the respondent's unpleasant (negative) colour, and with no craving the screen is filled with positive, pleasant, favourite colour. During BARS auto-training the respondents' skills to mediate present subjective clinical PAS craving manifestations with unpleasant colour and the experimental auto-training method have been mastered, and those psycho emotional states which displace PAS craving symbolic colour from the screen are selected, and it is substituted with favourite colour (symbol of healthy mode of life motivations).

Conclusions Usage of combined BARS biofeedback improved effectiveness of the training and allowed to objectivize and control the condition of the patient getting reliable visual and digital information about either regress or activation of PAS craving and potential relapse of addictive behaviour.

Clinical diagnostic criteria of modern spice addiction

I. Sosin^{1,*}, Y. Chuev², G. Misko², O. Goncharova²

¹ Kharkov Medical Academy of Postgraduate Education, Narcology, Kharkov, Ukraine

² Kharkiv Medical Academy of Postgraduate Education, Narcology, Kharkiv, Ukraine

* Corresponding author.

Introduction Populations of spice addicts in Ukraine demonstrate distinct tendency for steady spreading, and transitory psychotic episodes, overdosing and fatal cases are being registered in consequence of smoking. “Spice” are synthetic analogues of tetrahydrocannabinol.

Aims and objectives To develop an average personified clinical portrait of spice addict for more specified therapy.

Method Twelve patients who consumed spices systematically for 1–2 years were observed. Methods of examination: clinical psychopathological, psychological testing, clinical laboratory.

Results Main spice addiction diagnostic criteria were: Spice smoking, obsessive and uncontrolled anosognosic desire and craving to test on themselves effects of their action, pathognomonic tolerance increase, specific post-intoxication consequences. After the first smoke inspiration heavy intoxication with euphoria and loss of surrounding real perception, sexual disinhibition and craving to repeat smoking manifested after the first smoke inspiration. Then, spice smoking became subjectively pleasant, caused condition of intoxication with increased mood, fussiness, was accompanied with feeling of hunger, thirst, and hoarse voice. In the patients rather quickly (for 2–3 weeks) twice reduced duration of intoxication state from 40 to 20 minutes, loss of situation and quantitative control over smoking was observed. Clinical specifics of addiction for spices smoking is rather quick (from 5 to 10 trials) formation of psychic equivalent of addiction, extremely intensive and emotionally saturated craving for smoking, quick rise of tolerance with loss of situational and quantitative control over smoking.

Conclusions Definite rules in the development and formation of spice dependence is necessary to be considered while developing programs for therapy and prevention in clinical narcology.

Disclosure of interest The authors have not supplied their declaration of competing interest.

What are sweet dreams made of? Analysis of psychoactive substances into “gummies”: A retrospective descriptive study

A. Trabsa^{1,*}, E. Monteagudo², D.D. Mariona², M. Grifell², L. Galindo², L. González², P. Quintana², Á. Palma², P. Santiago², D. Sanagustin², M. Ventura³, M. Torrens²

¹ Hospital del Mar, Psiquiatria, Barcelona, Spain

² Institut de Neuropsiquiatria i Addiccions, Psiquiatria, Barcelona, Spain

³ Energy Control, Asociación Bienestar y Desarrollo, Psiquiatria, Barcelona, Spain

* Corresponding author.

Introduction Although psychoactive substances has a long history in recreational settings, research on its composition has focused only on tablets, crystal and powder, even though new formulation for new psychoactive substances are readily available for users.

Objectives To describe the presence of psychoactive substances and its characteristics in new formulations which had not previously been found in samples delivered to Energy Control from 2014 to 2015 in Spain.

Methods A total of 8324 samples were analysed from June 2014 to December 2015. Only those samples in gummy formulation were studied ($n=9$). Samples were analyzed by energy control, a Spanish harm-reduction NGO that offers analysis of substances to users. Analysis was done by gas chromatography-mass spectrometry.

Results From 9 samples of psychoactive substances in gummy formulation, the analysis detected that 55.5% contained multiple psychoactive substances: 6 samples contained 25N-NBOMe (66.7%), 1 2C-E (11.1%), 1 2C-D (11.1%). Two allylescaline (20%), 1 cocaine (11.1%), 1 THC (11.1%), 1 cannabinol (11.1%), 1 ketamine (11.1%), 1 caffeine (11.1%), 1 MDMA (11.1%), 1 N-acetyl-MDMA (11.1%), 1 metoxetamine (11.1%), 1 N-acetyl-MDMA), 1 2C-N (11.1%). The only substance found in active dosage was 25N-NBOMe. Six samples (66.67%) did not contain the substance expected by the consumer.

Discussion Incipient presence of gummies as new psychoactive formulation was found. The most prevalent drug was 25N-NBOMe; 66.7% did not contain the substance expected. This may pose a risk for potential harmful effects. All the gummies were known to be drug-carriers when bought. This could represent the presence of new formulations from June 2014 in the Spanish recreational market.

Disclosure of interest The authors have not supplied their declaration of competing interest.

¹ Chang Gung University, School of Nursing, Taoyuan, Taiwan

² Chang Gung Memorial Hospital at Linkou, Department of Hepato-Gastroenterology, Taoyuan, Taiwan

³ Chang Gung Memorial Hospital at Linkou, Department of Traumatology Orthopedics, Taoyuan, Taiwan

⁴ China Medical University Hospital, Department of Internal Medicine, Taichung, Taiwan

⁵ Chang Gung Memorial Hospital at Keelung, Department of Psychiatry, Keelung, Taiwan

* Corresponding author.

Background Excessive alcohol use has been associated with health, social and legal problems. Studies of alcohol-drinking problems have mainly focused on patients with alcohol-drinking problems and few studies have focused on their family members. The purpose of this study was to explore the perceptions of family members of problem-drinker patients about their own hazardous or harmful alcohol-drinking behaviours.

Methods In this qualitative descriptive study, participants were recruited from three hospitals randomly selected from northern and central Taiwan (2:1). Hazardous-drinker patients and their family members were screened using the Chinese version AUDIT. AUDIT scores >8 indicated harmful or hazardous drinkers. Data were collected in individual, audiotaped, in-depth interviews using an interview guide. Verbatim interview transcripts were analysed using ATLAS.ti, version WIN 7.0.

Results The sample of 35 family members with hazardous or harmful drinking behaviours perceived that their own alcohol-drinking behaviours were related to six major patterns: family habits, leisure activities with friends, work pressures, personal taste, a way to forget one's problems and to express happiness.

Conclusions We recommend that programs to prevent harmful or hazardous drinking should emphasize understanding standard amounts of alcohol in alcoholic beverages, recommended amounts of alcohol consumption for males and females, knowledge about the long-term effects of excessive alcohol consumption; offer

strategies to resist social pressure to drink; and build positive strategies for coping with stress.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1449

A comparative research of therapy regimens related to patients with alcohol addiction syndrome for the period 2000–2009 in narcological clinical hospital No. 17 of Moscow

B. Tsygankov*, S. Shamov, M. Zemskov
Moscow State Medical Dental University, Department of Psychiatry, Narcology and Psychotherapy, Moscow, Russia
* Corresponding author.

The incidence rate of alcohol addiction syndrome continues to increase worldwide. In the Russian Federation, there is a priority of the patient's rights for an effective and safe treatment of narcological disease. This is achieved using standardised, reproducible, statutory narcological patients diagnosis and management standards.

Research purpose Identify efficient algorithms for alcohol addiction syndrome treatment in a Narcological Clinical Hospital No. 17 of Moscow (NCH№17), allowed Narcological patients Diagnosis and Management Standards for the period 2000–2009.

Research objectives (1) Identify the key therapeutic treatment algorithms that were used in NCH№17 of Moscow in the period 2000–2009. (2) Compare the effectiveness of therapeutic regimens identified.

Data for study – hospital sheets of patients treated from 2000 to 2009 in NCH№17 of Moscow. Analyzed 520, included in the research: 401 hospital sheets of 118 patients.

Methods (1) Continuous sampling. (2) Statistical, Fisher's exact test, Microsoft Excel software (version 13.1.) and Statistica 5.1.

Results From 2000 to 2009 (1998, 2003 and 2005) have changed three times: legislative framework, focus, narcological patients' treatment regulation (Fig. 1).

Therapeutic algorithm was considered successful if the stage-by-stage approach was complied with. Algorithm inefficiency is designated as "failure of treatment stage-by-stage approach". Disadvantages of therapeutic regimens lead to complications. Polypragmasy influenced the development of complications. From the analyzed 118 hospital sheets (pursuant to Fisher's exact test), 72 patients had polypragmasy, 40% cases – proven cause was delirium, 20% – refusal of treatment (Fig. 2).

Fig. 1 Periods of application of different regimens are outlined: 2000–2002, 2003–2005, 2006–2009.

Failures of stage-by-stage approach in treatment of alcoholic patients

Fig. 2 Surrogate variable of complications is refused treatment.

Methamphetamine-induced choreoathetosis: A case report

M.L. Turk*, J. Smith

University of Virginia Health System, Psychiatry, Charlottesville, USA

* Corresponding author.

We describe the case of a 23-year-old male with a past psychiatric history of Obsessive Compulsive disorder, Generalized Anxiety Disorder, Cannabis Use Disorder, and a reported history of Bipolar II Disorder and ADHD, and no past medical history, who presented to the hospital for a psychiatric evaluation of erratic behavior. Per his family's report, the patient has not been attending to his activities of daily living and has had poor sleep and significant

weight loss for the past month. In the days preceding his presentation, he has experienced worsening irritability and rapid speech, and has been responding to internal stimuli and displaying odd repetitive movements of his extremities. On interview, the patient reported non-compliance to his prescribed Lithium and Paroxetine for the past three months. He also noted recently smoking methamphetamine on a daily basis for the past month and intermittently abusing cannabis, benzodiazepines and cocaine. His urine drug screen was positive for cannabinoids and amphetamines and the rest of his medical workup was within normal limits. On physical exam, he exhibited involuntary writhing and twisting movements of his extremities. An atypical antipsychotic was prescribed, after which his choreoathetotic movements resolved within 24 hours. The purpose of this poster is to highlight the possibility of developing chorea as a result of methamphetamine use, given the rarity of such cases, and to discuss whether the resolution of his neurological symptoms were a result of antipsychotic administration or were simply due to the natural course of methamphetamine discontinuation during hospitalization.

Psychological distress and alcohol use among adolescents

N. Charfi*, M. Turki, N. Smaoui, M. Maalej Bouali, L. Zouari, N. Zouari, J. Ben Thabet, M. Maalej
Hedi Chaker University Hospital, Psychiatry "C" Department, Sfax, Tunisia

* Corresponding author.

Introduction Anxiety and depression, as well as alcohol use are widespread among teenagers, and constitute a huge public health burden worldwide.

Objective To study the link between alcohol consumption and emotional distress (anxiety and depression) among adolescents.

Methods We conducted a cross-sectional study in May and June 2016. The sample consisted of 314 pupils from 4 colleges and schools in Sfax (Tunisia). Alcohol Use Disorders Test (AUDIT) was used to evaluate alcohol dependence. Anxiety and depression levels were evaluated using the "Hospital Anxiety and Depression Scale" (HADS).

Results The mean age was 16 years with a sex ratio of 1.08. Among the participants, 18.9% reported having drunk alcohol at least once and 42.37% of them still consume. The main reasons for alcohol initiation were the search of new experiences (78%) or pleasure and well-being (39%) and the curiosity (49.15%). According to AUDIT, 1.7% of alcohol users presented an alcohol misuse and 20% presented dependence.

The prevalence of anxiety and depression were respectively 56.1% and 23.7%. Anxiety was correlated to alcohol experimentation ($P=0.03$) and non-supportive environment ($P=0.003$). Depression was correlated to alcohol experimentation ($P=0.001$), AUDIT score ($P=0.009$), somatic histories ($P=0.02$), physical abuse ($P=0.02$), non-supportive environment ($P=0.016$) and graduating class level ($P=0.005$).

Conclusion Our study highlights the close association between alcohol consumption and emotional distress in adolescence, which seems to be bi-directional. When attempting to reduce the risk of alcohol consumption, we should focus a particular attention on adolescents studying in graduating class, reinforce adolescents' family support and prevent physical abuse.

Stability of problematic gaming and associations with problematic gambling: A three-year follow-up study of adolescents in the SALVe-cohort

S. Vadlin*, C. Åslund, K.W. Nilsson

Uppsala University, Centre for Clinical Research, Västerås, Sweden

* Corresponding author.

Aim The aims of the present study was to investigate the long-term stability of problematic gaming among adolescents, and whether problematic gaming at wave 1 (W1) were associated with problematic gambling at wave 2 (W2), three years later.

Methods Data from the SALVe-Cohort, including adolescents in Västmanland born in 1997 and 1999, at two waves were analyzed (W1, $n=1868$; 1035 girls, W2, $n=1576$; 914 girls). Adolescents self-rated the Gaming Addiction Identification Test (GAIT), Problematic Gambling Severity Index (PGSI), and gambling frequencies. Stability of gaming using Gamma correlation, and Spearman's rho was performed. General linear model analysis (GLM), and logistic regression analysis were performed, adjusted for sex, age, and ethnicity using PGSI as dependent variable, and GAIT as independent variable, for investigating associations between problematic gaming and problematic gambling.

Results Problematic gaming was stable over time, $\gamma=0.810$, $P\leq 0.001$, and $\rho=0.555$, $P\leq 0.001$. Furthermore, problematic gaming at wave 1 increased the probability of having problematic gambling three years later, GLM $F=3.357$, $\eta^2=0.255$, $P\leq 0.001$, and logistic regression OR=5.078 (95% CI: 1.388–18.575), $P=0.014$. Male sex was associated with higher probability of problematic gambling.

Conclusions The present study highlights the importance of screening for problematic gambling among problematic gamers in order not to overlook possible coexisting gambling problems. The stability of problematic gaming indicates a need for development and evaluation of treatment for problematic gaming and also for coexisting gambling problems.

ASD, SUD and gender

P.J.M. Van Wijngaarden-Cremers

Dimence, Centre for Developmental Disorders, Zwolle, The Netherlands

Introduction Autism and substance use disorder (SUD) is not the co-morbidity that is commonly considered. Yet these conditions have more commonalities than one would suspect.

Objective We will consider the evidence for co-morbidity between ASD and Addiction (Substance Use Disorders (SUD) and explore the influence of gender.

Method A pilot study of 80 admissions to an adult ASD unit will be presented.

Results The co-morbidity ASD and SUD in this study was very high (65% of the inpatients). There were no gender differences in prevalence in total but addiction to medication (32% in woman vs. none in man) and eating disorders (24% in women vs. 9% in man) was far more common in women whereas addiction to drugs (13% in man vs. none in women) was far more common in man.

Conclusions There are clear indications that a possible co-morbidity of substance abuse disorder should be considered in cases of individuals with autism spectrum disorders. There are no gender differences in prevalence of co-morbidity ASD and SUD in

total but addiction to medication and eating disorders seems to be much more common in women whereas addiction to drugs probably more common in man.

EV1454

Central nervous system grey matter decreases in volume in smokers impacting cognitive abilities:

A systematic review

M. Vnukova*, R. Ptacek, J. Raboch, G. Stefano

Department of Psychiatry, First Faculty of Medicine Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic

* Corresponding author.

Background Even though cigarette smoking is a leading cause of preventable mortality, worldwide tobacco is consumed by approximately 22% of population. Smoking is also one of the risk factors for cardiovascular disease and it impacts our brain processing as well as being one of the recognised risk factors for Alzheimer's disease. The tobacco toxins may cause these disorders, e.g., nicotine at high levels, which are inhaled, resulting in preclinical brain changes. Researchers suggest that there are differences in brain volume between smokers and non-smokers. This review examines these differences on the brain grey matter volume (GMV).

Material/methods In March/April 2015: MedLine, Embase and PsycInfo were searched using terms: "grey matter", "voxel based", "smoking" and "cigarette".

Results Studies found brain GMV decreases in smokers compared to non-smokers. Furthermore, gender specific differences were found, while thalamus and cerebellum was affected in both genders decrease in olfactory gyrus was found only in male smokers. Age group differences were also found and these may suggest pre-existing abnormalities that lead to nicotine dependence in younger individuals. Only one study found positive correlation between number of pack-years and GMV.

Conclusion Smoking decreases the volume of grey matter in most brain areas. This decrease may be responsible for the cognitive impairment and difficulties with emotional regulation in smokers compared with non-smokers.

EV1455

Anti-epileptic drugs in opiate addictions

S. Vucetic-Arsic*, S. Alcaz

Special Hospital for Addictions, Intensive Care Unit, Belgrade, Serbia

* Corresponding author.

Introduction Mood dysregulation came to be a hallmark in addiction diseases.

Objectives Antiepileptic drugs (AEDs) are used extensively to treat non-epilepsy disorders, such as mood disorder. Addiction disease may be triggered by bipolar disorder. Contemporary theories of addiction focus on pathophysiological mechanisms that imply a misbalance in the area of motivational behaviour, cognitive control, inhibitory function and decision-making processes.

The aim of the study was to confirm the clinical significance of AEDs use in the treatment of opiate addicts during hospital detoxification and in stabilizing period.

Methods The prospective study comprised 70 medical histories of the patients treated in hospital setting over a period August 2015–2016. The study included patients with diagnosis of an opiate dependence and related mood disorders based on the ICD-10 classification. The rate of opiate withdrawal syndrome was measured by Objective Withdrawal Scale (OWS).

Results Our data uncovered a significant correlation between addiction and bipolar disorders, since 21% of inpatients treatment have co-morbidity. According to a survey, 74% of patients were treated with AEDs during detoxification period and in outpatients setting 1 month later. According to OWS in 65% cases AEDs improved the mood and affect, numbness, sensitivity.

Conclusion AEDs role in opiate withdrawal syndrome was to normalize the affect, applied as an adjuvant therapy and also used during the recovery, in order to correct mood fluctuations. The high rate of co-morbid mental illnesses between addiction and other mental disorders argues for a comprehensive approach to evaluate each disorder concurrently, providing treatment as needed.

EV1456

Socio-demographic, clinical and therapeutic features of patients treated for schizoaffective disorder using cannabis

B. Walid*, I. Marrag, F. Ellouze, M. Nasr

Hospital, Psychiatrie, Mahdia, Tunisia

* Corresponding author.

Introduction Psychotic disorders were formerly associated with cannabis use. It could accelerate the course of the illness and thus, constitutes a severity factor in terms of prognosis.

Objectives To define the socio-demographic, clinical and therapeutic profiles of patients suffering from schizoaffective disorder (ASD) and who are consuming cannabis.

Methods A retrospective study of 16 patients diagnosed with ASD, who were hospitalized at the psychiatric department of Tahar Sfar Mahdia's hospital, and whose toxicology test results during the hospitalization came back positive for tetrahydrocannabinol.

Results Sixteen patients were gathered, all male, the average age was 26 years. The average age of first hospitalization was 25 years, 41.9% were unemployed; 76.3% of our sample were single. Three quarters of patients were hospitalized without consent. The average hospital stay was 30.33 days. Our patients had required during their stay an average dosage of antipsychotic, equivalent to chlorpromazine, of 752.42 ± 342.79 mg. The average scores of psychometric scales were: BPRS = 55.72 ± 14.11 , SAPS = 41.5 ± 14.80 and 42.11 ± 18.88 .

Conclusion Currently, it is recognized that prolonged use of cannabis is an exogenous risk factor. The association between cannabis and schizoaffective disorder may amend the treatment modalities. It requires, thereby, an integrated and simultaneous treatment of schizophrenia and addictive behavior.

The application of the attitudes towards suicide questionnaire (ATTS) in Tunisian elderly

W. Abbès^{1,*}, M. Manel², H. Kaouthar², C. Nada², Z. Nasreddine², Z. Lobna², B.T. Jihen², M. Mohamed²

¹ Hédi Chaker University Hospital, Psychiatry "A", Sfax, Tunisia

² Hedi Chaker University Hospital, Psychiatry "C", Sfax, Tunisia

* Corresponding author.

Introduction According to WHO, suicide is a major public health problem and the most affected age group by suicide in Tunisia is that of over 70 years.

Aims To study the perception of the Tunisian elderly of suicide.

Methods A cross-sectional study was conducted during a 3-month period from October to December 2015. Fifty persons aged at least 65 years participated to the study. We used an anonymous questionnaire with a specific scale: "Attitudes Towards Suicide Questionnaire" (ATTS).

Results The mean age of our patients was 67.5 years. Sex ratio was 1.27. Most of the participants were married (82%), unemployed (63.2%), with a secondary or high educational level (62%), and low income (73.5%). All participants were believers. As for religious practice, 74.5% of the recruited elderly made the fast and 73.5% were prayers. Among women, 70.8% wore the veil. Concerning the perception of suicide, it was on the dimension of "permissiveness" ($M = 1.88$) that our participants agreed less. Those who made prayers had lower scores of "permissiveness" ($P = 0.032$). Women who wore the veil had higher scores on the field of "incomprehensibility" than the unveiled ones ($P = 0.047$). Furthermore, 68% of our participants believed that suicide is stigmatizing.

Conclusions It might be time to try to lift the taboo and stigma through information and sensitizing campaigns on suicide. In this direction, studies of perception help to identify, somehow, "automatic thoughts" regarding representations of suicide and to try to develop an "alternative thinking" in the general population.

EV1458

Algeria, from social issue to self-immolation; autopsy of a "fashionable" suicide

N. Ali Pacha

A. Mira University, Medicine, Bejaia, Algeria

Introduction Self-immolation has been practised for several centuries in some cultures. Tolerated by Mahayana Buddhism and Hinduism. It is practised for many reasons: Sati (rituals), political protests, devotion and renouncement. In addition, it is also observed in some warrior cultures, like Rajputs.

The self-immolation trend began in Tunisia during government protests ("Arab spring" revolution) when a man named Bouazizi set himself on fire and died. Fiery copycat suicides spread throughout other countries. Algeria has also discovered this form of protest and faced a wave of self-immolation considered by some commentators to have reached epidemic proportions.

Objective Our goal is to show the kind of support that political and health authorities, with the help of psychiatrists, are trying to set up in order to achieve efficient prevention.

Methods In a case-control study, 20 consecutive case of deliberate self-inflicted burns admitted to the regional burn centre

(Douera Hospital, Algeria) were compared with 20 controls who were selected from the community and matched by sex, age and living area. Diagnostic and statistical manual of mental disorders (DSM IV) Axis I (clinical disorders) and Axis II (personality and mental retardation) diagnoses were assessed via detailed clinical interview.

Results There have been 69 cases of self-immolation, with an average age of 26 including 87% of men and from which 13% with a psychiatric history. Unemployment and housing crisis are the most common causes. Here, we will provide specific explanations about our country.

Conclusion It turns out that self-immolation is an extreme form of protest against the social malaise to make things change and does not due in the most cases to mental disease.

Role of alcohol use in suicidal behavior in public places

E. Baca-García*, M. Barrigón, F. Cegla Schvartzman, A. Sedano-Capdevila, L. Villoria-Borrego, M. Sanchez-Alonso
Hospital Universitario Fundación Jiménez Díaz, Psychiatry
Department, Madrid, Spain

* Corresponding author.

Introduction Suicide in public places is a relatively common emergency in which alcohol use could be a factor involved.

Methods A total of 169 patients were attended for SB in Madrid public places by SAMUR (Municipal assistance service for emergency and rescue) and transferred to FJD emergency room where all of them were assessed by the psychiatrist on duty. For all (but 47 of them), blood alcohol level was measured and other variables were collected: age, sex, history of suicide attempt and characteristic of the attempt. A descriptive analysis was made and then differences between those using alcohol and those not was made.

Results Our sample comprises 169 patients, 40.2% woman and 59.8% man (median age = 39.36 years). Alcohol was measured in 122 patients, being positive in 52.4% (median alcohol level = 95.09 mg/dL). We found that 64.6% of man had consumed alcohol against the 30.2% of women ($P = 0.000$). 64.8% of alcohol users were discharged, against the 35.2% that not users. We admitted 28.1% of the alcohol users and 56.8% of the non-users ($P = 0.007$). We did not found statistically significance differences when compared patients that consumed against patients who did not regarding previous attempts, behavior (ideation, intent, non suicidal self-harm) and method.

Conclusions When assessed SB, we found that most of the patients were man under the alcohol influence and most of them were discharged after being evaluated. The data does not reflect the seriousness of the SB, which opens the possibility of correlating the levels of alcohol with suicidal risk.

* Corresponding author.

This is an epidemiological study of suicide in East of Algeria (15 wilayas) through psychological autopsies (from 2000 to 2008) or more variables were studied to establish a standard profile of suicide in Algeria. The variables studied were: age, sex, occupation, place of residence, the existence of life events, psychiatric history and possibly a history of TS, a source of information (from whom we collected Information: father, mother, brother, sister. . .) and the proceeds used for suicide. In total, we identified 1263 cases of suicide with age 15 and older occurred in populations of East of Algeria during the period 2000 to 2008. The conclusion focuses on the emergence of certain variables can be risk factors namely age between 30 and 45 years, male gender, social and financial difficulties especially difficult life, the presence of a psychiatric diagnosis on axis 1 of DSM-IV and finally the lack of access to primary care in urban areas.

Finally, the authors highlight the prevalence per 100,000 population per wilaya and the average prevalence for the whole of east of Algeria.

Establishment of a comprehensive inpatient suicide prevention network: Taiwan experience and systemic review

T.C. Changchien*, Y.C. Yen

EDA Hospital, Department of Psychiatry, Kaohsiung City, Taiwan, ROC

* Corresponding author.

Introduction The complexity of inpatient suicide in a general hospital setting, whether medical or surgical, is not fully understood currently. It is a common sentinel event and an important problem of patient safety. However, its evidence is currently lacking. So, we present a healthcare system approach to enhance the effectiveness of inpatient suicide prevention in Taiwan.

Methods We reviewed available evidence about inpatient suicide. Some risk factors were detected. And we tried to improve our inpatient suicide prevention program with healthcare failure mode and effect analysis (HFMEA), which is a prospective qualitative analysis for numerous medical errors. In this study, HFMEA was used to reduce the likelihood of failure of current clinical practices in preventing inpatient suicide.

Results The psychiatric consultation rate increased after a series of improvement program. Besides, establishment of an integrated electronic medical system and the improvement of environment and facility safety are our main strategies. The HFMEA indicated that empowering staff with continuing education and case management by a full-time social worker and clinical psychologist were also needed. Furthermore, this hospital-based integrated suicide prevention program was accredited with the symbol of national quality of Taiwan in 2014.

Conclusion Our study provided systematic intervention to improve inpatient suicide prevention in a general hospital, and in Taiwan. The HFMEA is a useful tool to improve inpatient suicide prevention measures. We still need more information and evidence to promote the importance of inpatient suicide prevention.

Disclosure of interest The authors have not supplied their declaration of competing interest.

characteristics of suicidal behavior in a rural population

G.M. Chauca Chauca^{1,*}, L. Carrión Expósito¹, M.J. Jaén Moreno²

¹ UGC-Salud Mental Hospital Infanta Margarita, Cabra, Córdoba, Spain

² Instituto Maimónides de Investigación Biomédica de Córdoba IMIBIC, Hospital Universitario Reina Sofía, Universidad de Córdoba, Córdoba, Spain

* Corresponding author.

Introduction Suicidal behavior is defined as any behavior of self-harm with intent and knowledge of what is done. Suicide ranks among the 10 leading causes of death in the statistics of the world health organization.

Objectives The main objective of the study is to determine the sociodemographic characteristics of patients who have attempted suicide and the characteristics of this behavior.

Methods It is a descriptive cross-sectional study.

Results The sample consisted of 70 patients, with a mean age of 41.17 years, most of them were women (58.5%). In relation to employment status, 31.4% were working, 21.4% unemployed, 14.3% were retired and 32.9% had other employment status. Among the characteristics of suicidal behavior characteristics, mode, forecasting rescue, previous suicidal behavior, previous outpatient follow-up and consumption of toxic evaluated. The most frequent method chosen was the voluntary intake of drugs (77.1%). The 67.1% were diagnosed with depressive disorder followed by personality disorders (20%).

Conclusions In total there is a predominance of women in achieving some suicidal behavior, as well as a higher percentage among single, divorced or widowed (60%) versus married (40%). Also a higher percentage of patients unemployed, pensioners and others who do not receive income (68.5%) versus the occupationally active (22%). Another condition that must be evaluated in the suicide risk is having previously made a suicide attempt, in our study 54.3%. Since subjects with previous suicide attempt are four times more likely to try again. The results are also consistent with other studies that the most common disorder associated with suicide attempt is depressive disorder (67.1%).

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1463

Impact of nonideation states on youth suicide attempts

R. Copelan

Formerly, University of Colorado, Emergency Psychiatry, Pensacola, USA

Background Youth nonideation suicidality (NIS), distinct from impulsive deliberate-self harm (DSH), is a potential consequence of adjustment disorder (AD) or selective serotonin reuptake inhibitor (SSRI) adverse reaction. It is characterized by the absence of transient or enduring ideation. A new measure was constructed to evaluate the impact of NIS on attempt rates.

Methods Youth 8 to 24-years-old were recruited in this case control study. Entry criteria included DSH ($n = 50$), AD ($n = 91$), and SSRI ($n = 29$) emergent events with overt or suspected NIS, worsening of existing or new onset suicidality, or abrupt mental status or behavioral change. Exclusion criteria included sensorimotor deficit or primary depressive disorder. Ratings from the new measure utilized dichotomous as well as outcome scores, and compared to ratings from other validated scales, after controlling for depression and other matched factors.

Results High risk AD and SSRI groups presented with abrupt onset, high lethality attempt, intense motor restlessness, great

intra-psychoic distress, and irresistible suicidality. AD symptoms overlapped with SSRI presentations. Eighty-one percent of the AD sample reported no ideation; however, 96% made an attempt. For the SSRI group, 52% reported no ideation; however, 95% made an attempt. Sensitivity 80.3%, specificity 98.1%. Internal consistency 0.75 to 0.92. Test-retest scores 0.78 to 0.98, and neurodiagnostic correlations 0.70 to 0.98. Some scores correlated significantly with the “gold standard” Barnes Akathisia Rating Scale.

Conclusion NIS is associated with alarmingly high rates of youth suicide attempt. The new neuropsychological measure demonstrates practical screening value in unobvious NIS proposed to represent a heretofore unrecognized neural mechanism.

This paper discusses the relationship between alcohol consumption and suicidal behavior in Belarus

S. Davidouski^{1,*}, Y. Razvodovsky²

¹ Belarusian Medical Academy of Post-Graduate Education, Department of Psychotherapy and Medical Psychology, Minsk, Belarus

² Grodno State Medical University, Pathological Physiology, Grodno, Belarus

* Corresponding author.

Introduction Suicide is one of the main causes of premature mortality in Belarus. It is well recognized that drinking is among the major risk factors that are associated with suicidal behavior.

Aims This study was design to extend our understanding the relationship between alcohol and suicidal behavior.

Methods Risk factors for suicidal behavior (completed suicide and parasuicide) among residents of Minsk city and Gomel city were studied.

Results Among the residents of Minsk the maximum suicides risk was in the age of 46–60 years, and parasuicide at age 20–39 years. The ratio of men to women - 4:1; they were often BAC-positive (from 38.8% in 2015 to 42% in 2008). Among parasuicides sex ratio of about 1:1; 30% of men aged 20–39 years, were BAC-positive. Studies in the city of Gomel, has shown maximum number of parasuicides in the ages of 18–29 years (39.3% in women and 30.7% men). Among parasuicides the majority of men (57.8%) and a significant proportion of women (34.2%) were BAC-positive. Maximum number of those attempted suicide and dependent on alcohol were among men ages 30–39 years (66.15%) and 50–59 years (65.22%), among women in the age 30–39 years (45.45%).

Conclusions Acute alcohol intoxication is characteristic of young people who commit parasuicide. Chronic alcohol intoxication is a risk factor in middle-aged persons who commit suicide. Prolonged use of alcohol contributes to the development of comorbid mental disorders, during the crisis of middle age is manifested as an increased risk of suicides.

Physician suicide

M.A. Dos Santos

Universidade de Coimbra e Universidade Nova de Lisboa/IHMT, Faculdade de Medicina, Coimbra e Lisboa, Portugal

Introduction Physician Suicide is a potential health risks resulting from strains and burden associated with medical education and profession. Suicide is an occupational hazard. Each year in the United States, 300 to 400 physicians take their own lives.

Objective To provide a summary about physician suicide and its risk factors and mental health issues associated.

Methods The search was conducted using PubMed with terms: “suicide in physicians”, “physician suicide”, “suicide in doctors”, “physician depression”, by using a review of literature with documents in English.

Discussion Suicide is a major health problem. Suicide death is a self-inflicted with evidence that the person aims die. Mental disorders represent a large burden of disease worldwide and can also damage to physical health. The most common psychiatric diagnoses among physicians who complete suicide are affective disorders, alcoholism, and substance use disorders. In physicians, the female suicide rates are higher than that in males. The most common means of suicide by physicians are lethal medication overdoses and firearms. There are common risk factors, such as work-related stress, depression, negative life events, alcohol and isolation. In addition, there is a physicians’ tendency not to recognize depression in themselves and not to seek help.

Conclusions Prioritize to physician mental health, change professional attitudes and institutional policies, learn to recognize depression and suicidality, educate medical students, residents, routinely screen all primary care patients for depression that can help physicians recognize depression in themselves and to seek treatment for depression and suicidality because there is “no health without mental health”.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Suicide by jumping at beachy head in East Sussex – The impact of a suicide prevention patrol scheme

S. Durgahee^{1,*}, M. Isaac², J. Anderson³

¹ Sussex Partnership NHS Foundation Trust, General Adult Psychiatry, Brighton, United Kingdom

² Sussex Partnership NHS Foundation Trust, Older Persons Mental Health, Brighton, United Kingdom

³ Brighton & Sussex Medical School, Post-Graduate Medical Education Centre, Brighton, United Kingdom

* Corresponding author.

Introduction Suicide is a major public health issue. It is the leading cause of death among younger adults in the UK. Suicide by jumping is an uncommon method. About 23 people die each year by jumping from the cliffs at beachy head, Sussex. The beachy head chaplaincy established a suicide-prevention patrol at beachy head in August 2004. To date there have been no studies evaluating the impact of a suicide patrol as a prevention strategy. This study aimed to assess the impact of this suicide-prevention patrol.

Methods Data from local and national official statistics was gathered to examine the overall suicide numbers and rates of suicide by jumping vs. other methods. This included an in-depth scrutiny of coroners’ data and reports from the beachy head chaplaincy. A qualitative, phenomenological approach using in-depth interviews was used to evaluate the “lived experiences” of members of the suicide-prevention patrol.

Results The statistics reveal unexpected and at times, conflicting, results which will be offered for discussion. The thematic analysis of the interviews reveals insights into the motivations for volunteering; how a faith-based patrol works; the physical and psycho-social impact of the work; volunteers’ stories; the centrality of God within their work and motivation. For copyright reasons full details of the analyses cannot be made available before the conference.

Discussion We welcome an interactive discussion of the results.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Sociodemographic and clinical profile in elderly suicide victims: 34 autopsy case studies

S. Ellouze^{1,*}, I. Baati¹, W. Ben Amar², D. Trigui¹, W. Abbes¹, S. Maatoug², J. Masmoudi¹

¹ Hedi Chaker University Hospital, Psychiatry "A" Department, Sfax, Tunisia

² Hedi Chaker University Hospital, Forensic Medicine Department, Sfax, Tunisia

* Corresponding author.

Introduction The elderly suicide is a major public health problem that is gaining more and more ground, given the aging population problem. This has rarely been the subject of forensic studies in Tunisia.

Objectives To identify the sociodemographic and clinical characteristics of elderly suicide victims over 60 years and to determine what factors might increase suicide risk in this population.

Methods We conducted a retrospective study on suicide victims aged 60 and over, autopsied in forensic medicine department of the Habib Bourguiba university hospital in Sfax (Tunisia), on a 10-year period (January 2006–December 2015).

Results We identified 34 cases with an average age of 66 years. The sex ratio was 2.77. Suicide victims were alone in 38.2% of cases. They were inactive professionally in 32.4% of cases. Almost half of them (44.1%) had a psychiatric history, 40% of depressed pace, 26.7% of bipolar disorder and 13.3% of schizophrenia.

Three main factors were identified as precipitating the passage to suicidal act: family conflicts (26.5%), financial difficulties (11.8%) and loss of autonomy (5.9%).

Suicide methods were hanging (50%), immolation and drug intoxication (11.8%), hit by train and poisoning (8.8%), jumping from height (5.9%) and drowning (2.9%). In 55.8% of cases, suicide took place at home.

Conclusion Elderly suicide seems to be a huge but largely preventable public health problem. Its prevention is essentially based on the identification of risk situations and the detection and treatment of depression: major suicide risk factor in this population.

Resilience and attempted suicide in depressed patients

E. Gattoni^{1,*}, C. Gramaglia¹, D. Marangon², A. Feggi², C. Delicato¹, S. Di Marco¹, A. Venesia¹, P. Zeppego¹

¹ Università degli Studi del Piemonte Orientale, Traslational medicine, Novara, Italy

² AOU "Maggiore della Carità", SC Psichiatria, Novara, Italy

* Corresponding author.

Introduction Among the patients, 6.6% with past-year major depressive disorders attempt suicide in their life. Resilience (the ability to respond positively to adversity) and coping strategies (the ability to manage living stresses) may be protective factors against suicide ideation and behavior. A study conducted on 100 abstinent substance dependent patients suggested that suicide attempters had significantly lower resilience scale scores. Other authors demonstrated that intrinsic religiosity, resilience, quality of life were associated with previous suicide attempts in depressed patients [1,2].

Aim To examine the correlation among resilience, coping strategies and sociodemographic and clinical characteristics in depressed patients.

Methods From December 1st 2014 to December 31st 2015 we recruited inpatients and outpatients aged >18 years with a diagnosis of depression (current or past). At baseline, patients were assessed with Montgomery Asberg Depression Rating Scale, Resilience Scale for Adult and Brief-Coping with problems experienced; sociodemographic and clinical characteristics were gathered. Follow-up was conducted after 1 year in order to assess the possible presence of further depressive episodes and suicide attempts. Analysis was performed with SPSS.

Results and discussion Data collection are still ongoing; results and implications will be discussed. We expect to find higher attempted suicide rates in patients with lower resilience and less coping strategies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Observational study of suicide attempts in a community mental health unit

M. Guerrero Jiménez*, C.M. Carrillo de Albornoz Calahorro, J.M. Gota Garcés

Santa Ana Hospital, Mental Health Unit, Motril, Spain

* Corresponding author.

Introduction Concurrent with the recent global economic crisis there is a rising concern about the effect of recession on suicide mortality rates.

Aim To record patients treated urgently in community mental health unit of Motril, Granada (Spain) by attempted suicide.

Methods Descriptive study recording patients treated urgently in Motril community mental health unit who have done any suicide gesture from February 2015 until December of that year.

Results In total, 39 urgent assessments were recorded during the observational period.

The month of highest incidence was November, with 6 visits followed by August and October (5).

The most common method was voluntary drug intake.

Origin:

- 59% were remitted from the general hospital emergency department;
- critical care and emergency ambulatory devices: 1;
- primary care: 10;
- another specialist: 2;
- own initiative: 2.

Discharge diagnosis:

- 35.8% individuals did not meet criteria for any mental disorder, although some of them were classified with V or Z diagnosis according to ICD-10 for making a reactive gesture to an emotional crisis, couple breakups or economic problems;
- 11 of them meet criteria for various anxiety disorders, obsessive compulsive and adaptative crisis.

Discussion Knowing some peculiar characteristics in suicidal populations as well as the most prevalent pathologies, it could be adapted both the profile of nurse attendance and the type of resources needed to ensure effective patient care.

Conclusion Profile of patients attended for suicide attempt in an outpatient setting in a semi-rural coastal area is varied. It is worth

to mention that one-third of this population did not meet criteria for any mental disorder.

* Corresponding author.

Introduction Sleep disturbances are associated with an increased risk of suicidal behavior. The evidence primarily stems from studies based on questionnaires about sleep quality. In recent years, the availability of wearable health technology has increased and offers an inexpensive, appealing, and accessible way to measure sleep. Our aim is to assess the feasibility and acceptability of wearable sleep tracking monitoring devices in a sample of suicide attempters.

Methods A prospective, open-label, 12-months study will be conducted in the emergency department (ED) and psychiatric unit (PU) of the university hospital of Brest, France. Inclusion criteria are male or female aged 18 or over, surviving a suicide attempt, discharged from ED or PU, and giving consent. The sleep tracker and a smartphone will be given to the patient after discharge. He or she will receive brief training on how to use the sleep tracker. Patient will be asked to monitor their sleep during the five days following the discharge. The feasibility will be explored by analyzing the data proceeding from the sleep tracker. The acceptability will be assessed during the five-days follow up visit, using a standardized questionnaire.

Results Preliminary results of this ongoing study show that feasibility and acceptance may be related to technical features of wearable devices.

Discussion A better understanding of the bidirectional mechanism between sleep disturbances and suicide behavior will allow the design of tailored interventions to prevent suicide attempts.

Suicide configures failure in the mental health care of persons deprived of their liberty in terms of detection of risk factors, prevention, specific planning in terms of addressing thoughts of death or autolytic planning, trends, impulses and moods. The factors that unite in this catastrophe are multiple and depend not only on mental health care, but also on the circumstances that led to the deprivation of liberty, the family and the care of social continence

and the intimate relationship of the person with its existence. Also, security personnel who take care of people in confinement contexts have a preponderant role in suicide preference. Structuring the personality distorted, immature or insufficient, circumstances that lead to vulnerability and threaten the preservation of life in the context of constant stress and loneliness. The transdisciplinary work experience provides us with constant review and dynamic concepts and practices to predict, diagnose and prevent risky behaviors prone to the symptoms of self-injury or self-harm of patients. In this sense, we propose interdisciplinary interviews of entry, registry for the detection of risk factors, specific treatment in patients at risk. The transdisciplinary confluence is a tool to be implemented to quantify the results and propose to reduce the incidence of suicide in people in a confinement context.

Road traffic accidents and suicide rates in Europe

S. Kandrychyn^{1,*}, Y. Razvodovsky²

¹ Republican Clinical Medical Centre, Cardiology, Minsk, Belarus

² Grodno State Medical University, Pathological Physiology, Grodno, Belarus

* Corresponding author.

Introduction Road traffic death and suicide may have some similarity in their psychological correlates; furthermore, road traffic should be considered as a suicide method.

Aims The present study aims to explore the relationship between road traffic deaths and suicides in Europe.

Methods Rates of road traffic accident deaths and suicides and gross national income (GNI) per capita for 40 European nations were obtained from the world health organization official database. The total sample was divided on 22 eastern European nations and 18 western European nations.

Results Mortality rate from road traffic accidents in groups of all European nations is associated positively with suicides (Pearson $r=0.45$, two-tailed $P<0.01$) and negatively with GNI ($r=-0.64$, $P<0.0001$). At the same time suicide rates does not reveal a significant correlation with GNI. In the groups of eastern European nations road traffic deaths is associated positively with suicides ($r=0.57$, $P<0.01$) and relationship with GNI is not significant. As a contrast, in the groups of western European nations road traffic deaths is associated negatively with GNI ($r=-0.69$, $P<0.01$) and shows any significant relationship with suicides. Although in this group, suicides show some positive correlation with GNP ($r=0.45$, $P<0.05$).

Conclusions The present data indicate, therefore, that mode of ecological association between three studied indices is various in the different group of European nations what suggests the multifactorial complexity of violent death etiological mechanisms. At the same time, the data allow to suggest that socioeconomic factors are more essential in prevention of road traffic mortality than suicides.

EV1473

Bridgend “Bebo Internet Suicide Cult” and ritual violence in Wales

R. Kurz

Cubiks, IPT, Guildford, United Kingdom

Introduction In a small South Wales town 17 teenagers seemingly committed suicide through hanging in 2008 triggering national

media coverage. In the same region, several “Satanist” offenders were successfully prosecuted since.

Objectives This paper raises awareness of this “suicide epidemic” and its possible links to ritual violence ideologies.

Aims The research explores how “mind control” through secret societies can lead to suicide and murder.

Methods The research was prompted by client disclosures of a crime series that lead to a false “delusional” diagnosis. Review of the sparse literature and media coverage was used to ascertain themes.

Results Colin Batley, a self-styled Satanist high priest, was sentenced for child sexual abuse alongside 4 others. His son Damien had died through aspiration when filming himself in a “sexual stimulation game”.

Ian Watkins, disgraced singer of “The Lost Prophets”, was sentenced for abusing two babies provided by two “super-fan” mums. Peaches Geldorf tweeted their names, got a tattoo of O.T.O, a Satanist “kinky sex” group and was found dead a year later.

Albert and Carole Hickman were sentenced for sexually abusing an 11-year-old including “sucking blood”.

Matthew Williams cannibalised his victim before being killed with a police taser.

Conclusions “Hanging” and “Over-dosing” could be the result of suicide or of “being suicided”. The abuse crimes of all three Satanists convicted in the last 15 years in UK courts occurred in South Wales. Associated violent death in the vicinity of the cases and authority irregularities suggest the operation of an “Organised ritualised crime abuse network” posing challenges for psychiatry.

Characteristics of suicide attempters with a high lethality means

C.T. Lee*, S.Y. Lee, K.U. Lee, H.K. Lee, Y.S. Kweon
Uijeongbu St. Mary's Hospital, Department of Psychiatry, Uijeongbu, Republic of Korea

* Corresponding author.

Introduction Suicide attempts with higher lethality increase the likelihood of suicide completion. Accumulating knowledge on risk factors contributing to higher suicide lethality may help clinicians to allocate their limited resources to more endangered people.

Objectives To explore the factors associated with higher lethality in suicide attempts.

Methods All suicide attempters, who visited the emergency department of Uijeongbu St. Mary's hospital from January 2014 to December 2015, were reviewed retrospectively. We compared between the high vs. the low lethality group, of which had been recorded based on clinical judgment using *t*-test or Chi²/Fisher's exact test with two-sided *P*-value of 0.05.

Results Among the 753 suicide attempters, the assessed lethality was recorded in 736 cases. Low and highly lethal attempters were 426 (57.9%) and 310 (42.1%), respectively. For demographic variables, the high lethality attempters were significantly more likely to be older (48.3 vs. 44.78; *P* = 0.009), unemployed (61.0% vs. 56.5%; *P* = 0.042, without religion (90.9% vs. 84.9%; *P* = 0.017). For clinical variables, the high lethality attempters were significantly more likely have hopelessness (67.7% vs. 58.2%; *P* = 0.013) and a history of schizophrenia (4.5% vs. 1.4%; *P* = 0.023, while they did display any difference for mood disorders. The low lethality suicide attempts were more frequent in patients with comorbid personality disorders (9.2% vs. 4.9%; *P* = 0.031).

Conclusions These results are in line with literatures reporting higher suicide risk in people, who are old, unemployed, not having a religion, psychotic and hopeless. These may have been moderated by committing a higher lethal means of suicide at least in part and warrants additional investigations.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1475

Is prior suicide attempt a reliable indicator of short-term suicide risk amongst patients admitted to an acute suicide inpatient intervention unit in India?

S. Mishra

MTI Trainee, Newsam center, Secroft hospital, Psychiatry, Leeds and York Partnership Trust, Leeds, United Kingdom

Introduction Traditionally past suicide attempt is considered a strong reliable factor in predicting an immediate or short-term suicide risk. Considering the complex interplay of different variables associated with suicide, the absence of past attempts may not prove to be of lesser risk for a consequent attempt.

Aim To compare sociodemographic and clinical correlates within high-risk suicidal patients who have made a recent suicide attempt in the presence versus absence of past suicide attempts.

Methods Retrospective review of patient's records admitted to intensive care unit, applied suicide intervention and supportive treatment (ASIST) between 1st January 2015 and 31st May 2016 was conducted. Data was extracted for all consecutive admissions to ASIST, of adults (16 to 60 years) male patients with high risk for suicide.

Results Out of 109 at risk inpatients, 31% were recent attempters without past attempts and 13.5% were recent and past attempters. Rest included past attempters without recent attempt and non-attempters. Except for poor coping skills, which were significantly higher (Chi² = 13.97; *P* = 0.001) in the group consisting recent and past attempters, all other relevant sociodemographic and illness related correlates were comparable across these groups.

Conclusion Suicide risk may be associated with multiple factors. Apart from past attempts, a faulty coping style can be associated with risk for further attempts. Other correlates like age, marital status, employment and illness profile did not follow the traditional pattern in our study which makes them equally important while addressing suicide risk in Indian men.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

Fear from freedom, tendency to suicide

M. Mohammadi

Education Organization, physics, Tehran, Iran

The growth of social activities for women in Iran has had a two-sided outcome for women. The worst, the women have encountered the phenomenon of prison, which is a great problem in traditional and Islamic societies. The change of role expectations after the release from prison has imposed many restrictions on women so that there is not any vivid future for them. Lack of enough education and skill has deprived the prisoner women from retaining their pre-prison situation. The high number of suicide among prisoner women shows that subculture of encountering with prisoned women in Islamic societies is based on sin approach in that the women are sinners who will be sent to hell in the other world and they must see the punishment of their sin to be ready for the extreme heat. Disinterestedness in the interaction with other people and loving isolation are two characteristics of style life for these women. The efforts of authorities to return these women to normal life, unfortunately, have failed to work. This paper investigates

the reasons and roots of exclusion for prisoner women in Iran and Islamic societies.

Keywords Women; Islamic societies; Prison; Freedom

Suicides in the Kyrgyz Republic: Discrepancies in different types of official statistics

E. Molchanova^{1,*}, T. Galako²

¹ American University in Central Asia, Psychology, Bishkek, Kyrgyzstan

² Kyrgyz State Medical Academy, Psychiatry, Bishkek, Kyrgyzstan

* Corresponding author.

In order to develop the “prevention of suicides” component of the state program on mental health protection of the Kyrgyz Republic population for 2017–2030 years, a suicide situation in the country over the past 10 years was investigated. During collecting, processing and statistical analysis of data from different sources, a significant discrepancy was revealed between them.

According to the national statistics committee (NSC), in 2015 the level of prevalence of suicide was 6.93% per 100,000 of population, whereas, according to the information from the republican medical information center it was 4.82%. Over the last 10 years in the Kyrgyz Republic, a level of suicidal behavior among children, teenagers and young adults has still been rather high and 22.63% of suicide attempts were committed by persons aged between 18 and 22 years. A significant difference was revealed in the indexes of suicides among these age categories provided by NSC and the ministry of Inner affairs.

Due to religious and national traditions, suicide is a very sensitive topic in Kyrgyzstan. In a lot of cases, death from suicide is not registered or is disguised as accidents and other causes of death, so the figures may be considered reliable.

Thus, despite the relative standardization of suicides accounting by the separate departments, the further work is needed for coordination and harmonization of the data collection, as well as for development and implementation of inter-agency action plan to prevent suicides at the national level, taking into account the regional, cultural and ethnic characteristics.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Hospital Clínico San Carlos, Psiquiatría, Madrid, Spain

* Corresponding author.

Introduction A major risk factor for suicide is suicide attempts. The aim of the present study was to assess risk factors for nonfatal suicide attempts. Suicide attempt with high lethality have been interacting with certain clinical and demographic factors such as age, sex, psychopathology and adverse events, among others.

Methods Observational, descriptive and retrospective study of people who was admitted to a general hospital after suicide attempt.

Aim The aim of this study was to determinate variable associated to high risk of suicide. Describe and analyze demographic and clinical characteristics associated with serious suicide attempts as well as the methods used.

Results Of a total of 504, 23 patients was admitted after suicide attempt, 61% male, mean age 54.1; 60% required ICU; the most common method consisted of multiple drug intake 40%, 30% associated with toxic, mostly alcohol. Predominant summer and diagnosis of adjustment disorder.

Conclusion As is the case with suicides prevails male and summer. As to the most common method has been from medication, both men and women. We were surprised diagnosis of the most common reactions to stress. We conclude that the findings could guide a progressive change in the presuicidal pathology.

The emotional stroop test for screening of suicide risk

H. Pereira*, G. Esgalhado

University of Beira Interior, Psychology and Education, Covilhã, Portugal

* Corresponding author.

Introduction Suicide is problematic today, being one of the most potentially fatal psychological phenomena, so it is important to assess thinking about suicide or suicidal ideation.

Objectives In this study we aim to develop methodological procedures, in order to understand if the emotional stroop test for screening of suicide risk is a good measure of suicidal ideation.

Methods A cross-sectional study was carried-out among a convenience sample of 100 subjects. The data collection was done using a socio-demographic questionnaire, the emotional stroop test for screening of suicide risk, the suicidal ideation questionnaire and the beck depression inventory.

Results Regarding the degree of association between the score of interference of the emotional stroop test and level of suicidal ideation there is a strong negative correlation and statistically significant. There are statistically significant differences in the scores on the three sheets of emotional stroop test between subjects with high suicidal ideation and low suicidal ideation. Attention is impaired in the group with suicidal ideation.

Conclusions The emotional stroop test for screening of suicide risk is a useful, rapid and simple assessment tool that can to be used to detect symptoms of suicidal ideation.

⁴ School of Medicine, Department for Medical Statistics and Informatics, Osijek, Croatia

⁵ School of Medicine, Department of Psychiatry and Psychological Medicine, Osijek, Croatia

* Corresponding author.

Introduction Both suicide and mood disorders represent current and future global burden on public health system. Bipolar disorder (BD), part of a diagnostic group of mood disorders, is characterized by manic, depressive and mixed episodes with life-expectancy

much shorter than in general population. Patients with BD have 30 times higher suicide rate than the general population and 25–50% of these patients attempts suicide. About 15% of patients who attempted suicide eventually end their lives with completed suicide.

Aim The aim of our research was to distinguish personality features among bipolar patients with current depressive episode (BD-D) who attempted suicide.

Materials and methods The research was conducted among patients with depressive episode of BD (according to diagnostic criteria of ICD–10) who attempted suicide and had been admitted for hospital psychiatric treatment. For assessment of personality, we used the Temperament and Character Inventory (TCI, Cloninger R.) upon admittance. Our sample consisted of 31 ($n=31$) patient who met the above mentioned criteria. All patients given their written informed consent. The statistical analysis was performed using SPSS 17.0.

Results In our sample, we found, higher scores on harm-avoidance (HA), significantly higher scores on novelty seeking (NS) with significantly lower scores on persistence (P), self-directedness (SD) and cooperativeness (C) scales of the TCI. The Mann–Whitney–U test was used to compare samples.

Conclusion In our sample, suicide attempts are associated with temperament and character dimensions. These results confirmed our initial hypotheses on existence of specific personality features among that group of suicidal patients with BD–D.

EV1481

The ethno-cultural peculiarities of suicidal behavior in multinational Russia

B. Polozhy

V.P. National Research Center For Social and Forensic Psychiatry, Division for Ecological and Social Problems of Mental Health, Moscow, Russia

Introduction According to the data of 2015, suicide rate in Russia was 17.1 cases per 100,000 population. However, many aspects of the problem of suicidal behavior are not studied. This prevents the organization of the system of effective suicide prevention. In this regard, special attention deserves ethno-cultural factors, since they are essential to the moral and ethical attitude to the possibility of suicide and to potential willingness to formation of suicidal behavior.

Objective Study of the rate of suicide among different nations of Russia.

Methods Statistical analysis of suicide rate in constituent entities of the Russian federation from 2010 to 2015.

Results The specificity of suicide situation in Russia is that suicide rates in different ethnic groups of the population has the distinction of reaching 21: from 2.8 per 100,000 in the Republic of North Ossetia to 59.7 per 100,000 in the Altai Republic. This is due to cultural peculiarities of different ethnic groups, including the historically established their relationship to suicide. Taking in consideration these factors were elaborated the differential programs for suicide prevention. That has allowed to lower suicidal rate in Russia in 1.4 times for the last 5 years. That indicates the possible beneficial effects of the ethno-cultural approach in suicide prevention strategies.

Conclusion In planning programs suicide prevention in multinational countries should take into account the ethno-cultural characteristics of the residing peoples.

EV1482

Suicides and road traffic deaths in Russia: A comparative analysis of trends

Y. Razvodovsky

Grodno State Medical University, Pathological Physiology, Grodno, Belarus

Introduction It has long been recognized that there are difficulties in obtaining valid mortality rates for suicides. The evidence indicated that suicides are sometimes misclassified and “hidden” as accidental. Suicide by motor vehicle crash is a recognized phenomenon, leading to under-reporting of the actual number of suicides and inaccuracies in the suicides mortality statistics. Road traffic accident mortality and the suicides rates in Russia are both among the highest in the world. This phenomenon has attracted much attention in recent years, but remains poorly understood.

Aims The present study aims to test the hypothesis of the close aggregate level link between road traffic accident mortality and the suicides rates in Russia.

Methods Trends in sex-specific road traffic accident mortality and the suicides rates from 1956 to 2015 were analyzed employing a distributed lags analysis in order to assess bivariate relationship between the two time series.

Results The graphical evidence suggests that the trends in both road traffic accident mortality and the suicides for male and female seem to follow each other across the time series. The results of analysis indicate the presence of a statistically significant association between the two time series for male at lag zero. This association for female was also positive, but statistically non-significant.

Conclusions This study indirectly supports the hypothesis that many of road traffic accident deaths in Russia are likely to have been suicides. Alternatively, common confounding variables, including binge drinking and psychosocial distress, may explain positive aggregate-level association between the two time series.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

³ Università Vita-Salute San Raffaele, Division of Neuroscience, Milano, Italy

* Corresponding author.

Introduction Suicides that occur during psychiatric hospitalization are tragic events causing immense distress to relatives, peers, and physicians. Suicide risk is particularly high in patients with mood disorders.

Objectives To identify a clinical risk profile which can be predictive of suicide in patients undergoing a major depressive episode, hospitalized and within three months after discharge.

Methods We are going to include consecutively admitted depressed patients in San Raffaele Turro hospital (Milan), with a diagnosis of major depressive disorder or bipolar disorder, for a longitudinal prospective study. Demographical and clinical characteristics will be assessed. Barratt impulsiveness scale, aggression questionnaire, Hamilton psychiatric rating scale for depression, scale for suicide ideation, Columbia suicide severity rating scale will be administered to evaluate, respectively, traits of impulsiveness and aggression, severity of psychopathology and suicidal ideation. A follow-up program has been established to

evaluate suicidal ideation one month and three months after discharge.

Results Considering suicide rates in other psychiatric wards, we retrospectively analyzed in our mood disorder unit the inpatient suicide rate of the last 3 years. In this period, we admitted 1794 patients. The suicide rate has been cumulatively of 0.17% (4 patients): 0.16% in 2014, 0.16% in 2015, and 0.19% in 2016. In the same period, outpatient suicide rate has been of 0.39%; 57.14% of outpatient suicides happened within three months after discharge.

Conclusions Hospitalization and discharge are critical circumstances for psychiatric patients. Evaluation of risk factors will contribute to explain our ward suicide rate and hopefully to reduce it in the future.

EV1484

Suicidal ideation expressed in online video diaries: New form of sharing intention to die

D. Sendler

University of Lublin Medical School, Department of Psychiatry and Sexual Consultation Clinic, Lublin, Poland

Introduction Suicide risk is increasing among all population groups, and no effective prevention method has been established due to high variability of risk factors.

Objectives To (1) determine risk factors in people, who video-streamed unsuccessful suicide attempt, and (2) assess whether screening video blog websites is an effective suicide prevention.

Methods Participants ($n=24$, 14M and 10F, age range=19 to 53) with past history of suicidal attempts were recruited online to participate in encrypted video qualitative interview. Three scales assessed suicidal tendencies and Internet addiction: Columbia–suicide severity rating (C-SSRS), suicide assessment five-step evaluation and triage (SAFE-T), validated Internet addiction scale of own design. Reported data are mixed quantitative and qualitative measures.

Results Participants were stratified into two age categories (students vs. working professionals), and all were determined to be addicted to Internet. Each group engaged in minimum 15 suicides ideation-related postings, prior to attempting suicide. Young participants typically posted impulsive, quick messages capturing distress caused by peers and family conflicts; seeking short-time recognition was evidenced by eliciting more “likes” and “comments” for each post. Working professionals posted less, but each video was lengthier and messages were emotional, usually ending in tearful summary of life events leading up to suicidal thoughts. While students expressed anger with “the system” as motivation to die, working professionals had financial problems and trouble forming long-lasting friendships.

Conclusion People of all age groups increasingly document intention to die via blog video posts. These messages can be captured by prevention professionals who can reach out to troubled students and working adults.

Suicidal intent in people with major depression

D. Shukla^{1,*}, A.Q. Jilani², P. Jaiswal³, A. Nischal³, R.A. Kallivayalil⁴

¹ Dr. Ram Manohar Lohia Institute of Medical Sciences, Psychiatry, Lucknow, India

² Era's Lucknow Medical College, Psychiatry, Lucknow, India

³ King George's Medical University, Psychiatry, Lucknow, India

⁴ Pushpagiri Institute of Medical Sciences, Psychiatry, Thiruvalla, India

* Corresponding author.

Background Depression is most common underlying contributor among cases of attempted/completed suicide. There is dearth of information regarding suicidal intent among people with depression and its relationship with hopelessness among Indians.

Objective To evaluate and describe the intent of suicide in people with depression among north Indian population.

Methods This cross-sectional single point, study was performed at the department of psychiatry, King George's Medical University, Lucknow, India. Cases were in the age group of 18–60 years with major depressive disorder as per DSM-IV TR criteria. Following tools e.g. Hamilton depression rating scale (HRS), Beck's hopelessness scale (BHS) and suicide intent questionnaire (SIQ) were used for assessment.

Results Suicidal intent was observed among 68.1% ($n=49$) of study sample ($n=72$). There was no significant ($P>0.05$) association of suicidal intent with socio-demographic factors except domicile status. Suicidal intent was common among people with moderate to severe depression and those with hopelessness. The hopelessness was present among 70.8% of subjects.

Conclusion Suicidal intent is prevalent among people with major depression. Intervention at initial stage of suicidal intention would of importance for successful preventive measure. This emphasizes the need for evaluation of suicidal intent in cases of depression.

Implementation of the national register of suicide attempts as a preliminary strategy for the prevention of suicides in Poland

A. Gmitrowicz, R. Szmajda*, A. Baran, I. Makowska, P. Kropiwnicki

Central Clinical Hospital, Klinika Psychiatrii Młodzieżowej UM w Łodzi, Łódź, Poland

* Corresponding author.

Studies show that suicide attempts are a major independent predictor of suicide. Only in some countries of the world, there are national registers of these behaviors. Poland is among the countries where suicide prevention is at the stage of implementation of these strategies. One is the initial diagnosis of the prevalence of suicidal behavior (SB) in selected populations. The aim of the study was to assess the prevalence of SB in Poland on the basis of available databases, including data such as age, sex and mental disorders and the analysis of differentiation of selected indicators of SB.

Material and methods We analyzed available registers of completed suicides (CS) and suicide attempts (SA), carried out under reporting of the central statistical office (CSO, in the general population, based on death certificates), Police Headquarters (PH, the number of reported SB in the country) and the Institute of Psychiatry and Neurology in Warsaw (IPiN, the number of SB in all psychiatric institutions) and the department of adolescent psychiatry in Łódź (SB among hospitalized youth).

Results and conclusions Reported data on dissemination of SB in Poland are incomplete, which may affect the reliability of the assessment of the effectiveness of implemented strategies for the prevention of suicides. The aim should be to create a central register of SB, which will not only gather a well-defined data but also monitor how it is obtained.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1487

Clinical and psychological characteristics of patients with suicidal thoughts during prolonged depressive and anxiety disorders and their therapeutic correction

B. Tsygankov*, S. Surnina

Moscow State Medical Dental University, Department of Psychiatry, Narcology and Psychotherapy, Moscow, Russia

* Corresponding author.

Introduction This is an extremely important problem of determining clinical-psychological and personality-typological characteristics of patients with suicidal intentions. In the complex therapeutic correction of suicidal behavior, there is almost no use of such psychotherapy method as katathym imaginative psychotherapy (KIP).

Objective Study of clinical-psychological and personality-typological peculiarities and development of an optimal adaptation of KIP for the treatment of patients with suicidal thoughts.

Methods The study was included 52 patients with anxiety-depressive disorder and suicidal intentions; was used K. Leongard questionnaire, SCL-90-R, SR-45, J. Vagin questionnaire of suicidal motivation.

Results The investigated patients were divided into three groups with acute reaction on stress, personality disorder and schizotypal disorder. The first group has revealed the predominance of instrumental, anemic, anesthetic motivation, emotive and anxiety types of accentuation and high level of suicidal readiness. The second has identified anesthetic motivation, anxiety and cyclothymia type of accentuation with a moderate level of suicidal readiness. The third group included patients with symptoms of anemic motivation suicidal motivation, anxiety type of accentuation and a high level of suicidal readiness. The reduction of psychopathological symptoms in patients of the first group occurred in a shorter period of 18.0 ± 2.1 days, compared with the second – 25.0 ± 5.6 days, and the third group – 21.2 ± 2.1 days.

Conclusion In the main group, the highest suicide rates were in patients with anemic, anesthetic and motivation and anxiety type accentuation. Patients of the first group showed the best response to a comprehensive pharmacological and psychotherapeutic treatment.

EV1488

The confrontation of those who remain: Qualitative reports of relatives about 3 cases of suicide in a small city in the Northeast Brazil

R.M.C. Sena¹, J. Izidoro Jr², D.A.R. Silva¹, E.R. Turato^{1,*}

¹ UNICAMP, State University of Campinas, LPCQ, Laboratory of Clinical-Qualitative Research, Campinas, Brazil

² Municipal Health, Municipal Health Secretary of Pau dos Ferros, RN, Pau dos Ferros RN, Brazil

* Corresponding author.

Introduction Suicide is serious public health problem. In Brazil, suicides are more frequent in countryside and small cities.

Objective To understand how informants have confronted emotionally the suicide at home by listening to viewpoints reported by such relatives of the deceased.

Method Qualitative, exploratory design, conducted in a basic health unit area, in “Pau dos Ferros”, a city with 30,000 inhabitants, State of Rio Grande do Norte (RN), Brazil. Sample constructed by technique of “snowball”, in which the health team presented us the first family, whose member informed about the following; and this, the third one. Data collection through semi-directed interviews with open-ended questions in depth, and submitted to thematic analysis.

Results Individuals from relatives who had family bond with the suicidal people were interviewed. From analysis of transcribed interviews, three categories emerged:

- “she has never demonstrated” – possible non-perception of potential suicidal behavior by the family;
- “I got crazy” – feelings of relatives facing a hard scene of suicide and determined cultural questionings;
- “we have no professional support in following days” – absence of psychosocial support and healthcare problems.

Conclusions Possible mood oscillations from suicidal persons were masked by opposite emotional reactions of themselves, and/or oscillations were denied by the observers. Suicide scene seems to have provoked feelings of helplessness and guilt for relatives in not being able to avoid the dramatic act. Feelings of discomfort occurred facing curiosity from many persons who would raise uncomfortable assumptions about suicidal motivations. Family members complained about lack of more effective psychosocial care.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Predicting suicidal behavior by an accurate monitoring of RNA editing biomarkers in blood samples

D. Weissmann*, B. Vire, S. Van der Laan, N. Salvetat, S. Pointet, Y. Lannay, G. Marcellin, F. Molina

Alcediag/Sys2Diag, R&D, Montpellier Cedex 4, France

* Corresponding author.

Introduction Predicting suicidal behaviors is one of the most complex challenges of daily psychiatric practices. Alterations of RNA editing of neurotransmitter receptors and other proteins have been shown to be involved in etiology of different psychiatric disorders and linked to suicidal behavior. Additionally, an increase in expression levels of ADARs, the RNA editing enzymes, has also been observed.

Objective The objective of the present study was to test whether modifications in RNA editing profile of prime targets allow identifying disease-relevant blood biomarkers and evaluating suicide risk in patients.

Methods A clinical study was performed to identify an RNA editing signature in blood of depressed patients with and without history of suicide attempts. Patient’s samples were drawn in PAX-gene tubes and analyzed on Alcediag’s proprietary RNA editing platform using NGS. In addition, gene expression analysis by quantitative PCR was performed.

Results We generated a predictive algorithm comprising various selected biomarkers to detect patients with a high risk to attempt suicide. We evaluated the diagnostic performance using the relative proportion of the phosphodiesterase 8A (PDE8A) mRNA editing at different sites as well as the expression of PDE8A and the ADARs. The significance of these biomarkers for suicidality was evaluated using the receiver-operating characteristic (ROC) curve. The generated algorithm comprising the biomarkers was found to have strong diagnostic performances with high specificity and sensitivity.

Conclusions We developed tools to measure disease-specific biomarkers in blood samples of patients for identifying individuals at the greatest risk for future suicide attempts.

EV1490

Risk factors for suicide in the transgender community

A. Williams

Maricopa Integrated Health Systems, Psychiatry, Tempe, USA

Introduction Approximately 41% of transgender people attempt suicide at least once in their lives compared to the rate of 5% in the general population. Transgender patients who have attempted suicide once have a nearly 40% chance for making a third attempt in their lifetime. Addressing the high rate of suicidality among transgender people must be an important clinical concern during treatment. Screening for suicidal ideation is important when working with the transgender community. Knowing the risk factors that affect the transgender community and creating interventions to ameliorate these risk factors can decrease the negative outcomes.

Method A literature review of articles pertaining to the transgender community and suicide was performed. Of 20 articles reviewed, 14 were pertinent.

Results The literature review showed several unique risk factors contribute to the high rate of suicide in this population: lack of family and social supports, gender-based discrimination, transgender-based abuse and violence, gender dysphoria and body-related shame, difficulty while undergoing gender reassignment, and being a member of another or multiple minority groups.

Discussion Aiding the transgender patient to develop coping mechanisms for dealing with negative societal pressures and skills in widening their social supports may help to reduce risk factors and increase well-being for transgender patients. Assessing suicidal ideation in transgender patients, connecting them with contacts in the transgender community and utilizing CBT based techniques to reduce dysphoria and to aid in coping may reduce risk of suicide attempts. More research is needed in specific interventions in the transgender community.

Improving medical student empathy: Initial findings on the use of a book club and an old age simulation suit

T. Barry*, L. Chester, M. Fernando, A. Jebreel, M. Devine, M. Bhat

NELFT, Medical Education, London, United Kingdom

* Corresponding author.

Introduction Empathy is critical to the development of professionalism in medical students, but evidence suggests that empathy actually declines over the course of undergraduate medical education.

Objectives Improving medical student empathy by encouraging students to think about the person behind the illness.

Methods Two interventions were studied. From December 2015 until November 2016, a fourth year psychiatry medical student book club was conducted. Students were asked to read an autobiography of a lived experience of psychosis. The old age simulation suit aims to simulate the sensory and physical impairments faced by older adults with age related illnesses. A training session provided a transient experience of old age for the students.

Results Forty-four students completed the feedback on the book club. Twenty-eight (64%) stated that they strongly agreed with the statement 'the book club encouraged me to consider the person behind the illness'. Thirty-nine (89%) stated that after attending the book club their empathy towards people with mental health problems had increased. Eleven students completed full feedback following the old age simulation session. Empathy statements relating to living in an ageing body improved from the pre-test median score of 4 (range 1–7) to a median score of 6 (range 2–8) post-teaching session. Empathy statements focusing on sensory and physical impairments had pre-test score median of 3 (range 1–7) and post-test median 8 (range 3–9).

Conclusions Feedback from these sessions has demonstrated that with a little creativity, empathy training can be delivered to medical students with a positive impact.

Why a multidisciplinary workforce needs a multidisciplinary education team: Our experiences of providing integrated training in a community and mental health service

L. Chester*, T. Barry, M. Fernando, M. Bhat

NELFT, Medical Education, London, United Kingdom

* Corresponding author.

Introduction North East London NHS Foundation Trust (NELFT) provides an extensive range of integrated community and mental health services for people living in London serving a population of 1.5 million people. With an annual budget of £325 million NELFT is one of the largest community service providers in the United Kingdom (UK). NELFT is responsible for the education and training of the entire workforce and in August 2016, it employed a nurse fellow to work with the medical education fellows so it could focus on multidisciplinary team (MDT) teaching.

Objectives (1) Providing MDT teaching by delivered by a MDT medical education team.

(2) Improving the training experience of all trainees, nurses and allied health professionals in NELFT.

(3) Improving physical health knowledge for mental health staff.

(4) Improving mental health knowledge of physical health staff.

Methods Two psychiatrists and one nurse manager worked together on joint projects to deliver the MDT teaching. Teaching sessions where at least one psychiatrist and nurse manager delivered teaching on serious incidents affecting patient care, identification and management of sepsis in community settings and empathy training using an old age simulation suit.

Results Multiple teaching sessions were delivered to MDTs within the Trust. Staffs were receptive to learning in MDTs rather than traditional splits according to professions. Due to the success of this teaching and the reputation of the medical education team, neighboring Trusts have expressed an interest in working in partnership with the team to further enhance teaching and learning in acute and community settings.

Learning by doing, learning by seeing: Does observation of clinical simulation still count?

M. Fernando*, T. Barry, L. Chester, M. Bhat

NELFT NHS Foundation Trust, Medical Education Department,
London, United Kingdom

* Corresponding author.

Introduction Role-playing scenarios are widely used in psychiatry education, both as a means of assessment and for teaching various clinical skills. But can you get as much from them by learning vicariously as an observer? Fourth-year medical students from Queen Mary University of London were invited to a psychiatry practice OSCE (objective structured clinical examination), shortly before end of year exams. We created 96 places, approximately 40% of the year, but to maximize numbers students also rotated through the six-station OSCE circuit in pairs. For each scenario students alternated either undertaking the OSCE task or observing.

Objectives and methods We sought to identify if there was a significant difference in student experience depending on whether they were the 'candidate' or 'observer'. Students were asked to rate their learning experience in each station on a five-point Likert scale and this was analyzed using an ordinal logistic regression model.

Results While students rated their experiences as 'observers' marginally lower than that of 'candidates', we found no statistically significant difference (OR=0.629, $P=0.093$). Practice OSCEs took place over six half-days with different facilitators and role-players, but we identified no interaction from these factors. For one station on depression, we found a statistically significant interaction in which 'candidates' rather than 'observers' rated better experiences ($P=0.032$).

Conclusions Observation by learners is frequently used within simulated clinical scenarios and may have a number of potential advantages. However, while unable to examine the direct impact on knowledge or skills, we found no significant difference in student-reported experiences between 'candidate' and 'observer' positions.

EV1494

Breaking down the barriers to mental health crisis care: Evaluation of a training package for emergency department clinicians

M. Fernando*, M. Bhat

NELFT NHS Foundation Trust, Medical Education Department,
London, United Kingdom

* Corresponding author.

Introduction About one in 20 attendances at emergency departments (EDs) in the UK relate to mental health, yet recent work has shown that a majority of people presenting with mental health crises do not report positive experiences (Care Quality Commission, 2015). Although there are many reasons for this, one may be a lack of mental health training for staff working in EDs. In response to this, a new training module for multi-professional ED staff was developed.

Objectives and methods We aimed to assess the impact of this new module on clinicians' confidence in managing mental health presentations. Thirty-eight ED doctors and nurses across two centers were asked to complete surveys before and after receiving training.

Results Following training, we found improvements in confidence in each of five domains explored: assessing self-harm; managing someone with personality difficulties; assessing psychotic symptoms; distinguishing between physical and psychotic

symptoms; and, managing psychotic symptoms. These improvements were seen for clinicians across both centers.

Conclusions The results show that training can help to improve confidence around mental health. This is particularly important given that before the training was developed a survey of local ED doctors had shown that 31% felt under-confident in managing mental health conditions. Since developing the training, it has been further enhanced at the request of local EDs to include video-based scenarios. We continue to assess its impact in improving the confidence of ED clinicians (as well as their knowledge, skills and attitudes towards mental health), and ultimately the benefit to patients experiencing mental health crises.

Designing an instrument to assess the competence of cognitive analytic therapists in training

E. Gimeno^{1,*}, C. Chiclana²

¹ University of San Pablo CEU, Faculty of Medicine, Department of Psychology, Valladolid, Spain

² University of San Pablo CEU, Department of Psychology, Faculty of Medicine, Madrid, Spain

* Corresponding author.

Introduction Since its origins, cognitive analytic therapy (CAT) has become a focused and more effective alternative that can be approached from the first line of action by mental health teams. However, since CAT incorporates in its intervention aspects of other currents, it is possible that its limits and specificity may have blurred. Furthermore, therapists in training use to report difficulties related to this. For that reason, assessing the competence of CAT therapists in training becomes so important, as it promote the reflection of the therapist in its training and provides professionals necessary skills to ensure a better quality care for their patients.

Aim and objectives The aim of this study was to design an instrument to identify the main training problems in CAT therapists which allows therapist's competence evaluation.

Methods For this purpose, a specific tool to detect the main problems in the implementation of the psychotherapy by self-report was administered and evaluated by two therapists in training during its clinical practice.

Results The main implementation problems detected had to do with collusions and the temporary adjustment of the sessions. The therapists reported a high satisfaction with the instrument, which was valued as useful to be aware of the problems in CAT training and with clearly explained contents.

Conclusions The tool has been shown to be useful to assess therapist's competence and to take awareness of collusions allowing the therapist to avoid them.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Developing a guide to choose psychiatry in Spain

C. Gómez Sánchez-Lafuente*, R. Reina Gonzalez,

E.M. Rodríguez Sánchez

Hospital Universitario Virgen de la Victoria, Psychiatry, Málaga, Spain

* Corresponding author.

Introduction Choosing a medical specialty is not easy. In Spain, when medical students finish the university degree, they have to take an exam called popularly MIR if they want to start a spe-

cialty. If the exam is passed, that person receives a number result of his academic record during university and test result. The number indicates the order of election, so number 1 chooses specialty and hospital first and so on. The Spanish healthcare system offers between 220 and 250 places to start the Specialty of Psychiatry in 121 hospitals across Spain.

Methods We designed a semi-structured questionnaire with 30 questions specific for the purpose of this work. The questionnaire was spread by social networks and email to reach as many medical doctors undertaking postgraduate training in psychiatry as we could.

Results One hundred and thirty people responded to the questionnaire. Fifteen were not psychiatry trainees. We obtained information from 80 hospitals (66%). Thirty-three hospitals (41%) have specific training in psychotherapy. Sixty-nine (86%) apply electroconvulsive therapy regularly. Teaching during training is given together with psychologists and nurses in 36 hospitals (45%), with psychologists in 32 (40%), only psychiatry trainees in 12 (15%). Psychiatry trainees do general emergency guards in 62 hospitals (77%).

Conclusion At the moment of writing this, the guide has been consulted by 14,600 people and visited over 40,000 times. This guide may help medical students to discover Psychiatry Training and to choose the best hospital that fits their interests.

Disclosure of interest The authors have not supplied their declaration of competing interest.

⁵ School of Philosophy, University of Tuzla, Department of Psychology and Pedagogy, Tuzla, Bosnia-Herzegovina

⁶ Faculty of Islamic Pedagogy, Department of Social Pedagogy, Zenica, Bosnia-Herzegovina

* Corresponding author.

Introduction Bosnia-Herzegovina (BH) citizens, affected by 1992–1995 war, developed serious mental health posttraumatic consequences. Their needs for EMDR (eye movement desensitisation and reprocessing) treatment increased. The Humanitarian Assistance Programmes UK & Ireland (HAP) work in partnership with mental health professionals in Bosnia-Herzegovina (BH) from 2010.

Objectives We aim to build a body of qualified and experienced professionals who can establish and sustain their own EMDR training.

Method Authors described educational process considering the history of idea and its realization through training levels and process of supervision which was provided from the Humanitarian Assistance Program (HAP) of UK & Ireland with non profit, humanitarian approach in sharing skills of EMDR to mental health therapists in BH.

Results The trainers from HAP UK & Ireland completed five EMDR trainings in BH (two in Tuzla and three in Sarajevo) for 100 recruited trainees from different BH health institutions from different cities and entities in BH. To be accredited EMDR therapists all trainees are obliged to practice EMDR therapy with clients under the supervision process of HAP UK&Ireland supervisors. Supervision is organized via Skype Internet technology. Up today seven trainees completed their supervision successfully and became European Accredited EMDR Psychotherapists, one of them became European Accredited EMDR Consultant.

Conclusion Five training of Bosnia-Herzegovina mental health workers to effectively use EMDR with enthusiastic help of EMDR trainers from HAP UK&Ireland resulted with seven European accredited EMDR psychotherapists, and one of them became European accredited EMDR consultant. This will increase psychotherapy capacities in postwar BH.

EV1498

Surviving psychiatry on-calls

C. Holt*, R. Mirvis, S. Butler, A. Howe, P. Lowe, J. Mullin, D. Mirzadeh, R. Sedgwick, T. Zacharia South London and the Maudsley NHS Foundation Trust, Core psychiatric training programme, London, United Kingdom
* Corresponding author.

Introduction Out of hours, there is only one on-site junior doctor. First year psychiatry trainees (CT1s) and GP trainees may have no prior experience in psychiatry. On-call shifts are therefore potentially daunting for new trainees.

Objectives Expand the resources available for trainees when on-call.

Methods We issued questionnaires to CT1s asking if they would have appreciated more information about on-call scenarios and in what format.

Based on the questionnaire results we implemented some changes. These were:

– a printed “pocket-guide” summarising common on-call scenarios;

– a training video on common on-call scenarios.

The handout was given to new trainees in February 2016 and in August 2016. The video was shown to new trainees in August 2016. Trainees provided feedback on the resources.

Results Of 24 CT1s, 15 (63%) were “neutral” or “disagreed” that they had felt prepared for on-calls.

CT1s wanted additional resources, especially a paper handout or phone download.

Feedback on the “pocket-guide” from trainees in February 2016 ($n=8$) was positive (62.5% reported increased confidence in on-call situations). Feedback is also being collected from trainees who received the guide in August 2016.

Trainees in August 2016 ($n=36$) liked the video – no trainees “disagreed” with statements asking if the video had been useful.

The video improved the confidence of trainees about on-call situations by an average of 2.8 points.

Conclusions We have expanded available resources relating to on-calls and improved confidence. Further improvements would include making resources more easily available in downloadable formats.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Ecological momentary assessment and physiological self-evaluation improve mindfulness of stress-related events during interprofessional training. Meta-analysis of a pilot study

C. Lazzari^{1,2,*}, I. Masiello³

¹ North Essex NHS University Foundation Trust, United Kingdom

² General Adult Psychiatry, Pescara, Italy

³ Department of Clinical Science and Education, Karolinska Institutet, Södersjukhuset, Clinical Education Centre, Stockholm, Sweden

* Corresponding author.

Introduction Self-reflective learning improves interprofessional education (IPE).

Objectives Promoting ecological momentary assessment (EMA) of IPE via an online app. This shall allow contextual recording of students' heart rate during and after pivotal moments of their training, thus improving mindfulness of stressful events (MSE).

Aims To make health care students mindful of the effect of their anxiety about learning, patient safety and performance.

Methods Thirty-two undergraduate students contextually recorded their heart rate with a pulse-oximeter before and after each learning moment: discussion of a clinical case during ward rounds (ClinDis), attending patients as an interprofessional team (BedPat) and self-reflective practice at the end of each day of training (SelfRef). Results were recorded on a dedicated app linked to an online survey. Meta-analysis with Tau squared (t^2), Cochran's Q and I^2 provided the results.

Results Meta-analysis (Fig. 1) of IPE events was significant at $P=0.003$, with $t^2 = 16.515$, $Q (5d.f.) = 17.913$, and $I^2 = 72.088\%$. The bedside care had the higher statistically significant heterogeneity in the before-after event with $t^2 = 53.275$, $P = 0.001$, $Q (5d.f.) = 10.803$ and $I^2 = 90.74\%$ due to an increase in heart rate after patient care (BedPatAft).

Conclusions EMA reinforces self-reflection in IPE by making students mindful of the impact of educational emotions on team performance and patients' quality of care.

Fig. 1 Results for contextual heart rate during interprofessional education.

Introduction Csikszentmihalyi defines “flow experience” as the state of mind students experience when the average skills and challenges while learning are above their own average.

Objectives Delle Fave, Massimi, & Bassi optimal experiences are used to assess students' flow experience during interprofessional education (IPE).

Aims To use the emotions comprising the Milan school eight-channel model [“afraid, concerned, bored, relaxed, in control, excited, happy (‘flow’), and glad”] to assess flow experiences of undergraduate health care students during interprofessional training.

Methods Twenty-seven undergraduate health care students undergoing IPE training recoded their flow emotions during discussion of a clinical case in ward rounds, patient care in interprofessional teams, self-reflective practice at the end of each day of training and supervision of teachers. Statistical evaluation using meta-analysis with Tau squared (t^2), Cochran's Q and I^2 provided the results (Table 1).

Results As reported in Table 1, interactions with teachers ($I^2 = 60.98\%$), patient care ($I^2 = 58.87\%$) and discussion of clinical cases ($I^2 = 63.31\%$) reported higher variability, significant at $P < 0.05$. The most frequent emotions were “relaxed” (> 66%) and “in control” (> 66%) but not “flow” (> 20%).

Conclusions Results show that challenges were below the skills possessed, which can slow down the learning process.

Table 1 Results for flow experiences in interprofessional education.

Eight emotions	Interaction with teachers		Self-reflection after IPE training		Patient's care with IPE team		Discussion of clinical cases in ward rounds	
	%	Statistics	%	Statistics	%	Statistics	%	Statistics
Afraid	0	$t^2=0.024$	0	$t^2=0$	0	$t^2=.021$	10	$t^2=.02$
Concerned	0	$Q(7df)=17.94$	0	$Q(7df)=8.29$	0	$Q(7df)=17.93$	0	$Q(7df)=19.23$
Bored	0	$P=.012$	0	$P=.307$	0	$P=.017$	20	$P=.007$
Relaxed	66.7	$I^2=60.98\%$	40	$I^2=15.63\%$	66.7	$I^2=58.87\%$	30	$I^2=63.61\%$
In control	66.7		60		66.7		70	
Excited	0		0		0		0	
Happy (flow)	16.7		20		0		20	
Glad	33.3		40		16.7		20

Doctor–patient communication issues for international medical graduates and medical graduates of foreign origin in Ireland

C. Maddock*, F. Kelly

Louth Meath Mental Health Service, Health Service Executive Ireland, Psychiatry, Dublin, Ireland

* Corresponding author.

Introduction The proportion of international medical graduates (IMGs) in Ireland has increased from 13.4% in 2000 to over 33% in 2010. Many of their countries of origin have different cultures, expectations of the doctor–patient relationship and communication styles than Ireland. These differences can adversely impact on the quality of care provided by IMGs. There is a lack of research on the impact of cultural differences on communication in the Irish context.

Methods Semi-structured interviews were conducted with 16 IMGs in Drogheda Department of Psychiatry. Transcripts were analysed using nVivo10, a specialised computer programme for conducting qualitative analysis and analysed thematically.

Results General themes emerged relating to IMG experience of cultural differences in medicine and psychiatry and cultural differences in communication. IMGs did not find their proficiency in English to be a barrier to communication but did find accents, culture-specific sayings and non-verbal cues to be challenging. Differences in doctors' status relative to patients and different expectations of the doctor–patient relationship were challenging and, at times, frustrating and annoying. It was generally recognised that training in cross-cultural communication skills would be beneficial to new IMGs although a small minority recognised no such issues. Significant differences in attitude to patient confidentiality in Ireland versus the country of origin were identified.

Conclusions Consideration should be given to providing specific cross-cultural communication skills training for all IMGs training in Ireland focusing not just on verbal and non-verbal communication but also differences in the doctor–patient relationship, patient and relative expectations and medical confidentiality requirements.

European Federation of Psychiatric Trainees Exchange: Benefits to trainees and organisations

A. Rebowska

TEWV, Newberry Unit, Darlington, United Kingdom

Introduction During my time in Gothenburg, I have spent my first week with the team on the emergency inpatient ward. During my second week in Sweden, I have visited inpatient assessment unit where in depth psychological and psychiatric evaluations can be conducted. My final day was spent in a secure state institution providing accommodation and care to young people at risk of absconding or presenting with challenging behaviours.

What did I learn Through the participation in the program I was able to gain first-hand experience of different models of healthcare delivery and I intend to implement some of the positive ideas into the services in the UK. Similarly, I hope that the host organisation may benefit from hearing how care is provided in the UK.

During my trip to Sweden, it was the first time I had an opportunity to deliver a presentation to an international audience. This highlighted new challenges such as language barrier and lack of familiarity with jargon, systems and practices that we take for granted within the NHS. I have learnt from the experience and I have now a better idea how to improve my presentations in the future. I have gained a lot of confidence in my presentation skills by speaking in front of a large audience of clinicians that I have not met before.

A quality improvement project focused on assessment of risk level of outpatient psychiatry patients

T. Tuvia*, M. Kats, C. Aloezos, M. To, A. Ozdoba, L. Gallo
Montefiore Hospital, Psychiatry, Bronx, USA

* Corresponding author.

Since the implementation of the Clinical Learning Environment Review by the Accreditation Council for Graduate Medical Education, there has been an emphasis on training residents in health care quality as well as patient safety. As such, psychiatry residency training programs have had to incorporate quality improvement (QI) projects into their training. We developed a QI curriculum, which not only included resident and faculty participation, but also encouraged other staff in our department to focus on patient safety as well as improving their performance and the quality of care provided to the patients.

In this poster, we present the development of our curriculum and will include a successful QI project to highlight this. This project focused on creating an algorithm to help assign patient risk level, which is based on evidence based risk factors. This project was created due to a survey conducted in our clinic which demonstrated that clinicians, and in residency training in particular, identifying and managing high risk patients can be anxiety provoking for trainees. We will present the specifics of this QI project, and additionally outline the steps that were taken to develop and integrate the QI project into clinical practice.

Objectives (1) Learn how to successfully incorporate a QI project and curriculum into a psychiatry residency training program.

(2) Understand both resident and faculty perspectives on what resources facilitated participation in QI.

(3) Present the development of a quality improvement project focused on risk assessment of outpatient psychiatric patients.

The effect of vitamin B1 on the change of appetite related to premenstrual syndrome in young women

S. Abdollahifard^{1,*}, M. Maddahfar²

¹ Jahrom University of Medical Sciences, Jahrom, Iran

² BHOWCO Trading GmbH, Frankfurt am Main, Germany

* Corresponding author.

Introduction Many women in the premenstrual period may be faced with physical and psychological changes that restricted the acceptance of the responsibility of daily living, jobs and reduced quality of life outdoors. One of these mental disorders is the changes in appetite. Preventing the initiation is the first step in reducing premenstrual syndrome, is very important. Vitamin B1 (Thiamin) may reduce symptoms of PMS through affecting the performance of coenzymes in the metabolism of carbohydrates.

Objectives This study was conducted to determine the effect of vitamin B1 on the change of appetite related to PMS.

Methods In this double-blind placebo-controlled clinical trial, 100 students with PMS residing at dormitories of Jahrom University were divided randomly into two groups, vitamin B1 and placebo. The severity of mental symptoms specially change in appetite and

desire to eat sweets in two cycles, before and during the intervention, was recorded by the students. The data were analyzed using descriptive and inferential statistics.

Results The comparison of vitamin B1 group before and after the intervention showed that vitamin B1 reduced mean mental (35.08%) symptoms significantly ($P < 0.0001$). The reduction of severity was observed in desire to eat sweets was 2.42%. The average of mental symptoms severity of PMS has been reduced in vitamin B1 group, and the comparison was significantly different.

Conclusions Therefore, vitamin B1 is recommended for reduction of symptom severity of PMS include desire to eat sweet. This vitamin can be used to reach a major goal of midwifery, without any side effects.

“Hear me out”: Experiences of mothers suffering from severe mental illness with health care providers – A qualitative perspective

D. Banerjee*, G. Desai, P.S. Chandra

National Institute of Mental Health and Neurosciences, Psychiatry, Bangalore, Karnataka, India

* Corresponding author.

Background Contrary to popular myth, majority of mentally ill women are mothers with increasing number of them seeking help. Little is known about their own experiences in this regard and the extent to which their needs are met.

Objectives To assess the barriers and facilitators in seeking help from mental health care providers in matters of pregnancy and parenting.

Methods The study used qualitative design with social constructivist paradigm. A purposive sample of 30 mothers with severe mental illness was obtained. Data was collected through one-to-one in-depth semi-structured interviews. After verbatim transcription, inductive thematic analysis was used to explore transcripts.

Results Most women considered motherhood “central” to their lives and almost all of them experienced the burden of the “dual role”. Main barriers in seeking help were stigma, treatment side effects, wrong information and time constraints. Whereas self-advocacy, early engagement, education of women and involvement of the family with service providers were the facilitating factors. The prime expectations of the mothers as identified were early and direct communication, patient audience and basic guidance in regards to child health and parenting issues.

Conclusion Women who are mothers and also users of mental health services face special challenges in managing the contradictory aspects of their dual identity. Hearing their voices are essential for service provision and ensuring adequate mental health needs. Early and direct intervention along with understanding and addressing critical areas are necessary for proper care of both the mother and child.

Correlation between self-efficacy and well-being, and distress, in women with unexplained infertility

B. Batinic^{1,*}, J. Lazarevic², S. Dragojevic-Dikic³

¹ Clinic for Psychiatry Clinical Centre of Serbia, Faculty of Philosophy, Department of Psychology, Belgrade, Serbia

² Faculty of Philosophy, Department of Psychology, Belgrade, Serbia

³ Obstetrics and Gynecology Clinic “National front”, Department of Obstetrics, Belgrade, Serbia

* Corresponding author.

Introduction One of the most difficult aspects of unexplained infertility treatments are feelings of uncertainty and the perception that infertility is beyond one’s personal control, both of which make the infertility situation more threatening and stressful.

Objectives The aim of this study was to explore the correlation between general self-efficacy and infertility specific well-being and distress among women with unexplained infertility.

Methods The sample consisted of 97 women with unexplained infertility aged between 22 and 46 years old (mean age: 33.58), who were recruited from the obstetrics and gynecology clinic “National front”. Mean duration of conception attempts was 3.10 years. The General Self-Efficacy Scale and the Infertility Specific Well-Being and Distress Scales were applied in the study.

Results The mean score on the General Self-Efficacy Scale was 32.77 (SD = 4.624), on the Well-Being scale 3.22 (SD = 0.984) and on the Distress scale 1.94 (SD = 0.754). There was a positive correlation between intensity of infertility specific well-being and general self-efficacy ($r = 0.502$; $P < 0.01$) and a negative correlation between infertility specific distress and general self-efficacy ($r = -0.265$; $P < 0.01$). Women with unexplained infertility with higher self-efficacy expressed higher levels of well-being and lower levels of distress.

Conclusion The results of our study indicate that women with unexplained infertility who perceive their problems as being beyond their control express higher levels of stress and lower levels of well-being. Psychological treatment of women with unexplained infertility should focus on the aspects that can be influenced through psychotherapy.

Women with hysterical manifestations: Menopause, gender and mental health

N. Bokhan^{1,*}, E.V. Lukyanova²

¹ Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Administration, Tomsk, Russia

² Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Clinical Psychiatric Unit, Tomsk, Russia

* Corresponding author.

Introduction Aging and menopause as a medico-social determinant of female gender influence on mental health. Female gender in the period of menopause is associated with the end of fertility that affects adaptation to changed conditions, decreases intellectual and physical possibilities, narrows role positions, leads to non-psychotic mental disorders (NPMD).

Objective To identify influence of the age, menopause, female sex, sociodemographic parameters on hysterical symptoms in structure of NPMD.

Material In the borderline states department, 93 female patients with hysterical manifestations in structure of NPMD were treated. **Methods** Psychopathological, clinical-dynamic, clinical-catamnestic, psychometric, psychological and statistical.

Results In 100%, the hysterical symptoms in the puberty leveled at reproductive age, intensified in climax: 72.04% - pre-menopause ($P < 0.05$), meno-, postmenopause - 13.98% each. Sociodemographic characteristics (marital status, social status, place of living, education, family composition, family relations) were not interrelated

with frequency of hysterical manifestations in the structure of NPMD ($P > 0.05$). There were more married (68.82%) than divorced (15.05%), widowed (10.75%), single (5.38%); more working (70.97%) than pensioners (22.58%), unemployed (6.45%); more living with husband (51.61%) than with husband and children (17.21%), living alone (15.05%), with adult children (16.13%); more townswomen (80.65%) than villagers (19.35%); education more often secondary (51.61%), high (45.16%) than elementary (3.23%); disharmonic family relations more often (70.97%) than harmonic (13.98%), indifferent (15.05%).

Conclusions Age, menopause, female sex are reliably ($P < 0.05$) connected with intensification of hysterical symptoms in the structure of NPMD in difference from sociodemographic parameters not associated with frequency of hysterical manifestations.

World maternal mental health day

A. Bowen

University of Saskatchewan, Nursing and Psychiatry, Saskatoon, Canada

Introduction As many as 20% of mothers experiences some type of perinatal mood and anxiety disorder (PMAD) worldwide. Women of every culture, age, income level, and race are at risk for PMADs with potential effects to mother and child.

Objectives To promote awareness of maternal mental health and PMADs.

Method An international task force met via online videoconference to make plans for the inaugural World Maternal Mental Health Day. The task force soon grew to include representatives from around the globe with a common goal to increase awareness of and influence policy about maternal mental health. This presentation will discuss the process, successes, challenges, and engage participants in future social marketing strategies for World Maternal Mental Health Day. International reach and impact will be discussed.

Result Organizations from 12 countries were involved in this event, with twitter and landing page activity across the globe. A unique logo was developed and numerous organizations endorsed the event. An international social media campaign included a Twitter Feed “#Maternal Mental Health Matters” starting in Australia, Facebook page, and landing page. The first World MMH Day was held May 4, 2016.

Conclusion Increased awareness will continue to drive social change with a goal of improving the quality of care for women worldwide who experience all types of PMADs and to reduce the stigma of maternal mental illness. World Maternal Mental Health Day will be held each year on the first Wednesday of May, close to “mother’s day” and “mental health week” in many countries.

Evaluation of capacity to love, depression, and anxiety in women according to their relationship status

I. Busch^{1,*}, N.D. Kapusta²

¹ Policlinico G.B. Rossi, UOC Psicomatica e Psicologia Clinica, Verona, Italy

² Medizinische Universität Wien, Universitätsklinik für Psychoanalyse und Psychotherapie, Wien, Austria

* Corresponding author.

Introduction Associations between psychiatric disorders and relationship status as well as the impact of psychiatric symptoms on the quality of romantic relationships have already been demonstrated but the association between psychiatric symptoms and the capacity to maintain romantic relationships has been rarely examined.

Aim To investigate anxiety, depressive symptoms and capacity to love (CTL) in single women (sw) and those in a relationship (rw).

Methods Two hundred healthy adult females (100 sw, 100 rw; mean age 27.8 ± 8.1 yrs and 27.3 ± 8.1 yrs, respectively) completed the PHQ-4 and the CTL-Inventory. Differences in anxiety and depressive symptoms and CTL between both groups were assessed by independent-samples *t*-tests. Moreover, correlations between CTL, anxiety and depressive symptoms in each group were investigated.

Results Sw showed a significantly higher level of depressive symptoms (mean_{sw} \pm SD_{sw} 1.59 ± 1.66 , mean_{rw} \pm SD_{rw} 1.07 ± 1.37 , $P = 0.016$) and a significantly lower CTL (mean_{sw} \pm SD_{sw} 126.81 ± 12.60 ; mean_{rw} \pm SD_{rw} 137.13 ± 11.26 , $P \leq 0.001$) than rw but no differences occurred for anxiety symptoms.

Among sw, CTL negatively correlated with depressive ($r = -0.37$, $P < 0.001$) and anxiety symptoms ($r = -0.44$, $P < 0.001$) whereas in rw, a negative correlation occurred only between CTL and depressive symptoms ($r = -0.43$, $P < 0.001$).

Conclusion Our results suggest that single women, compared to women in a relationship, show a lower CTL and suffer more from depressive symptoms.

Furthermore, a lower CTL is associated with more anxiety and depressive symptoms, thus suggesting that future therapeutic approaches to depression and anxiety should also take into account relationship conflicts and CTL. As a crucial personality trait, CTL might be an important moderator of coping with common psychiatric symptoms.

EV1510

Particularities in immigration amongst homeless women in Girona

F. Calvo^{1,*}, C. Giralt¹, C. Xavier²

¹ Institut d'Assistència Sanitària, Cas Girona, Girona, Spain

² FPCEE Blanquerna, Universitat Ramon Llull, Psychology, Barcelona, Spain

* Corresponding author.

Introduction Homelessness is a problem which affects all the areas of those who suffer it, affecting their health seriously. These risks increase when the affected person has carried out a migratory process. Another risk factor, apart from immigration, is to be woman.

Objectives To analyse the gender demographic differences in a total cohort of homeless people in the city of Girona in 2006 and continued until the present day.

Methods Prospective longitudinal study of the total population of homeless people in Girona. In 2006, a list was made of all the homeless people detected by both specialized and non-specialized teams which have been followed until the present day.

Results The total number of women in the sample is lower ($n = 106$, 11.2%). There are fewer immigrant than autochthonous women ($\text{Chi}^2 = 23.1$, $\text{df} = 1$, $P < 0.001$).

After following the total homeless population in 2006, we can confirm that currently we can still identify 62 people in the territory (6.7%). In this subsample there are no differences between genders (man: $n = 54$, 6.5% vs. woman: $n = 8$, 7.5%; $\text{Chi}^2 = 0.21$, $\text{df} = 2$, $P = 0.89$). That is, men and women remain in their homeless condition in a proportional way. This fact presents great limitations, since we do not know what happened with the other 93% of the initial sample.

Conclusions The masculinisation of the homeless people from Maghreb has tended to increase the gender differences in the homeless population, in itself more masculine. This presents a risk of increasing the invisibility of homeless women.

A case report highlights the neglect problem of pregnancy denial

E. Di Giacomo^{1,*}, M. Calabria², F. Colmegna³, B. Pucci⁴, M. Clerici⁵

¹ PhD program in Neuroscience, Doctorate School of the University of Milano-Bicocca, Psychiatric Department, S. Gerardo Health Care Trust, Milan, Italy

² University of Milano Bicocca, School of Medicine and Surgery, Italy

³ S. Gerardo Health Care Trust, Psychiatric Department, Monza, Italy

⁴ S. Gerardo Health Care Trust, Obstetric & Gynecologist Department, Monza, Italy

⁵ Milano, Italy

* Corresponding author.

Pregnancy denial was observed in a patient after her second delivery. Contrary to the first pregnancy, she denied weight gain, body changes and baby movements. She reported using a contraceptive pill throughout the entire pregnancy. After a short home delivery without assistance, she was admitted to obstetrical department and referred for psychiatric evaluation. Mrs. T. accepted psychiatric follow-up appointments and was followed up for 6 months. She was initially assessed using the SCID II Interview, Beck anxiety and depression interview, WHOQOL (WHO quality of life), and childhood trauma questionnaire. She denied pregnancy concealment and during the period of assessment and follow-up there was no evidence of intimate partner violence. Her female newborn was healthy without consequences of oestrogen/progesterone absorption (hypoplastic left heart syndrome, gastroschisis, hypospadias or congenital urinary tract anomalies) in one year follow up. The patient was discharged after 6 months of clinical outpatient follow-up. This case stresses and emphasizes the health and risk outcomes for both mother and child linked to an underestimated but serious phenomenon such as the denial of pregnancy.

Reviewing the relation between the automatic thought patterns of university students and their levels of cultural intelligence

G. Ergün*, A. Güzel

Mehmet Akif Ersoy University, Department of Emergency Aid and Disaster Management, Burdur, Turkey

* Corresponding author.

Purpose This research aims at reviewing the relation between the automatic thought patterns of female university students and their cultural intelligence levels.

Method The research was planned to be descriptive. The universe of the research was composed of female university students in staying student hostel. The sample was determined to be the whole of the universe. A written permission was taken from the management of hostel regarding the research. Cultural Intelligence Scale and Automatic Thoughts Scale; the form towards socio-demographic data prepared by the researchers was used. SPSS-19 software programme were used to analyze the data.

Results The participants were a total of 400 people, with %100 female. Automatic thoughts scale of respondents found a total of 85.23 points. This score is above average. That is more negative perceptions of student life. Cultural intelligence scale total score of 81.21 was found. Cultural intelligence level of students is above average. There was correlation between the two scales.

Discussion and conclusion Statistically significant relations were determined between Cultural Intelligence Scale and sub-scales regarding Automatic Thoughts Scale.

Keywords Cultural intelligence; Automatic thoughts; University student; Female student

Associations between gender and outcome of acute psychiatric admission, looking specifically at length of stay and type of admission

J. Beezhold, U. Farooq*, J. Isaac, A. Shepherd
The University of East Anglia, Norwich Medical School, Norwich, United Kingdom

* Corresponding author.

Introduction There is little published data regarding the association between gender and outcomes in acute inpatient psychiatry. We present outcomes from a study of 5601 acute psychiatric admissions.

Objective The objective of this study was to identify associations between gender and outcome of acute psychiatric admission, looking specifically at length of stay and at whether they were detained in hospital.

Methods The relationship between gender and acute psychiatric inpatient length of stay and detention status was analyzed for all admissions over 90 months from Sept 2002 to Feb 2010. There were 5601 consecutive admissions included in this study, 2862 of which were male and 2739 were female. There were no exclusions. Data was complete for more than 99% of subjects, and was extracted from part of routine service data on an anonymous basis. The subjects were admitted into two acute inpatient wards in central Norfolk. Data was analyzed using SPSS. Ethics consent was granted by the research ethics committee.

Results The study showed no significant difference in average length of stay (female = 32.98, male = 32.11; $P = 0.595$). Additionally, no significant difference was found linking gender to detention status (26% female, 25% male; $P = 0.517$) as opposed to informal or voluntary admission.

Conclusion The study found no evidence of a gender bias regarding overall length of stay and legal status in acute admissions. Further research should be conducted in this area to examine whether there is any gender bias in outcomes relating to diagnosis.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1514

Impact of postpartum depression on quality of life

R. Feki*, I. Feki, D. Trigui, I. Baâti, R. Sallemi, J. Masmoudi
CHU Hédi Chaker, Psychiatrie A, Sfax, Tunisia

* Corresponding author.

Introduction Women during the postpartum period experience many physiological, psychological, and social changes. Quality of life (QOL) is a sense of well-being and arises from satisfaction or dissatisfaction with various aspects of life including health,

employment, socioeconomic state, psychological-emotional state, and family.

Objectives The purpose of this study was to identify influence of childbirth experience and postpartum depression on QOL.

Methods This is a descriptive cross-sectional study regarding 150 postpartum women receiving cares in the hospital of Sfax and examined during the first and the sixth week post-delivery. Data collection tools in this study were demographic questionnaire, Edinburgh Postnatal Depression Scale (EPDS), and world health organization quality of life-bref (WHOQOL-bref). Data were analyzed using SPSS.

Results The mean age of our sample ($n=150$) was 29.61 years. During the sixth week study period, 126 of 150 were examined. A personal psychiatric history of depression was found in 9.3% of cases.

The current pregnancy was undesired in 15.3% of cases.

The prevalence of postpartum depression in the first week was 14.7% and 19.8% in the sixth week after delivery.

The mean score of quality of life was 81.62 ± 9.09 .

Scores of quality of life and all its dimensions were significantly lower in depressive women.

Conclusion Because enormous changes develop in postpartum women, we suggest supportive measures for mother by her mother-in-law family, and caregivers to improve the QOL and health status of the mother and her child and to prevent postpartum depression.

The psychological effects of unmarried women “a field study on a sample of unmarried women in Algeria”

L. Fekih^{1,*}, B. Mounis²

¹ Université Abou-Bekr Belkaid Tlemcen, Psychology, Tlemcen, Algeria

² Université Abou-Bekr Belkaid Tlemcen, Philosophy, Tlemcen, Algeria

* Corresponding author.

Background The present research was designed to determine the psychological stress as experienced by unmarried women in the education sector, and how to help them to discover the meaning of their presence in the framework, innovation and achievement, art, science, comprehension, love and adaptation in life.

Aim This research aims to identify the various problems and mental disorders that unmarried women suffering from, and to determine the differences between unmarried women in terms of the psychological problems resulting from “unmarried” in: ages, kind and professional status.

Method The method used in this research is purely descriptive following the collected data from the sample of 200 unmarried women. The tools that were used in this research as follow: Self-Confidence Scale, Psychological Stress Scale, “List of Information Collection for unmarried women”; we proceeded with some statistical techniques.

Results The findings of this research were:

- emotional problems are the most common problems experienced by unmarried women;
- the present study indicates the presence of depressive symptoms in 17%, which can evolve toward psychotic depression as dysthymia (loss of interest in daily activities, hopelessness, low self-esteem, self-criticism, trouble concentrating and trouble making decisions, effectiveness and productivity, avoidance of social activities, feelings of guilt and worries over the past, insomnia. . .);
- the impact of unmarried on late stages have more negative impact, and psychological effect on them was more severe and the greatest harm.

Conclusion The advancement of women in the age without marriage or “unmarried women” is origin of psychological stress and low self-confidence.

Disclosure of interest The authors have not supplied their declaration of competing interest.

Gender differences on mental health distress: Findings from the economic recession in Portugal

D. Frasquilho*, G. Cardoso, A. Ana, M. Silva,

J.M. Caldas-de-Almeida

CEDOC, Chronic Diseases Research Center, Nova Medical School, Universidade Nova de Lisboa, Lisboa, Portugal

* Corresponding author.

Introduction Evidence from past economic recessions shows that increased risk of mental distress is likely to occur. Until now, little is known whether distress levels differ by gender in countries highly hit by the economic recession.

Objectives The aim of the study was to characterize and analyze the differences in mental health distress in men and women during the current economic recession in Portugal.

Methods A subsample of 911 participants from the 2008 national mental health survey, were re-interviewed in 2014/2015. Sociodemographic data was collected and mental health distress was evaluated using the 10-item Kessler's Psychological Distress Scale (K10). Chi-square statistics were used to investigate differences between men and women in mental distress as a categorical variable.

Results Mean mental distress differed significantly according to gender, $\chi^2(1) = 13.716, P = 0.001$. The results showed that a much higher proportion of women (18.5%) revealed to be under psychological distress compared to men (9.9%).

Conclusions Distress levels during the economic crisis in Portugal differ significantly by gender. More women reported to be distressed compared to men. There are several hypotheses for a differential expression of psychological distress between women and men during the recession, such as different gender roles which asserts that differences are due to gender and country based coping resources but also due to several determinants of mental health such as income, employment and social status. Further research is needed to better predict a variety of characteristics that are important for this outcome.

Complementary and integrative medicine approach for climacteric disorders

D. Gamus

Sheba Medical Center, Complementary and Integrative Medicine Service, Tel-Hashomer, Ramat-Gan, Israel

Introduction Menopausal symptom clusters of vasomotor symptoms (VMS), sleep and mood symptoms may last for years and might lead to an increased risk of depression.

While hormone replacement therapy is still the most effective therapy for reducing VMS, which are the most prominent symptoms of menopause, the majority of women prefer to choose nonhormonal therapies, either because of medical contraindications or personal beliefs and turn to complementary and integrative medicine (CIM).

The objective of this presentation is to review the evidence on nonpharmacologic, nonherbal management treatments of CIM in climacteric disorders.

Methods A systematic review of PubMed database was performed using the key-words: acupuncture, hypnosis, yoga, massage, homeopathy and menopause.

Results The research of CIM modalities is evolving. The 2015 position statement of the North American menopause society (NAMS) recommended the use of CBT and hypnosis for the management of VMS. The most recent studies on the effect of acupuncture on VMS however yielded conflicting results: while NAMS concluded that acupuncture is not recommended for managing VMS, later studies produced a positive evidence both for managing of VMS and menopause-related sleep disturbances by this therapeutically modality. There is also some evidence that acupuncture, massage and yoga may alleviate symptoms of depression and that individualized homeopathic treatment may be more effective than placebo for depression in perimenopausal and postmenopausal women.

Conclusions These findings suggest that acupuncture, hypnosis, yoga, massage and homeopathy may be adopted as a part of multimodal approach in treatment of climacteric disorders.

EV1518

Marital separation among some poor Bangladeshi women: Analysis of some cases

N. Hasan

Homemaker, Dhaka, Bangladesh

Objective This paper intends to show the challenges faced by poor Bangladeshi Muslim women from lower socioeconomic status, in case of divorce or separation in marriage. Participants will also learn how they earn for their living and how they raise their children if any. This paper will also present the obligations of marriage in Islam, which may reduce the hazards in their life.

Method Some women were interviewed from lower socioeconomic status from slum area of Dhaka. Researcher took their consent before interview had started. They were asked about their age, educational status, duration of marriage, type of work they do for livelihood, whether they get any maintenance money from the husbands in case of separation, expenses for raising children if any, any criticize from the friends and relatives, etc. The answers were noted carefully.

Results After critical analysis of the interview it was revealed that they were leading their lives on their own, most of them were not aware of their rights relating to marriage in Islam. Two of the women had to pay dowry. Some of them were addicted to tobacco leaf taken with betel nut and PAN, a special form of leaf.

Conclusions In conclusion, it can be said that these women lead their lives with courage. They need to be educated about their marriage rights in Islam and legal help. At a time, men should be educated about the marriage rights of the wives and the evil effects of dowry in the society.

EV1519

True story of Bangladeshi women with childhood trauma who heroically faced the trials of life

N. Hasan

Homemaker, Dhaka, Bangladesh

Objectives At the conclusion of this presentation, the participants will be able to know how three women victim of childhood trauma; terribly suffered and tackled their situation. They were born in a developing Muslim country.

This paper also intends to aware people about victims of childhood trauma and their need for mental and social support.

Methods Personal interview with these three subjects who were close persons of the researcher. Description of their suffering and way of tackling it were noted. The words were carefully placed as a story.

Results Two of the subjects sexually abused by close relatives in their childhood. The third one was abused for as long time as 17 years. All the subjects suffered severely from headache and flatulence from childhood, insomnia and terrifying dreams, sense of insecurity, depression, PTSD.

Despite all the grief and pain, these three became highly educated, holding well position in the society and directly indirectly working for distressed women.

Conclusions The author concludes that childhood trauma can damage a victim in many ways in her entire life.

Social support, sharing the incidents with others, counseling may reduce her pain.

Religious acts like prayer, reading Holy Book, remembrance of Allah, serving humanity and helping distressed women may console the victim.

These three women's heroic lives may give motivation for women with childhood trauma. Even they may inspire others to act like heroes in hardship of life.

EV1520

The comparison of mental health and marital satisfaction of fertile and infertile women referred to infertility center of Jahad Daneshgahi In Qom

S. Heidari^{1,*}, K. Berjis², L. Ahmadi²

¹ Tarbiat Modares University, Humanity, Tehran, Iran

² Infertility Center of Jahad Daneshgahi, Gynecology, Qom, Iran

* Corresponding author.

Introduction Infertility is a complex issue that affects individuals' mental health. Also marital satisfaction can be affected by fertility status of couples. Then, it is one of the most important features of life satisfaction. So, the study of mental health and marital satisfaction of infertile and fertile women is considerable.

Objectives This research has been done with the aim of study and comparison of marital satisfaction level and mental health of the women who have infertility problem with those who does not have this problem.

Method In total, 180 persons (90 infertile women and 90 fertile women) were participating in this study. Participants were comprised of those referring to infertility center of Jahad Daneshgahi in Qom. They filled the general health questionnaire (GHQ) and enrich marital satisfactions questionnaire have been used. Acquired information analyzed with the independent *t*-tests and one-way variance analysis.

Results Results showed infertile women have less mental health rather than fertile women and also according to results, there was significant difference in satisfaction level of the fertile and infertile women. The number of unsuccessful pregnancies whether in fertile women or infertile women didnot have considerable effect on the marital satisfaction, while, effect of this factor on marital satisfaction level of the infertile women was higher than that on the fertile women.

Conclusion Generally, by inclusion of limitations in this plan, it is inevitable to emphasize on negative consequences of the infertility on spouses' life and it is important to pay attention to its different dimensions.

Psychological and psychiatric consequences of violence against Women[☆]

M. Kachaeva^{1,*}, S. Shport²

¹ Federal Medical Center for Psychiatry and Narcology named after V.P. Serbsky, forensic psychiatric department, Moscow, Russia

² Federal Medical Center for Psychiatry and Narcology named after V.P. Serbsky, scientific secretary of the Institution, Moscow, Russia

* Corresponding author.

Introduction Domestic violence against women has increasingly been recognized nationally and internationally as a serious problem. Violence against women is a troubling phenomenon in Russia. Meanwhile domestic abuse against women often results in long-term mental health problems.

Objectives The main aim of the study was to find out the psychological and psychiatric consequences of violence against women and to determine the origins of crimes committed by abused females.

Materials and methods A cohort of 18 females was examined by forensic psychiatrists. All women had committed crimes of violence (murders, attempted murders). Details of background, psychiatric and offending history were extracted. Each item was assessed with the help of descriptive statistics.

Results A research has been carried out on the basis of psychiatric and forensic psychiatric assessment of two groups of women who had a long history of violence by their husbands or partners. Clinical assessment has revealed depression, anxiety, low self-esteem, post-traumatic stress disorder, drug abuse. All women underwent forensic psychiatric assessment as they had committed serious crimes of violence. The research has revealed two types of homicides. Women of the first subgroup displayed pathological altruistic motivation of their children. Women of the second subgroup had committed homicides of their husbands and partners whose violence towards women escalated in severity.

Conclusion The research shows the necessity of domestic violence prevention by legal provisions and multidisciplinary research with participation of psychiatrists, psychologists, sociologists, human rights advocates and feminist societies.

Disclosure of interest The authors have not supplied their declaration of competing interest.

EV1522

Coping behaviors in mothers with an atypical child

M. Kékes Szabó

University of Szeged, Department of Applied Pedagogy and Psychology, Szeged, Hungary

Nowadays an increased interest seems to be developing concerning the coping strategies of parents with an autistic child. Several studies focused on the gender differences or tried to explore the effect of the levels of the child's behavioral symptoms. Although most of the previous studies made comparisons at a single point

in time, some longitudinal research also came to light in the last decades. The results usually confirmed characteristic patterns of the parents' coping behavior. The aim of this study was to compare coping behaviors in mothers with a child living with autism spectrum disorder (ASD) or Down-syndrome (DS), since until now there has been no investigation into this question, even though it plays an important role in stressful occasions that are inevitable and frequent concomitants of these families' life. This time a cross-sectional study has been carried out. The selected research method was composed of semi-structured interviews, self-administered questionnaires and participant observation. 5-5 mothers were involved in the study with a child living with ASD or DS. In addition to this, five mothers with a typically developing child also participated in the research. The age of the children varied between four and nine years. According to the earlier studies, a higher level of stress was experienced by atypical children's mothers, and emotion-focused coping strategies were also more often used by them. Task-focused coping was associated with a lower level of experienced stress in the family system. However, further studies are needed to explore other correlations of the examined field.

Disclosure of interest The author has not supplied his/her declaration of competing interest.

EV1523

Screening for perinatal anxiety disorder in Serbian women

B. Kitanovic^{1,*}, D. Milutinovic²

¹ Clinical Hospital Center "Zvezdara", Primary Health Center (PHC), Belgrade, Serbia

² Primary Health Centre Pozega, Mental Health Unit, Pozega, Serbia

* Corresponding author.

Perinatal generalized anxiety disorder (GAD) has a high prevalence of 8.5%–10.5% during pregnancy and 4.4%–10.8% postpartum which is higher or as high as in general population. Despite its attendant dysfunction in the patient, this potentially debilitating mental health condition is often underdiagnosed due to difficulty in distinguishing normal versus pathological worry and non-existent screening tool for perinatal GAD. The maternal dysfunction can potentially impact mother–infant bonding and influence neurodevelopment outcomes in the children.

Objective To screen 100 women for anxiety symptoms during pregnancy and postpartum at the primary health center "Zvezdara".

Methods One thousand women were screened for anxiety symptoms using the GAD-7 and DSM-IV. Questionnaire that covered key demographic and obstetric information and GAD-7 and DSM-IV, were administered at the third trimester of pregnancy, and 8 weeks postpartum. Women were identified as at high risk for anxiety, cut-off scores of 5, 10, and 15 were taken as the cut off points for mild, moderate, and severe anxiety, respectively.

Results Ten percent of the sample was screened positive for mild anxiety symptoms during pregnancy. Subsequently, efforts were made to follow-up women with a postnatal GAD-7 and 7.2% percent were screened positive during postpartum.

Conclusion Clinicians should be aware of the frequency and level of anxiety symptoms during pregnancy and postpartum. Therefore, it is very important to identify women at high risk. Be aware that GAD is one of the risk factors that complicate pregnancy.

Sex differences in experimental studies of depression: How can clinical research benefit?

N. Kokras*, C. Dalla

National & Kapodistrian University of Athens, Department of Pharmacology, Medical School, Athens, Greece

* Corresponding author.

Introduction Sex differences in depression and antidepressant response in humans are modestly studied and results are controversial. Experimental studies using animal models may provide insights that could be useful in clinical trials.

Objectives The objective is to summarize findings from preclinical studies on sex differences and suggest how such preclinical research might be of use in clinical research.

Aims Specifically it is aimed to summarize evidence for both sexes in relation to the phenotype of depression, its endophenotype and the antidepressant response.

Methods A selection of experimental studies on sex differences in stress and antidepressant response was performed and their findings were linked to potential confounders or methodological issues that might obscure the results of clinical trials.

Results In preclinical studies, behavioral indices and models are adjusted for both sexes, in order to properly identify sex differences in primary outcomes. This is not routinely happening in clinical studies when using depression rating scales, which is the analogue of behavioral indices. Moreover, preclinical studies show sex differences at the baseline behavioral response and underlying mechanisms that often converge following antidepressant treatment. This is also a neglected issue in human studies. Finally, preclinical research suggests that when researching on potential biomarkers for depression and antidepressant response sex should be an important factor to consider.

Conclusions Cautious exploitation of findings on sex differences from preclinical research could improve the design and quality of clinical studies for disease biomarkers and novel antidepressants and facilitate the drug development in a gender aware manner.

EV1525

The psychological effects of abuse and battering on wives and partners: Case study in the Philippines

S.F. Lu

University of the Philippines Manila, Department of Social Sciences, Manila, Philippines

Introduction In the country, the most prevalent form of violence against women is physical abuse/maltreatment or wife/partner battering based on both records of the Philippine national police, and the women in especially difficult circumstances.

Objectives This study looked into the psychological effects of abuse and battering on wives-partners.

Aims This paper will also give a description on how battered wives acquire a learned helplessness behavior due to uncontrollable events or situations.

Methods The methods used were structured interview method and case method, and interview with a psychiatrist in the hospital where the three cases had consultations.

Results Wife battering refers to violent acts such as psychological, sexual or physical assault by an assailant against his partner

with the intent of controlling by inducing fear and pain. It is a common incident being violated under RA 9262. Three cases were studied. One was stabbed 12 times by her live in “matador” partner who works in a slaughter house. The second case was about a partner who was forced to do sexual favors for her husband that were animalistic and perverted. On the third case, while married, she noticed that the man was also sexually perverted. He also raped their daughter.

Conclusion All three cases also manifested depression in various forms with varying symptoms. Case A was diagnosed with post-traumatic stress disorder (evaluation made by the psychiatrist). Case A manifested symptoms of depression, panic of being attacked again by assailant who is at large.

Keywords Abuse; Battering; Wives and partners; Depression; Psychological effect

Gender differences in external factors affecting psychiatric visits in a Greek hospital

G. Lyrakos^{1,*}, E. Kornarou², D. Menti¹, V. Spinaris¹, I. Spyropoulos¹

¹ General Hospital Nikaia “Ag. Panteleimon”, Psychiatric, Nikaia, Greece

² National School of Public Health, Epidemiology and Biostatistics, Athens, Greece

* Corresponding author.

Introduction According to previous literature, there are important differences, based on gender, on the external factors that affect psychiatric visits of individuals. Females are, in general, more likely to report being affected by family and emotional issues whilst men are less likely to do so.

Objectives To examine gender differences in external factors affecting psychiatric visits.

Aims To investigate whether females report different external factors, which impact on the decision to visit a psychiatrist, compared to males.

Methods In this study, there were 1205 participants, out of them 685 were males (56.8%) and 520 females (43.2%). The mean age was 45.54. Convenience sampling method was used and participants were recruited from the general hospital of Nikaia, “Ag. Panteleimon”, in Athens, Greece, from 01/01/2012 to 31/12/2015. The data were analysed through the SPSS software.

Results There were significant gender differences in external factors reported for psychiatric visits, as $\chi^2(8): 185.608, P < 0.001$. More specifically, more women reported being affected by family problems (5.5%) compared to men (2.6%). Additionally, more females reported being affected by emotional issues (7%) compared to men (5.6%) and psychological issues were more important for women (13.9%) compared to men (7.5%), as well. However, more men reported addictions as the external factors impacting on psychiatric visits (23.1%) compared to women (6.6%).

Conclusions There are significant differences in the external factors affecting psychiatric visits between men and women. Further investigating such differences could help us better understand the reasons affecting the individuals’ decision to seek psychiatric help.

Domestic violence (DV) against women still lacks rigor in its identification and denouncement, which makes it an under diagnosed condition.

Physical and psychic well-being of women who are victims of DV is threatened hence it is essential to discuss this subject as a health matter. Furthermore, health professionals are usually DV victims' first contact. In 2009, Margaret Chan from WHO stated that "Preventing violence against women requires a multi-sectoral approach, and in this context the health sector has a central role to play which includes helping to identify abuse early, providing victims with the necessary treatment, and referring women to appropriate and informed care."

Portuguese Health Ministry has created, through the legal dispatch No. 6378/2013 of may 16, an integrated intervention model on interpersonal violence throughout life, entitled Ação de Saúde sobre Género, Violência e Ciclo de Vida (ASGVCV), made operational by Equipas para a Prevenção da Violência em Adultos (EPVA) teams.

What is mommy doing in the bathroom? A typical case of postpartum psychosis

G. Montero^{*}, I. Alberdi, B. Serván, M. Villanueva, R.Á. Baena,
L. Niell, J. García-Albea

Instituto de Psiquiatria y Salud Mental, Department of Psychiatry,
Hospital Clinico San Carlos, Madrid, Spain

* Corresponding author.

Objective We report the case of a 41-year-old woman brought by her husband for behavioral disorder during the last week. As background, she had her first vaginal delivery after a risky pregnancy a fortnight ago, which required uterine arteries embolization for intense uterine bleeding; and an adjustment disorder eight years ago.

Results The patient presents a wordy and inadequate speech, as well as insomnia for the last seven nights. She has injuries in both of her hands due to intensive cleaning of her home and genitalia. Her condition is fluctuant, remaining for hours in the bathroom after breastfeeding and behaving strangely at night, with an irritable mood and being unable to care for their child.

She also has a fever of 39°C, with thrombocytosis (850,000 platelets) and a c-reactive protein up to 20 as relevant alterations, attributed to mastitis and consequences of the recent intervention. Olanzapine at a dose of 10 mg per day was introduced after stopping breastfeeding, with very good tolerance and complete clinical remission within a few days, with the diagnosis of postpartum psychosis and suspected affective disorder of the bipolar spectrum.

Conclusions Puerperal psychosis is misdiagnosed in at least 50% of cases, with a prevalence of 1–2/1000 births, and appears more frequently between the 3rd and 9th day after delivery. The risk for both mother and child is severe and it must be treated immediately, being its evolution in general favorable. Most of the risk factors and clinical manifestations for this condition are described in this case.

Affirmative competence and practices of mental health professionals with LGB clients: An Ibero-American study

H. Pereira

University of Beira Interior, Psychology and Education, Covilhã,
Portugal

Introduction There are not many studies about affirmative competence and practices among mental health professionals working with lesbian, gay, and/or bisexual (LGB) clients.

Objectives The objectives of this research are to assess the levels of affirmative competence and practices of professionals in Ibero-American countries.

Aim We aim to compare differences regarding gender, country of origin, religious beliefs, political orientation, sexual orientation, age, education, marital status, and possessing specific training related to working with LGB clients, in order to determine the predictive association of the variables under study.

Methods The sample consists of 630 therapists from various countries various Ibero-American countries: 23% from Portugal, 23.2% from Brazil, 19.1% from Spain, 6.7% from Mexico, 6.7% from Argentina and 18.6% from other countries. Ages ranged from 19 to 75 years old, with a mean age of 41.46 years. The socio-demographic questionnaire, the Sexual Orientation Counselor Competency Scale, and the Affirmative Practice Questionnaire were the measures used.

Results The results show statistically significant differences when comparing marital status, sexual orientation, political orientation, religious beliefs, level of education, and specific training concerning LGB issues. Age, gender, and country of residence show no statistically significant differences. The linear regression model demonstrates that there is a significant predictive value between affirmative competence and practices with LGB clients.

Conclusions This study indicates that mental health professionals should undergo some type of academic or professional training and/or possess experience in regards to working with LGB clients, in order to enhance their approach when working with this population.

* Corresponding author.

Introduction The complex phenomenon of violence against women is determined by gender relations that, from a historical and social construction of female and male, and the biological differences which gives unequal power between men and women. This results in increased vulnerability of women, exposing them to physical, psychological and sexual violence. The history of vio-

lence in the early life of trapped women can contribute to their involvement in crimes and misdemeanors.

Objective To review the production of national and international scientific knowledge about the effects of violence on women's health before her incarceration.

Aims Meet the publications about the consequences of violence on women's health before she was imprisoned.

Method Integrative review of scientific literature to answer: "What are the implications of violence on women's health before their incarceration?" Studies of the last 5 years delimited in the databases LILACS, PUBMED and PsycInfo. Selected primary studies with women incarcerated people over 18 years, in Portuguese, English and Spanish language. Excluded studies that addressed violence inside the prison and wife as perp. An instrument for identification of studies and their categorization was used.

Results Sixteen selected articles that have addressed the prevalence of post-traumatic stress disorder, suicide, drug abuse, sexual abuse and re-victimization (where the abuser was usually a family member or intimate partner).

Conclusion There is a lack of a specific instrument to investigate the occurrence of violence against women before being arrested. Scientific and policy initiatives are required to develop specific intervention strategies for women incarcerated victimized before prison.

Introduction Violence is a social and relational problem of humanity. When coming across a feminine jail population, the violence problem can take diverse proportions. Beyond being perpetrators of some sort of violence, these women can also be victims throughout their lives and even during their period of imprisonment.

Objective Describe the social representations that imprisoned women have concerning daily experiences in prison.

Aims Knowing the meaning of daily experience in prison to women.

Methods Qualitative exploratory-descriptive field study, carried through with 15 prisoners of the feminine prison of Ribeirão Preto (SP-Brazil). A semi-structured interview was used. Results submitted to the content analysis technique.

Results "Daily experiences with violence in prison": they revealed feelings of abandonment and indifference to their health; they denounced suffering physical and psychological violence from employees and other female prisoners; the relation between them is marked by conflicts and aggressions. "Consequences of the arrest in the women's lives": complained about the loss of contact with their familiars; there were relieves about lack of support and system's indifference for the readjustment in society.

Conclusions This study contributed as stimulus and reference for the implementation of other researches with populations of prisons, amongst them the ones that aim to establish strategies for the reintegration of these women in society and the shift of paradigms

related to them. Moreover, with the intention of supplementing researches with incarcerated women, we suggest studies that also have familiars and professionals (or visitors) as subjects.

Intimate partner violence and cognitive aspects of the perpetrator

Z. Scherer^{1,*}, E. Scherer², L. Reis¹, J. Rodrigues¹, L. Cavalin¹, D. Silva¹

¹ University of São Paulo, Ribeirão Preto College of Nursing, Psychiatric Nursing and Human Sciences, Ribeirão Preto, São Paulo, Brazil

² Ribeirão Preto Medical School Hospital, University of São Paulo, Neurosciences and Behavioral Sciences, Ribeirão Preto, São Paulo, Brazil

* Corresponding author.

Introduction Violence against women, committed by an intimate partner, is a serious public health problem. On an international scope it has been researched the relation between intimate partner violence and cognitive aspects of aggressors.

Objective To investigate if couples use violence to resolve conflicts and if there are differences in cognitive aspects of men in couples where there is intimate partner violence when compared to couples who have a harmonious relationship.

Method The Revised Conflict Tactics Scale (CTS2) was used. The cognitive aspects of male partners was investigated by Wechsler Adult Intelligence Scale (WAIS-III), certain factors such as verbal and executive functions, to compare the testing results of men who have committed violence against their partners with those who did not.

Results Thirty-one couples with intimate partner violence police reports and 31 couples who, according to their own perceptions, said to maintain harmonious marital relationship. The comparisons between groups allowed observing that even among couples who judge to be in a peaceful relationship, violent behaviors were detected. These behaviors tend to be naturalized and not considered as violence by partners. In regard to men's cognitive aspects, especially those related to WAIS-III verbal skills and impulse control, they possibly exert some influence to intimate partner violence.

Conclusion The possible influence of cognitive aspects of the perpetrator on violence against women could be reduced through long-term actions, especially those concerned to early education, since this is the appropriate way to culturally change and to develop satisfactory social and cognitive skills of the individual.

⁵ *Capri Cardiac Rehabilitation, Treatment, Research, Rotterdam, Netherlands*

* Corresponding author.

Introduction Five to 8% of women of reproductive age suffer from moderate to severe symptoms of premenstrual syndrome associated with substantial distress or functional impairment.

Objective To determine the efficacy, tolerability and acceptability of Vitex agnus castus (VAC, chaste-berry) preparations for treatment of premenstrual syndrome (PMS).

Methods After an extensive literature search all randomized controlled trials of VAC in women with PMS and/or premenstrual dysphoric disorder were included.

Results We found 17 randomized controlled trials of VAC in the treatment of PMS of which 14 studies could be included in the quantitative analysis. All trials, except one, found the Vitex agnus castus preparation to be more efficacious than placebo, pyridoxine and magnesium for either total symptom score or individual symptoms or symptom clusters. Unfortunately, the majority of trials is hampered by a high risk of bias. The pooled effect of VAC in placebo-controlled trials was large (Hedge's g : -1.21 ; 95% CI: -1.53 to -0.88), but heterogeneity extremely high ($I^2=91\%$). We could not single out distinct factors that could explain this heterogeneity. The funnel plot and Egger's tests suggest the presence of bias over the full set of studies and effect sizes.

Conclusion Although meta-analysis shows a large pooled effect of VAC in placebo-controlled trials the high risk of bias, high heterogeneity and risk of publication bias of the included studies preclude a definitive conclusion. The pooled treatment effects should be viewed as merely explorative and, at best, overestimating the real treatment effect of VAC for PMS symptomatology.

Disclosure of interest P.S. reports personal fees from H. Lundbeck A/S, outside the submitted work. The other authors have not supplied their declaration of competing interest.

Introduction In today's societies, pressures from the idea of thinness are omnipresent and lead to a corporal dissatisfaction with an excessive preoccupation of the body's image. Obese persons are often targets of stigmatization and are vulnerable to negative feeling about their physical appearance.

Aims To evaluate the worries towards the weight and the shape of the body among obese women.

Methods Our study was a transversal study, descriptive and analytic. A total of 42 obese women were included. Obesity was defined by body mass index (BMI) ≥ 30 and divided into 3 classes: class I: moderate obesity ($30 \leq \text{BMI} \leq 34.9$); class II: severe obesity ($35 \leq \text{BMI} \leq 39.9$); class III: morbid obesity ($\text{BMI} \geq 40$). Patients were studied by mean of body shape questionnaire (BSQ-34) (Considering score $\text{BSQ} < 80$ lack of altered body image perception and score > 140 excessive preoccupation).

Results The mean age of participants was 33.6 years. The average BMI was 37.42 kg/m^2 ($30.45\text{--}56.26 \text{ kg/m}^2$). Third (35%) of women had a high educational level, 41.4% were inactive, and 70.8% had an average socioeconomic level.

The average BSQ score was 108.31 (47–188). The majority of women (78.1%) had excessive preoccupation about their body image. The BSQ score was correlated to morbid obesity ($P=0.014$). Women aged between 20 and 3 years were significantly more preoccupied about their body image ($P=0.046$).

Conclusion Majority of obese women were preoccupied about their body image. Young women and those having morbid obesity seemed more preoccupied about their body image.

Spectrum of medical and social problems in the female opium addicts

F. Shigakova

Tashkent Institute of Postgraduate Medical Education, Department of psychiatry and Psychotherapy, Tashkent, Uzbekistan

Aim The work was initiated to study peculiarities of medical and social problems of the female opium addiction.

Materials and methods We examined 56 female opiate addicts aged from 18 to 56 (mean age 31.8 ± 1.09 years) hospitalized at the tertiary detox center (Tashkent). Twenty of the examinees (35.7%) were managed for the first time, 36 patients (64.3%) being treated iteratively.

Results and discussion Seventeen women were employed, only three of them were working in their specialization. Thirty-nine patients were either unemployed or engaged in the unskilled labor, that is, the one being out of tune with their education level. Eight examinees served penal servitudes, eleven women being detained without imprisonment. The findings reflect disorders in social adaptation of the most examinees. Drug addiction onset time varied from 19 to 25 years (22.1 ± 1.12 years in the average), but the age range from 20 to 23 was the most frequent one. Duration of episodic taking ranged from 1 month to 2.5 years (2.4 ± 0.7 months in the average). In 10 patients (20%) withdrawal syndrome has formed rapidly, in 1–2 months. Drug dose is partially associated with a patient's ability to pay and heroin accessibility.

Almost half of our 56 examinees had drug using husband, cohabitant or sex partner. Quality of remissions was found to greatly depend on a drug using sex partner.

Conclusions Medical and social consequences of the female drug addiction are quite severe to mention early psycho-social disadaptation, prostitution and illegal actions, including thefts, document forgery, drug pushing.

Background Emotional intelligence (EI) assessment has become an effective technique in exploring individual competencies. In the medical educational, there is a growing evidence for relation between academic achievement and emotional intelligence.

Objective To examine relation between academic achievement and emotional intelligence among medical students.

Method A cross-sectional study of 189 female university students using paper-based Bar-On Emotional Quotient Inventory: Youth Version was conducted. Bar-On EQ-i:YV consists of 7 sub-scores which estimate various domains of emotional intelligence along with general mood. The academic achievement was assessed via self-reported Grade Point Average (GPA).

Result The average Intrapersonal score of participating students was 14.9 ± 3.4 and Interpersonal was 41.7 ± 4.9 . The students scored 32.0 ± 5.0 in stress management scale and 31.9 ± 4 in adaptability. The lowest score achieved in the Emotional Inelegance scale was 32.5 whereas the top score was 71.3. The average general mood was 47.1 ± 6.4 and the positive impression ranged between 6 and 23 (17.3 ± 2.8). Positive week correlations were defined between the GPA and self-efficacy ($r=0.13$) and Adaptability ($r=0.08$) though these correlations were statistically insignificant ($P>0.05$). Linear regression model showed that domains of Bar-On scale could explain up to 33% of changes in GPA ($R^2=0.33$) with significant effect of self-efficacy, adaptability and general mood scores ($P<0.05$).

Conclusion Medical students showed high level of emotional intelligence which positively affect their academic achievement. Therefore, improving the emotional intelligence domains can help students improving their academic achievement.

Introduction Individuals with social anxiety disorder do poorly in residential treatment programs for the treatment of drug dependence. This is not surprising given the social nature of residential rehabilitation where group work and close social interactions are required.

Objectives Given the social nature of residential rehabilitation, we were interested in exploring whether we could address social anxiety symptoms prior to treatment entry and therefore enhance the likelihood that an individual would enter treatment and stay in treatment.

Aims To conduct a randomised control trial to evaluate whether treatment of social anxiety symptoms prior to treatment entry improves treatment entry and retention.

Method Treatment seeking substance users ($n=105$) completed intake assessment interviews for entry into a residential rehabilitation program. Assessment comprised the Mini International Neuropsychiatric interview (Mini), the alcohol, smoking and substance involvement screening test (ASSIST), the Liebowitz Social Anxiety Scale (LSAS). Participants were randomised to either a four-session social anxiety intervention or treatment as usual (which was to remain on the waiting list until treatment entry). A survival analysis was conducted to examine whether the intervention impacted on treatment retention.

Results The treatment did not significantly impact on treatment but the intervention group were significantly more likely to remain in treatment and this effect was only found in women.

Conclusion For individuals with social anxiety disorder brief evidence based intervention focused on ameliorating social anxiety

symptoms (e.g., cognitive behavioural treatment) may improve the retention in treatment. This effect appears to be gender specific.

Introduction Fear of giving birth may affect many pregnant women. Fear of childbirth leads to an increase in C-section demands and the ratio of C-section births. Group therapy addresses at least 8 people at the same time, which both saves time and treatment expenses.

Objectives The objective of this study was to evaluate the impact of group art therapy for the management of fear of giving birth.

Methods Thirty women volunteers in the third trimester of pregnancy who were attending a public women's hospital and who had fear of giving birth were included in the study. They were randomly distributed to 2 groups. First group ($n=15$) received 6 sessions of group art therapy. Second group ($n=15$) received 6 sessions of psychoeducation regarding fear of giving birth. Each weekly psychotherapy session lasted 130 minutes.

Results By the end of the six weeks Beck depression scale (BDS) scores, Beck Anxiety Scale (BAS) scores and Wijma delivery expectancy/experience questionnaire version A (W-DEQ) scores decreased significantly in the group art therapy group ($P<0.001$). In contrast, the psychoeducation group showed no significant changes in terms of BDS, BAS, W-DEQ scores.

Conclusions Our study shows that group art therapy may be a promising cost-effective treatment method to manage fear of giving birth in pregnant women. The study needs to be replicated in women coming from different cultures and socioeconomic statuses to establish group art therapy for the treatment of fear of giving birth.

Early maladaptive schema domains in the first day of menses and 15 days after the menses in healthy volunteers

B.Ö. Ünsalver^{1,*}, A. Ulu², G. Hızlı Sayar²

¹ Uskudar University, Medical Documentation and Secretariat, İstanbul, Turkey

² Uskudar University, Psychology, İstanbul, Turkey

* Corresponding author.

Introduction Premenstrual syndrome (PMS) symptoms may affect the physical, psychological and social lives of many women of the reproductive age group. Most women report being extra-sensitive and have difficulties with emotional regulation and some patients report worsening of their psychiatric symptoms during the premenstrual period. Early maladaptive schemas (EMS) are developed early in childhood and may remain dormant until they are activated by situations relevant to the particular schema.

Objective We hypothesized that some of the psychological symptoms of PMS may be related to EMS activation and that this activation is due to the hormonal changes of the menstrual cycle.

Aims Our aim was to measure any changes regarding the EMS domains between the first day of menses and 15 days later.

Methods One hundred and ten women from an architectural and engineering firm were enrolled in the study. After ruling-out psychopathology with Symptom check-list-90-R, remaining women ($n=65$) filled out young schema scale short form (YSS-SF) on the first day of menses and 15 days after menses. The time of probable ovulation was defined as 15 days after the first day of menses.

Results YSS-SF scores regarding the schemas of defectiveness, insufficient self-control, failure to achieve, vulnerability to harm or illness were significantly decreased by the 15th day of menses

($P<0.05$). Abandonment, social isolation, dependency, enmeshment and self-sacrifice schema scores remained similar on the first and 15th days.

Conclusions EMS activation may contribute to the PMS symptoms, therefore schema therapy may be an option for those women suffering from PMS.
